THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1635.—*January* 3, 1890.

CONTENTS.

PROSPECTIVE AND RETROSPECTIVE.

THE Jubilee Year of Photography just closed has furnished occasion for taking note of the progress of our Art-Science in its many phases and applications; the Congresses of London, Paris, and Berlin have each dealt with it in turn, and yet the subject is far from being exhausted. The reports show steady advances all round, with vastly increased number of votaries and new resources in the way of materials and apparatus. The practice of photography has now become so much simplified, that hosts of recruits have been attracted to us, many of whom may eventually be induced to pursue their studies in a more scientific or artistic spirit than that which served as the first motive in taking up the camera. Scarcely any public event now escapes being recorded, and where no camera is seen, it is not safe to assume that the photographer is not secretly working amongst us. Cumbrous apparatus is all but banished in favour of smaller appliances for producing negatives of the required delicacy, which can afterwards be enlarged. Weighty glass is giving way to light celluloid films, and bulky carriers to roller-slides, so that pedestrians and cyclists no longer hesitate to carry the needful outfit amongst their impedimenta, and they find dark-room accommodation provided for them at many points along their route.

To keep pace with the growing demands—commercial and otherwise—the London Chamber of Commerce has added a photographic section, which may be expected to deal with questions of piracy and commercial immorality, standards of weights and measures, and, what is equally important, provide the machinery for referring to arbitration all sorts of matters in dispute. It may eventually undertake the testing of lenses and chemical products, stamping them as with a hall mark when approved.

The notable increase in the number of amateur clubs and local societies, with discussions and proceedings calling for review or report, made it imperative to increase the size of the NEWS, and in the month of October it was expanded from sixteen to twenty pages. Advantage was taken of this change to introduce new paper and type, more attention being paid also to the quality of the pictorial illustrations. In this manner it is hoped to combine the very desirable features of prompt report and technical excellence. Attention has likewise been given to the column headed "Answers to Correspondents," which, for the first time, has been placed under separate management. The new arrangement has been of great service to subscribers in the country and abroad, who have freely availed themselves of the facilities offered for pushing their enquiries at head-quarters. An outcome of such intercommunication is the discovery that a wide-spread desire exists for practical instruction in the photo-mechanical processes, and suggests that the time has arrived when classes for the practice of Collotype, Woodburytype, &c., might very well be formed in one or more of our technical institutes.

As with the camera at public festivals, so the lantern display has come to be regarded as indispensable for lecture illustration. The tourist, naturalist, and historian alike resort to it as a ready means of enlivening a narrative or illustrating a point in science. The painted slides have given way to photo-transparencies, for which an endless number of requisites have been put upon the market. Scenes on land and sea, the starry heavens and nebulæ, gigantic explosions, street scenes, objects in motion, and the movements of animals, are all made to tell their tale through the instrumentality of the rapid plates now put into the hands of the photographer, and if he is not satisfied with the old developers, there are two new ones at least—pyrocatechin and eikonogen—with which he may feel inclined to experiment. Orthochromatic photography has been made the subject of further study by Mr. Andrew Pringle and Mr. C. H. Bothamley; new methods of platinum toning by Mr. Valentine Blanchard and Mr. Lyonel Clark; the acid fixing bath has been again revised, and flash lighting for home portraits has scored a success during the past year; whilst theoretical photography and measurement of density in negatives have received a fair share of attention from Professors Carey Lea, R. Meldola, W. R. Hodgkinson, and Capt. Abney; but whether the photo-chloride or oxy-chloride theory, or neither, is to be adopted, stands over for decision to another year.

PHOTOGRAPHIC TOURISTS' BAGGAGE.

IN the PHOTOGRAPHIC NEWS YEAR-BOOK for 1890 is an article by Mr. Fleetwood Pritchard, which gives useful practical information to the photographic tourist proper; that is to say, to the traveller who does not confine his expeditions to well-trodden routes, but who, independently of railways and other conveyances, carries all his luggage knapsack-fashion on his back. Such is the best method of travelling both for health and for information; the photographer is then free to quit the main routes frequented by the English; he can traverse footpaths and put up at wayside inns wherein a foreigner is rarely seen; he can talk with the villagers in their mountain homes, can enter into their joys and their sorrows, and see the people as they actually are. The photographer who is "put through" by tourists' agencies, or who independently traverses the ordinary routes, finds English spoken at all the large hotels, and everything about him made as English as possible, so that for the purpose of gaining some kinds of information he might as well have remained at home.

Supplementary to the suggestions of Mr. Pritchard, it is our object to point out additional precautions which should be taken in advance by the photographic tourist proper. One of these is that he should have a written list of all the articles he may require in his travels, keep this list permanently attached to the inside of his knapsack, and make additions to the written items as experience may dictate. In places where there are no shops within several miles, and where the few shops then to be found contain only articles of immediate necessity, such as those of food and clothing, the omission of trifling things obtainable at once in towns will sometimes be the cause of considerable annoyance. For instance, if he should desire to develop a few plates when away from home, to make sure on the spot, ere it is too late, that he has obtained some of the more important photographic records of his travels, he requires a few two or three-ounce bottles for his solutions, especially those solutions which are most liable to oxidation in the air. In the wayside inn or the mountain cottage he may find nothing but wine-bottles, which are scarcely good for the purpose, and the kindly hostess may empty her little bottle of *eau de Cologne* to one of those vast receptacles to oblige the stranger. A cork or two may be wanted; a wine-cork has to be cut down, and in a small bottle may more or less freely permit the passage of both air and liquids. The said photographic tourist never for a moment thought of putting a few gummed labels in his baggage, and having mixed his solutions, finds gum to be practically an article never seen in his temporary domicile; but after an hour's delay, when he cannot conveniently spare any time, some freshly-manufactured flour paste is obtainable. More serious is the omission of filtering paper of any description. He should never take out new apparatus if he can help it, however expensively it may have been made; the apparatus should always be well tested by experimental work for a week or two before he starts. The means for making small improvements or corrections are frequently not present in districts remote from towns. In fact, preparation for travel with light photographic baggage in regions far from the larger centres of human industry requires a considerable amount of care and forethought, which can be appreciated only by those who have had the experience.

One of the best things ever suggested in relation to tourists' baggage originated with Mr. William England, who, in the days of old, advocated the use of basket portmanteaus in place of ordinary portmanteaus; the former are very light, and give great protection to any glass articles they may contain. Captain Abney tried and publicly endorsed the merits of this plan, so also did Mr. Fleetwood Pritchard. Such portmanteaus should be lined with thin india-rubber cloth; they may be either specially made to hold apparatus in compartments, or the elegant French palm-baskets, resembling portmanteaus in form, may be bought ready-made at moderate prices in certain shops near Covent Garden. Our own workmen are not competent to manufacture them, so they have to be imported. With properly-constructed focussing glasses, focussing cloths will in time become unnecessary for small cameras, and the best cloth for the purpose, as originally published by Captain Abney, is common mackintosh; it is absolutely opaque and very light; moreover, it will always be useful as a protection for the table in the hotel bedroom when photographic operations are carried on thereupon. A wipe afterwards with a sponge or duster cleans the cloth. In studios, Italian cloth is excellent for focussing purposes, but it is altogether too heavy and bulky for tourists' baggage. In hot sandy places, where dust penetrates everywhere, Captain Abney's plan of rubbing a part of the interior framework of each slide with glycerine is good. One writer complained that it was bad because the glycerine found its way on to his plates; probably he applied too much glycerine, and had common slides; the place for the glycerine is in the grooved portion, where there is countersinking.

The perfecting of tourists' baggage is a subject which will demand closer public attention than it has hitherto received, for the requirements of not a few photographers bear relation thereto.

A "BRILLIANT NEGATIVE."—Many will perhaps say that it is better known than described; but, if a description had to be given, it would mean a plate in which the silver deposit ranged from opacity to clear glass, with a wide range of tone between. In many cases the description would be correct, and, if the colour of the negative were of the blackish or bluish grey obtained by the use of sulphite of soda or ferrous-oxalate, the resulting print would, no doubt, be a brilliant picture. But tinge the film yellow or orange, and the "brilliant negative" will give only hard, "soot and whitewash" prints. This was the rock on which the old collodion workers split; they found that with gelatine plates and pyro-ammonia development, what they had learned to regard as brilliant only produced irredeemable hardness. I should, therefore, be inclined to define a "brilliant negative" as one that gives a brilliant print, that is, a picture with a minute quantity of pure black and white, and a wide gradation of tone between.—*Journal of the Photographic Society of India.*

INTENSIFYING COLLODION NEGATIVES WITH HYDROKINONE.

BY DR. J. M. EDER.

For the purposes of photographic reproduction the collodion process is still of the greatest value. For photo-lithography, zincotype, lichtdruck, &c., collodion plates are better adapted than gelatine emulsion, because they more readily reproduce faint lines with clearness.

In the reproduction of line subjects, intensifying is generally effected by means of iodide of mercury, followed by blackening with sulphide of ammonium. We thereby obtain a very dense opaque deposit. For more delicate negatives, of half-tone subjects particularly, the well-known mixture of pyrogallic acid, nitrate of silver, and citric acid, has been hitherto employed. Captain Hübl, of the Imperial Military-Geographical Institute in Vienna, has introduced with success a process of intensifying with hydrokinone, nitrate of silver, and acid, resembling in action the old pyrogallic method, but safer to work.

With an unfixed wet collodion plate, this intensifier not only effects a harmonious strengthening of the picture, but it acts also by continuing the action of the developer which has preceded it, in bringing out details. Applied after fixation, it intensifies without injury to the clear shadows.

The action of this intensifier is, however, not like that of mercury solution, which acts only in proportion to the amount of reduced silver present, but a larger proportion is deposited upon the high lights, thus assisting in the production of brilliancy.

Captain Hübl mixes his re-developer according to the following formula:—10 grammes of hydrokinone are dissolved in 1,000 grammes of water, and so much acid is added that when the solution is mixed with one-third of its volume of a three per cent. nitrate of silver solution, it remains clear for the space of five minutes. The addition of a few drops of sulphuric acid or of five grammes of citric acid fulfils this condition. This intensifier is more delicate in its action than that composed of iron and silver, and has the great advantage over pyrogallic acid, that fixed negatives may be treated in full daylight, and the action renewed without danger as many times as may be desired.

At the Imperial School and Institute for research in photography and reproduction processes in Vienna also, Hübl's hydrokinone developer intensifier for wet collodion plates is worked with the best results, and is highly recommended by the staff.

In accordance with the foregoing formula, solutions were made of

A.—Hydrokinone	... ...	10 parts
Water	... ...	...1,000 „
Citric acid	... ...	6 „
B.—Nitrate of silver	... ...	1 part
Water	.. ..	30 parts.

Before use, 3 volumes of A (hydrokinone solution) are mixed with 1 volume of B (silver solution).

For a somewhat under-exposed negative, the plate is intensified with the accustomed sulphate of iron solution before fixing; by this means detail is got out. A properly exposed and fully developed negative, on the other hand, is intensified after fixing.

Negatives intensified with hydrokinone become so dense, that they suffice perfectly for all kinds of reproduction processes, photo-lithography, &c. If, however, complete opacity is desired, the plate intensified with hydrokinone is afterwards treated with iodide of mercury and sulphide of ammonium. We recommend all photographers who still work the wet collodion process to give the hydrokinone intensifier a trial.

ORNAMENTAL PRINTING IN PHOTOGRAPHY.

Much use can often be made of fine ornamental engravings found on ball orders and menu covers, also of scenery engravings, paintings, embossed, painted, or otherwise decorated plaques, in ornamental printing.

First, select your engraving, an assortment of which can generally be found in art stores or stationery supply houses. An engraving with a bust or view in a circle, or some other shape, gives most satisfactory results. If you wish to mount the print on regular size mounts, you will have to take the proportions into consideration, but as that would make selection difficult, the best plan would be to cut the mount to suit the print; the edges could be bevelled, and the whole mounted on a larger size gilt edge mount.

When the engraving is selected, place it in a good light, square to the camera, make a negative, and take a proof. With a thin-bladed and very sharp knife, cut out the circle or opening in the proof, being careful to make a single clean edge cut. Stick the centre cut-out exactly in the opening on the negative, and adjust the outside on the portrait negative you wish to print from. Take off a good print from the ornamental negative, which will now be blank inside the circle, in which space the portrait or view is to be printed. By holding the negative to the light, the print can be adjusted by looking through; the printed border will be protected by the cut-out around the portrait.

It is desirable to find a larger engraving than the finished work is to be, as reducing adds to its fineness.

If an engraving with a circle cannot be readily obtained, a landscape can be used, and a white card cut to any desired shape, with edges bevelled or otherwise ornamented, and artfully placed on. It adds to the effect if the corner be curled upward a trifle. This gives the form to cut out by.

Portraits can be *vignetted* in, in place of using forms, by aid of "dodgers." A good dodger can be made by cutting a card to the desired shape, and pasting on layers of white tissue paper, each layer a trifle larger than the one before. This grades off the light, and very little movement will be necessary. Tie a thread to it, and let it hang in contact with the negative over the spot you wish to keep blank, moving it slightly while printing. Then, to protect the border while the portrait is printing, make a dodger by cutting a hole through a card, and trimming the opening with tissue, to be used in the same way.

If a circle, oval, or arch-top form be used, the form can be embossed after the print is mounted and burnished. Many photographers already have one of the old embossing presses, and a new iron pattern to fit the form could easily be obtained.

An ingenious printer will see many ways in which to use the above for decorating showcases, reception rooms, for holiday trade, for use on silk handkerchiefs, hat crowns, &c. If you are looking for something new, perhaps this will assist you, as it has never been used by the profession at large.—*Boston Photographic Review.*

PHOTOGRAPHIC CLUB.—The subject for discussion on Wednesday, January 8th, will be "The Best Way of Storing Negatives"; and on January 15th, "Intensifying and Reducing Negatives."

LEWIS MORRIS RUTHERFURD.

THE *Scientific American* of December 14 gives a portrait of this scientist, together with an interesting account of his career. Mr. Rutherfurd, it appears, was born in New York in 1816, and comes of distinguished lineage, his grandfather being John Rutherfurd, twice elected to the United States Senate. Senator Rutherfurd's father entered the British Army at the age of seventeen, and after taking part in the Canadian campaign, resigned his commission, married a daughter of James Alexander—thus making him a brother-in-law of Lord Stirling—and became a citizen of New York.

His grandson (Lewis Morris Rutherfurd) selected law as the profession which he proposed to follow, and studied under Governor William H. Seward (afterwards Secretary of State in President Lincoln's cabinet) in Auburn for two years, and then in New York City with George Wood, who was at that time one of the foremost lawyers in the country.

In 1837 Mr. Rutherfurd was admitted to the bar of the New York State Courts, and entered into partnership with Peter Augustus Jay, the son of the Chief Justice who administered the oath to President Washington in 1789, with whom he continued until Mr. Jay's death, in 1842, and then he became associated with Hamilton Fish, who was afterwards Secretary of State in President Grant's cabinet. Mr. Rutherfurd continued in active practice until 1849, when he went to Europe. On his return he did not resume his profession, but thereafter devoted his leisure to studies in astronomy and optics. He erected an observatory in the garden of his residence, and there did his principal scientific work.

One of his earliest contributions was concerning the "Companion of Sirius," whose discovery had just been announced by Alvan G. Clark, the well-known maker of telescope lenses.

In 1861 he began a series of experiments with the view of determining the best form of instrument for the purpose of continuing Fraunhofer's observations upon the spectra of the heavenly bodies. He adapted Bunsen's and Kirchhoff's simple form of spectroscope, consisting of a condensing telescope with adjustable slit, a scale telescope with photographed scale of equal parts showing bright lines upon a dark ground, a flint glass prism of 60°, and an observing telescope with Huygenian eyepiece, magnifying about five times, the whole firmly but lightly mounted on seasoned wood, and provided with an adapting tube in front of the slit, by means of which the spectroscope is attached to the eye-tube of the equilateral. A year later he published his results in a paper, giving the fixed lines exhibited by the moon; also the lines and bands of Jupiter and Mars, with maps of the spectra of seventeen of the fixed stars, and including a full description of the instruments that he used.

This was the first work to be published after the great revelations of Bunsen and Kirchhoff, and was the first attempt to classify the stars according to their spectra. While Mr. Rutherfurd was engaged in making these researches on the spectra of the stars, he discovered the use of the star spectroscope, by means of which it is possible to show the exact state of achromatic correction in an object glass, and is particularly adapted for the rays that are used in photography.

In 1864, after many experiments in various directions, but all undertaken for the same purpose, he succeeded in devising and constructing an objective of $11\frac{1}{4}$ inches aperture and about 15 feet focal length, corrected for photography alone. It was constantly used by him in making negatives of the sun, moon, and star groups.

At the January meeting of the National Academy of Sciences, in 1864, he presented a paper "On Photographs of the Solar Spectrum," accompanied by a picture that he had taken by means of bisulphide of carbon prisms. It contained more than three times the number of lines that had been laid down within similar limits on the charts by Bunsen and Kirchhoff.

He also was the first to show the double character of the D sodium lines in the spectrum, finding that it "is resolved into fourteen fine and close lines, with a beautiful and symmetrical band of finely doubled lines stretching towards A."

About the same time he published criticisms on different forms of spectroscopes that had been used by Secchi, Airy, and Donati, and in 1865 produced an automatic form of a six-prism spectroscope, which still continues the best in use.

In 1868 he built a new objective, with 13 inches aperture and about 15 feet focal length. This glass was an ordinary achromatic, such as is used for vision, and was converted into a photographic objective by the addition of a third lens of flint glass, which made the proper correction, and could be affixed in a few minutes. With this instrument Mr. Rutherfurd made several photographs of the moon that are of remarkable beauty, and have never been surpassed in delicacy or exactness. One taken on February 27th, 1871, is stated by Warren de la Rue to be the finest in existence.

He constructed a micrometer for the measurement of astronomical photographs for use upon pictures of solar eclipses or transits and upon groups of stars, of which he has measured several hundred, showing, as it is claimed by him, that the photographic method is at least equal in accuracy to that of the heliometer or filar-micrometer, and far more convenient.

In 1870 he constructed a small ruling engine, which produced inference gratings on glass and speculum metal that were superior to all others until the recent productions of Professor Henry A. Rowland, of the Johns Hopkins University. With one of these gratings he obtained a photograph of the solar spectrum that for a long time was unsurpassed.

In 1883 failing health led to the discontinuance of his scientific work, and in December of this year he presented his astronomical instruments to the observatory of Columbia College, where they are mounted.

Besides membership in various other scientific bodies, Mr. Rutherfurd is an associate of the Royal Astronomical Society of Great Britain, and his work has been recognized by the gift of various diplomas, orders, and medals, both at home and abroad.

THE EYE AND THE CAMERA.—The eye requires at least a tenth of a second to close, so that all separate motions which are quicker than that appear blurred to one looking at them. It can easily be understood, therefore, how a photograph obtained of a moving object by an exposure of one-hundredth, or even, as sometimes is done, by one-thousandth part of a second, while accurately reproducing the exact position of the object at the time of photographing, is not a representation of the subject as it appears to the human eye. It does not convey the idea of motion even, but rather of "*petrified* motion," as some one has said, and seems grotesque and unnatural. Such photographs, however, give investigators an opportunity, which they otherwise could not have, of studying separate motions, and are often of the greatest value.—*W. I. Lincoln Adams.*

PURIFICATION OF LITMUS.—Dr. Otto Foerster, says the *American Druggist*, prepares the pure colouring matter of litmus in the following manner:—Commercial litmus of best quality is first extracted by ordinary alcohol in the cold, then digested with water, the solution filtered and evaporated. This is a combination of the processes proposed by Wartha and Mohr. The residue is again dissolved in water, the solution filtered, and the filtrate precipitated with absolute alcohol mixed with a little glacial acetic acid. The precipitate is collected upon a filter and washed with alcohol. This causes a violet, fluorescent colouring matter to remain in solution. The remaining residue is once more dissolved in water, and the precipitation, filtration, and washing repeated. At this stage a red colouring matter, which has a violet tint in an alkaline liquid, remains in solution. After once again repeating this process, only a small amount of the last-named colouring matter remains in solution. The precipitate upon the filter is then dried, being repeatedly moistened during the drying with alcohol, for the purpose of expelling the acetic acid. The precipitate is then again dissolved in water, and the solution filtered. Finally, the colouring matter is precipitated with alcohol rendered faintly alkaline with ammonia, then collected upon a filter, washed with pure alcohol, and dried.—After *Zeitsch. f. anal. Chem.*, 1889, 428.

A FEAT IN PHOTOGRAPHY.

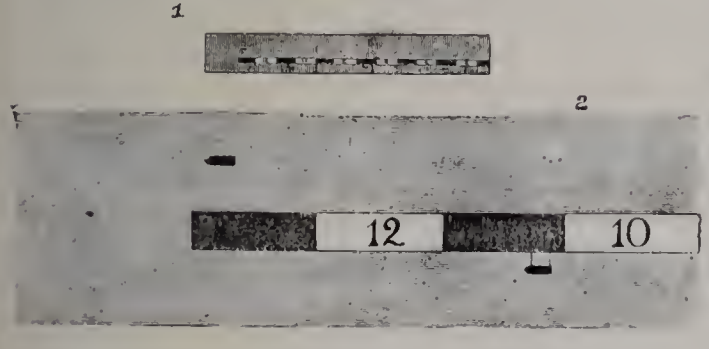
TROTTING horses, leaping acrobats, running hounds, even a locomotive at full speed, have proved comparatively easy subjects for instantaneous photography, but certain other moving objects have severely tested the skill of the photographer as well as the capacity of the apparatus employed.

Perhaps the most difficult feat yet attempted in the line of photograpy is that of catching an impression of a bullet or a cannon ball as it flies across the field of the camera. This has been accomplished with varying degrees of success, but most of the specimens of this class of work hitherto produced have been at the best mere streaks, not in any way resembling the projectile. This failure to procure a sharp impression is shown by the photograph itself to be due to lack of shutter speed.

A recent invention, to which we alluded a short time since in an article on "The Tachyscope," has apparently obviated this difficulty, so that it can no longer be said to be impossible to secure a recognisable picture of a flying projectile.

Last year Mr. Ottomar Anschutz, of Lissa, Prussia, tried some very interesting experiments at Gruson, near Magdeburg in Germany, which demonstrate the practicability of photographing a flying bullet by daylight. Mr. Anschutz constructed a small camera of great strength, in which he arranged a shutter of his own invention, which in this case was operated by an eight hundred pound weight. The shutter is arranged immediately in front of the sensitive plate, and consists simply of a curtain having a narrow slit as long as the plate, the width of the slit being variable. This slitted curtain passes over the entire face of the sensitive plate, exposing successive portions thereof to the action of the light. This arrangement insures a brief exposure of all portions of the image of the moving figure, thereby producing an extremely sharp negative. The slit in the shutter during this experiment was adjusted to a width of 0·002 of an inch.

[Figs. 1 and 2 represent the relative sizes of the photograph and its enlargement.]



In the field of the camera, which covered a space of 46 feet, Mr. Anschutz drew a canvas curtain, and at every $13\frac{1}{8}$ feet suspended a projectile 12 inches long, for comparison with a projectile of the same kind to be fired from a cannon. At a distance of 200 feet a wire netting was placed, which was connected electrically with Anschutz's drop shutter. The projectile passed through the wire netting at a velocity of 1,312 feet per second, and its image was caught on the sensitive plate after having sped along the canvas curtain a distance of 42 feet. The shutter passed over the plate in the short space of 75-1,000,000 of a second. The numbers marked on the canvas indicate the distance in meters. The projectile shown below the space between the 10th and 12th meters is one of those suspended for comparison; the other shown above the 13th meter is the one photographed in its flight.

The photograph we reproduce was furnished us by the United States Photograph Supply Company, of No. 3, East 14th Street, New York City, who represent Mr. Anschutz in this country.—*Scientific American.*

PHOTOGRAPHING INTERIORS.—Mr. G. Alpers says that gelatine plates should be exposed proportionately much longer than wet collodion ones. He had made the photograph of an interior with the aid of this last process, exposing for three hours, and he desired to reproduce this same interior on a gelatine plate which was from ten to fifteen times more sensitive. He supposed that an exposure of thirty minutes would be sufficient, but in developing he obtained almost nothing, and he was obliged to give an exposure of five hours. The author explains this singular fact as follows:—Bromide of silver is much more sensitive than the iodide of the same metal to the intense rays, whilst it is not more sensitive than iodine to the very weak rays. This explains why the negatives of portraits on gelatine are generally harder than those on collodion. To reproduce interiors having windows placed opposite the objective, the author covers them with red tissue paper, which he removes for a few seconds at the end of the exposure.—*Invention.*

A SUBSTITUTE FOR CHRISTMAS CARDS.—The *Birmingham Weekly Mercury* recently offered a prize in a "Suggestion Competition" for the best idea for something that would make a good substitute for Christmas cards. In their Christmas number of December 21st, they state that the two best suggestions are equal, and they have therefore divided the prize. One of the winners of the divided prize suggests that Christmas cards should be coupons to entitle the recipient to a chance in a prize etching or engraving lottery. The other winner is Mr. E. Smith. His suggestion is as follows:—"The popular form of Christmas greeting I would suggest as an equivalent for Christmas cards would take the form of photography. I would suggest that the large photographer of the city, the local photographer of the small town, and the amateurs who are now numbered by thousands, should carry out next year the following scheme. The pictures to be sent to our friends may be: (1) Family groups in interiors produced in the evenings by the aid of magnesium light, and printed by the artistic and permanent bromide process. The family may be engaged at dinner, playing some game, reading, writing, romping, &c. (2) The provision of multiplied copies of some object or objects of interest in a town or village, either printed faintly, or a part blocked out for the printing from another negative or single figures or groups in the foreground. (3) The pourtrayal by the same means as No. 2 of a scene in which the recipients are persons having some interest in the past, and in which the recipient may be represented, if necessary, by a friend who makes up for the absent man. Unless the friend was something of an actor in the posing, he had better be kept well in the background, or be nearly hidden by the other *dramatis personæ*. These would be *tableaux vivants*. For them the larger and wholesale photographers would have to keep background negatives, foreign, as well as home views. The merits of the scheme are that a more personal and interesting character can be given to the photographs than is possible with the vague and multiplied Christmas cards; that it would foster an artistic and dramatic taste, and afford scope for amusement, ingenuity, and humour in the carrying out; that the cheaper ones would entail less trouble, as well as cost, to those not having sufficient leisure; that the cards, conveying the next best representation of their friends, and their present or past surroundings, to the presence of the friends themselves, would be valued and treasured; that they would afford winter work as well as summer to the photographer, amateur as well as professional; and that the scheme would undoubtedly further develop photography as a fine art.

PHOTOGRAPHING WINTER SCENES.

ROUGHLY speaking, there are two classes of winter pictures which the photographer meets with on an outing. A typical landscape of one class is a snow-covered landscape in which trees, shrubs, buildings—everything—are completely enveloped in white. The trees and bushes glitter with ice; the fields sparkle beneath the sun. There are no contrasts, but only a mass of brightness, glitter, and glare. In order to photograph it satisfactorily, we must select a time of day when the sun is at one side of our camera and a little behind it. This is in the early morning or in the afternoon, according to the point of view which we have chosen for our camera. When the sun is obscured, the shadows are soft and the snow is devoid of reflections. On such days the winter picture we have selected can be photographed with advantage. The exposure should be rather short on such a day, for the light is rather weak, and the brisk development which is required will give a proper contrast and brilliancy to the negative. Isolated bits of frost work, a glittering bush sparkling with ice jewels, or a fence-corner covered with dazzling whiteness, should be photographed in a similar manner. Such subjects are very satisfactory when reproduced by the camera.

The other, and perhaps the largest class of snow scenes, is quite different from the one we have been considering; it is therefore photographed quite differently. In this class we have winter pictures of the greatest contrasts: dazzling whites and profoundest blacks; a field covered with glittering snow, edged with the darkest trees. The photographer must now overcome contrast, and give softness to the picture. As before, overcast days are chosen, and the exposures are made in the morning or afternoon; but the exposure must be ample, and the development very slow. This will aid in overcoming the brilliant contrasts in the natural view. Orthochromatic or colour-sensitive plates may be used with advantage in photographing such scenes. The developer should be rather weak, especially in beginning the process. It may be strengthened as development goes on, until the proper density is secured in the negative.

For developing negatives of the first class spoken of, the developer can be of full strength in order to bring out all the contrasts there may be in the picture, but it should be used cautiously, especially when first applied to the plate. In the development of snow pictures there is opportunity for the greatest skill. A well-selected and exposed plate may be lost by careless or ignorant development; while, on the other hand, errors in exposure may be to a great extent corrected by judicious developing. The new developing agent, eikonogen, has been used with good effect in this kind of work, as it renders the most delicate details in the half-tones and shadows.

Fixing, washing, and the subsequent processes are, of course, the same in this as in other classes of photographic work; but in toning and mounting winter pictures there is room for the exercise of good taste. Do not tone a winter picture to a warm brown, and mount on a chocolate card. Let the toning be carried to the cold blacks and whites, and mount on white or pearl cardboards. Bromide paper is peculiarly appropriate for winter negatives, and the platinotype may also be used with good effect. Ferro-prussiate or "blue" paper is especially suitable for printing many snow negatives, and when slightly worked over with colours harmonising with the appropriate blues and whites of the cyanotype, a delightful art feeling can often be given a blue print of a winter landscape. These additional touches, however, must not be overdone, the merest retouching here and there being all that is necessary to bring out a most pleasing result. They may be mounted with good effect on larger sheets of heavy paper, and framed in plain wood, narrow and light. Bromides and platinotypes should be similarly mounted.—*Abstracted from the Photographic Times.*

THE HARVARD COLLEGE TELESCOPE.

THE photographic telescope presented to the Observatory of Harvard College promises to be the most perfect instrument of its kind. It will have a lens of about twenty-four inches aperture, and a focal length of about eleven feet. It will differ from other large telescopes in the construction of its object-glass, which will be a compound lens of the form used by photographers, and known as the portrait lens. The focal length of such a lens is very small compared with its diameter, and much fainter stars can be photographed in consequence. The advantage is even greater in photographing nebulæ or other faint surfaces. Moreover, this form of lens will enable each photographic plate to cover an area several times as great as that which is covered by an instrument of the usual form. The time required to photograph the entire sky is reduced in the same proportion. A telescope of the proposed form, having an aperture of eight inches, has been in constant use in Cambridge for the last four years, and is now in Peru, photographing the southern stars. It has proved useful for a great variety of researches. Stars have been photographed with it too faint to be visible in the fifteen-inch refractor of the observatory. Its short focal length enables it to photograph as faint stars as any which can be taken with an excellent photographic telescope having an aperture of thirteen inches. The eight-inch telescope will photograph stars about two magnitudes fainter than can be taken with a similar instrument having an aperture of four inches. A corresponding advantage is expected from the increase of the aperture to twenty-four inches.

Other advantages to be anticipated from the use of such an instrument will arise from the opportunities which the photographs will give for continuous and detailed study. With them work can be done at any place and any time, and, by multiplying copies, by any number of observers. And with them more could be added by a single lens to our knowledge of the stars than could be obtained by any number of telescopes of the usual kind. Professor Pickering is seeking the best possible location at which to mount the instrument. Owing to the difficulty in maintaining regular observations in the Eastern States that arises from the prevalence of cloudiness, he suggests one of the mountains of southern California as likely to offer the most favourable climatic conditions attainable.

THE Christmas number of the *Photographic Times* is both poetic and artistic. It contains no less than five poems, and four illustrations exclusive of the ordinary illustrative cuts. The illustrations include "Christmastide in Shakespeare's Country," from a negative by Dr. J. L. Williams, the reproduction being by the Photogravure Company, of New York; a dog portrait, from a photographic portrait of a painting reproduced by the Electro-Tint Engraving Company, who also reproduce a film negative, by Mr. W. J. Stillman, of "The Facade of the Duomo of Florence;" there is also a pretty child picture by Husnik, with a descriptive article of his method known as "Leimtypie."

PICTURES SENT BY LIGHTNING.

For some time the transmission of pictures by electricity has been discussed as within the range of possibility, and we now find in *The Boston Herald* an account of an interview with an inventor residing in New York, according to which the problem has actually been solved; provided, of course, that the whole matter is based on fact, and not fiction. This is how our contemporary publishes the event, in the form of that favourite American mode of an interview.

"What would people say of a newspaper that published, say, a dozen pictures of the recent Sullivan-Kilrain prize fight, taken from instantaneous photographs, transmitted by telegraph, and reproduced in its columns within six or eight hours after the battle?" This was the extraordinary question put by L. Ginochio, a chemist, electrical expert and successful inventor, and it naturally caused the gentlemen who heard him to open their eyes wide in astonishment. M. Ginochio smiled. "I have not suggested an impossibility," he said; "indeed, I have already completed a machine which will do just the very thing I have mentioned. I have applied for a patent, and while its construction is to some extent a secret, I am willing to show you the machine in operation."

In his laboratory and experimenting rooms on West Thirty-fourth Street were a number of electrical machines of various descriptions. Great coils of wire lay around on the floor, and on tables were rolls of "No. 32" wire, as fine as the hair of a woman's head. Telephones, battery cups, galvanometers, electric switches, and other apparatus lay about in seemingly hopeless confusion. On a table was a box of about 20-in. square, attached to wires on an electric battery. A "feedboard" or shelf projected on one side of the box. "This is the machine that is to revolutionise newspaper pictorial art," explained Mr. Ginochio. "It is filled with clockwork, and operated by a strong electric battery. Its mate is at the other end of the line. Now you can write a signature or a letter, and it will transmit either, with the identical characters formed by your pen. But that would be nothing. Auto-telegraphy has been known for fully ten years. But this will carry out the auto-telegraphic idea to the fullest extent. You can write as much as you please, thousands of words if you like, as newspaper men and others frequently have to do, and this machine will chew it up—that is, transmit it as fast as you write. Indeed, the writing can be done on a continuous roll, and when a score of lines are written, the top of the roll can be fed to the machine while the writer continues filling up the rest, and without tearing the roll. It can be regulated so as to keep pace exactly with the pace of the writer, and by the time he has finished the machine will be on its last lap, and will end its task almost immediately. The newspaper or other office receiving the matter will thus have it in the writer's own handwriting, and within a few moments after it has passed out of his hands."

"But how is it proposed to transmit pictures?" "By the same method. The paper to be used will be washed with a weak solution of chloride of calcium, which will make it a conductor. The ink will be the non-conductor or insulator. The pictures will have to be reproduced with pen and ink at the point of sending, and with this as the only delay they can be transmitted without difficulty, every line and shadow being reproduced with extreme fidelity." "Have you tested the machine?" "I have, and found it worked like a charm. So long as the clockwork keeps running it cannot get out of order. This machine is designed especially for the use of the daily press, and will enable our newspapers to produce accurate and excellent pictures of events in the issue immediately following, instead of, as now, waiting a day or two for the artist. You can readily understand how such an instrument could be applied on a leased wire, where voluminous press reports have to be sent daily or nightly. Every reporter could then be his own operator. The delay in filling despatches would be obviated, and the slow-going Morse transmission superseded. Besides, another point in its favour, which all electricians will appreciate, is that the broader surface presented magnifies the electric ratio so greatly that, even at a time when ordinary telegraphic instruments are unavailable, on account of storm or for other causes, this machine will unfailingly give a connection strong enough to do the work required."

"What will the instruments cost when completed?" "I cannot tell yet, but they will be within the reach of every enterprising newspaper, you may be sure." The pictures transmitted by Mr. Ginochio's machine, though faint, are described as sufficiently distinct for all purposes. The minutest detail is reproduced with the fidelity of a photograph. Of course only pictures that have been first drawn upon the prepared paper can be transmitted. The time consumed does not exceed many seconds. A grinding noise, like the slow running down of a clock, is heard in the machine while in operation. With a few touches at the hands of a competent draftsman the pictures are sent to the engraver or electrotyper. If properly prepared in the first instance before transmission, Mr. Ginochio says they will not require retouching at all, as the machine will report electrically every mark upon the paper. Mr. Ginochio, the inventor, is an Italian by birth. His father was a man of considerable rank in the household of the first Napoleon, and was with the "Little Corporal" through many of his troubles. The son, who came to this country when a child, is a veteran of the civil war. He is stated to have many electrical and other patents now in operation in different parts of the States, but if his transmission of pictures by telegraph should prove a success, it would no doubt do more for him than all his other inventions.—*Invention.*

PROCESS work, it is said, has so diminished the demand for good box-wood for wood-engraving, that it is becoming difficult to procure, the best having nearly trebled in price in recent years.

INK FOR WRITING ON PHOTOGRAPHS.—The following formula is said to produce an ink serviceable for marking proofs; the writing being executed on a dark portion, the lines soon bleach by the conversion of the silver into an iodide:—

Iodide of potassium	10 parts
Water	30 ,,
Iodine	1 part
Gum	1 ,,

LONDON "IN CAMERA."—In an article in the *City Life* of January 1st, illustrated by five reproductions of instantaneous photographs by Mr. T. C. Hepworth, the writer says:—"The time is coming when we shall see London as it really is. A good many artists have tried to depict it, with more or less success. Hogarth drew its seamy side, Cruikshank its extravagant aspect, John Leech the picture of the middle class. All these attempts had their excellences, but to look at them now they seem to be more or less caricatures. In a hundred years hence, when future generations gaze at the instantaneous photographs taken in the London streets to-day, they will see the good-and-bad citizens of the nineteenth century exactly as they are."

TRADE UNION OF PHOTOGRAPHIC WORKMEN.—Mr. Arthur G. Field, Maidstone, sends us a letter advocating the formation of a photographic trade union. His proposal, he says, has no connection with an attempt to found a so-called "National Photographic Union" formed merely of representative photographers to guard the interests of the trade, but is in favour of the foundation of a *trade union*, to which every photographic *worker* (male or female) may belong on proving his or her capability. The object, he explains, will be as follows:—By paying a sum weekly (say 6d.) a fund will be created which will be applied to the payment of "donation benefit" or "unemployed benefit" to those out of work (say 10s. weekly). In case of disputes with employers the payment will also be made. By a system of qualification, either by apprenticeship, by receipt of wage for a number of months, or by examination, the ability of members will be assured. Each branch will send its monies to London, and London will make all payments of benefits to the branches—"centralisation, but federation," with direct responsibility of the executive to the smallest bodies capable of exercising electoral power. Those interested in the project are invited to communicate with our correspondent as above.

Notes.

Our suggestion last week *apropos* of the possibility of utilising Hansom cabs when on the rank for the purpose of obtaining instantaneous photographs of scenes in the streets of London appears to have "caught hold." The *Daily News* comments upon it, and prophesies that some one before long will be tempted to put the suggestion into practice. The *Daily News* does not name the source of its inspiration, but we do not grumble, as our contemporary has on nearly every other occasion when it has quoted from our pages—not seldom by the way—given us due credit. The *Globe* looks upon the photographic cab-driver as a person not to be encouraged. It is bad enough to know, it remarks, that one's private conversations may be handed down to posterity by the cabman who writes shorthand, but it is worse if the said conversations will be illustrated with "instantographs" of the tops of our hats and the ends of our noses. Frightful as this possibility may appear, it is within measurable distance, though the operators may not be cabmen with a fancy for photography.

The *Daily Graphic* is still an object of curiosity with those who know the stupendous difficulties to be overcome. We stated a week or two ago, upon reliable information, that wood blocks would be mostly used, as being more quickly produced than "process," though much more costly. The editor of *Science and Art*, who was present at the reception given at the *Graphic* office, states that but for photography and photo-mechanical printing, the scheme of a daily illustrated paper could not be carried out. The editor of *Science and Art* does not give any official information, and in the absence of this, we are inclined to adhere to our statement, and for more reasons than one. Whatever the *Graphic* will do, will be done artistically. Mr. Thomas' policy has always been to produce the best thing possible, and this policy will be carried out in the daily paper.

Mr. Thomas' notion is that a *rara avis* in the shape of a reporter who can sketch may be caught, and this is the kind of thing he wants to cultivate. We are afraid, however, that it will be a long time before he will get a man equally good with the pen and pencil. There are a few reporters with a taste for sketching, but to sketch with a pencil is one thing, to prepare a sketch ready for photographing, or to draw on the ordinary transfer paper suitable at once for zincography, is another. What the *Graphic* will probably do, will be to expect sketches as well as they can do them from its reporters, and have them "touched up" or redrawn by its own artists. This system has been going on for years both at the *Graphic* and *Illustrated London News*, and enables them to produce a number of highly finished drawings of scenes in all parts of the world, the foundation of which were the merest skeletons furnished by travellers. In this way a good deal may be done, but as for photography, it is out of the question. Even with the assistance of the electric light, the time required is longer than that in which a wood-cut can be produced.

The respective merits of photography and hand-drawings have been pretty warmly discussed by astronomers in regard to their own particular study, and the general opinion appears now to be that photography has advantages which drawings lack. It would seem as if very much the same battle was about to be fought by microscopists. When photography was applied to the microscope, everybody was in its favour; there are, however, signs of a reaction. Anyway, advocates of the older method of representation are not wanting. Mr. W. J. Simmons, in the *American Monthly Microscopical Journal*, urges that photography is too indiscriminately faithful; it perpetuates details, such as dirt and extraneous matters, which may well be left out of a drawing accurate enough for all practical purposes. Photography does not compel the thorough study of the object necessary when you sit to draw it, besides which it involves the expenditure of more time and money than many can spare. Mr. Simmons admits that photography is useful to correct the inaccuracies in a drawing, but, as a discipline for accurate observation, photo-micrography is inferior to drawing, and cannot be regarded as a substitute.

The automatic machine may perhaps revive the taste for the stereoscope—in a way. In Paris the two things have been combined. You drop in the usual penny, and apply your eyes to a pair of lenses arranged after the fashion of an opera-glass. Pictures are then displayed in rapid succession, one picture lasting seven seconds, until the contents of the box are all exhibited. The pictures are illuminated by the electric light, which is started by the mechanism which receives the penny. The automatic machine which delivers photographs of popular actresses is, we believe, not a very brilliant success. The automatic stereoscope might answer for a time.

The question of the site of the National Portrait Gallery has been settled. The new building is to be situated at the back of the National Gallery, on a piece of ground which, owing to the alterations effected by the construction of the Charing Cross Road, looks at the present moment a very dismal blank. The Office of Works, it is satisfactory to see, has an eye to the future, for it has got permission from the Treasury to purchase from the County Council the rights in a small triangular piece of ground which, if it were built upon, would effectually obscure the view of the new gallery. It is perhaps vain to expect that the glance of the Office of Works will be carried still farther into the future, and to hope that the new building will be constructed with an eye to the possible erection of a new National Gallery worthy of the art treasures possessed by the nation.

OSCAR GUSTAV REJLANDER.

BY H. P. ROBINSON.

THE idea of an exhibition of all that could be gathered together of the works of O. G. Rejlander at the Camera Club was a happy one, and will serve to recall to the memory of many photographers the great artist and genial friend who honoured our art with his genius; and he was the greatest genius who ever gave up to photography talents which would have enabled their possessor to shine in any form of art.

Rejlander was one of the earliest friends I made through photography, and it gives me great pleasure to respond to the request of the Editor of the PHOTOGRAPHIC NEWS to say a few words on the man and his works. I first met him at a meeting of the Birmingham Photographic Society in 1858. He was then living in Wolverhampton, and shortly after our meeting he came to visit me at Leamington; from which time until his death in January, 1875,* we continued in the closest friendship, and for many years, in photographic criticism, our names—perhaps because we had the same aims, and partly also, probably, for the sake of alliteration—were coupled together, a conjunction of which I have always been proud; and it is a curious coincidence that our works have again come together, or, rather, followed each other, in the "One Man" exhibitions of the Camera Club.

At the time I have mentioned, Rejlander had made himself famous by many pictures which were far and away, in all essential art qualities, beyond anything that had ever been before shown, and especially by his wonderful composition which represented allegorically "The Two Ways of Life." This was first shown at the Art Treasures Exhibition at Manchester, in 1857, to which exhibition, by the way, I had sent my first poor efforts at pictorial photography. This famous picture, as was also much of his best work, was executed at Wolverhampton, in a small studio in which many a photographer would scarcely have found room to photograph a single head. Here this astonishing group, consisting of about thirty figures, and attempting the highest poetry in art with so much success as to gain respect, if not approval, from all, was put together. Anyone but an enthusiast would have seen the impossibility of success with such a subject in such materials, but amid difficulties that would have scared most men, Rejlander saw only the end, and if he did not succeed in reaching it, his failure was almost as honourable as complete success.

Apart from the subject, which is allegorical, and partly carried out by the use of the nude—now ruled, and rightly, to be outside the natural limitations of the art—the picture is a marvel of skill and excellence. In composition and in clearness of story telling it has never been surpassed in any art, and the apparent impossibilities he overcame have always been a wonder to those who know most of the means by which it was produced. No photograph has ever met with so much criticism, for and against. It was rejected at an Edinburgh exhibition, not, however, on its artistic merits; a picture intended to convey the highest moral was rejected because of its supposed immorality. It would take too much space here to trace the courses of the two youths, who are represented as going the two ways of life, the one to the good and the other to the bad. In 1858 Rejlander was persuaded to read a paper before the Photographic Society of London—the only one he ever read—in which he explained the meaning of every figure. At the same time, with the generous intention of being of use to photographers, and to further the cause of art, he, unfortunately, described the method by which the picture had been done; the little tricks and dodges to which he had to resort; how, for want of classic architecture for his background, he had to be content with a small portico in a friend's garden; how bits of drapery had to do duty for voluminous curtains; a simplicity into which others also have fallen, and thereby gave the clever critics the clue they wanted, and enabled the little souls to declare that the picture was only a thing of shreds and patches. It is so much easier to call a picture a patchwork combination than to understand the inner meaning of so superb a work as this masterpiece of Rejlander's! He had a sense of the injustice of judging a work by the method of its production. He says in his paper, "I have a lively presentiment that the time will come when a work will be judged by its merits, and not by the method of its production; and then, with some fostering care, things can and will be done that scarcely believers, and never unbelievers, yet dream of in their philosophy."

This picture was Rejlander's greatest effort, and I much regret that the committee of the Club was not able to secure a full-sized copy for exhibition: the small reduction gives a very inadequate idea of the large picture. In his paper the artist promised other and greater efforts in succeeding years; this promise was never destined to be fulfilled. He often regretted that he never afterwards found time, and, indeed, the means—for such pictures are expensive to produce—to carry out his intention. He felt that such ambitious work was not properly appreciated, but he never lost faith in the method of combination printing, of which he was the originator, and occasionally employed it for smaller pictures up to the last. One of these, now in the Camera Club Exhibition, I greatly value. He was always brimming over with happy ideas, and would at any time prefer to express himself in a picture than writing. I was once in the middle of a now long-forgotten controversy, endeavouring to defend our art from those who could only see in it a mechanical trade, when I received the little picture I have mentioned from him. He was a volunteer as well as an artist. The photograph represents Rejlander the artist jumping up from before his easel to introduce Rejlander the volunteer. The contrast between the artist in velvet coat and broad-brimmed felt hat, and the same man in the same picture in his regimentals, was startling. Under it was written "O. G. R. introduces himself as a volunteer to H. P. R.," thus delicately and pleasantly conveying that his help was at my service.

In ordinary manipulation Rejlander could not be called a perfect photographer; so that he conveyed his thoughts clearly, he did not care for delicacies of development or clean plates. To him art was a vehicle for conveying a thought. It was the thing to be said, not the manner of saying it, that demanded all his powers. He could never see the beauty of the indefinite. Being without affectation, a sound artist and real poet, nothing short of real art and true poetry would satisfy him. Though most original, he abhorred the eccentric.

Perhaps, after all, it was in fertility of ideas and imagination, and the readiness with which he used them, that he was at his greatest. As an example of his readiness, here is an illustration. He once sent home a portrait of a bright little boy dressed in velvet coat and knickerbockers.

* Both Almanacs record his death as taking place in January *and* June. This was obviously impossible. The real date was January 18th, 1875.

The boy had one hand in his pocket, and the action bent the figure a little aside. The picture was rejected because the figure was not upright. Rejlander immediately wrote underneath it, "I've got a pocket too!" and the picture was at once a tremendous success. Yet I remember an occasion when it happened that a title he strongly objected to turned one of his pictures into the most popular photograph of the day. It happened this way. He sent to an exhibition a picture of a very little boy yelling furiously. He was then making experiments in expressions to illustrate Darwin's "Expression of the Emotions in Man and Animals!" and entitled this photograph "Mental Distress." In his notice of the exhibition, a former Editor of the PHOTOGRAPHIC NEWS, the late ever-regretted H. Baden Pritchard, called the howling youngster "Gink's Baby." This hit the humour of the hour, which was then much interested in a book of that name, and it became the photograph of the day and sold by thousands; but Rejlander was never reconciled to the loss of his scientific title. Many examples may be quoted of his happy thoughts, both pathetic and humorous, but it would be difficult to describe them so as to do them justice, unaccompanied by the pictures. "Grief," "Night in London"—a most moving picture of a ragged and desolate boy seated on a doorstep—and "'Tis Light within—Dark without!" a blind woman singing, are examples of the pathetic that occur at the moment; while the humorous are represented by "Did She?" one man (Rejlander himself) telling an amusing secret to another, whose face expresses a full appreciation of what he hears, and "She is looking at me, the dear creature!" an ugly and vain old man smirking and looking out of the corners of his eyes.

In the very interesting book of Darwin's I have mentioned, are several figures in which Rejlander has tried to express in his own person the expressions intended to be conveyed. The contrasted figures of Anger and Humility on Plate VI., figures 2 and 3, are perfect, and show what possibilities as an actor were in him had he followed that branch of art.

Personally, Rejlander was beloved by all who knew him. His winning ways, his kindly genial charm, his ever fresh and humorous anecdotes, his quaint thoughts and original expressions, his enthusiasm for all art, and especially for the art of his adoption, his simplicity and sincerity, endeared him to his many friends. He was never known to use a word that would hurt the feelings of others; he preferred to be silent rather than condemn the work of another, and always took great delight in praising the attempts of a brother photographer when he honestly could. His was not one of those envious natures that cannot brook any success not his own; he rejoiced in the progress of the art, even when it was accomplished by other hands. He was absolutely free from petty jealousy. It was not necessary, nor his way, as it unfortunately is the way with some photographic aspirants, to denounce all art and artists so that he may stand in the foreground on his own little molehill. He was a rare man, a great artist, and a loving friend.

ELIMINATION OF HYPO.—Writing on the claim so often and so generally made, "that salt in the water in which prints are washed is a powerful aid in ridding them of hypo," Mr W. H. Sherman contends that "the function of salt water containing prints impregnated with hypo is to seriously hinder its elimination;" and that "it is, therefore, a serious mistake and loss of time to use it for the purpose of facilitating the accomplishment of that object."

Notices of Books.

THE OCEAN OF AIR: METEOROLOGY FOR BEGINNERS. By Agnes Giberne, with Preface by Rev. C. Pritchard, F.R.S. *(Seeley and Co., Limited, Essex Street, Strand.)*

THE student of photography in its scientific aspects should include in his course of study the principles not only of chemistry and optics, but also of meteorology, between which and photography there is a close relationship, for while in this day the changes of weather are recorded photographically (as shown in the book under notice), those changes themselves affect photography to a degree that is more commonly experienced than understood. Temperature affects not only the developing, fixing, and toning baths, but also lenses, which not unfrequently suffer, for instance, from the effects of frost, owing to the contraction of the brass rims, while condensed moisture ("water-dust," as it has been termed) on the glasses in cold weather is a common form of inconvenience. If it were necessary still further to urge the importance of meteorological study, argument might be found in the necessity of taking account, for the production of successful results in photography, of the optical conditions of the atmosphere, the requirement of attention to the correct representation of clouds in landscape, the hygroscopic properties of many substances used in photography, and the usefulness of some ability to calculate the probability of weather changes.

Though the volume before us is professedly written for beginners, and may not contain such specific information for photographers as is given, say, in Mr. Vincent Elsden's admirable papers in our pages some years since on "Meteorology for Photographers," still it embraces much that is well worthy the study of all who wish to obtain, in simple and graphic language, a general and intelligent conception of the nature of the phenomena in the midst of which we live. The interest of photographers in Miss Giberne's book will certainly not be decreased by the fact that it is illustrated by sixteen admirable illustrations engraved from instantaneous photographs.

MEASURING THE SPHERICAL AND CHROMATIC ABERRATION OF OBJECT-GLASSES FOR THE MICROSCOPE. C. J. A. Leroy.—In the present state of construction the problem of achromatism may be considered as solved, whilst this is far from being the case with aplanetism. The correction of spherical aberration requires, therefore, to be studied for the improvement of objectives.—*Chemical News.*

KIDDERMINSTER PHOTOGRAPHIC EXHIBITION, MARCH, 1890.—Several intending exhibitors having misunderstood rule 1 of the prospectus of the above, the Secretary desires to state that the entrance fee in each class is 2s., covering any number of frames. Also, in answer to the questions of numerous enquirers, he announces that the date for sending in application for space will be extended to February 1st, 1890.

PERMANENCE OF NEGATIVES.—Negatives developed with pyro. are quite as permanent as those treated with the ferrous-oxalate developer, if care be taken to ensure perfect fixation. Leave the negative in the fixing bath fully three or four minutes after it has been apparently fixed, and years will find its colour and printing qualities unchanged. With the ferrous-oxalate developer errors in exposure may be corrected to a certain extent, but not so much as with pyro. When development flags, a drop or two of the fixing solution will accelerate the action of the ferrous-oxalate developer considerably, but nothing will save a much under-exposed plate. As with pyro, the bromide of potassium or ammonium acts as a retarder of development.—Editor, *Journal of the Photographic Society of India.*

THE PROGRESS OF QUINOL DEVELOPMENT.*

BY ALFRED MASKELL.

THE difference of working with quinol is chiefly this: that whereas with pyro you commence with the bath uncompleted in composition and by tentative action, now that this is added according to the behaviour of the negative, with quinol you select the bath of suitable energy and modified composition, and allow the action to go on until its duty has been fulfilled in all particulars of which it is capable. Supposing the right one is not at first selected, still you cannot go wrong provided the succession of baths is in an increasing ratio of energy. The method of pyro development is not so applicable in this case. There appears to come a point when increasing quantities of alkali do not produce the same progressive effect, at the same time that in the composed bath there is great latitude in their proportional quantities without producing fog. With a properly composed developer we commence development with a strength of alkali which we do not intend to augment, and the action is allowed to proceed in assisting to bring out all possible details of which it is capable, the quinol concurrently acting its part in building up the requisite amount of density. A greater proportion of quinol will produce greater density, but the normal proportion can in every case be made to produce the same intensity of density, whether the bath be new and powerful, or old and worn out. In the latter case the action must always be slow, its application being to cases of extreme exposure. A point to be remembered is that in the repeated use of the same developer, the bath becomes more and more charged with a powerful restrainer, produced by the bromide of soda resulting from the combination of the bromide given up by the plates previously developed with the soda of the developer. I will now proceed with a description of what I consider the best method of using the quinol developer. This consists simply in a selection, from what may be called a battery of baths of different degrees of energy, of that one most suited to the exposure which the plate has received. For short exposures a new and powerful bath; for long, an old and previously used one. If you use a new bath for a prolonged exposure, you will infallibly fog. With an old bath for long exposures, interiors, dark woods, and so on, you will get fine contrasts; if the old bath refuses to develop, add quite new solution, as may be necessary. For instantaneous work a new bath has been recommended, but I think the addition of a third of an old bath is better. Warming the solution will produce greater energy. It must be borne in mind that a new bath may be too strong or too weak, according to its composition; it may be too strong, also, for instantaneous work taken in June, although correct for that done in January; therefore you must know the primary standard of the bath you use, and regulate accordingly. For contrasts, use an old bath; for softness, a more powerful and less exhausted one. Development should be carried on until the negative appears to veil over, the details almost entirely disappearing.

My practice is to keep the most energetic or least used baths in five or six four-ounce bottles, keeping them full to the glass stopper. As a plate is developed by one I mark the label accordingly, whole-plate, half-plate, lantern-plate, &c., as the case may be. You soon, in this way, acquire a sufficiently accurate idea of the state of energy of the contents. I have never thrown away any solution since I first used quinol, as it is always useful, however much exhausted.

For lantern plates or bromide paper you must use new, or, at any rate, clear solutions; but quite a couple of dozen lantern-plates may be developed in the same four ounces of developer. The question of warm tones for these depends on the protraction of the exposure and the development in a weak or used bath. The alkalies ordinarily used, as I before stated, are the carbonates or hydrates of soda or potash. The caustic alkalies are undoubtedly the most energetic, but I myself prefer the fixed ones. The hydrates tend to frilling; besides, within reasonable limits, I am contented with the slower development. For those who prefer to buy their developers ready made, there are a large number in the market. The Hintokinone of Messrs. Hinton and Co. is very good, both for lantern slides and bromide paper. The ready-made preparation which I have found the best is that made by Messrs. Mercier, of the Faubourg Montmartre, the salts being sold in crystals, with instructions for making up. So far as I know by weighing these, it consists of 61 grains quinol, 492 grains sulphite of soda, and the same weight of carbonate of soda to 18 ounces of water, the sulphite being tinged with cosine, perhaps to give the bath a non-actinic colour. Mr. Mercier says, in his description, that an organic corrective is added, capable of neutralising the most feeble traces which may remain of free—that is, of uncombined—soda. I do not know what this corrective may be; perhaps he adds something in the nature of acetic or gallic acid.

The formula which I prefer is that of the Photo. Club of Paris. It consists, roughly speaking, of ½ of an ounce quinol, 2½ ounces sulphite of soda, and 5 ounces carbonate of soda, all avoirdupois weight, with the addition of 8 to 10 drops acetic acid. The exact composition, together with a few other formulæ and additional remarks, will be found in the paper which I lay on the table, and with which I need not weary you by reading at length. With the exception that the quinol is not dissolved in alcohol, it appears to me to be identical with M. Balagny's first published formula.

An excellent method of intensification is to bleach with mercury, and redevelop with a used quinol bath. Some months ago I soaked a dry plate in quinol developer and exposed it; on immediately returning to the dark room, I found the development completed. There is no practical utility in this, but it has struck me that the idea might be applied to enlargement with a view of controlling the simultaneous exposure and development. If time permits, at the conclusion of the discussion, I propose to try this experiment here with the aid of the optical lantern and limelight. If at all successful, several modifications will suggest themselves.

I will now bring under your notice the examples which have been so kindly placed at my disposal by Messrs. Mawson and Swan, together with a few others—not so many, I regret to say, as I had hoped to be able to present to you. In producing these specimens, I acknowledge the difficulty of coming to a reliable conclusion from a cursory examination of them. Conclusions, to be of value, require very careful and minute study, and it would not be possible to give this to them in this room, and at the present time; still, it is the best that can be done under the circumstances, and they are worth something to you, at all events, even now.

The experiments made by Mr. Clark were upon a

* Continued from page 875, vol. xxxiii.

graduated sensitometer screen. I will not be hardy enough to deny the value of these; at the same time, it must be remarked that the light used was artificial, and the varying colours of natural objects which we have to translate into black and white were wanting. I cannot do better than hand round Mr. Swan's examples, with a *résumé* of the remarks made by himself on the reading of his paper. The next is the result on a somewhat difficult subject of an exposure of two minutes, the correct exposure being about two seconds. I may mention that I placed the negative in a very old bath, and simply left it to itself for four hours. A better mode of development might have been employed, but this was purposely done. There is also a print from it. The others are comparisons of pyro and quinol, part of some experiments with this object which I was unable to complete. I show also on the screen some slides to illustrate different tones or colours. Many of them are by Mr. Victor Corbould, who will, I dare say, explain to you his method. I have also a selection of negatives on Eastman films, kindly lent to me by Mr. Ashburner. I selected them out of several hundred for the specialities which they illustrate, and the excellence of many of them will, I think, be generally admitted, notably the one on the very thin skin, which has a fine amount of gradation. This 5 by 4 negative I show to illustrate the yellow stain of under-exposure on some plates; it is a Thomas's thick-coated extra rapid. These two on Thomas's thick-coated ordinary show a curious eating away or disintegration of the film, which I have remarked now and again. This is an instantaneous exposure with a hand-camera on a Lumière plate, the day in September rather dull.

(To be continued.)

PHOTOGRAPHIC SURVEY OF WARWICKSHIRE.*

BY W. JEROME HARRISON, F.G.S.

The Warwickshire of To-day.—And, lastly, we come to our own times. It is clearly our duty to secure, so far as in us lies, a faithful representation of the state of things as it is to-day. For every year we are "making history," and such a record will be just as much prized by posterity as we should ourselves prize it did it exist for the past. Just think what would be the value of good photographs of Bacon and of Shakespeare; or of Queen Elizabeth and her minister Cecil. Looking forward into the centuries, we can discern a time when no less value will be assigned to Mrs. Cameron's grand photographs of such men as Herschel and Tennyson; with those by other workers of our good Queen Victoria, and her "men of mind," Salisbury and Gladstone.

We must accumulate portraits, then, of all our local worthies. And to them we must add street scenes—secured with the hand-camera—from all our towns; delineations of the avocations of the people must also be obtained, from the country labourer in his smock-frock—a garment now rapidly disappearing—to the skilled artisan of the city, seated before his lathe. Nothing that illustrates contemporary life must be omitted; the policeman, the soldier, and the volunteer must adorn our albums; and we must go "slumming" to depict the shady side of life.

Most congenial will be the task of recording the cottage and village scenery of Warwickshire. I have travelled round the world, I have spent many holidays in various parts of the British Isles; and I can assert, without fear of contradiction, that for characteristic pictures of rural and home life our county is unequalled. Take the string of Shakespearean villages along the Avon, for example:—

> "Piping Pebworth, dancing Marston,
> Haunted Hillborough, hungry Grafton,
> Dadgeing Exhall, Papist Wixford,
> Beggarly Broom, and drunken Bidford."

Let anyone who loves English scenery drive (with his camera under the box-seat) from Warwick, through Charlecote (the home of the Lucys), to Stratford; and thence on to Evesham and Tewkesbury, calling at the villages named in the above *quatrain* (said to have been penned by Shakespeare) *en route*. Let him not hurry—take a fine week in (say) June—and I will answer for it that he will ever afterwards mark that excursion with the whitest of white stones.

In writing this brief account of our county, I must acknowledge my indebtedness to Mr. Sam. Timmins's recently published "History of Warwickshire;" but I have also studied most of the original authorities from Dugdale to Halliwell. Our noble Free Reference Library contains practically everything that has been published on Warwickshire; and some useful county books are also to be found in the Old Library.

If we are to "survey" Warwickshire in earnest, we must become students as well as photographers (and to my mind this will be one great good resulting from the task); we shall have to think of something else besides the beautiful and the picturesque; and we must remember that its associations may dignify the meanest dwelling, and render of world-wide interest the most prosaic surroundings.

Scientific Studies for Warwickshire Photographers.—Archæology—the study of the past—and Ethnology—the study of the inhabitants of the district at the present day—we have already touched upon. But there is much work also to be done in Geology, Botany, and Zoology.

The Geology of Warwickshire.—The coloured maps issued by the Geological Survey show the different strata of which the surface of the county is composed; and in a book which I wrote in 1881* a general description of the rocks of the county will be found.

Every landscape depends for its main outlines upon the rocks which lie beneath the soil; and for those who can "read the rocks" the study of the scenery of any district has a double pleasure. The oldest rocks of Warwickshire are the Cambrian quartzites and shales which lie between Atherstone and Nuneaton. These had been wrongly assigned to the Carboniferous period by the Geological Survey, and the discovery of their true age was made by Professor Lapworth and myself in 1882. The quartzites (altered sandstones) are magnificently exposed in a series of immense quarries, and they are traversed by great masses of dark, igneous rocks. The shales are well seen in the Stockingford railway cutting.

In the Warwickshire coal-field, photographs of the surface works, collieries, and colliers might be secured; while, descending beneath the surface, the flash-light would enable us to secure interesting records of the mines and miners.

Of the Triassic strata which succeed, there is a fine

* Continued from page 872, vol. xxxiii.

* "Geology of the Counties of England, and of North and South Wales." Kelly and Co. 8s. (Now out of print.)

section of the red sandstone, sixty feet in vertical height, at Hockley Cemetery, in Birmingham. Elsewhere the Triassic rocks are but seldom exposed, and we must be content with noting the level plains and rolling hills produced by their marls and sandstone.

The Liassic strata—limestones and clays—which rest upon the Trias, are quarried at Wilmcote, Binton, &c., in South Warwickshire. The fossils contained in these and in other local rocks, of which there is a grand series in the Warwick Museum and in the Museum of the Mason College, Birmingham, will form interesting subjects for our cameras.

Lastly, we have the Drift, including those confused beds of clay and sand, often containing great blocks of rock (erratics), which have been conveyed from Wales or from Scotland by the agency of ice during the glacial epoch. The immense boulder which lies in Cannon Hill Park (Birmingham) is a fine example of such a travelled block; but there are hundreds of others, and they are continually being destroyed—the farmers blow them up with dynamite. So, too, with the sections—the quarries, railway cuttings, &c.—where the solid rocks are finely exposed. They change from day to day, until at last they are grassed over and lost. Let it be our task, by the aid of photography, to record their features for ever for the students of geology.*

The Botany of Warwickshire.—The flora of our county has been carefully studied and described by Messrs. William Matthews, M.A., J. E. Bagnall, A.L.S., W. B. Grove, B.A., and other specialists. Artists have long visited our parks—Packington Park especially—to portray the grand old trees which adorn them, remnants of the old forest of Arden. Photography can admirably record every twig and leaf. It is certain that good photographs of plants, especially if taken while growing in their native haunts, would help to vivify the dry leaves of herbaria, and they would be much valued by those who study and teach botany. I have seen some exquisite work in this direction done by one of our members, Mr. Charles Pumphrey. Let me advise those who make this branch a speciality to photograph trees either early or late in the day, when the nearly horizontal rays illuminate their trunks. Let photographs of the same tree be taken at different seasons of the year; then shall you be able to prepare a series of "dissolving views," in which the tree shall be shown to bud and blossom, be covered with leaves, and anon be bare, yet beautiful with frost-rime.

(*To be continued*).

CAMERA CLUB NOTICES.—Thursday, January 2nd, 8 p.m., Lantern Evening; Monday, 6th, 8.30 p.m., Smoking Concert; Thursday, 9th, 8 p.m., Mr W. H. Walker, "The New Rollable Celluloid Film;" Thursday, 16th, 8 p.m., Mr R. Tindall, "Plane Polarisation of Light;" Monday, 20th, 8 to 9.30 p.m., Mr. Roberts will be prepared with the lantern if any member or members send him advice to the Club that they would like to try slides; Thursday, 23rd, 8 p.m., Rev. T. Perkins, "English Church Architecture as a Subject for Photography"; Thursday, 30th, 8 p.m., Mr. T. R. Dallmeyer, "On some Practical Deductions from the Law of Conjugate Foci"; Monday, February 3rd, 8.30 p.m., Smoking Concert; Thursday, 6th, 8 p.m., Lantern Evening; Thursday, 13th, 8 p.m., Mr. Graham-Balfour, "Landscape."

Patent Intelligence.

Specifications Published.

16,894.—*November 20th*, 1888. "Photographic Cameras." WILLIAM RITCHIE BAKER, 94, Seaside, Eastbourne, Sussex, Chemist.

According to this invention the camera is made to contain a number of sensitized plates which can be used in succession. The plates are arranged one in front of another in a receptacle at the back, or it may be at the sides of the camera, and an opening furnished with a close fitting cuff or sleeve is provided, so that the hand can be introduced to arrange the plates without the admission of light. When the pile of plates is at the back of the camera they are separated from one another by opaque paper or the like, so that the front plate can be exposed to the light without the others being acted upon. When a picture has been taken the front plate is removed and placed at the back of the pile, leaving the next plate in position for the next picture.

In place of employing a transparent screen of ground glass for receiving the image whilst the lens is being focussed, as is now usual, I employ an opaque screen, and view the image upon it by a hinged mirror or other convenient means. I prefer to hinge the screen so that, when in position for receiving the image, it lies in front of the pile of plates at the back of the camera, but can be drawn up and made to lie against the inner side of the top of the camera when it is desired to take a picture.

In order that the screen may occupy exactly the same position as the plate to be acted upon, I place springs at the back of the pile of plates, so that the screen, when lowered, forces the pile slightly backwards, taking the place of the front plate. When, however, the screen is drawn up out of the way, the springs force the pile of plates forward again into position.

The camera is provided with two doors, one at the top and the other at the bottom. That at the top serves as an opening through which the opaque screen can be viewed, whilst that at the bottom is for the manipulation of the plates, as above described.

In order to render the camera as compact as possible, I carry the lens upon the end of a drawer which, when pulled out, gives the requisite focus length, the focussing being performed by adjusting the distance to which the drawer is pulled out.

I do not fix the lens rigidly to the end of this drawer, but I connect it to it by mechanism in such a way that when the drawer is closed the front of the lens lies flush with the end, but when the drawer is pulled out the lens is protruded.

The inventor claims:—

1st. A photographic camera having a receptacle or changing box carrying the sensitive plates or other media, this said receptacle or changing box being arranged to move within the body of the camera in a backward or forward direction, an opaque focussing screen arranged on the front face of the said receptacle or changing box, a hinged mirror, and a suitable close fitting or sleeve.

2nd. In a photographic camera the combination of an opaque focussing screen with a movable receptacle or changing box holding the sensitive plates or other media.

3rd. In a photographic camera the combination of an opaque focussing screen with a mirror, and a suitable aperture and door in the door of the camera, for viewing the said mirror.

14,537.—*16th September*, 1889. "Photographic Cameras." WILLIAM SCORER, Watchmaker, Jeweller, and Photographer, North Street, Havant.

The inventor says that his invention consists of a front to be used as part of a photographic camera, to hold the lens in any convenient position opposite the slide containing the sensitive plate, and which has the means of moving the opening containing the lens to any convenient position, the device being a great improvement upon the usual vertical and horizontal slides to which the lens is usually fixed. This form of front, he says, is particularly adapted to the form of camera having a parallel

bellows, but may also be used to advantage with a camera having a taper or conical bellows, having also a rising front. He describes several other devices in the construction of photographic cameras.

16,593.—*October 21st*, 1889. "Optical Illusions." JACOB KELLER, Merchant, of 10, Perlenpfuhl, Cologne, and GUSTAV CASTAN, Sculptor, of 13, Stühlerstrasse, Berlin.

The invention chiefly relates to new combinations and arrangements of mirrors, which give the visitor the impression that he is placed in a labyrinth formed by colonnades or arcades, mirrors and painted views.

Although the apparatus occupies a very small space, the inventors say that the visitor believes himself to stand before endless colonnades, and, if tempted to enter the same, he finds himself suddenly stopped by a mirror, from which the deep colonnades seem to extend to the right and to the left.

They say that one illusion represents a tropical garden, and the background forms the entrance to a Moorish Temple, while palms and exotic plants are placed between the mirrors. Owing to the multiple reflection, the single entrance appears like an entire mosque, surrounded by a tropical garden. The space in which the visitor stands occupies scarcely two square meters, but the whole looks like a great palm garden in a tropical country.

The invention also comprises a specially constructed camera or kaleidoscope, which has the shape of a regular tetrahedron. The upper three sides of the tetrahedron are formed by three large triangular mirrors, the edges of which are ground and fitted together, so that the whole appears to be made of one piece. The chamber is entered from below through a circular staircase, and a second staircase serves for the exit.

The visitor ascending the spiral staircase sees a great number of repetitions of his own image from the front, from the back, and from both sides. Four or five persons standing together in the kaleidoscope appear as an innumerable crowd.

The following are considered the essential features of the invention :-

1. That the mirrors and passages are inclined to each other at an angle of 60° or at a multiple of 60°, the horizontal section of the individual compartments being composed of equilateral triangles.

2. That the mirrors and passages are all alike as regards their width and height, as well as the shape, size, and design or decoration of the frames or borders.

3. The kaleidoscope, which is accessible only from below, while the sides or walls are composed of large triangular mirrors, which form three adjoining sides of a regular tetrahedron, and are therefore placed to each other and to the floor at an angle of 60°.

The specification is accompanied by drawings.

THE PHOTOGRAPHIC YEAR.—In its record of the leading facts of progress made in photography since January, 1889, the *Photographic Times* calls attention to celluloid as a substitute for glass in photography, and as a material well suited for making focussing screens and other articles requiring great lightness and strength ; to magnesium for illuminating subjects by artificial light. "In development," it says, "hydrochinon has waxed and waned in popular esteem, and eikonogen has largely taken its place, especially among amateurs. Pyro continues to be largely used, however, by all classes of photographers. Lantern slides and photo-micrographs are being made in greater numbers than ever before, and the colour-sensitive plate is being more largely used. Dry plates have improved in quality during the past year." Our contemporary then goes on to note the increase in the number of photographic clubs, of amateur photographers, and of photographic instruction books ; and concludes by expressing the opinion that "the improvements made in photographic optics and the manufacture of cameras, tripods, and other apparatus, make it possible for photographic practical workers to do better work with greater facility than ever before. The outlook was never brighter for a new year."

Correspondence.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

SIR,—The Photographers' Benevolent Association is now so well and favourably known to most of your readers that I feel emboldened to ask space for this short communication.

The Association has, after a long struggle with the apathy of those whom it wished to benefit, at last become the recognised charitable centre of the profession. Its objects are already widely known, and during the sixteen years of its existence there has not been a single charge against the committee of unfairness or injustice in their awards. This the committee freely acknowledge is in a great measure due to the careful investigation which each case has received at the hands of the secretary, Mr H. Harland. Owing to the pressure of other business this gentleman is compelled to resign his position in February next, and the committee have, in consequence, to seek for a successor to him. This affords a favourable opportunity to replace a paid secretary by an honorary one, provided that a gentleman, either amateur or professional, can be found able and willing to devote a small portion of his time to the duties. It has been several times pointed out that the secretary's salary, small though it is, forms a serious item in the yearly balance sheet, and it is with the hope of being able to still further benefit their poorer brethren that the committee now appeal to the photographic community for a volunteer in this capacity. It may be mentioned that the duties are simple, and can easily be performed by anyone who has had any business experience.

The chairman of committee, Mr. W. Bedford, 326, Camden Road, N., will be pleased to furnish further particulars, list of committee, &c. *Pro* Committee P.B.A., E. CLIFTON.

REPRODUCTION AND COPYRIGHT.

SIR,—I read the first of the notes in your issue of December 13th with some astonishment. From it I conclude that in your opinion when a photographer has given permission to a certain newspaper to reproduce a photograph, he should henceforth consider the copyright, as far as this kind of reproduction is concerned, at the disposal of the newspaper to whom permission to copy has first been granted. Permission to reproduce photographs in newspapers and magazines is being made too cheap, and I think most photographers of experience will agree with me that the advertisement obtained from the average illustrated paper reproduction is not likely to give the photographer adequate repayment, save in exceptional cases, for the use of his copyright.

A late experience of mine of the wiles of illustration hunters may be of interest, and perhaps instructive to some of your readers.

A publishing firm wrote me requesting permission to produce a wood-cut from a photograph of mine for a magazine (specified, and sample copy sent) circulating, as was evident from its general character, among a class of people by whom it could not possibly be of any account to me whether my picture were seen or not, even if it had been well reproduced, which I knew from previous experience it would not be. My answer was that the photograph in question could be used as requested on payment of one guinea. This was agreed upon, a print of the photograph sent and the invoice ; but being somewhat more wary than the firm had evidently anticipated, I wrote on the invoice that permission to copy was granted *only for the particular paper specified*. This did not suit the publishers at all, and they wrote me to the effect that permission to reproduce could not be accepted under *conditions*. Thus, although the request had only been made for a specified paper of limited circulation, the intention was evidently to make indiscriminate use of my copyright for small consideration.

There is very exceptionally any encouragement to professional photographers to produce pictures except the love of it, and the expense is to many a very serious consideration ; and surely anything which makes the practice of art less burdensome to the pocket of the photographer should receive the support of the photographic press.

The experiences and opinions of others of your readers in this connection would be interesting.

There is also another matter which I should like to mention, and on which I believe there is considerable misconception. I have heard it stated by men one would expect to know, that a photograph must be registered *before* publication in order to make copyright securable; also that to mark a photograph copyright which has not been registered is a fraud. Now, as I understand the Act, copyright in a photograph *belongs* to the producer of such photograph, or to the person paying a valuable consideration for its production; and such owner of copyright can secure legal protection against infringement whenever he likes to register his copyright, but cannot obtain any compensation for infringement previous to registration. This is quite a different thing to total loss of copyright through neglect of registration previous to publication. I believe a clear and correct statement of the law in connection with such cases would be of immense value to photographers.

Rothill, December 30th. RALPH W. ROBINSON.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

AT the technical meeting of this Society held on the 31st ult., the chair was occupied by Mr. ATKINSON.

Some photographs of groups of theatrical subjects, taken upon the stage with magnesium flash lamps, were exhibited by Mr. F. Downer, of Watford. In one of these groups there were whitish streaks, extending about a quarter of the distance from the sides towards the centre of the plate. He enquired the opinion of the members as to this appearance.

Mr. W. E. DEBENHAM suggested that they were probably due to the flashes shining upon the lens, and giving rise to what were called "ghost" images. When very bright artificial light was used, the camera ought to be shaded from such light by a hood.

Mr. CHAPMAN JONES thought that that was the probable explanation of the markings.

The CHAIRMAN showed a photograph of a family group taken with flash lamp. The picture was somewhat weak and flat.

Mr. L. WARNERKE thought that too much magnesium had been used. A very small quantity sufficed if it was thoroughly burned. When it was attempted to burn a large quantity, not only did some escape burning, but the duration of the flash was so long that movement on the part of the sitters became probable.

Mr. FRIESE GREEN had tried the magnesium flash lamp commercially for about three months, but had had to give it up. The pictures taken with it generally failed to give satisfaction to the sitters.

Mr. CHAPMAN JONES asked if there was any magnesium flash lamp that burned the metal quickly enough.

Mr. WARNERKE replied that there was, provided that only a small quantity was used.

Mr. CHAPMAN JONES enquired whether Mr. Warnerke had found it advantageous to dry the magnesium powder before using it.

Mr. WARNERKE replied that he dried it after purchase, and then preserved it in a bottle for use.

Mr. CHAPMAN JONES had found that a mixture of freshly-dried magnesium and chlorate of potash exploded with such rapidity that fourteen grains of it would shake the windows of the room in which it was used, but that after an hour or so it lost this power of extremely rapid combustion.

Mr. WARNERKE showed a lamp for burning magnesium ribbon, of which he had spoken at previous meetings. It was made in Berlin, by Ney, and had several points of novelty about it, the chief of which was the contrivance for automatically striking down the burned ribbon at short intervals. This action made a clicking sound, and as it was repeated at the rate of once for a little more than an inch of ribbon burned, it was practicable, by counting the clicks, to know and regulate the amount of magnesium used for the exposure. For copying purposes he held the lamp during about seven clicks, on each side of the picture. This equalised the lighting, and prevented irregularities in the surface of the picture from showing in the negative. The exposure he had mentioned, representing about fifteen inches of ribbon, was what he found to be right for copying an engraving half its real size when using a plate giving fifteen on the sensitometer, and a lens of the portable symmetrical character. There was a hood in front of the lamp furnished with a groove into which a ground glass could be fitted for ordinary work, and coloured glasses for orthochromatic work. He had come to the conclusion that for copying it was folly to use daylight. The certainty of exposure, as well as the convenience of lighting so as to obviate the irregularities of surface from showing, were advantages on the side of the magnesium lamp far outweighing the trifling expense attached to it. As to the smoke, the chimney belonging to the lamp could be contrived by a paper tube to any opening connected with the outer air. He had tried condensing chambers in which the fumes passed over a surface moist with acid, but they proved a failure.

Mr. DEBENHAM asked whether Mr. Warnerke had tried Meydenbauer's condensing chimney, in which the result was brought about by keeping the magnesia diluted with as little air as possible.

Mr. WARNERKE had not tried it. He then referred to eikonogen, which was in his opinion much better than any other developer that he had tried. He had worked one mixture for a whole week, developing a plate in it occasionally, and found it good to the last. He found caustic potash better than the carbonate. The formula used was a concentrated one as follows:—

Sulphite of soda	10 parts
Boiling distilled water	100 ,,
Eikonogen...	10 ,,
Caustic potash	10 ,,

The sulphite was first dissolved, then the eikonogen, and lastly the potash. It was filtered and bottled away whilst hot. For use he diluted with two or three parts of water if he wanted strong contrasts, and with from nine to ten for softer pictures. During his visit to the Paris Exhibition he had met with M. Maret, who was working on physiological subjects, where he only exposed for about the $\frac{1}{300}$ part of a second, using hydrokinone. On comparing with eikonogen, however, they found the power of the latter in bringing up detail to be very much greater.

Some photographs of large size (about 21 by 17) of American scenery by Jackson, taken direct, were shown by Mr. Friese Greene.

WEST LONDON PHOTOGRAPHIC SOCIETY.

ON the 27th December, a technical meeting of the above Society was held at the Addison Hall, Mr. C. GARNER RICHARDSON, M.A., occupying the chair. Mr. St. Clair Buxton, F.R.C.S., Mr. W. H. Whitear, and Mr. Miller were elected members.

The discussion upon Mr. Stein's paper on Hand Cameras was adjourned until the second meeting in January.

The SECRETARY (Mr. Hodges) informed the meeting that the annual exhibition would be held on the 10th January, at half-past seven, and would remain open on Saturday, 11th, from three to half-past nine. Mr. Mial, the inventor of the Facile Detective Camera, attended and explained its construction to the members.

In reply to the question, "Would the addition of sulphurous acid to the fixing bath have an injurious effect on the negative?"

Mr. STEIN said the effect would be to liberate sulphur, which would be prejudicial to the negatives.

Mr. HODGES thought it not advisable to add any acid to the fixing bath, and least of all sulphurous acid.

Mr. RICKFORD desired to know the proper quantity of magnesium ribbon to burn when reducing half-plate negatives to lantern size by reduction in the camera.

Mr. BENNETT had produced many slides in that way, and had found three to five feet necessary, and burnt about three inches behind the negative.

Mr. WINTER thought the amount excessive.

Mr. COBB showed some bromide prints which had been bleached by immersing in a solution of bichromate of potassium acidified with hydrochloric acid, and, after exposure to light, redeveloped with ferrous oxalate. The tones produced were warm brown.

Mr. HODGES said the degree of warmth would depend upon the amount of re-exposure given. Bromide prints would tone to a good brown with the ordinary uranium intensifier.

Mr. LESLIE SELBY recommended bleaching with mercury, and subsequent treatment with sulphite of soda, as advocated by Mr. A. R. Dresser.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

THE above Club held an exhibition on Monday, December 16th, consisting of members' work. There were six classes for competition, to which were contributed about 200 pictures, and 150 lantern slides. The judges were Messrs. S. Herbert Fry and Charles W. Hastings.

The following are the classes and prizes taken in each :—Class I.—(Landscapes in Silver, any size), first-class certificate, C. Beadle ; second ditto, J. W. Marchant ; hon. mention, W. T. Goodhew. Class II.—(Landscape in Platinum or Bromide, any size), first-class certificate, W. T. Goodhew : second ditto, C. Beadle ; hon. mention, Geo. R. Martin. Class III.—(Portrait, not less than four admitted to competition), first-class certificate, H. Beckett ; special class, formed by request of the judges (Figure Studies), first-class certificate, R. B. Lodge. Class V.—(Lantern Transparencies, not less than six admitted to competition), first-class certificate, C. Beadle ; second ditto, H. Walker. Class VI.—(Enlargements), first-class certificate to A. Le Vierge ; second, W. Sweeting. The "*Amateur Photographer* Bronze Medal" was awarded to Mr. W. T. Goodhew, for his picture of the waterfall in Battersea Park. In the evening there were two lantern displays, followed by vocal and instrumental music.

In the mounting of some of the exhibits, the prints were squeegeed into optical contact with the glass, leaving a considerable margin of clear glass round the edge, and then placed in the frames with a piece of plain oak a short distance from the glass.

The exhibition was to some extent marred by pictures being hung too high through insufficient room, as although the hall was capable of holding six hundred people, the available space was largely occupied by recesses and windows.

PHOTOGRAPHIC SOCIETY OF IRELAND.

A TECHNICAL meeting was held at the Society's rooms, 15, Dawson Street, Dublin, on Friday, December 20th, Mr. LOUIS MELDON in the chair.

Dr. COSGRAVE read some notes on Ilford lantern plates, relative to his experiments with those plates under varying periods of exposure to the light of an ordinary gas jet, the results obtained being exhibited at the same time through the lantern.

Dr. SCOTT showed in the same manner a set of these plates, some exposed to the light of a paraffin lamp, and some to that of magnesium wire, the developer being eikonogen with all. Very rapid results were obtained with the magnesium wire.

Mr. CONAN brought forward the subject of the construction of the dark room proposed to be fitted up on the Society's premises. An interesting discussion followed, in which many of the members took part.

The negatives taken during the excursion of the Society in September were handed round for inspection and criticism.

Eleven new members were elected, and seven proposed.

RECEIVED.—"Wintering on Lakes Le Arau and Marapouri" ; a Photographic Diary by Alfred H. Burton. Some of Mr. Burton's diaries have in past years been reproduced in the PHOTOGRAPHIC NEWS, and this, the latest account of his photographic experiences in opening up new country, reprinted from the *Otago Daily Times*, is of a very interesting character. At the end of the Diary is a catalogue of the views taken during Mr. Burton's trip.—Messrs. T. Fletcher & Co's., New Patent Calendar for 1890 is a combination of illustrated catalogue and calendar.

Answers to Correspondents.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 6, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

THE REV. F. C. LAMBERT writes to make a correction in his note on the "Champion Class," at page 113 of the YEAR-BOOK. The reader is requested to run his pen through the word *not* at the end of the fifteenth line, in the sentence, "Why should he (*not*) run again in another race."

S. T.—Your reference is at fault; the specification refers to a totally different matter. We have made another search without finding any record of a patent having been applied for in Great Britain.

W. L. (Java).—We have been to inspect the enlarging lantern at £6 6s. It is a thoroughly efficient instrument, with 5-inch compound condenser, and front combination lens fitted with rack and pinion, triple wick lamp (not quadruple), in Russian iron case, oak mounted, and all suitable for quarter-plate negatives; but if you wish to use it with your larger size, 7¼ by 4½, it will be necessary to begin by reducing them to appropriate dimensions, and then afterwards to amplify in this particular form of apparatus

BOSTON, U.S.A.—Calcium chloride in collodion. Since answering you on this point a fortnight ago, we have found a reference to the use of chloride of calcium for making a special chlorobromide collodion emulsion said to be used, when tinted with chlorophyll, for taking photographs of the sun. The statement occurs in Mr. Hermann Gunther's letter to the NEWS of Aug. 9th, 1889 (see page 525 of last volume), and is an ingredient of the collodion formula therein given as that of Dr. Zenger. Half a gramme of calcium chloride, and three and a quarter grammes of cadmium bromide, are used for salting the collodion.

A. M. M.—Great credit is due to you for the admirable summary of photographic literature which appears in the "Abstracts" given in the December number of the *Photographic Journal*. There will be, at times, some overlapping, for the paper on eikonogen by Prof. G. D. Liveing did not first appear in the journal to which reference was made.

H. B.—You can get the illustrated catalogue of the Paris Salon at the Slade School of Art Depôt, 137, Gower Street, W.C.

E. L., and GRAINED.—Read first Mr. W. K. Burton's "Manual of Collotype, Zincography, and Photo-mechanical Printing" (Marion and Co., Soho Square) ; you will then see what apparatus you require. The lithographic press and other items, such as rollers and ink, can be procured of Messrs. Hughes and Kimber, and Mr. Winstone, of Shoe Lane. You should not begin with 12 by 10 plates, but get experience with half-plate or cabinet size, and gradually work upwards when the technical difficulties are fairly mastered. We cannot refer you to any school of instruction.

J. M. G.—The round white spots on your silver print are evidently the result of some accidental splashes of acid, or of a corrosive metallic salt; but, when moistened with water and tested with blue litmus paper, we failed to get any indication of free acid, which may, however, have evaporated off meanwhile.

PRINTER.—A plough cutter, such as used by bookbinders and stationers, would answer your purpose. Enquire of Messrs. Waterlow and Sons, Limited, Finsbury Works, E.C. It is figured in their catalogue.

J. E. (Oxon).—The ether saturator can be procured of Mr. W. C. Hughes, 82, Mortimer Road, Kingsland, N.

W. GEORGE.—Every carbon print shows a slight relief when developed and dried. The degree of prominence will depend somewhat upon the character of the original negative, but upon applying to the Autotype Company, 74, New Oxford Street, your special requirements may be met by varying the amount of pigment or chemical quality of the tissue.

BAVON.—This question has often been asked of late. Only those who have been appointed photographers to the Queen, or to the Prince of Wales, have the right to use the Royal Arms. Such persons hold an official document, signed by the Comptroller of the Household, notifying their appointment.

Several other correspondents in our next.

CONTENTS.

BRITISH PHOTOGRAPHERS AND FOREIGN FORTIFICATIONS.

EXAMINATION of the periodical photographic literature of this country for many years past, proves that when London and some other British photographers have but a few days to spare, and wish to spend those three or four days on the Continent, Antwerp is selected as the place to visit in the great majority of cases. The reasons for this may readily be seen. A boat train leaves at night when the engagements of the day may be supposed to be over, and on board the boat a complete night's rest may be obtained; especially has it been so of late years, since the accommodation for passengers by this route has been so liberally improved. The daytime is thus left unbrokenly and on land at the disposal of the traveller. In addition to these advantages of that particular trip, Antwerp is a great city abounding in picturesque architectural food for the camera.

Short photographic excursions of the same kind to France are scarcely ever described in the photographic journals; yet Havre, like Antwerp, is a place which can be visited with a complete night's rest on board the boat, both in going and returning by the London and South Western route. A great impediment to short photographic excursions to any French port is, the uncertainty whether the holiday-seeker may not get into trouble by innocently taking pictures too near fortifications, for several cases have been published of late years of unpleasant treatment by French officials of perfectly harmless landscape photographers. Of course, on this side of the water we are liable to see but *ex parte* statements of each case, the aspects whereof might appear in a different light were the other side of the case put forth from a French source. Broadly speaking, it is a recognized fact that the average English are not popular on the Continent, and this arises chiefly from the offensive manners of a portion of our countrymen; perhaps some English photographers who have found themselves in trouble on the other side of the water, would have been better treated had they been decently affable.

Last Monday, when returning from more southern parts, we called upon some of the officials of the Photographic Club at Havre, and inquired whether the presence of the surrounding fortifications would cause the prohibition of out-door photographic work by any English photographers who might visit the city for a few days' holiday. They replied that nobody would interfere with their photographing inside Havre itself, and that they did not think that there would be any objection to their photographing along the beach, but would make inquiries on the subject. On the other side of the mouth of the Seine are the two pretty little seaside places of Trouville and Honfleur, and the time of reaching them from Havre by small passenger boats is three-quarters of an hour. They are good places for camera work, and especially is this the case with Trouville and its neighbourhood. Unfortunately, however, there is at present but one boat a day, with a few exceptions in the course of each month, to either place, and that boat does not start daily at the same hour; the service is a tidal one. A new pier is nearly completed at Trouville. It is said that when it is finished communication with Havre by small passenger boat will be kept up at regular hours, and several times a day. A good service of boats and trains between Havre, Trouville, Le Mans, and forking off at the latter place to Tours and Angers, would be a great boon to English tourists visiting the Loire district.

THE LAW OF COPYRIGHT.

SOME useful information about the law of copyright in relation to photographs, given this week in our correspondence columns, is of value because it comes from a legal source, Mr. Fleetwood Pritchard. The selling of a photographic print by its owner does not, it seems, prevent his copyrighting the picture at a subsequent date. We believe it to be the same with books. The whole subject of the law of copyright as applied to photographs is about to be taken up by the Photographic Section of the London Chamber of Commerce, when these and other technical points of interest to photographers will no doubt be well threshed out by experienced persons commercially interested in the subject, and whose deliberations will be fortified by authoritative legal advice from one or two members of the Section.

THE LATE COL. RUSSELL'S CONTRIBUTIONS TO PHOTOGRAPHY.*

BY PROFESSOR RAPHAEL MELDOLA, F.R.S., F.C.S.

In the coure of preparing a series of lectures on Photography, which I delivered at the Finsbury Technical College during the early part of the year 1888, I had occasion to search the literature of this subject, and was much interested to find how largely we are indebted for the advancement of modern photography to the work of our late member, Colonel Russell, of Stubbers, of whom an obituary notice has already been published in the *Essex Naturalist* (vol. i., p. 139). As an Essex worthy, whose merits as an investigator are so widely known, both in this country and on the Continent, it seems only a just tribute to his memory that his labours in the cause of science should find record in our pages. It is with this object that I have undertaken to give a brief sketch of his photographic contributions.

Before the introduction of the gelatine dry plates, which are now so generally used, the process invariably adopted by photographers was that in which the plate was first coated with a film of collodion containing a soluble iodide —or bromide and iodide—and then sensitised by immersion in a silver nitrate bath.

The collodion process was first suggested by a Frenchman (Legray) in 1850, but its practical working out is due to our own countrymen—Scott-Archer, Fry, and the late Dr. Hugh Diamond, in 1851.

There can be no doubt that the use of collodion marks one of the greatest epochs in the history of photography, and the method thus introduced for convenience of manipulation and certainty of results far transcended any of the older processes. But in these times of restless activity in every department of science, it is not likely that a process which possessed so many disadvantages should be allowed to rest without attempts being made to improve upon it or to supersede it.

The drawbacks to the old wet collodion process are familiar to all who have worked at it. The plate had to be coated, sensitized, exposed, and then developed as soon as possible after removal from the camera. In field work the dark tent had to be dragged about as a part of the necessary paraphernalia, and in addition to this and the camera the photographer was obliged to carry with him a stock of chemicals, such as bath solution, developer, fixing solution, &c., to say nothing of sometimes finding himself driven to extremities for want of a supply of clean water. The amateur of the present time lives in a golden age of photographic facilities; he knows nothing of the agony of learning to coat a glass plate with collodion with perfect uniformity and smoothness, using only a minimum of the viscid solution, performing the operation with the greatest possible speed, and returning the excess to the bottle without pouring it up his sleeve or over his boots. Who that has had to manipulate the collodion process under a tropical sun will forget the anxiety consequent upon the transport of bottles of ether into temperatures of something over 100° F. in the shade? I have vivid recollections of the Eclipse Expedition of 1875 to the island of Camorta, in the Bay of Bengal, somewhere about 8° from the equator. Our observations were to have been chiefly photographic, and we were well equipped with photographic materials. But the experience gained at home went only a little way towards helping us to manipulate collodion in a temperature at which the ether evaporated almost as soon as the film was spread over the plate. The tents had to be kept wetted with water, and the dark slide was brought out of the tent and fixed in its telescope camera swaddled in wet cloths to prevent the too rapid drying of the sensitive film.

These and other difficulties are now experiences of the past. At the present time a complete photographic equipment, weighing only a few pounds, can be taken into the field, and the plates or films developed at leisure any time after exposure. The sensitiveness of modern dry plates so far transcends that of the old collodion process that instantaneous effects can be secured by any amateur possessed of ordinary skill. It is desirable that Essex people should know what a large share the late Colonel Russell had in bringing about this state of affairs.

The most obvious way of getting rid of the difficulties of working the wet collodion process out of doors is, of course, to coat the plate with a dry sensitive film, which can be prepared some time before being actually required for use. Attempts were accordingly made to prepare sensitive dry plates soon after the introduction of the collodion process, the first important step in this direction having been made by Professor Taupenot, in 1855. This investigator coated his plates with ordinary iodized collodion, sensitized in a silver bath, washed out the excess of silver nitrate, and then coated with iodized albumen and dried. Before use the plates were sensitized by immersion in a silver acetate bath, and then washed and again allowed to dry. Taupenot's dry plates were the first successfully used by photographers, but they were very insensitive and uncertain in their action.

An improvement was introduced in 1858 by Fothergill, who used ordinary albumen instead of iodized albumen for coating the sensitized collodion film, thus doing away with the second sensitizing operation. Passing over certain minor modifications in the dry plate processes introduced by subsequent workers, we come to the year 1861, when Russell put the finishing touch to the method of collodion dry plate photography. The plate was first of all coated with gelatine as a substratum, and then received the film of bromo-iodized collodion, which was sensitized in a silver bath in the usual way. After washing out the silver nitrate the plate was coated with a solution of tannin and then dried. The tannin, known technically as a "preservative," restored the sensitiveness lost by the removal of the silver nitrate, and thus placed in the hands of photographers a really dependable dry plate possessed of greater sensitiveness and durability than any other dry plate known up to that time. Russell's tannin dry plates soon came into general use; his work on the process was published in 1861, and reached a second edition in 1866, both editions having been translated into German.

In these days of rapid photography, we should consider a tannin dry plate a very insensitive thing to work with, being at the best less sensitive than a good wet plate. But the other advantages of the dry plate outweighed this one disadvantage, and the favour with which the tannin process was received showed how eager photographers were to dispense with the cumbrous appliances of the wet plate method. From this discovery of Russell's to modern dry plate photography it is but a step, that step being the precipitation of the silver iodide or bromide in the collodion itself in the form of an emulsion, instead of coating the plate first with the salted collodion, and then forming

* A lecture delivered before the members of the Essex Field Club, and reported in the *Essex Naturalist*.

the sensitive silver salt by immersion in a silver nitrate bath. Emulsion photography is *par excellence* the photography of the present time, and there can be no doubt that the success of Russell's dry plates largely contributed to its introduction.

Important as was the advancement rendered possible by the use of tannin as a preservative, this is by no means the only noteworthy photographic achievement with which our late member must be credited. Only a year after the introduction of his dry plate method, Col. (then Major) Russell made known the use of ammoniacal solution of pyrogallol (pyrogallic acid) as a developing agent, a discovery which marks a distinct epoch in the history of the art, and of which the practical utility makes itself felt at the present time. Prior to the year 1862, the developers in use by photographers were of an acid character. Gallic acid mixed with silver nitrate had been used by Fox Talbot for developing his paper prints as far back as 1840. Pyrogallol was known to be a more powerful developer than gallic acid both by Liebig and Regnault in 1851. The use of ferrous sulphate, the active substance in the "iron developer" of the old collodion process, was known to the late Robert Hunt in 1844. When dry plates first came into vogue, acid development had to be resorted to as the only known method of bringing into visible existence the invisible image formed by the action of light on the photographic plate.

For certain chemical reasons, which need not be entered upon in detail here, an acid developer is eminently unsuited for dry-plate work. The early experimenters in this field were not only at a disadvantage as regards the comparative insensitiveness of their plates, but this slowness of action could not be compensated for by using a stronger developer, because the free silver nitrate, which is an essential constituent of an acid developer, would be reduced, and metallic silver deposited all over the film; that is to say, the plate would become fogged. It is, of course, impossible to trace the precise origin of the idea which led to the use of alkaline pyrogallate. It appears that experiments had been made by Anthony, of New York, in 1862, having for their object the increased sensitiveness of dry plates by exposing them to ammonia vapour before use, and about the same time Glover attempted to increase the sensitiveness by the action of ammonia vapour after exposure and prior to development. Whether Colonel Russell was aware of these experiments there are at present no means of ascertaining, but it is not improbable that his attention may have been directed thereby to the use of ammonia. The fact that dry plates could be developed by means of a neutral solution of pyrogallol without free silver nitrate was made known by Mudd, Wardley, and Wharton Simpson in 1861. All the conditions for the introduction of alkaline development were therefore ripe, and the important discovery was announced by Russell in 1862, and about the same time, but independently, by Leahy. The importance of alkaline development is too well known to photographers to require specially enlarging upon. It will suffice to say that the powerful developer given to the world by our late member put dry-plate photography on an entirely new basis. Want of sensitiveness could be overcome by increased developing power; in fact, the reducing action of ammonium pyrogallate is so great that it tends to fog the plate unless restrained by suitable means. In connection with the general theory of the development of the photographic image, this discovery was of the highest order of importance, and its bearings were fully recognised by Col. Russell. In the old process of acid development, the image is built up by the deposition of metallic silver from the developing solution, whereas in alkaline development the image is formed chiefly out of the silver reduced in the film itself. For the full establishment of this most essential distinction between the two kinds of development we are also indebted to our late member. In the course of a controversy carried on in 1865 with Carey Lea, of Philadelphia, Russell proved his point most convincingly by a beautifully devised experiment. He showed that if an ordinary collodion negative after development is treated with nitric acid, the whole of the picture is dissolved off, and the plain film left in its original condition; the silver image is here simply raised in relief upon the surface of the film, and the acid dissolves it off. He then showed that a negative dry plate developed by the alkaline method, and treated with nitric acid as before, gave a transparent positive of the picture sunk in depression; the silver image is in this case imbedded in the film instead of being raised upon its surface, and the acid accordingly dissolves it out, leaving its counterpart in depression. This proof not only convinced Russell's antagonist and the photographic world at large of the truth of his views, but the experiments led to that which is dear to all Englishmen, and which is, in the minds of many, the only true measure of success, viz., a practical result. He published the details of a method in 1868, based on the foregoing experiments, by means of which a reversed negative, or a transparent positive, could be obtained from a dry-plate negative by treatment with nitric acid after alkaline development and before fixing. This process is now obsolete, but it has its historical interest, as being the outcome of a theoretical discussion.

The value of Col. Russell's introduction of alkaline development in 1862 does not, however, end with his own application of the process to the dry plates then in vogue. The germ of the discovery which has revolutionized modern photography was in existence in 1864, when Bolton and Sayce made known their collodion emulsion process, which was followed up by many workers, and culminated in the introduction of gelatino-bromide emulsion by Dr. Maddox in 1871. From that time emulsion processes have steadily been gaining favour, and now are almost exclusively in use. From the very beginning of their history, in 1864, these processes had therefore the benefit of Russell's method of alkaline development, by which, or by some analogous plan—such as the ferrous oxalate developer—are they only workable. It will thus be seen that the influence of our late member's work makes itself felt, as was stated previously, at the present time. Whether Col. Russell continued his photographic work in later times I have not been able to ascertain, but his name does not occur among the more recent investigators in this department of applied science. It is possible that the few years during which he occupied himself with photography represented but a passing phase of the many-sided pursuits to which he was attached. That he has left a permanent mark in this field will be gathered from the present sketch, and the genial naturalist and ardent sportsman must certainly take rank among Essex worthies as an original investigator in a department of science widely remote from those other pursuits by which he is, perhaps, more generally known to the members of the Essex Field Club.

THE number of the English eikonogen patent is stated to be 5207, March 26th, 1889.

REPAIRING BROKEN NEGATIVES.*

BY HUGH BREBNER.

THE operation of mending broken negatives so that the lines of junction will barely be visible, and will scarcely show in the print, is one requiring at once time, good daylight, carefully arranged paraphernalia, and a sure and skilful hand.

Before proceeding to work, I should like to draw attention to, and to emphasise the fact that when an ordinary negative is broken, and the bits of glass are pieced together, the print will show a harsh black and white line at every junction, or if printed while revolving, the desirable loss in sharpness will be disagreeably counterbalanced by a painful gain in the breadth of the "fuzzy" line.

Dry plates to-day are so much more reliable and perfect than they used to be, and our familiarity with their treatment so great, that the stripping of a film, even from a surface prepared to hold the gelatine firmly, presents no difficulties which a very little care and skill cannot overcome. The subsequent replacing of the pieces of the broken film upon a fresh piece of glass, and the method whereby the edges of the gelatine shall be brought together so that the direction of the fracture can with difficulty be detected in the print, and can very easily be touched away, are the points upon which I have more particularly to dwell.

The denser the image, the less will the line of junction show; and, when the mending is at all skilfully effected, a soft, thin line on the most transparent portions will be the only trace. Landscapes, also groups and vignettes, are less liable, for the same reason, to exhibit traces of the mended line, than are plain or cameo heads. If, however, it be important that no line be at all visible, all sign of inequality of tint—beyond that characterising the picture—may be got rid of without much difficulty, and with considerable certainty.

If the negative has been modelled and varnished before being broken, the varnish must, of course, be removed with methylated spirit in the usual way, and it is perhaps better to treat even an unvarnished (broken) negative to a preliminary bath of spirit, or, in its place, alum may be used, as this toughens the film and prevents extreme expansion. Having carefully preserved each chip, examine each for tiny splinters of broken glass, and when found remove them. Lay the chips, well separated from each other, to prevent further chipping, in a large, flat bath full of acidulated water (HCl). After some time, by preference just when frilling begins at the broken edges, take out chip after chip, and successively plunge each under water in another bath, and drag the fingers against the broken edges upwards and backwards till the margin of the film is loosened on two edges of the chips—whether triangular or lozenge-shaped. Then, with only a slight modification of the action of the fingers, fold back the film upon itself, and with repeated touches free it entirely from the glass. It will be found that this can very easily be done where the cut is clean, and where the film is of equal thickness. It is a very much more difficult operation if the attempt be made to begin upon the original margin of the plate. Throw away the bits of glass, or piece them together somewhere else as a guide. Throw each film as it is detached into a vessel of gently moving water, so that the films may expand equally. Immerse the films in pure methylated spirit to shrink the expanded film, and thereby recover density.

Have ready a clean piece of glass, and, having lifted out the largest piece of film as wet as possible, throw it down on the glass and rapidly spread it out, right side up, in the place it should occupy. Now, holding the film in its place at the edge, incline the glass so that the superfluous moisture may flow off, when the film will adhere to the glass of its own accord. Next, pick out a piece of film which fits the first, treat it as the last, and bring it roughly into position. Do the same with the remainder of the pieces. Place the glass on a modelling-desk, and, with a large, soft brush, moisten piece after piece; drag each into closer juxtaposition with the piece above it; and when the edges just overlap and nothing more, partially dry the brush, and drag the point or heel along the two edges. This will cause them to adhere more firmly to the glass, and prevent the tendency to slip down. It is much better to have a slight overlap than to have an exact meeting of the edges at first, or to leave a gap between, and for the following reason: as the films dry they contract, each towards its own centre; consequently the edges of neighbouring pieces are dragged away from each other, and unless some allowance is made for this, it is difficult to bring them exactly together ultimately. When the films are very nearly dry take a smaller brush, and with its heel drag gently along the finer junctions. In most cases this will be sufficient to bring the edges into simple contact without any overlap. Where the overlap is more marked, wet the brush, and with it moisten the two films slightly near, and at that part of their edges. When the gelatine is moist enough it becomes pliable, and contracts or expands at the slightest touch of the brush. If the film be too moist it will be too elastic, and will regain its former position the moment the controlling pressure is withdrawn. If, on the other hand, it be too dry, it will not budge one jot from its place. Therefore the simplest way to bring the edges loosely together without overlapping is to moisten the film, pretty freely at first, from an eighth to a quarter of an inch from the edge, and with the heel of the dry brush to drag it towards the centre, and at the same time by withdrawing the moisture cause the film to adhere to the glass in the desired position. The final touch to each junction should be a soft, dry scrape along the crack.

If the last operation has been performed perfectly and with sufficient judgment, the negative when dry will be ready to print from, or to intensify. But it is seldom—except in the case of very simple fractures—that no overlap or gap is visible when the film is hard-dry. Consequently a final treatment is generally necessitated. This varies: with an overlap, no matter how thin, a white line will result in the print; therefore the edges must be again moistened and dragged asunder. But with a gap, which would print as a black line, the piece of the film should be moistened at first near the centre, and then gradually towards the edge, and when amenable to expansion, dragged or stretched gently with a dry brush away from the centre towards the edge. Should the gap be wide, it may be necessary to work on two pieces of film, but in all cases the drawing of the picture should determine which piece should be moved, and in what direction. The best position of the edges of the moist films when the centres are dry is that of an inverted V, thus Λ: when the edges take this shape they had better not be pressed flat, unless they are very nearly dry indeed. Blisters caused by air-bells may be led from under the surface with a wet brush.

* Abstract of a paper read at a meeting of the Edinburgh Photographic Society.

This is a rough skeleton outline of the operations most commonly required, but occasionally the negative is too thin; sometimes an edge gets broken, and now and again a piece gets lost. As the application of an aqueous solution of mercuric chloride would simply cause all the pieces of film to float off, the mended negative should receive a coating of quickly setting gelatine before being intensified, or the broken negative itself might be slightly intensified before stripping. Where the edges are broken or frayed, the remedy is a touch of gelatine and a few strokes of the modelling pencil. When pieces are lost the same treatment may be adopted, but I have personally found it preferable to cut out a piece of another negative—worthless otherwise—of the same shape, but somewhat smaller than the space to be filled, and then fit it in after soaking it. Where a very faint bright line marks the junction of the films, the raised portion of the negative may easily be pared down with a sharp lancet or round-pointed knife blade. When this is overdone the modelling pencil again comes into requisition.

In conclusion, I may add that I have only once failed to make a very passable bit of work of any mending I have undertaken, and on that occasion the fracture took the form of a glittering star, and the number of pieces was exactly fifty-two.

THE PROGRESS OF QUINOL DEVELOPMENT.*

BY ALFRED MASKELL.

IN conclusion, I may say that it would appear that we have not yet come to the end of newly-proposed developers. New re-agents will, in all probability, continue for a considerable time to be brought forward; unless—and this perhaps is not beyond the bounds of probability—the time should arrive when the sensitive plate is impressed in the camera and requires only to be rendered permanent; going back, in fact, to some extent to earlier methods. For myself I would wish for a truce. I should consider it as a relief that things for a time might remain as they are; no new discoveries in the shape of developers, printing methods, detective cameras, and so on. Then we might apply ourselves seriously and with greater calmness to the means we have at present at our disposal—which are great indeed—and perfect some systems which have been neglected. I dread the arrival of the automatic penny photographic machine, which it is promised we are soon to see at all the railway stations. I am not pleased as a rule with the discovery of any new device for saving time and trouble, and I do not look forward to the time when photography will become such an easy process that any child may work it. I believe that in our art, as in all other arts of the best periods, the finest results are to be produced when time is considered as no object. In it, as in all arts, machinery and automatic appliances encourage the production of shoddy and clap-trap imitation. I will scarcely hesitate to say, in fact, that I would gladly almost go back to the days of Daguerreotype: had not one discovery followed so fast on the heels of another, it is possible, indeed, that that process, beautiful as it was, admirable for the very defect in some eyes of producing only one copy of a picture, and for certain subjects never since surpassed, it is possible, I think, that the Daguerreotype might have been so modified and improved in the method of working as to have held still at the present day a higher place in the public favour than it holds now as an almost forgotten process; remembered more with a kind of reverence than for the results it is capable of producing. It is, then, almost against the grain that I have to advocate what is, to a certain extent, akin to the automatism which I am more inclined to deprecate. It is necessary, however, to march with the times, and while I think the evil of our too rapid progress is manifest and unavoidable, the very evil itself is productive of good by the inducements it holds out for thousands to the study of practical art which they would otherwise not undertake. Of these the feeble and insincere will fall out of the race, or at least will remain unnoticed, heroes only to their immediate circle; a few will come to the front to illustrate the page of photographic history.

* Concluded from page 12.

FORMULÆ.

Paris Photo. Club.—Boil a litre distilled water; put equally divided into two litre bottles; while warm, put into one 75 grammes sulphite of soda, in the other 150 grammes sodium carbonate, powdered immediately before using. Shake till dissolved. To the sodium sulphite solution add 10 grammes quinol, and shake well till dissolved; to this add 8 to 10 drops acetic acid crystallised. Leave all to cool. When cold, mix by pouring rapidly the quinol solution into the carbonate, and filter the whole into a third litre bottle. The solution should be perfectly clear.

For Instantaneous Work:—

Concentrated solution of sod. carb. (pure)...	300 c.c.
Concentrated solution of sod. sulph. (pure)...	150 ,,
10 per cent. alcoholic solution of quinol ...	50 ,,
Rain or distilled water	500 ,,

Mr. Swan's:—

A.—Quinol	80 grains
Citric acid	10 ,,
Sod. sulph.	80 ,,
Distilled water	20 ounces
B.—Caustic potash...	160 grains
Sod. sulph.	160 ,,
Distilled water	20 ounces
C.—Bromide pot.	24 grains
Distilled water	1 ounce
D.—Caustic potash	160 grains
Distilled water	20 ounces

For normal exposures use equal parts of A and B, adding 5 minims of C for every ounce of solution. For over-exposed plates use D instead of B, with an extra quantity of C. For under-exposed plates omit C, and, in extreme cases, add 6 or 8 grains more of sulphite to every ounce of developer.

Dr. Vogel:—

Quinol...	5 grammes
Sodium carb.	75 ,,
Sodium sulph....	40 ,,
Water	900 c.c.

or carbonate of potash 75 grammes instead of carb. soda. Addition of about 5 per cent. of a 40 per cent. solution of caustic potash shortly before developing accelerates better than applying pure caustic potash

With Metabisulphite of Potassium as Preservative:—

A.—Quinol	10 parts
Metabisulphite	4 ,,
Water	250 ,,
C.—Caustic soda	50 ,,
Water	500 ,,

For every 100 parts of water take 10 parts A and 10 parts B.

Concentrated Solution:—

Quinol	1 gramme
Citric acid	5 decigrammes
Sodium sulph.	1 grammes
Water to make	100 c.c.

Five c.c. of this contain 1 decigramme of quinol.

With Acetatate of Soda :—

A.—Quinol	...	...	...	10 parts
Metabisulphite	...	...	...	4 ,,
Water	...	...	...	250 ,,
B.—Sodium acetate	...	...	...	50 ,,
Water	...	...	...	400 ,,

As a Further Accelerator :—

Sod. acetate	...	...	...	5 parts
Water	...	...	...	40 ,,

For Bromide Paper :—

(Thomas) A.—Sodium carb.	...	...		60 grains
Water	...	...		1 ounce
B.—Quinol	...	...		12 grains
Sod. sulph...	...	...		60 ,,
Water	...	...		1 ounce

Mix equal parts, and add the same quantity of water ; or better, use hintokinone 1 to 12 of water. Alum bath is good ; no acid bath.

Mr. Victor Corbould's Method of Producing Warm Tones in Lantern Slides.—Make up your normal quinol developer, and having previously *over-exposed* your plate, develop until the image just appears ; then immerse in a solution of caustic potash 5 grains, water 2 ounces, when the image will come up quickly, but will not be too dense. The colour obtained by over-exposing about six times the normal exposure with Thomas's plates is a warm sepia.

GENERAL NOTES.

Contrary to early instructions, it is advisable to rock the bath during development.

Mr. De St. Priest says that with a bath three times as diluted as the ordinary formula, the time of exposure may be shorter than with a more concentrated bath, the development being, however, slower.

From time to time take the plate out of the developer and leave development to proceed for a minute or so ; the action is more rapid.

For yellow stain, try, after fixing, washing, and drying, a bath of water 100 c.c., hypo 10 to 20 grammes, alum 5 grammes, hydrochloric acid or gallic acid 2 to 5 c.c. Let stand and filter.

In using quinol with carbonate of potash or soda, the colour, says Dr. Vogel, is considerably influenced. This depends on the quantity and kind of salt added. With the formula, sulph. sod. 40 grammes, quinol 5 grammes, carbonate of soda 50 to 150 grammes, water 900 c.c., green pictures result up to 75 grammes carb. sod. ; tone gradually improves to black as more is added. Carbonate of potash does not give green tones.

The method of soaking plate in quinol solution for one minute, taking out and completing the development in the alkali solution, is recommended. Once set going, plates can be passed on from dish to dish, saving time with large batches. The soda solution should always be used with a portion of already used bath.

Papier-maché trays should be kept clean and full of water, otherwise the action of the developing solution breaks up and dissolves the surface. If left in glass measures, funnels, &c., to dry, it causes a hard deposit ; leave them full of water with a drop or two of hydrochloric acid. The hypo bath, if exposed to air for any length of time, throws down a thick, muddy deposit if plates are not washed between development and fixing.

With chloride plates a small quantity of bromide of ammonium or potassium is advisable, the action on these plates being very energetic, and liable to cause fog.

For yellow fog, sometimes produced by accidentally leaving a negative in developer for a very long time, put, after fixing and washing, into a bath of

Sol. of red prussiate of potash ...	½ per cent.	1 part
Sol. of hypo.	10 per cent.	1 ,,

Mix at time of using only, and use in subdued daylight.

"A1," for January contains an article on "Photography," by Walter E. Woodbury, in which, among the illustrations, are two designed to show, respectively, the difference between a photographer's impedimenta now, and years ago.

PHOTOGRAPHING LIGHTNING.

IN our issue of July 26th, we printed a paper entitled "Instructions for Taking Photographs of Lightning," read at a meeting of the Photographic Club by Mr. William Marriott. We give now some extracts from a communication by the same writer, taken from the *Quarterly Journal of the Royal Meteorological Society* for October. Speaking of the storm which passed over London on June 6th, Mr. Marriott says :—

The storm was remarkable for the brilliant and continuous display of lightning, and was without doubt the grandest storm that has been witnessed in the metropolis for many years. Occurring just after sunset, the conditions were very favourable for carefully watching the storm and for photographs to be taken of the lightning.

One of the most remarkable features of the storm was the persistent and repeating character of the lightning. Many of the flashes appeared to remain visible for a perceptible length of time, some people being able to count 6, 7, 8, and even 10 before the flash disappeared. There were numerous instances in which the lightning appeared to repeat itself three, four, or more times. It is probable that these were distinct flashes following precisely the same path. This supposition is confirmed by some of the photographs of lightning which were taken during the storm. Mr. Nimmies, of Balham, obtained two photographs, each with four distinct flashes following precisely the same path and sinuosities, and only separated from each other by a very small amount of space. These appeared at the time to Mr. Nimmies as one flash. Fortunately the photographic views include some railway signals, and an examination of these reveals the fact that there are four distinct images of the signals. The space between the images of the signals agrees precisely with the space between the flashes of lightning. As the camera was held in the hand and not clamped to a tripod, it is clear that the camera was moved slightly during the exposure, and what appeared to the eye as one flash was in reality a succession of four flashes. A similar repetition of flashes is shown on several other photographs, and in each case the camera was held in the hand.

A most interesting photograph was taken by Dr. Hoffert at Ealing. This was obtained while the camera was being swayed to and fro. It shows three similar parallel flashes which took place during the movement of the camera in one direction. The space between the flashes is traversed by faint bands of light parallel to the direction of motion, which appear to indicate the existence of a residual illumination of a phosphorescent character in the intervals between the successive flashes. A second series of three flashes is shown in the upper part of the photograph, as well as a dark flash ; while a third series of two flashes, but with a wider interval between them, is also shown on the plate.

Some photographs showing flashes like a broad band or curtain of light were also obtained during this storm ; but in each case it has been ascertained that the camera was either held in the hand or not securely fixed. These seem all to lead to the conclusion that a lightning flash is not instantaneous, but has a much longer duration than has generally been supposed to be the case.

Three or four photographs showing dark flashes were obtained during this storm, the most notable being those taken by the Rev. A. Rose, at Emanuel College, Cambridge, and by Mr. A. W. Clayden, at Tulse Hill, London. The latter gentleman has since made a number of experiments in photographing the sparks from an electric machine, which tend to show that the dark flashes were due to photographic reversal.

In the discussion which followed the reading of the paper, the following expressions of experience and opinion were elicited :—

The President (Dr. Marcet) remarked that Mr. Wimshurst had photographed the sparks from his electric machine while the photographic plate in his camera was revolving between 3,000 and 4,000 times per minute, and had obtained a sharp image

of the spark. Mr. Wimshurst believed from these experiments that no movement of the camera during the process of photographing a flash of lightning could in any way fog or blur the image.

Mr. Whipple said he had attributed the double images shown in the lightning photographs previously received by the Society to the fact that the cameras had been exposed behind a window. He had made experiments which had tended to confirm his supposition, having drawn chalk lines upon a blackboard and photographed them at various angles through plate-glass. The photographs obtained exhibited very similar appearances to those shown in the lightning photographs. The dark flashes, too, had appeared to him to be due to internal reflection, but on this point he had been unable to make experiments. In the present series of photographs both the dark and ribbon flashes were shown; and in the case of the ribbon flashes he felt compelled to abandon his idea of their being the effect of refraction through a window, as both Dr. Hoffert's and Mr. Shepherd's pictures, in which latter a flash was splendidly doubled, were taken without the intervention of a window between the camera and the flash. It was exceedingly difficult to reconcile these lightning photographs with Mr. Wimshurst's photographs of the electric spark, especially supposing the flash lasted so short a time as it was usually stated. It certainly seemed that lightning flashes, instead of being so rapid in their movement, were very persistent. In the storm on June 6th he distinctly saw a beaded flash, and, like Dr. Tripe, he found himself much better able to follow the course of the lightning than he had been hitherto, because his eyes had now become educated, and he knew what to look for.

Dr. Hoffert said that in one case he noticed the lightning had a distinct fluttering appearance, showing that the lightning was sufficiently slow to make its movements apparent. He did not think that Mr. Wimshurst's photographs of electric sparks could be taken as an analogy, as the conditions in nature were so different. It was difficult to understand that any oscillation of the flash could have taken place, as the forms of the flashes in the photograph taken by himself were similar. He was unable to explain the dark flash, but from experiments he had made he had been led to believe that the phenomenon was not due to excess of exposure.

Dr. Green suggested that the dark flashes in the photographs were produced by yellow flashes, as intense yellow gave a negative effect.

Mr. Ranyard said: If we assume the ribbon flashes to have a real existence, the photographs seem to show that the ribbon never curls or turns to one side; all the turns are made so that the cross lines of the ribbon remain parallel to a fixed line. It follows from this that each edge of the ribbon is a plane curve, and the ribbon always remains between two parallel planes. A ribbon flash seen from any point between these planes would appear to project into a straight ribbon. Mr. Marriott and he had wished to determine whether there was any connection between the direction of the wind and the cross lines of the ribbon, or whether the cross lines were parallel to some fixed line in space, such as the earth's magnetic axis. He had therefore tried to observe the curvature of the lightning flashes seen in different directions during the great storm, but he had not been able to recognize any direction in which they appeared to be all straight flashes, and he had not seen any ribbon flashes or dark flashes. When he came to see the photographs taken during the great storm, his faith as to the real existence of ribbon flashes was still further shaken. There were some photographs which showed three or four parallel flashes of lightning, and three or four separate images of a railway signal post lit up by the lightning, proving that the plate must have shifted between the flashes, which were absolutely alike, turn for turn. The images of the signal post were separated by distances which corresponded with the distances between the lightning flashes, and we must consequently assume that the three lightning flashes all followed the same course in the air. This is what might theoretically be expected, for the first flash would heat the air and form a path of least resistance which subsequent flashes would travel along, as water follows the turns of a pipe. A somewhat similar photograph had been taken by Dr. Hoffert, who had intentionally moved his camera from side to side, proving that recurrent flashes occupied a considerable portion of a second, and that between each flash there was a phosphorescence which left a trace on the plate very similar to the gauge-like traces with which we were already familiar in the ribbon flash photographs. It was a very significant fact that all the photographs of ribbon flashes, as far as he was aware, had been taken with cameras held in the hands, or, at all events, with cameras which were not screwed to a fixed support, but were only held against a window-sill by the hand of the operator. And he thought that we have in these photographs evidence of the nervous condition of the operator, and of the magnitude of the jump or start which the flash gave rise to. Dr. Hoffert's photograph, as well as the other photographs of multiple flashes, showed that all the flashes took place in the same direction, for all the flashes thinned out in the same direction. There was no evidence of lightning striking first backwards and then forwards, as had been suggested.

PHOTOGRAPHY IN FRANCE.

BY LÉON VIDAL.

JUBILEE BANQUET—MUTUAL AID ASSOCIATION—ISOCHROMATIC PLATES—FLASH TORCH—MICRO-PHOTOGRAPHS—MONOCHROMATIC LIGHT—PHOTOGRAPHIC GUN—COLOURATION OF NEGATIVES—BIBLIOGRAPHY.

Second Banquet of the Fiftieth Anniversary of Photography.—A fête, commemorative of the invention of photography, took place on the 16th of last month under the auspices of the Syndical Chamber of Photography. The idea was to give to those persons prevented from attending the banquet on the 19th of August, the opportunity of taking part in a manifestation organised with the same view. The fête, which was particularly attended by professional photographers, was of the most cordial character. The President of the banquet, in drinking to the fraternal and solid union of photographic corporations, explained the necessity for creating amongst the whole of photographers an association of mutual aid, which would come to the help of unfortunate members or of their widows and children. The appeal of Léon Vidal was taken up, and generous offers were spontaneously made. The association was created, and on its foundation it is necessary to constitute itself formally by adoption of statutes of association. The invested funds are to be permanently inalienable, pensions and other aid being taken only from the revenues. The annual subscription is fixed at six francs, and perpetual membership—that is to say, freedom from any subsequent contribution, at 100 francs. The association includes foreign as well as French photographers. This useful work was wanting to the photographic body, and it is a good thing to have filled up the gap. The sitting of the French Photographic Society of the 3rd inst. presented nothing of great interest. Below we sum up the principal events.

Edwards's Isochromatic Plates.—The photographs from these plates, accompanied by those obtained on ordinary plates, were defective as examples from a cause which was pointed out. The impression prevailed that the ordinary plate had been taken in a bad light, whilst the isochromatic photograph is better, being more directly lighted. We are not ignorant of the difference shown by two reproductions, one of which is taken upon an ordinary, and the other on an isochromatic plate; but we like, when the two results are produced together, that they should possess a character of ingenuousness such that the observations called forth by Mr. Edwards's proofs could not be made.

M. Attout Tailfer, who, according to his own statement, has better formulæ than others for isochromatising plates, endeavoured to demonstrate that the proofs communicated had been reproduced under identical conditions; but he did not succeed in convincing anyone. It is time to have done with the myth of pretended patents relating to isochromatic preparations, and it appears to us to carry simplicity and complaisance to excess for persons to tell us that certain patents prevent them from practising orthochromatic photography. The truth is that this method belongs to all the infinite variety of colouring products, of coloured screens, and of processes and formulæ capable of leading to the same result, and it is no more in the power of a commercialist to place himself as a barrier against the application of orthochromatism, than it is in the power of a colour-merchant to prevent a painter from using red or any other colour. Such commercial pretensions are of an unworthy stamp, and based upon the ignorance of the greater number, and the timidity of the few. It is time, we repeat, to have done with such trammels to the progress of photography.

Flash-Torch for Producing the Magnesium Flash.—This little apparatus, conceived by MM. Merville and Lausiaux, looks exactly like one of those fuse boxes which smokers use for lighting their cigars. It consists of a metal reservoir of the size of a small match-box. On this reservoir are two small tubes, one to take a rubber pipe connected with an elastic ball, the other receives a blazing match. The air and the magnesium powder, projected by the rubber ball, come out enveloping the blazing torch, and the magnesium flash is thus produced. The little box in question will contain twelve charges—that is to say, enough pure magnesium for twelve flashes. Simple and exceedingly portable, this little apparatus is destined to be a success.

Micro-photographs of Wood Sections.—A very interesting communication on this subject was made by MM. Thil and Thouronde. Micro-photographs, to the number of about 400, were executed to the order of the Minister of Agriculture. Mons. Thil, Inspector of Government Forests, has, in very precise language, pointed out the reach of this application of photography, which permits of the classification of woods in families and species, thanks to the comparison alone of the intimate structure of the fibres and cellular network. By this means we are enabled, with the help of simply thin cuttings, to give, so to say, a complete anatomy of each species, and to notice easily the essential differences which exist between wood of different species, although belonging to the same family; all the more, therefore, can we recognise classification in families. Micro-photographic pictures, projected by the lantern, served to demonstrate clearly the truth of the propositions affirmed. This is a new example, and one of the most conclusive kind, of the numerous services that photography may render to the sciences. This considerable work does the more honour to Mons. Thouronde that his preliminary studies of micro-photography naturally indicated him to the choice of the Minister in view of the present important application.

Baths for Holding Liquids for Mono-Chromatising Light.—It is to Mons. Thouronde that is due a presentation of these baths formed of two sheets of glass and a third with a round aperture; against this the outer plates are cemented, a small hole being left for the introduction of coloured liquid, sulphate of copper, or whatever it may be. The advantage presented by this arrangement is that of giving dishes with vertical sides, very sound, and convenient to use. There is no danger of any injury to the instruments from the escape of a liquid which is often injurious to them.

Hand Apparatus.—Photographic Gun.—Mons. Carette described the action of this little apparatus, which we had already seen at the Universal Exhibition. It is essentially a small camera mounted on a handle like the stock of a pistol, the exposure being made by pulling the trigger. It is also fitted with two short telescopic legs in front, by means of which it may be used standing on a table or other support, and levelled if need be. This well-schemed instrument must be added to the collection, already so numerous, of photographic *vade-mecum*.

Yellow Colouration of Negatives.—Mons. Hervè, who had not clearly understood what M. Balagny had desired to express at the previous sitting of the Society, delivered a long dissertation upon the yellowing of gelatine plates in pyrogallic acid. The misfortune was that he had missed the point of the question, and that an hour was lost from his not having listened. Mons. Balagny replied that he only spoke of the canary yellow veil which is produced on plates after their immersion in hyposulphite of soda. He stated afresh that the preliminary washing of the negative in water acidulated with citric acid constitutes a preventive means, permitting us to avoid with certainly all yellow veil. We think for our own part that all that is necessary is washing with plain water; a negative sufficiently washed is freed from all trace of alkaline salts, carbonate of soda or of potash, and remains clear and without the slightest colouration. When the development has been long we must insist more strongly still upon thorough washing, in order to better penetrate the film of gelatine which has been more deeply impregnated with alkaline salts.

Bibliography.—MM. Gauthier-Villars and Son have just brought out a treatise on photography with pellicular processes by Mons. G. Balagny. This work includes two vols. The first is dedicated to generalities—flexible films, theory and practice of the three developments, iron, pyrogallic acid, and hydroquinone. The second includes pellicular papers, the general application of pellicular processes, phototype, contretype, and transparencies. There are in this work many things pointed out which it is useful to consult.

HASTINGS AND ST. LEONARD'S PHOTOGRAPHIC SOCIETY.—The annual general meeting will be held January 13, in the large room of the Brassey Institute, when Mr. A. R. Dresser will give a paper, with illustrations by lime light. An exhibition of photographs, lantern slides, transparencies, photographic appliances, and apparatus, will be held in the Public Hall, Hastings, on February 25th, 26th, and 27th. The following will be the classes and awards:—Class I. (Photographs), gold medal for the best photograph in the exhibition; silver medal for the best landscape or seascape, interior or genre subject, not enlarged; silver medal for the best portrait, not enlarged; silver medal for the best enlargement; six bronze medals to be distributed at the discretion of the judges. Class II. (Lantern Slides), silver medal for best set of six lantern slides; two bronze medals for the next best sets. Class III. (Scientific—Photo-micrography and Stellar Photography), bronze medal. Messrs. H. P. Robinson, J. Gale, and J. B. B. Wellington will be the judges. The proceeds of the exhibition, after paying expenses, will be given to the Hastings, St. Leonard's, and East Sussex Hospital. Further particulars may be obtained from the Hon. Secretary, Mr. A. Brooker, Memorial Buildings, Manchester.

COLD WEATHER NOTES.

BY C. BRANGWIN BARNES.

NOTWITHSTANDING the oft-repeated announcement to the public of "weather no object," it is still a fact acknowledged by photographers, amongst themselves, that photographs produced in the winter are not so good as those produced during what is generally termed "the season." There are many reasons why such should be the case, but it should be borne in mind that there are ways and means of getting over—or, at any rate, minimising—the troubles to which operators and printers are heirs in the winter of their discontent. I do not suppose, for a single instant, that the few hints I am about to make will convert that "winter" into "glorious summer," but they may perchance be of some slight assistance to some fellow worker, and it is with this hope that I am sending them forth. Of course, the old hand will say that I am giving him nothing new; that my notes are merely old wheezes that he was aware of long ago: but there are still many new workers in the profession who may not have been so blessed, and it is for their benefit that I am now writing.

To commence with the studio, it will be found that if the lens be left therein over night, the glasses will be covered with moisture in the morning, which moisture should always be carefully removed before using the lens. The same will be found on both focussing screen and eye-piece. I have found that a short focus lens, as a rule, is better to use in winter than a long focus, as there is usually a certain amount of mist in the atmosphere, which, interposing between the sitter and the camera, is often the cause of a foggy image. Although it is the rule to keep the studio at a fair temperature during the day, the fire is usually let out when the hours of operating are over. This should not be the case, as, if the stove is kept burning until retiring time, and then filled up with small coke, so as to keep just alight till morning, there will be no trouble with the snow, which would otherwise settle on the roof, and cause some trouble to clear off, to say nothing of the risk of a pane or two being broken, or of an early sitter having to be taken with side-light only. The small fire burning all night will also render it a possibility to keep plants alive in the studio all through the winter, which is a decided advantage.

It is not only the studio that requires to be kept warm, but the dark room also, as many a weak and misty image owes its defects to the coldness of the room and the developer. If the dark room be kept warm, the various solutions will be in better working order, and, what is more, so will the operator. It is far from pleasant to have to thaw the tap to get at the water with which to mix the developer, nor is the pleasure at all enhanced by the use of that same developer for some twenty minutes or half an hour, especially if the fixing solution has just been mixed with some more of the same ice-cold water. If there be no means of warming the dark room, the solution should be kept elsewhere, as a developer only a few degrees removed from freezing-point will never yield so good a result as one at a normal temperature, and the temptation to increase its rapidity by strengthening it is not only more costly, but of very little use. When the water is supplied direct from the main, without the intervention of a cistern, no amount of warmth in the dark room will be of any use, unless a quantity is drawn off from the tap and allowed to stand for an hour or so.

The following developer is, I find, a very useful one for winter purposes, as the main body of the solution, being ready mixed, can be kept in a warm place until wanted for use, added to which, it gives negatives of a colour very close to that of the wet collodion process:—A. To. ½ lb. of sulphite of soda (pure) add 50 ounces of boiling water, and ¼ lb. of common washing soda; when cool, make up to 100 ounces with water. B. 1 ounce of pyrogallic acid; make up to 7 ounces with *rain or distilled* water, and add 4 drops of nitric acid. To develop, take 30 parts of A to 1 of B. Some operators object to the use of soda. When such is the case, the sulphite should be mixed with the boiling water, and 2½ ounces of liquid ammonia added thereto when cool. This developer is merely an adaptation of that issued by Messrs. Pollard and Graham with their plates, such adaptation acting well with me, but may require some further modifications in other hands. I would in no case advise the addition of bromide, although a bottle containing the following solution should always be at hand ready for an emergency, such as an over-exposed plate:—

Bromide of potassium	1 ounce
Water	10 ounces

One or two drops of this added to the developer will be found to have a marvellous effect. When ammonia is used in place of soda, bromide of ammonium will be found preferable to bromide of potassium.

All negatives should be varnished before a single print is taken from them, but if it is necessary to take a print in order to test the density of a doubtful plate, a thin sheet of mica should be inserted between the film and the albumen paper, as at the present season of the year the gelatine film is very apt to take up some silver from the paper, and so ruin the negative, or at any rate cause considerable waste of time and trouble. In a former article I recommended the use of an old, untoned print to back up the fresh paper during printing, and would now again draw attention to the same, as it will be found to have a really marvellous effect in preserving the colour of the print, and every tyro knows that a yellowed print never tones up like a good one. The practice of warming the toning bath is one I am unable to commend, as it has a tendency to cause mealiness in the prints. If the bottle containing the solution is kept in a warm room, the toning will be found to proceed as regularly and as rapidly as in summer. The hypo bath should be mixed with warm water and used when cold, and chilled water used for the first washing or two after fixation. By this means blisters will be avoided. Saturday's prints should be left over until the Monday to tone, as the prolonged washing they would otherwise get tends not only to rot the paper, but to eat away the albumen, and so cause premature fading of the prints.

CRYSTAL PALACE PHOTOGRAPHIC EXHIBITION.—A special class will be formed in addition to the published schedule, and a silver medal will be awarded for the best picture, irrespective of subject, to be selected by the judges from amongst those pictures which have never been previously shown at a public exhibition. Pictures entered for this prize will be equally eligible for award in their several classes. Two additional silver medals will be given: one for the best picture, irrespective of class, in the amateur section; and one for the best picture, irrespective of class, in the professional section, neither picture having taken any other award in this exhibition. The whole of the exhibitors in the apparatus division will be asked to adjudicate upon these supplementary awards. The applications for space this year, we are informed, are already far ahead of previous shows.

Notes.

Mr. Ralph Robinson, in his letter last week entitled "Reproduction and Copyright," has contrived to miss the point of our contention. Our proposition was not that the principal of a newspaper should consider he had the right to dispose of the block made from a photograph, but whether a certain firm of photographers should place a prohibitive fee upon the right to produce electros from that block for sale to other papers. The whole qestion is one of market value, and while, as we said, the firm in question knows its own business, we still maintain that it loses rather than gains by its high charges.

Mr. Robinson appears to have in his mind photographs which involve a good deal of time and expense, and which are intended to be pictures in the highest sense of the term. If not, it is hard to understand the relevancy of his remark that "There is very exceptionally any encouragement to professional photographers to produce pictures except the love of it, and the expense is to many a very serious consideration; and surely anything which makes the practice of art less burdersome to the pocket of the photographer should receive the support of the photographic press." But all this is wholly outside the point at issue. It is very desirable that portrait photographers should make their pictures as artistic as they can, but we presume no professional photographer can afford to ignore the fact that he is engaged in a business which must be made to pay if he values his peace of mind. The manufacture of as many negatives as possible in one day is the aim of the average portrait photographer, and if he wishes to increase his business, advertisements are not to be despised. We therefore contend that the advertising of a photographer's name in a newspaper *is* a *quid pro quo* in the cases we have in our mind, namely, where the portraits of nonentities are taken in the ordinary way of business, and the photographer has been already paid for making the negative.

To descend from theory to practice. It has become the custom of late years for both the *Illustrated London News* and the *Graphic* to go in extensively for portraits, not merely of celebrities, but of the rank and file who have obtained mention, perhaps for the first and last time in their lives, in the newspapers. Among these may be classed a large proportion of the members of a new House of Commons, and, descending in the scale, we come to the members of the London County Council, the London School Board, and other organizations. Most of these portraits have absolutely no market value; but if, through any accidental circumstance, one of the common-places takes the chair, say, at a local meeting, the editor of the local paper may contemplate the advisability of giving his portrait. For cheapness and convenience, he goes to the agency which acts for the illustrated papers, and selects the portrait. In every case but that of the firm he mentions, he finds that an acknowledgment of the photographer beyond the price paid for the electro is all that is demanded. But if the portrait happens to have been taken by the Stereoscopic Company a fee of 10s. is demanded. Thus he may find that, while the electro itself is but 5s., the right to use it costs double as much. We do not question the right of the Company to charge what they like; we only question the policy.

The matter *per se* is one wholly of pounds, shillings, and pence; but we have dealt with it at some length, because of its importance, and also because out of it arises a new aspect of the ancient question, which has always troubled the minds of photographers—the ownership of the negative. The law on the point is not so settled as some suppose. The custom of the trade is that the ownership and copyright are vested in the producer, but that, to quote the words of Mr. W. E. Debenham in an article on the subject which appeared in the PHOTOGRAPHIC NEWS of December 7th, 1888, "the right to the possession of the negative ought not to imply any right to the use of the negative, otherwise than by permission or desire of the sitter." Of course the permission to reproduce by an illustrated paper is given in every instance by the sitter to the Stereoscopic Company, but if the Company makes money out of copyright charges, ought not the sitter in equity to claim a portion? Whether anybody under the circumstances would so claim has nothing to do with the matter; the point is, that the fee, whenever it is obtained, is a comfortable addition to the price paid for making the negative. The growing tendency to illustrate newspapers and journals of every class, especially in regard to portraiture, has made the photographer an important factor, and his policy surely should be rather to give facilities than check them.

The mining prospector is just now a very important personage. His mission is to go roaming about all over the world in search of auriferous properties. He is obliged to be very astute, and not disclose his real object, so as to get the property for "a mere song," after which he proceeds to plant it on the London investment market at an enormous profit. In order to do this, he makes an extensive use of photography. Why photographs of the surface of the ground should be a proof of gold contained beneath is not for us to say, but purchasers of gold mining shares find a comfort in gazing at such pictures, and therefore the prospector takes care to indulge them. Thus we read in a financial paper that "Mr. —— is, according to American advices, roaming around the Candelaria mine, and taking photographic views, in order to once again appear before English investors with pretty views of a 'splendid property.'" This is an advance; hitherto the prospector has been content to employ a photographer; he now takes the photographs himself. It is the safer plan.

The camera is an object of dread to the untutored savage. It is not so much the uncanny look of the

thing when it is planted on its three legs, with the operator's head beneath the focussing cloth, which frightens him, as the picture itself. One can quite understand the innocence which prompts the child of nature to imagine, when he sees the counterfeit presentment of himself and his companions, that a portion of his actual being has actually been transferred to the glass. In the days of witchcraft a photographer most assuredly would have been hanged as a wizard. After a while the savage gets reconciled to the phenomenon, especially when he finds he has not come to much harm, but further acquaintance with photography itself does not always remove his suspicions. A curious instance of this comes from Afghanistan.

Some traveller in the country of the Pathans beyond Quetta, who had a camera with him, gave the natives their first knowledge of photography, and this appears to have been received with much disfavour, for, on the surveyor of the Madras Government Department proceeding thither on a professional mission, he met with a hostile reception. It is true he had not got a camera, but he was in possession of a theodolite, and this, in the eyes of the Pathans, was much the same thing. The dislike to the camera, it appears, springs from the fact that it takes pictures upside down. But, in addition, the Pathans imagine, when the surveyor is using his theodolite, that he can see through the walls of houses, with the appalling result that the ladies of the household are photographed standing on their heads by the infidel! It was a mistake for the first photographer in the Pathan country to allow the natives to look at the ground glass screen of the camera. He forgot that a little learning is a dangerous thing.

Rejlander, as Mr. H. P. Robinson pointed out last week, read but one paper before a photographic society. He was not given to rushing into print, and, as Mr. Robinson has said, preferred to convey his thoughts by means of his art. It was in conversation with him that one was able to obtain his ideas on the possibilities of photography, and fresh, original, and valuable they were. At a dinner of the South London Photographic Society he made a speech full of home truths, expressed in a quaint racy fashion. It was so difficult to get any of Rejlander's opinions on paper, that a member who was present who wrote shorthand, hailed the opportunity and took down his speech, which made its appearance in the YEAR-BOOK for that year. It is rather curious to see in some memoranda found after his death how he foreshadowed the detective camera. "Except truth of drawing," he wrote, "expression is, I think, the most important thing in a portrait, and the expression which is unpremeditated and unconscious the best. I should be very glad to possess a lens that did not need focussing. I should carry it in my pocket, and with a dry collodion process I would catch positions and expressions in a crowd far better than with my own eyes, for those poor orbs have to obey fixed laws; they cannot even see a man clearly in the street while looking at a spot in the window frame."

PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

TONING ALBUMEN PRINTS—MAGNESIUM FLASH-LIGHT STUDIO—WINTER PICTURES—DEVELOPERS FOR PRINTS ON GELATINO-CHLORIDE PAPER.

Toning Albumen Prints.—An entirely reliable formula, which has been in use for many years with satisfactory results in one of the most eminent photographic establishments of this country, is the following. Two solutions are made up:—

Solution No. 1.

Water	1,000 c.c.
Acetate of soda	50 grammes

Solution No. 2.

Water	1,000 c.c.
Gold chloride	1 gramme

For use take:—

Solution No. 1	100 c.c.
Solution No. 2	50 c.c.
Water	100 c.c.

Carbonate of soda, sufficient to neutralise the bath.

After the bath has been used for toning, one-half of it is poured into the residues, and every day half a bath of the above-given proportions is added to the rest remaining in each case. If it is intended to tone in the evening, then the addition to the toning bath should always be made in the morning of the same day. This toning bath can be recommended to the profession in every respect.

A Magnesium Flash Light Studio.—Professor Schirm, of Breslau, some weeks ago opened a new photographic studio at Berlin, in which instantaneous pictures are taken only by magnesium flash light. The well-known flash lamp, constructed by Professor Schirm himself, is used. A system of seven to nine lamps for a single portrait, and double the number and even more for groups, is employed. The lamps are suspended from the ceiling, and can be pushed to and fro on iron rails, which run parallel to the walls. Four lamps are kept burning nearly alongside of the sitter, three in front, one behind sideways to illuminate the background. With the whole set of lamps a pair of bellows is combined, by the aid of which all the lamps are lighted at once. Besides, the pair of bellows are by electrical contact combined with the shutters of the objective lens; as soon as the cap is removed from the lens, the pair of bellows are released by means of electricity, and the magnesium lights produced. When, however, the bellows are compressed for about one and a half inch, the circuit is at once closed, the cap of the lens being closed at the same time. In this way the exposure amounts only to one-tenth of a second, though the magnesium lights are burning for a somewhat longer time. The same arrangement is used for the production of prints and of enlargements. If a print is to be produced of a portrait negative a very short time after the exposure, a piece of wet gelatino-bromide paper is squeegeed on to the fixed and washed negative whilst still wet, then exposed at a distance of three to four feet from the flash light, and developed with eikonogen. The new studio is declared a decided progress by such authorities, for instance, as Professor H. W. Vogel, who devoted to it a leader in his journal.

Winter Pictures from the Hartz Mountains.—A well-known meteorologist has on a cold, but splendid winter day, de-

scended the Brocken, the celebrated scene of the St. Walpurgis Night in Goethe's "Faust," and, by the aid of an academy camera, taken several highly interesting photographs of the snow-covered scenery. A few of them we reproduce here in block form. Figs. 1, 2, and 3 show a group of scanty pines, standing on the brows of the mountain, being so completely covered with rime in all their branches, that they have entirely lost their original

Fig. 1.

form, and look like the strangest forms of animals or masses of rocks bristling with ice. In bright sunshine

Fig. 2.

they present a magnificent appearance. The wanderer, wading with difficulty in the deep snow covering all the rugged rocks and glens, perceives these ice-blocks only when he is quite near, and then finds himself surrounded by white figures, not unlike white bears or praying nuns. Fig. 4 shows a telegraph pole, which by the rime has been transformed to a figure something like a huge fungus. The wire of the telegraph is now always removed at the beginning of the winter, because it has

Fig. 3.

formerly been torn by the weight of the adhering ice; three years ago, at an occasional research, the wire be-

Fig. 4.

tween two poles was found to bear a charge of ice amounting to 1,100 pounds.

Developers for Prints on Gelatino-Chloride Paper.—Dr. E. A. Just, of Vienna, the well-known manufacturer of photographic papers, publishes the following developing formulæ, which are also recommended by Dr. Stolze as excellent.

1.—*Hydroxylamine Developer.*

a. Caustic soda 10 parts, water 1,000 parts.

b. Hydroxylamine hydrochlor. 5 parts, alcohol 100 parts, water 200 parts.

c. Potassium bromide 1 part, water 50 parts.

For brownish-black tones, are mixed :—

Solution	*a*	...	...	...	...	...	100 parts
,,	*b*	...	...	...	...	...	17 ,,
,,	*c*	...	...	...	...	...	1·5 ,,

For sepia tones, are taken (the time of exposure being at the same time doubled) :—

Solution *a*	100 parts
„ *b*	12·5 „
„ *c*	1·5 „

For reddish-brown to red tones, are taken (the time of exposure being four to eight times as long as in the first formula) :—

Solution *a*	100 parts
„ *b*	8·5 „
„ *c*	1·5 „

II.—*Eikonogen Developer. Solution* A.

Water	300 parts
Sodium sulphite	4 „
Potassium meta-bisulphite	1 part
Eikonogen	1 „

Solution B.

Water...	300 parts
Soda (crystall.)	4 „
Glacial acetic acid	1 part

With sufficient exposure, equal parts of solution A and B give beautiful red to reddish-brown tones. Subsequently the prints are treated with an acid bath of water 500, glacial acetic acid 1.

III.—*Neutral Citrate Developer.*

The neutral citrate of ammonium has the advantage over the acid one, that it does not mould as quickly as the latter, 600 parts of citric acid are dissolved in 2,000 to 3,000 parts of distilled water, which solution is neutralised with ammonia in the same manner as in the case of ammonio-acetate. The following are mixed :—

Ammonio citrate solution	150 parts
Sulphate of iron solution 1 : 3	50 „

The clear greenish solution does not become muddy, even with sulphate of iron in excess. With short exposures, beautiful blackish-grey tones are obtained ; with prolonged exposures, sepia tones, and, if the solution is diluted, red tones. To prepare a stronger developer, 168 parts of citric acid are dissolved in 500 parts of water, which solution is neutralised with ammonia (0·91 spec. weight), and diluted with water up to 800 parts. Then are mixed :—

Ammonio-citrate solution	100 parts
Sulphate of iron in crystals...	15 „

After this has completely dissolved, well set, and to some degree oxidised in the air, the developer is ready for use. The developer becomes blackish-green by oxydation, but it may be recovered if, after some iron-wire has been put into it, it is made slightly acid by means of citric acid, and exposed to the light.

IV.—*Hydroquinone Developer.*

This developer is one of the best, especially if it is not used freshly prepared, the tones resulting being vigorous and of beautiful gradation. For *black tones*, are mixed :—

Water...	300 parts
Hydroquinone	1 part
Sodium sulphite	6 parts
Potassium metabisulphite	0·33 „
Potash	11 „

For *red tones* :—

Water...	600 parts
Hydroquinone	1 part
Sodium sulphite	12 parts
Potassium metabisulphite	0·33 part
Caustic potassium	1·5 parts
Potash	4 „

A very good formula is also the following by Detaille Frères :—

Water	30 parts
Hydrokinone	1 part
Sodium sulphite	7·5 parts

mixed with

Water	60 parts
Potash	15 „
Acetic acid	1·5 „

This developer gives *black tones*. For *red tones* the following is recommended :—

Water...	50 parts
Hydroquinone	1 part
Sodium sulphite	7·5 parts

mixed with

Water...	400 parts
Potash	15 „
Acetic acid	6 „

PHOTOGRAPHY OF THE INSANE FOR PURPOSES OF PSYCHIATRIA.*

BY DR. EDER.

Instantaneous photography has been employed for some time in psychiatria, and for the illustration of works on diseases of the mind and nervous system.

The true-to-life pictures of the sick in their various phases, convulsive attacks of all kinds, such as Charcot, for example, takes for his object-teaching, or such as are to be found in the annual reports of the Insane Asylum at St. Servolo, point out to us the manner in which the instantaneous photography of the insane in the various asylums should be practised.

The professional man is very often able to hit upon the correct diagnosis from the appearance of an insane person, from his carriage, his face, the play of his mind. Undoubtedly, by photographing a number of carefully chosen so-called "classical" cases, pictures would be obtained which would be valuable, either for object teaching or for the study of the individual cases ; besides, much would be suggested by the study of the facial mechanism in the various mind diseases ; for example, in melancholia, and mania. These instantaneous photographs furnish such true representations of the circumstances that every professional man can recognize from them the characteristic symptoms of the disease, which cannot be said in regard to pictures of the insane drawn by hand.

Especial attention was turned to this work on the part of the Imperial-Royal Institute and Experimental School for Photography, and on the invitation of Dr. Krajatsch, head physician in the Lower Austrian National Insane Asylum at Kierling-Gugging, photographs of various insane patients were made by Dr. Eder and Professor Lenhard. A Voigtländer Euryscope of 66 mm. opening and a shutter by Thury and Amey were used. The photographs were perfectly successful, and the collection was a gathering point for doctors and other visitors at the last exhibition of the Imperial Royal Institute, and a specimen picture—reproduced in collotype by the students at the Institute—was inserted in the illustrated catalogue of the exhibition.

Photographic Club.—The subject for discussion on Jan. 15 will be "The Intensification and Reduction of Negatives."

* Translated for *Wilson's Photographic Magazine* from the *Photo Archiv.*

PHOTOGRAPHIC SURVEY OF WARWICKSHIRE.*

BY W. JEROME HARRISON, F.G.S.

Zoology of Warwickshire.—In the minute life which occupies our ponds and ditches there is a never-ending field of work for the photographer who combines the camera with the microscope. Some of us know, too, that it is better fun to hunt with the camera than with the gun: and we hope to be able to photograph the local birds, &c., in their native haunts, and so to secure pictures which shall surpass the best efforts of the taxidermist.

Methods of Conducting the Photographic Survey of a District.—There are several ways in which the photographic survey of any district may be carried out.

1. First we have what may be called the "no method." Each member of the society or body by which the survey is to be carried out wanders at will over the district, photographing whatever pleases his eye, and sending in his negatives or prints to the managing committee. It is not necessary to point out the demerits of such a scheme.

2. If there is any good, modern, and tolerably cheap county history in existence, it might well furnish the ground-work for a general photo-survey. Lists of all the places and objects named in its pages should be drawn up, and grouped according to locality; each division being then allotted to those workers who have volunteered their services. For Warwickshire the recent publication of an admirable county history,† by Mr. Sam. Timmins, offers a capital opportunity, the more especially as the book itself contains no illustrations. Any member who wishes to form a very valuable and interesting volume can do so by pulling Mr. Timmins's book to pieces—which is just what its reviewers have *not* done—interleaving it with a series of illustrations such as I have suggested, and then having it rebound.

3. But for an exhaustive photo-survey of Warwickshire, or of any other district, I believe the plan must be based upon a large scale and accurate map; and we must go to nature herself for our illustrations. Fortunately we are now provided with a map or maps—the work of the Government Ordnance Survey—which is in every respect admirable.

(*a.*) *The Old One-inch Ordnance Map.*—Warwickshire was mapped on the scale of one inch to one mile as long ago as 1830. This map is sold in "quarter sheets" at one shilling each, each quarter sheet including about 160 square miles. The entire county on this scale makes a map 59in. by 42in., which is sold in sheets for 17s. 6d.

(*b.*) *The New One-inch Ordnance Map.*—The map described in the last paragraph is now, in some respects, out of date. But a new one-inch map is being prepared—by reduction from the six-inch map—which will be a great improvement. It will be similar in size and price to the old one-inch map. We can hardly expect to have this map for Warwickshire for a period of several years.

(*c.*) *The Six-inch Ordnance Map.*—This is the ideal map for the work of a photo-survey. Its large scale—six inches to every mile—allows every field, and even every tree, to be depicted. The orientation of buildings is clearly shown, so that the photographer can see beforehand when the light will fall suitably upon any building, ruin, &c., that he may have to travel a long distance to photograph. The issue of the Warwickshire map on this scale is very nearly complete. The county is contained in two hundred quarter sheets, each measuring 18in. by 12in., and including six square miles. They are sold at one shilling each, and 195 have been published.

(*d.*) The *Parish Maps* are on the still larger scale of twenty-five inches to a mile. Four of these parish maps contain an area equal to one quarter sheet of the six-inch map. Each parish map measures 38in. by 25¼in., and contains an area of a little more than 1½ square miles. These also are all but complete for Warwickshire; and in some cases, as in Stratford, the ruins of Kenilworth, &c., they will be very useful to the photo-surveyor.

(*e.*) Lastly, there are the town plans, on the scale of 125 inches to a mile.

Plan now proposed for the Photo-Survey of Warwickshire:—

1. A committee must be appointed, by whom the details of the plan can be formulated.

2. The maps of the county on the six-inch scale must be purchased. For each sheet of the map there must also be a light cardboard box* bearing the same number as the map. In this box, mounted prints of all the photographs taken from objects contained in that sheet of the map should be kept.

A similarly numbered set of negative boxes† would be needed to contain the negatives belonging to each sheet of the map.

3. All photographers who would be willing to place their services at the disposal of the Society should send their names—in pairs if preferred—to the committee.

4. The committee would decide on a certain patch of country to be surveyed—say that included on twelve sheets of the six-inch map, if twenty-four names were received. They would then allot the maps by ballot or otherwise among the workers, giving one map to each pair.

5. Let us suppose that two friends, A and B, are allotted a certain area, say that contained in one quarter sheet of the six-inch map, including an area of six square miles.

They carefully study the map and draw up lists of the promising points. They read up the history of any churches, ruins, or other monuments of the past included within it. Then they visit it for the first time, *without their cameras.* They walk across and across the district, calling perhaps at the inns, the farm house, or the rectory, gaining information and jotting down places and times when the light will be favourable. On their next visit they are accompanied by their cameras, and the negatives necessary to illustrate the area—perhaps only two or three, perhaps ten or twenty—are soon secured; or a second and third visit are paid if necessary. Prints are then taken and lantern slides made, and the results are handed over to the committee.

6. If a sufficient number of subscribers could be obtained, it would be very desirable to publish, perhaps monthly or quarterly, a selection of the most interesting photographs obtained, accompanied by descriptive letterpress. There must be many people in the county who would prize such a local record.

7. The principal books and works of reference upon the county should be added to the library of the Society, and lists of the large collections of books, &c., on the same subjects contained in the local libraries should be posted on the walls of the club rooms.

* Continued from page 13.

† Published by Elliot Stock, price 7s. 6d.

* Those sold for holding pamphlets, papers, &c., by Stone, of Banbury, would answer well for this purpose.

† Those made by Arundel and Marshall, Penn Street Works, Hoxton, London, are recommended.

8. One night in each week might be considered a "rendezvous night," on which all who were interested in the work of the survey should meet at the club rooms; and on (say) one evening in each session of the Society there might be a more public display of the results which were being obtained. The year's work in this direction would naturally form an important feature of the Society's annual exhibition.

(To be continued.)

Specifications Published.

18,099.—30*th November*, 1889. "Improvements in Photographic Cameras." THOMAS PARSONS WATSON, 313, High Holborn, London, W.C., Optical Instrument Maker.

The invention relates to improvements in photographic cameras of the Kinnear or other collapsible type, particularly those which are collapsed and folded by laying the camera front face downwards upon the baseboard. The improvements have for their object generally to render the camera lighter, more compact when folded for carrying, and more easily erected and closed than existing cameras of similar types. In order that the improvements may be more readily understood, they are illustrated in drawings accompanying the specification, and with reference thereto are described.

The first improvement relates to the pivoting of the frame—in which the rising front is fitted to slide—to the travelling frame of the baseboard by means of lateral gudgeons, and it consists in providing means whereby the said gudgeons will be securely retained in their bearings when the camera is in use, but may be readily removed therefrom when required by a simple backward swinging movement of the camera front, which may be effected by one hand.

The improvements have secondly for their object to provide means whereby the rising front will be retained at any height at which it may be set, whilst free motion of the front in its guides will be permitted after the front has been laid face downwards upon the baseboard. The purpose of permitting this free sliding motion of the front is, that when the bellows-body is being collapsed by the back frame of the camera being folded forwards, the front may be free to adjust itself, so as to avoid undue strains on the bellows-body.

The invention relates, lastly, to an improved self-engaging catch for locking the baseboard and back together when the camera is folded up.

The following are the claims:—

1. The combination with the lateral gudgeons of the front supporting frame, and with L-shaped bearing notches therefor; of spring latches adapted to lock the gudgeons in their notches as described; and of abutments on the front frame adapted to act on the spring latches by a backward tilting motion of the front frame, substantially as and for the purpose specified.

2. The combination with a notched edge of the rising front, of a spring bolt mounted on the front supporting frame, and adapted to engage with the front for the purpose of supporting it at the desired height, and of means, substantially as described, whereby, when the front is laid down on the baseboard, the bolt will be disengaged, and the front free to slide and adjust itself in the supporting frame, as specified.

3. Fitting the front to slide in its supporting frame by the convex edges of the former being received in corresponding concave grooves in the latter, and notching the convex edge of the front for engagement with a spring bolt, substantially as specified.

4. The self-engaging spring catch for locking the baseboard and back together, the catch being constructed and operating in the manner specified.

711.—30*th November*, 1889. "Improvements in the Production of Films Sensitive to Light, and of Materials for Assisting or Continuing the Effect of Light on Photographic Films." ALEXANDER FERDINAND YORK SCHWARTZ, Chemist, and Dr. FRIEDRICH HERMANN MERCKLIN, Chemist, both of Hanover, in the German Empire.

In the course of their complete specification, the patentees say:—

1. If, in the preparation of a photographic film by the emulsion method, silver oxymethyl-sulphonate—which is also soluble in alcohol—or a compound of the silver oxymethyl-sulphonate with the oxymethyl-sulphonate of an alkali or of ammonia, or a mixture of the said bodies, is added to the finished emulsion, in the proportion of 1 to 2 parts of the said oxymethyl-sulphonate or mixture to 100 parts of the halogen silver contained in the emulsion; or if the said addition is made before the ripening of the emulsion; or if, in the preparation of photographic films by the processes in which the film, impregnated with metallic chloride, bromide, or iodide, is dipped into a silver bath, we add silver oxymethyl-sulphonate, or a double compound of the silver oxymethyl-sulphonate with the oxymethyl-sulphonate of an alkali or of ammonia, we obtain photographic films which are more sensitive to light—even to weak light—than the films prepared by the ordinary methods.

2. If an ordinary dry plate is bathed before exposure in a neutral aqueous solution containing from 0·1 to 0·2 per cent. of the silver compounds mentioned under 1 for a period of half to three minutes, according to its sensitiveness, or in an equally diluted aqueous and slightly alkaline solution of the form-aldehyde, or of the para-form-aldehyde, or of the oxymethyl-sulphonate of an alkali or of ammonia, or of a mixture of these salts, and if the plate is then slightly rinsed and again dried, the photographic results are similar to those obtained if the films have been treated by method 1.

Instead of bathing the dry plate before exposure, it may be bathed after exposure; or, instead of applying the said compounds in the shape of a special bath, a few drops of a neutral 1 per cent. solution of the alkali, or of the ammonia-oxymethyl-sulphonate, or of their mixtures, may be added to one of the usual developing mixtures.

3. If the ferrous oxylate developer is prepared by means of the ferrous oxymethyl-sulphonate, or, better still, by means of the combination of the same with the oxymethyl-sulphonate of an alkali or of ammonia, only about a quarter of the usual quantity of iron is necessary in order to obtain equally good results as with the ordinary iron developer, whereby the durability or stability of the developer is increased.

4. The oxymethyl-sulphonate of hydroxylamine in alkaline solution gives excellent results when used as a developer.

The claim is :—

The use of form-aldehyde, or of para-form-aldehyde, or of the compounds of form-aldehyde—which must be considered as salts of the oxymethyl-sulphonic acid—with an alkali, ammonia, iron, silver, or of a mixture or combination of the said salts, either alone or in combination with other suitable substances, for the preparation of highly-sensitive photographic films, and for the production of chemicals or solutions which assist or continue the effect of light on photographic films.

17,198.—*26th November*, 1888. "Improvements in Photographic Shutters." EDMOND PERKEN, FREDERIC LOUIS PERKEN, and ARTHUR RAYMENT, trading as Perken, Son, and Rayment, of 99, Hatton Garden, in the city of London, Wholesale Opticians, and WALTER PEAD, of 99, High Street, Ramsgate, in the county of Kent, Artisan.

The shutter slide is made very thin, of any suitable materials —advantageously thin sheet metal—which travels loosely in guides advantageously formed in and by the frame of the shutter. On the upper end of this slide is a projecting pin or stud, under which a spring-actuated lever secured to the said frame is placed, and the end of the said lever is held by a catch, which may be actuated by a pneumatic releasing apparatus, as is well understood, or otherwise, as desired. The said lever, on being released by said catch, throws up the shutter slide, and so gives the exposure, the slide falling again by its own weight, or, for a very short exposure, assisted by a spring. A lever, actuated by the pneumatic release, makes contact with the slide when open, and regulates the length of exposure, or by any other convenient arrangement.

A break arrangement may also be provided, so as to hold the shutter open for the purpose of focussing.

The description is accompanied by a sheet of drawings.

The claims are ;—

1. A shutter slide sliding freely in the shutter frame, and unattached to any other parts of the apparatus, in combination and acting in conjunction with a spring lever, which throws up the said shutter slide, and leaves the latter free to fall again by its own gravity.

2. The combination of the shutter slide and spring lever with the releasing catch or trigger, one part of which engages with said lever, and the other part having a pin thereon to engage with a notch on the slide, arranged and acting substantially in the manner and for the purposes hereinbefore described.

18,796.—*December 22nd*, 1888. "Heads for Camera Stands." JAMES HEBER TAYLOR, Little Trinity, Cambridge, M.A., Queen's College, Oxford, M.A., Trinity College, Cambridge, B.Sc., London.

The objects of this invention are primarily to provide a ready means by movements of rotation only, of changing the position of a photographic camera, constructed to take pictures on oblong plates from the position in which the long side is horizontal to that in which the long side is vertical, so that the camera in each position shall be in a position of stable equilibrium over, or nearly over, the centre of the tripod stand. Secondarily, to enable the camera to be directed upwards or downwards at any required angle.

The camera is attached to a block which is pivoted horizontally between the ends of two parallel bars, so as to turn freely round from one side of the bars to the other. The bars are pivoted towards their other extremities about a horizontal axis parallel to the axis of the block, these pivots being carried on a stage which is attached to or may form part of the tripod head. Short extensions of the bars beyond these last-named pivots are used for the purpose of securing the bars when at right angles to the stage, *i.e.*, the stage being horizontal when the bars are vertical.

The bars may also be secured at any required angle or inclination by a strut jointed to the bars, and made to engage with the side of the stage opposite to the pivots which connect the stage with the bars.

The stage forms a flat surface on which the camera may rest when the bars are either horizontal or vertical.

The camera, when vertical or inclined, can be held in a position overhanging the stage and admitting of back focussing.

The camera may be attached to the block by a base-screw of the ordinary type. By movement around the base-screw the camera may be inclined upwards or downwards when the bars are vertical. A slot in the block, at right angles to its axis, makes the same apparatus available for different cameras not differing greatly in dimensions. Or with the same object the block may be pivoted not directly to the parallel bars, but to an inner frame which slides between the bars, and is capable of being clamped at any desired point. Or sometimes I provide a dove-tail projection upon the base of the camera, and parallel V-guides are attached to the block at right angles to its axis of rotation, and suitable means of clamping the camera when in position are provided. The lengthening of these guides beyond the length of the side of the projection from the base of the camera makes the same piece of apparatus available for cameras differing somewhat in dimensions.

The block may have within it a turn-table to which V-guides are fixed.

The stage may be rigidly attached to a triangle-head for the tripod stand, but by preference I attach it by a central pin which forms a vertical axis, about which the whole stage rotates as a turn-table on the tripod-head.

The inventor claims : —

1. Constructing a reversing head for camera stands of block parallel bars and stage substantially as described, so that an oblong plate may be quickly changed from the horizontal to the vertical position of the long side, the camera in each position being above or nearly above the centre of the tripod head.

2. The combination of the parts mentioned in claim 1 with provision for depressing or elevating the axis of the lens through any desired angle with the horizontal, and fixing it there by suitable clamps or other device.

3. The combination of either of the forms described in claims 1 and 2 with a turn-table for attachment to the triangle of a tripod stand.

4. The combination of either of the forms described in claims 1 and 2 with a triangle head for a tripod stand.

5. The combination of either of the forms described in claims 1 and 2 with turn-table and triangle head for a tripod stand.

ALBO-CARBON gas-burners increase the light about 30 per cent., and they can easily be adapted to most enlarging lanterns. —*Photographic Scraps.*

EDINBURGH PHOTOGRAPHIC SOCIETY.—The first popular meeting of the session will be held in Queen Street Hall, on Wednesday, the 29th January. A varied series of transparencies, the work of members, will be shown on the screen, accompanied with descriptive remarks.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—On Tuesday, January 14th, at 8 p.m., at the Gallery, 5A, Pall Mall East, the following papers will be read : —"Control in the Density of Negatives," by Mr. Chapman Jones, F.C.S., F.I.C., "Distance beyond which all Objects are in Focus with any given Lens," by Sir David Salomons ; "Eikonogen as a Developer," from Professor W. K. Burton.

PARIS EXHIBITION.—The French Ambassador, it is stated, will present, in the name of the President of the French Republic, the decorations conferred upon British subjects in connection with the Paris Exhibition, on Saturday, January 25th, when Sir Polydore de Keyser, the president of the British Section, will entertain his Excellency and the council of the section, with other guests, at dinner at the Mansion House, which has been placed at his disposal by the Lord Mayor.

VERY LIKE.—"It's a good picture, but its no likeness," was the criticism of his own portrait made by a well-known violinist. His family had agreed upon this harsh verdict without a dissenting voice, until the artist appealed to the youngest o the household, a bright little boy. "Who is that, Dick ?" he asked, pointing to the picture. "Papa," was the immediate answer. "So it is my dear. You see, sir, your son is a better judge of the likeness than you. So you think that you'd know it was papa, my boy ?" "Oh yes, sir," was the innocent reply. "It's very much like him about the fiddle !"—*Cassell's Saturday Journal.*

Correspondence.

REPRODUCTION AND COPYRIGHT.

SIR,—From a letter of Mr. Ralph Robinson's in the PHOTOGRAPHIC NEWS of last week, it appears that there is an impression in the minds of some photographers that it is useless to register the copyright of a photograph after it has been published. This is a misconception. As Mr. Robinson points out, the copyright is the property of the photographer, whether it has been registered or not, but he has no power to prevent others from infringing it until it has been registered, which, however, he can do at any time. The law relating to copyright in photographs depends almost entirely upon the Copyright Act of 1862. By the first section of that Act, the author of every photograph, provided he retain the negative, is entitled to the copyright in that photograph, unless it has been executed on commission, in which case it belongs to the person for whom the photograph has been taken. Of course nearly all portraits taken by the professional photographer are taken upon commission, and therefore the copyright in the negative does not belong to him, and he cannot register it. By later sections of the same Act, anyone infringing a copyright is liable to certain penalties, and if he continues to do so, he may be restrained by the Court. And by another section every copyright is to be registered at Stationers' Hall, and no action shall be sustainable, nor any penalty be recoverable in respect of anything done before registration. But there is nothing in the Act limiting the time within which the copyright must be registered. Hence, if the photographer retains the negative, he is entitled to the copyright, and can register it whenever he likes, but until he has done so it is practically of no use to him, as he has no power to prevent infringement.

There is no provision in the Act or elsewhere requiring photographs, the copyright of which has been registered, to be marked with the word "copyright," and legally it has no effect whatever, the only object being, I suppose, that it may warn others, and thereby prevent them from copying it. At any rate there appears with me to be no probability of any person being held guilty of fraud who so marks a photograph when it has not been registered.

As to the first part of Mr. Robinson's letter, here again he has the law with him. If he grants a license to a publisher to reproduce one of his pictures in a certain newspaper, and it is afterwards reproduced in a second newspaper without his further permission, he will have a right to recover damages from the publisher of the second newspaper for infringement of his copyright. It is, however, advisable that photographers should not make use of the word "copyright," when giving permission to publishers to reproduce their pictures, unless they really intend to assign the copyright altogether. As a rule they should merely say that they grant the publisher a license to reproduce the photograph in a certain specified newspaper. Such a license to be of any value must be in writing.

C. FLEETWOOD PRITCHARD.

3, *Paper Buildings, Temple, January 7th*, 1890.

ART PHOTOGRAPHY RECOGNIZED AT LAST.

SIR,—For fifty years photography has been struggling against prejudice, jealousy, and almost overpowering influence, to establish itself, not only as an art, but as a fine art, and at the end of that time it may be said to have succeeded, although there perhaps still linger in some minds those fragments of doubt which are so difficult to eradicate.

It begins its second century not only hopefully but jubilantly for its art prospects. To those who are able to discern the signs of the times, the indications are most auspicious. Two examples that appear this month are worth quoting.

The *Art Journal* has never cared to recognise its claims heartily from the time it said of one of our exhibitions, "With the photographic exhibition it is not necessary to speak of individual works as we would of the production of the painter: the cases are not parallel. The painter employs, or should employ, eye and hand, governed by a presiding mind; the photographer uses a machine, and requires a 'little' judgment. The artist works from within to that which is without; the photographer employs external agents to do his bidding."

What a change do we now see! The volume of the *Art Journal* for this year opens with a splendidly illustrated article on "Winter Photography for the Artist," by Mr. H. P. Robinson, a photographer and writer to whose example and writings in articles which have appeared principally in the PHOTOGRAPHIC NEWS, I think I may say, without fear of contradiction, we are mainly indebted for the great advance that has taken place in the art quality of photography of late years. There may be further improvements and developments, but we shall always owe to him the solid foundation on which they may rest.

The other auspicious sign appears in the January number of the *Nineteenth Century*, in an exhaustive article on the progress of art during the last decade.

Mr. Marcus B. Huish, the editor of the *Art Journal*, recognizes photography as an art, a graceful concession to photography by the chief representative of the other arts worthy of being put on record. He says: "As for photography, no one who has visited the successive exhibitions held by the various societies connected with it can have failed to recognize the advance which has taken place—an advance which, if continued, must soon give its professors a claim to admission within the ranks of artists." Surely there could be no more satisfactory recognition of photography as a fine art than that of the editor of the *Art Journal!*

GEORGE MAITLAND.

SUNDRY NOTES AND CORRECTIONS.

SIR,—I have read with very great interest Mr. H. P. Robinson's admirable sketch of the life and work of O. G. Rejlander, whom I had the honour of knowing for many years as one of the most genial members of the Solar Club. He was of Swedish origin, and died at the age of sixty-one, the date given by Mr. Robinson in a foot-note (page 9) being quite correct—January 18th, 1875. I was present at his burial on the following Saturday, 23rd, at Kensal Green Cemetery, when Mr. J. D. England attended as one of the military escort or guard of honour, Artists' Corps, to fire three volleys over his grave. This leads me on to say that I have a copy of Rejlander's double—the artist O. G. R. introducing the volunteer O. G. R.—and that I remember another use being made of this photograph by way of compliment to Mr. J. E. Mayall, apologising for coming uninvited to his house at Hove Place, Brighton, on the occasion of the volunteer review of Easter, 1871, when the late H. Baden Pritchard and myself were also there as invited guests. The print was then marked "Rejlander's Apology."

A Correction.—In my article on the new naphthol developers in the YEAR-BOOK (page 125, end of thirteenth line), for "Mr. Stenning" read Mr. J. H. Stebbins, Jnr., of New York, as being the claimant who first suggested the use of these naphthol compounds for photographic development (see the NEWS, last vol., page 733). Further on, I find that my statement of proportions for mixing the developer (YEAR-BOOK, page 126) has infringed the regulation that the quantities should be expressed in percentage amounts. The 70 grains of Meldola's naphthol acid, being equivalent to 87½ grains of eikonogen, make, with water one pint, a one per cent. solution of the latter, and this agrees in strength with that used by Messrs. Fradelle and Young, E. Vogel, Jnr., and G. Mansfield, in their experiments, as the following re-calculated table will show:—

	Vogel.	Spiller.	Fradelle.	Mansfield.
Eikonogen	1	1	1	1
Sulphite Soda	8	5	4	2
Water	100	100	100	100
Carb. Potash	12	10	—	—
Carb. Soda	—	—	1	—
Caustic Soda	—	—	—	1
Water	100	100	100	100

I am glad to learn that Mr. Warnerke gives so good an

account of the new naphthol developer, but fear he will find the use of so much caustic potash rather corrosive for a gelatine film.

Like Mr. Elder,* I have made a good search at the Patent Office for any specification bearing the name of Dr. M. Andresen, and claiming the use of eikonogen, but failed to find any such entry or record. The statement to this effect in the printed paper of instructions, and the pretended claim to be actual discoverer, are both alike quite unwarranted.

JOHN STILLER.

PHOTOGRAPHIC TOURISTS' BAGGAGE.

SIR,—In the course of an interesting article on the above subject in your issue of January 3rd, the writer, in recommending the use of portmanteaux made of basket work, makes a statement which may possibly be injurious to an enterprising and increasing trade. This is, that English workmen are not competent to make the palm-baskets at present imported from France, so that they have to be made abroad.

The real reason why these articles are not manufactured in England is that the demand for them is decreasing, and their sale comparatively small, baskets made of willow being usually preferred as being at once lighter, cheaper, and more serviceable. It is therefore not worth while for English makers to take up the manufacture of them.

It may not be known to the writer of the article that almost all the trunks used by travelling theatrical companies are now made of a foundation of wicker-work covered with leather, &c., and that trunks made in this way last three or four times as long as those made of wood, iron, or leather. Several hundred workmen are employed in England in this industry, which cannot be approached by foreign competition.

Since I have been an amateur photographer, I have often marvelled at the weighty leather cases photographers carry. I made a wicker-framed case for my own use to hold a half-plate set—camera, four slides, lenses, and accessories—which, together with green-baize lining, only weighed twelve ounces; and I am confident that by paying special heed to weight-saving, a strong and waterproof case of this size might be made weighing eight ounces complete. The cost would be perhaps half that of the usual waterproof cloth or leather case now in use.

Should you be at all interested in this matter, I will send for your inspection the case I now use. I have no trade interest to serve in this matter, my own business being entirely wholesale, and lying in quite a different direction; but I am moved to pity by the appearance of perspiring photographers, weary and heavy laden with their leather cases under the August sun.

W. SCALING.

Nottingham, January 14th.

BRIXTON AND CLAPHAM CAMERA CLUB.—On Friday, 3rd inst., the President, Mr. A. R. Dresser, gave a new year's address, and showed a number of enlargements from hand-camera negatives taken during a recent tour in Brittany, and also about a hundred slides which were exhibited by means of the oxy-hydrogen lantern. A show of photographs, the work of members, will be held on Monday evening, 20th inst., from 7.30, and also all day on Tuesday, 21st, at the Club Rooms, 35, Bedford Road, Clapham, S.W. Visitors are invited.

FATHER PERRY.—A private telegram has been received at Liverpool from the Catholic Bishop of Demerara announcing the death on Friday last in British Guiana, of dysentery, of the celebrated Jesuit astronomer, Father Perry. Father Perry, who was born in London, was in his fifty-eighth year. In 1882 Father Sidgraves, another Jesuit, was delegated by the Government to report on the transit of Venus, and last year the services of Father Perry were again requisitioned by the Government to report on the solar eclipse. It was on this expedition on the coast of Guiana that Father Perry fell ill, and has now fallen in the midst of his scientific labours.—*Daily News.*

* PHOTOGRAPHIC NEWS, p. 835, of last volume.

Proceedings of Societies.

CAMERA CLUB.

THURSDAY, January 2nd, was a lantern evening at the Camera Club, and there was a large attendance of members. The chief part of the exhibition consisted of a selection from a number of slides lent by the Birmingham Photographic Society. After these, other slides were shown by Mr. T. Charters White (general landscape and microscopic), Mr. Frank Howard (landscape and landscape with figure), Mr. Rooper Leventhorpe (pictures taken in North Italy), Rev. C. F. Fison (English country scenes), Mr. F. Howlett (a series of views on the Thames), and in conclusion a set by Mr. J. B. B. Wellington, of landscape and landscape with figure. Some of Mr. Wellington's slides were especially effective, and attracted much attention.

The subject for Thursday, January 16th, is "Plane Polarization of Light," when an address will be given by Mr. R. Tindall. The lecture will be illustrated; meeting at 8 p.m.

EAST DULWICH AND PECKHAM PHOTOGRAPHIC SOCIETY.

THE above Society held its first annual exhibition on Friday, 3rd inst., in Shawbury Hall, Lordship Lane, when a large number of visitors testified their appreciation of the first fruits of the Society. Running briefly through the exhibits, the work of Mr. Edwards, the President, of course attracted notice. His set included the celebrated gold medal picture, "Woolpits," the residence of Sir Henry Doulton, and a very fine picture of Lambeth Palace from the river. As, however, Mr. Edwards refrained from competition, other exhibitors were able to view the appreciation of his work with becoming equanimity. The Vice-President, Mr. Howell, showed a series of forty-year old Talbotypes. Mr. Gardner exhibited a frame of lantern slides of "bits" at Hastings, which were favourably received when passed through the lantern later in the evening. Mr. Rice was represented by a fine collection of platinum prints—views of the Temple Gardens, Kew Gardens, and places of local interest—which were admired for their sharpness. Mr. Kelly's contribution consisted of a series of fine views of Scottish scenery, most of them in Oban. The cloud effects in these pictures were admirable. Mr. Kirby showed very satisfactory results of the summer outings in the shape of pictures of Surrey scenery. Other members also exhibited good work.

After time had been allowed for the inspection of the photographs, the Society's lantern—a fine specimen of Pexton's Grand Triple—was requisitioned, and some effective lantern slides were shown by Messrs. Gardner, Farmer, Exner, Dowling, and Boydell, after which the president announced the results of the competition. Mr. Kelly secured the silver medal, and, as Messrs. Rice and Dowling dead-heated for second place, the former took the bronze trophy, and an extra medal was awarded to Mr. Dowling. First and second certificates were awarded to Messrs. Kirby and Boydell respectively. It was intended to give a certificate for the best set of lantern slides, but, in the opinion of the judges, the work of the five competitors mentioned above was so equal in merit that it was decided to withhold the certificate. The prizes were presented by Mrs. Banks, wife of the treasurer.

The proceedings were diversified by vocal and instrumental music.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE second ordinary meeting was held in the Professional Hall, 20, George Street, on Wednesday, December 4th, 1889; the chair was occupied by Dr. DRINKWATER.

The following candidates were admitted as members of the Society:—Messrs. Wm. M. Ramsay, Philip R. D. Maclagan, William Burn, James Hay, Robert Irvine, J. Rymer Paterson, and William G. Tait. Five gentlemen were nominated for election at the January meeting.

Mr. HUGH BREBNER then read a paper on "Repairing Broken Negatives" (see page 20) and accompanied it with a demonstration.

Mr. M'KEAN said that if the broken negative were covered with tissue paper, and the light allowed to fall in the direction of the fracture, the print would be only slightly marked. While recognising the value of Mr. Brebner's remarks, he thought that a negative must be a very valuable one before a photographer could afford to take up so much time in repairing it if it got broken.

Mr. MITCHELL said, with reference to joining the detached pieces of the film, he found he could scrape a film down more uniformly at the juncture when he rubbed it over with the retouching medium before commencing that operation upon it. His difficulty was to intensify a negative which had been treated in the manner described.

Mr. AYTON said he would be inclined to differ slightly from Mr. Brebner's procedure. The most of his (Mr. Brebner's) difficulties were caused by the expansion of the gelatine film, and could be obviated by using methylated spirit, and specially hardening the film. His own method stated briefly was—if the broken negative were varnished, remove the varnish with methylated spirit and ammonia, wash out the spirit, soak in chrome alum, dry, immerse in a weak solution of fluoric acid to loosen the film off the broken glass, wash out the acid, put the loosened film into methylated spirit, and finally place the pieces in position on a new glass. It would be found that the negative did not require intensification.

The CHAIRMAN called for a vote of thanks to Mr. Brebner, a motion which was cordially responded to by the members present.

The specimens of members' work, which had been hung on the walls by Mr. Stewart-Smith, were then inspected by the members present.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE ordinary meeting was held at the Masonic Hall, Surrey Street, on Tuesday evening, January 7th, Mr. B. J. TAYLOR in the chair. It was agreed, on proposal by Mr. Councillor Thos. Firth, seconded by Mr. B. Nowill, that a lantern exhibition be held early in February for the benefit of the public hospital and dispensary.

Mr. H. STANIFORTH presented the Society with one of his patent limelight regulators.

Mr. PRESTON gave a practical demonstration, showing the different lights for the optical lantern—viz., the three-wick lamp, with luxor oil, the oxy-hydrogen, and the ethero-oxygen. The two latter were thought to be about equal in brilliancy, the oxy-hydrogen the best for safety, and the ethero-oxygen the most convenient for giving exhibitions in country villages where the ordinary gas is not to be had.

DEVON AND CORNWALL CAMERA CLUB.

THE Devon and Cornwall Camera Club held their first lantern-slide competition on Monday evening, at the Club Rooms, Athenæum, Plymouth. Mr. R. Murray took the chair, and the hon. treasurer took charge of the club lantern, projecting a fourteen-foot disc upon the screen at the end of the hall, brilliantly illuminated by limelight. A numerous and varied assortment of lantern slides was then shown in rapid succession; and on examination of the voting papers at the close, it was found that Mrs. Carnell had been awarded first prize with 61 votes; Mr. R. Murray taking the second prize with forty votes. A number of slides made by Mrs. Carnell, Messrs. Micklewood, Murray, and others, were afterwards shown, some being copies of "Leech's Sketches in *Punch*," creating great amusement.

After the close of the competition, the hon. treasurer, Mr. A. A. Carnell, was heartily congratulated on being the winner of the gold medal given by the Britannia Works Company at the "photography" competition, for the best six lantern-slides on Alpha plates, in Class X., scientific micro-photography, and for also winning a silver medal (equal first with Mr. F. H. Exans) at the same competition. This competition, held a few weeks back, was open to the world, and nearly 18,000 slides were sent in for competition.

ABNEY CAMERA CLUB.

ON 3rd inst., the VICE-PRESIDENT in the chair, Mr. FLACK gave a demonstration on bromide paper printing.

In referring to developers, he said that he preferred hydroquinone, it being less trouble to manipulate. For light, he usually employed magnesium ribbon, burning one inch at about eighteen inches distance, with a plate of opal glass in front of the negative.

At the close, he developed several prints, some with ferrous oxalate, and some with hydroquinone, the opinion of the members present being that the tone given by the former on Ilford paper was preferable.

After the usual vote of thanks, the HON. SEC. announced that on Jan. 17th he had promised to read a paper on the "Chemistry of Photography."

PHOTOGRAPHIC SOCIETY OF PHILADELPHIA.

A MEETING of the Society was held on December 4th, 1889, with Mr. FREDERICK GRAFF in the chair.

After the transaction of routine business a paper was read by Mr. THEODORE H. LUDERS, "On Development with Pyrogallic Acid in connection with Ammonia in Vapour," and Mr. Morris Earle showed some novelties in photographic appartus, which he had collected during a trip to England and the Paris Exhibition. Among these, he described a panoramic view camera which he had seen in Paris. A film or paper negative was used, and bent into a semicircle with the lens in the centre. By a lever on top of the camera the lens could be revolved so as to cover different portions of the plate successfully. The light was admitted to the lens (which was of fixed focus) through a diaphragm in front in the form of a perpendicular slit, the opening revolving with the lens as it was turned. A unique feature possessed by the camera was the fact that if in one portion of the view dark objects predominated, requiring long exposure, the lens could be allowed to cover that portion of the view for a greater time, and less exposure be given to the brighter parts of the view, simply by properly manipulating the lever attached to the lens.

Mr. JOHN G. BULLOCK called attention to the late explosion of flash-powder in this city, with its terrible result in the death of three persons. He thought it right that the published minutes of the Society should caution all to look with distrust upon flash-powders of a yellow colour, and if they prove upon examination to contain picric acid along with powdered magnesium to consider them highly dangerous. Picric acid upon standing in mixture with powdered magnesium for a length of time is supposed to form picrate of magnesium, a highly unstable combination more dangerous than dynamite. A person finding a vial of such flash-powder in his possession had best dispose of it at once, but with great care. He is advised against pouring water upon it or burning it, but rather to throw the whole vial into a river or down some gorge where it would be scattered without doing harm. The very act of removing the cork from the bottle might be attended with serious results. The danger of picric acid flash-powders increases with age.

Dr. MITCHELL fully agreed with Mr. Bullock, and considered all flash-powders, except those composed of pure magnesium, more or less dangerous, differing only in degree. Magnesium has a tendency to absorb moisture, in which state it readily combines with picric acid, forming the dangerous picrate of magnesium. Even a single ounce of such powder would be exceedingly dangerous.

Mr. ROSENGARTEN called attention to a method of preparing ground glass for focusing screens by the use of hydro-fluoric acid in combination with carbonate of soda.

Dr. WALLACE spoke of the use of a solution of plain boiled starch spread upon a plate of glass, and allowed to dry, thus forming a very fine surface for a focussing screen.

Mr. WOOD described a method of focusing without the use of any screen. If the position to be occupied by the plate is determined by a metal strip located in the usual position of the ground glass, by placing a focusing glass against this strip it will show (over a limited area, of course) the image usually projected on the screen, and a proper focus can thus be readily

obtained. A piece of plain glass can also be used in this manner as a support against which to place the focussing glass.

Dr. MITCHELL asked the experience of members in regard to films, stating that he had found some rolls to be very good, and others not. He had noticed markings like long transparent lines, as though scratched with a needle.

Mr. LUDERS suggested that they may have been damaged in unpacking.

Mr. WOOD stated that he had lately returned from a trip of over a thousand miles on which he had used films, and his feeling was that hereafter he preferred the weight of glass to the uncertainty of films. He thought nothing had yet been discovered to equal the perfect surface of glass, and the certainty of its results.

SOCIETY OF AMATEUR PHOTOGRAPHERS OF NEW YORK.

THE regular monthly meeting was held on December 10th at 122, West 36th Street, Vice-President DAVID WILLIAMS in the chair.

Mr. A. PEEBLES SMITH read a short paper on "The History of Flash-Light Photography," illustrating his remarks with lantern slides, all of outdoor flash-light pictures and interiors of theatres. He said that he had invented a safe powder, especially in bringing out the greens and reds.

Mr. G. D. MILBURN took a flash-light picture of the audience, using the new No. 2 Kodak camera, making a circular picture of 3½ inches. He also explained the instrument, which has a very simple shutter, and a fixed focus lens. Before the evening was over he made a lantern slide from the negative, which was thrown on the screen.

Miss CATHERINE WEED BARNES read a paper on "Photography from a Woman's Standpoint." She is the first woman who has ever read a paper before a photographic society in the United States.

Mr. JAMES H. STEBBINS, Jnr. showed photographs of a pinhole sensitometer device he had used in testing sensitive plates. His results were very instructive. He also gave the result of his experiments on the solubility of "eiko." in distilled water at different temperatures.

Mr. F. C. BEACH exhibited Eastman's transparent film negatives (instantaneous exposures) developed with the "Ultimate Single Solution Eiko." developer sent by Messrs. Queen and Co., of Philadelphia, and of the ordinary eikonogen two-solution developer. The latter gave more density, and worked more quickly.

Mr. HENRY J. NEWTON made a few remarks on a mixed hydroquinone and eikonogen developer. The eikonogen, he contended, was slower than hydroquinone when a caustic alkali was used with the latter.

A lantern slide exhibition, illustrating New York and Paris Exposition, is to be given by the Society at Chickering Hall, New York, February 5th.

THE Solar Eclipse Expedition to South America from the Lick Observatory has telegraphed, we read, that their observations of the solar eclipse on December 22nd were entirely successful.

RECEIVED.—Sample bottle of Tylar's plate backing, which is to be applied either with a dabber enclosed, or preferably with a roller squeegee. When dry—which is the case in a few minutes—the plates can be placed in the dark slides. Before developing the plate, the backing is removed by using a sponge and warm water.——"The Magic Lantern—its Construction and Use," published by Perken, Son, and Rayment, is a welcome addition to the instructions on a subject of more especial interest at this season of the year. The book is divided into fourteen short chapters of useful information comprised in small compass.——"Photographic Scraps," issued monthly, gratis, by the Britannia Works Company, and from which we have on several occasions quoted valuable "bits," appears as a double number this month.

LONDON AND PROVINCIAL.—Report received too late for insertion.

Answers to Correspondents.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

C. G.—Old ferrous oxalate developer. The thick deposit formed in your stock-bottle is probably due to the separation of the ferrous oxalate itself. If so, you have only to pour off the clear top liquid, add just enough of a saturated solution of neutral potassium oxalate to redissolve the precipitate, and pour back again the main bulk of developer into the stock-bottle. Thus fortified, it only requires to be filtered, and is ready for use.

ALPHA.—Zincographic reliefs, &c. See answer to E. L. last week; there is also Dr. Schnauss' work recently published (see advertisement on page xii. last week). Two special articles, by Mr. W. T. Wilkinson, in the YEAR-BOOKS, will be of interest to you: these are "Photo-Engraving on Zinc," 1887, p. 53, and "Printing on Zinc in Bitumen," 1888, p. 75.

VAL. JACKSON.—The new general catalogue of Brin's oxygen and compressed gas appliances duly to hand. Templeton's and Lennox Browne's oxy-hydrogen lamps, and the lime-light projector, cannot fail to be useful to photographers.

W. C. HUGHES.—We thank you for sending the particulars of ether saturator to our correspondent at Charlbury.

W. B. (Reigate).—Meldola's naphthol acid is only very slightly soluble in alcohol, but dissolves freely in an aqueous solution of sulphite of soda. It might be worth while trying to dissolve it in alcoholic ammonia, but such a solution would not keep very long.

D. O.—We are glad to learn that our efforts were successful.

T. F.—You are probably aware that the ordinary terms for taking a portrait do not usually cover for possession of the negative. All will turn upon your having a written or special agreement about the delivery of negatives. This point settled, your course of action is quite clear, but not otherwise.

COLLOTYPE.—1. Husnik's substratum. A mixture of albumen and silicate of soda cannot be expected to keep good for any length of time; it had better be made fresh as wanted, unless you coat at once a number of plates. 2. This is rather a matter for experiment. If you *must* push on the successive stages of the process as quickly as possible, you might find it advantageous to add a small quantity of chrome alum and acetic acid to the other ingredients when preparing and sensitising the gelatine.

C. S. T.—Letters received and answered by post.

E. A. C.—The advertisement column should be resorted to for announcing your press for sale, and the fact that you give lessons on the working of the photo-mechanical processes.

A. J. S.—The first spools of Eastman tissue on flexible celluloid were sent out on New Year's Day. Yours ought to be on the road, if not actually received by this time.

C. M.—An amyl-acetate standard lamp, with pure silver wick-holder (Mr. C. H. Bothamley's modification), was described in the NEWS of 9th August last.

S. W.—It is already to be had. See advertisement at head of page xi. last week.

L. F.—Mr. H. P. Robinson begins the January number of the *Art Journal* with a chapter on the value of photography for the purposes of Art illustration, and Captain Abney is to follow. Now that all the English and American illustrated magazines and journals are depending so much upon the photographic processes, the subject assumes great importance. Even the *Vienna Weekly News* comes to us beautifully printed in English, and with a fine photo-reproduction of a Tyrolese scene—a view of Gries, near Bozen.

A. M. M.—Received; an answer shall be sent by post.

J. A. C., J. C. S., and other correspondents received.

VOL. XXXIV. No. 1637.—*January* 17, 1890.

CONTENTS.

BASKET-WORK IN PHOTOGRAPHY.

BEFORE this subject is allowed to drop for a time, it may be well to point out to those photographic tourists who have not given attention thereto, some practical points worthy their attention. A basket-case should be so made that it can be used like a portmanteau in towns, and like a knapsack in the country, and should be furnished with locks and keys, so that it can be left in cloak-rooms at railway stations. Straps with fastenings and small padlocks are convenient for locking. The ordinary handles of a basket do not look well when the latter is carried knapsack fashion; there is something incongruous; like the red tails of the soldier's coat which organ-grinders give their monkeys, the coat-tail and the natural tail of the monkey do not harmonise. An actual maker of knapsacks for some members of the Alpine Club and others—Mr. Price, of Great Marylebone Street, London—has devised an excellent handle, consisting of a piece of bamboo covered with leather, and with a leather loop at each end; the straps supporting the knapsack pass through the loops. This round rigid handle gives great ease in carrying the case as a portmanteau, and can be slipped off and put inside when the case is used as a knapsack.

The basket case should be narrow, flat, and long, for the same reason that leather cases for photographic apparatus are now made narrow and flat. It is convenient to have the case long enough to take the folded legs inside, along the top. The straps should be so made that the case comes high up on the shoulders, otherwise a tiring, "dragging" feeling results; and in front of the shoulders the strap should be very broad; in fact, one inventor has patented a kind of web to come instead of the strap at this particular place. In knapsacks the straps should never cross or pass in front of the breast.

One basket-maker told us that the English cannot make the elegant palm baskets turned out by the French; another wrote in these pages last week that they can do so, but do not. In any event, that is the class of basket, but of different shape and lighter make, which hereafter will come into use with photographic apparatus, and who the makers may be concerns the basket-manufacturing trade more than it does photographers.

THE PHOTOGRAPHIC SOCIETY OF NANTES.

LAST week some particulars were published in this journal in relation to Havre as a place easily reached from London, and admirably adapted to meet the requirements of landscape and architectural photographers, so soon as a boat service at regular hours, and several times a day, shall have been established across the mouth of the Seine to Trouville. From the latter place the banks of the Loire and the central French wine districts are in communication by rail, but chiefly by local lines, which cross several of the great trunk railways of France. The only trains at present running somewhat long distances almost directly south from Trouville are those between Caen and Le Mans, and can only be reached from Trouville by waiting about at junction stations. Were this not the case, and were Le Mans in direct communication, by boat and train, with Havre *via* Trouville, instead of with Caen, the route would be an excellent one for those English who have but a few days to spare, to reach the region of the lower reaches of the Loire, and to change the fogs and rains of London at the present season for the bright, cold, sunshiny weather of the Loire valley. The stretch of country between Tours and Nantes is so little visited by English tourists that through tickets thereto are not issued by British railway companies or tourists' agencies.

In the west of France photographic societies are rare. A photographic club was established at Havre last year, and Nantes has its photographic society. We are not aware of the existence of any other photographic organisation in the extensive region between these two places.

The *Société Nantaise de Photographie* has its studio and laboratory at Passage Raymond 9, Nantes, and was founded in April, 1881. At its start it had twenty members, but the number steadily increased. In the second year of its existence it began to organise a "regional" photographic exhibition, and in 1886 it invited all the photographers of France to the Photographic Exhibition at Nantes, an exhibition which more than fulfilled the expectations of its promoters. At the present time the Society has 142 members. Its laboratory for the free use of its members has been established three years, and there is a studio adjacent

thereto. The Nantes Society does not publish what may be strictly termed a *bulletin*, but every month it sends to its members a printed report of its meetings, followed by divers formulæ, and a variety of extracts from photographic journals, all contained in four large pages. It has an English correspondent, Mr. A. Seouman. The president of the Society is M. Bascher; vice-president, M. du Hanlay; treasurer, M. Tassain; secretary, M. Tremant; co-secretary, M. Jollan de Clerville; librarian, M. du Minchy. Sometimes the Society issues a photo-mechanical or other print with its monthly report. We noticed, while looking through the collection in the bureau a few days ago, that occasionally in past years some aristotype prints have been so sent out; how these latter will look nine or ten years hence is a question the future will solve. The Nantes Photographic Society works in correspondence with the Photo-Club of Paris, the Versailles Photographic Society, the Photographic Society of the North of France, and the Artistic and Photographic Society of Limoges.

In its monthly reports we read that a photographic society has just been formed in Auvergne, with its establishment at Clermont-Ferrand, cours Sablon 55. In describing its constitution, M. Félix Gaude, the president, drew attention to one of the rules which promised to welcome all photographic tourists at Clermont. Unhappily, says the report of the Nantes Society, another article informs the said tourists that they must pay ten shillings towards the expenses of the Auvergne Society if they desire to make use of the laboratory. The Nantes journal adds :—"Hospitality is not Scotch at Clermont-Ferrand," which French expression of opinion about the Scotch may be interpreted in two different ways, when compared with the statements which caused it to be brought forth.

The Nantes Society has just resolved to buy an optical lantern for a double purpose; that is to say, it will be used at the meetings of the Society for the projection of lantern pictures, and at other times it will be placed, under certain conditions, at the disposition of any individual member who desires to exhibit his slides for the amusement of his friends.

A committee of the Nantes Photographic Society has just sent in its report on the Paris Exhibition of 1889. It says that broadly speaking, there were no great novelties at the Exhibition, no indisputable advance marking a point of new departure. Improvements, however, were numerous, and the merit of the pictures exhibited by the great masters in photography was beyond all praise. Several amateurs also exhibited, and their work was good enough to satisfy the most fastidious. The most striking displays made at the Exhibition by photographers were those of Messrs. Chalot, Lumière, Van Boch-Boyer, Pérou, Walery, and Nadar. Some platinotypes upon Japanese paper, put on view by Chalot, are described by the committee as "one of the most ravishing exhibitions." Nadar's show was the most expensive and elaborate connected with the Paris Exhibition; it cost the firm 30,000 francs.

SENDING PICTURES AND WRITING BY THE ELECTRIC TELEGRAPH.

BY F. H. VARLEY, M.I.E.E., F.R.A.S.

THE transmission of autographs and written messages, or portraits, through telegraph circuits, is of itself no new feat. In the early dawn of practical telegraphy we have the invention of Bakewell. Those who are more particularly interested in this invention will find it described in the writings of Dr. Lardner, and in Golding Bird's "Natural Philosophy."

Bakewell's apparatus consisted of two synchronous clocks, which caused a style made of fine iron wire to rotate over a plane made of prepared paper supported on a metal base; during each revolution a continuous impelling movement was given to the arm carrying the style, so that instead of moving in a circle, it traced a series of gradually expanding volutes whenever a current of electricity was made to pass. The paper received a mark or line in Prussian blue, produced by the electro-chemical action set up between the iron of the style and the paper chemically treated with a solution of ferrocyanide. To transmit a message or design, all that had to be done was to write or scratch with a pointed style upon a varnished metallic surface in order to remove those portions in a similar way to preparing a plate for etching. When this was done, the transmitting plate was fixed down upon the bed-plate of the transmitting instrument. The clockwork of both the sending instrument and that of the receiving instrument at the distant station were started simultaneously. As the contact style of the sending instrument passed on to the bare metal, a current was established; this current being conveyed to the iron style of the receiving instrument passed to earth by conduction through the chemically-prepared paper, and produced a Prussian blue mark corresponding to that of the scratched or removed portion of the varnished surface of the transmitting plate. As the arms of both the sending and receiving instruments swung round at equal rates, tracing a series of volutes, beginning near the axis, and finally ending at the full diameter of the plate, it is readily seen that, as the blue mark depends upon the electric circuit being closed, such blue marks will correspond to the removed portions of insulating varnish of the transmitting plate.

Since the time of Bakewell not much had been done until 1863, when Casselli made a series of highly interesting experiments with a much improved apparatus. The chief feature of Casselli's apparatus consisted mainly in regulating and controlling the speed of his apparatus, so that both sending and receiving instruments were made to beat in unison, also that the ruling was in straight or parallel lines. This apparatus was established on one of the London to Liverpool circuits of the Electric and International Telegraph Company, and continued to work for some time very satisfactorily. Music scores, autographs, portraits, sketches, and bills of lading, were sent with unerring fidelity. The transmitting plates being mostly responsible for any of the vagaries, I enclose some of these pictures, which, as they are the only specimens I possess, I will ask you to kindly return them after inspection :—First, a sketch portrait of the late Prince Consort; second, a sketch portrait of a Turk; third, agricultural scene; fourth, a note of introduction, with portraits, front view, and profile of the person to be introduced.

I think it is very desirable to keep these results on record, as they undoubtedly form very important stepping

stones to the advancement of this subject, and from what I gather from the description of M. Ginochio's anto-telegraph, in your issue of the 3rd inst., I should imagine it to be actuated by an equivalent mechanism, though whether it is an improvement upon the work of Casselli, it is impossible and premature to judge. But, remembering that in 1863 photogravure was non-existent, and the artist employed to make the transmitting plates was only just learning his work, I think we may say that Casselli made not only a very practical demonstration, but also an important step in the advancement of auto-telegraphy.

With improved mechanism and plates prepared by one of the photogravure processes, I see no difficulty in producing and telegraphing highly finished works of art. Then the next question comes:—What about the commercial aspect? Why did the press not support Casselli in 1863? The answer may be that illustrated literature was not so general as now, and the time not ripe for its full appreciation; but with the new journalistic ventures, such as the *Daily Graphic*, which doubtless will meet with many competitors, it may become—and doubtless has become—an absolute necessity of the age, rendering it expedient to take this work up again from a fresh standpoint, beginning where Casselli had to leave off from want of proper encouragement, appreciation, and support, and to so develop the process as to make it perfectly reliable and correct in the minutest details. The undertaking is one involving a considerable expenditure of time and money, but that should not be an obstacle to so important an achievement in these days of advancing enterprise.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—The Annual Exhibition will be open for two days only, but it will be very representative, as nearly 400 exhibits have been forwarded, ranging from about 20 by 16 to quarter-plates.

HASTINGS AND ST. LEONARD'S PHOTOGRAPHIC SOCIETY.—In a notice last week of the Exhibition to be held in February, the address of the hon. secretary was incorrectly stated. It should have been Mr. A. Brooker, Memorial Buildings, Hastings.

FRENCH ECONOMY.—The medal question at the late Paris exposition seems to be giving no little dissatisfaction. It seems that the awards were numerous enough to satisfy everyone, but to get an award was one thing, and to get the medal awarded another. The managers of the exposition issue certificates of the awards, but the lucky (?) exhibitors can only get the certificate honoured by paying for the article thereby represented. Every successful exhibitor must pay the full value of the gold or silver medal which he in his ignorance of French usage supposed he had honorably gained.—*The Beacon*, Chicago.

THE SWING BACK.—Of all the contrivances about a camera, none perhaps is so often misused as the swing back. Many a time its employment would have been more honoured in the breach than in the observance. To have a swing back means that it must be used on all occasions, whether the taking of the building demands its employment or not. What is of more importance than tilting the camera and applying the swing back, is keeping the camera level wherever possible. Do not tilt and use the swing back every time. Very often a better view of a high building can be had by levelling the camera at the building from a window at a suitable height opposite. Determination of the proper lens is of the greatest importance in architectural views—what focal length will best secure the object in proper proportion. It is well to use a wide-angle lens which covers a plate the next size above; for instance, if the view is to be on a $6\frac{1}{2}$ by $8\frac{1}{2}$ plate, use a lens for 8 by 10. With such a lens we can raise the front without straining. A swing back, however, is like a Texas revolver—rarely needed; but when that rare time comes, it is needed badly.—*American Journal of Photography.*

A BIOGRAPHY OF J. H. SCHULZE.

BY JAMES MEW.

THE already announced inventor of photography, John Henry Schulze—or Johann Heinrich Schulze, to give his exact German name—was one of the most able physicians and distinguished philosophers of the eighteenth century. He was born—or, as his German biographer expresses it, "first saw the light of this world"—on the 12th May, 1687, at Colbitz, in the Duchy of Magdebourg in Prussia, in the house of a poor tailor. His father (Matthäus) supplemented a precarious income derived from the reseating of breeches, with the nurture of bees. It is possible that his son's name would never have been enrolled in the blazoned annals of medical and philosophic fame—for the father's purse held no quantity with the son's abilities—had it not been for the exertions of a certain Andr. Albr. Corvinus, the pastor of his native hamlet, who first made John Henry's acquaintance at the immature age of six, learning his accidence in the village school.

Corvinus took young Schulze to himself, and the boy, besides sitting down at the intellectual feast of the village pastor, was careful to pick up such stray crumbs of learning as fell from the table of his children's education. In this desultory manner he seems to have taught himself the rudiments of Greek and Latin. On a day came Corvinus into his garden, and lo! his *protegé*, forgetful of fruit and flower, lost to the outer world of sunshine, was buried deep in the pages of a Greek Testament behind the paternal bee-hive! The good priest, delighted with the sight, made him a present of the book out of hand; and who then was happier among articulately speaking men than John Henry? All the time he could spare from his regular course of study he devoted to the Evangelists, collating, comparing, and criticising with his 'prentice-brain their textual anomalies and variations; and, after the fashion of Browning's Grammarian, weighing with minutest care the relative forces of *men* and *de* and *oun*.

At the recommendation of Corvinus, Schulze was received as a pupil at the Royal Pædagogium, in the University of Halle (Friedrich's-Universität) in 1697. As he was one of the earliest, so he became one of the most distinguished scholars of that seat of learning. Afterwards he was admitted, without pay, a pensioner of the Orphans' Home in the same town. The head master of the Pædagogium—the famous theologian Franke—following the good example set by Corvinus in the matter of young Schulze, loaded him with benefits—moral, intellectual, and physical—for the full space of twenty years. It is rare, indeed, to find a Mecænas in this work-a-day world; the fortunate Schulze found Corvinus and Franke. Without such happy chance, where would have been our young philosopher and adolescent physician? Blushing unseen, most probably, and wasting his sweetness on the desert air, as so many embryo poets, painters, philosophers, and physicians have done before Agamemnon and after.

In 1701, Schulze seized the forelock of opportunity, and made acquaintance with a language of the East. One Solomon Negri, a learned Arab from Damascus, at the importunate request of Franke, consented to stay a year's space at Halle to give any pupil who wished it, the profit of his instruction. Schulze was one of the first volunteers, and for that whole year learnt nothing but Arabic. After Negri had returned to his own place, Schulze studied for some time medicine at the University under the direction

of the then celebrated Professors Stahl, Richter, and Eckebrecht.

His thirst for varied knowledge was not yet assuaged. He proceeded to dive into antiquities and philology under the experienced guidance of Christopher Cellarius. From time to time, however, he returned to his old Eastern loves, encouraging these pursuits with an occasional attendance at the Oriental lectures of Michaelis, and studied Syriac, Chaldee, Samaritan, Æthiopic, and Rabbinic. He learnt Romaic at the feet of Anhard Adlung, from Constantinople, who lent him several rare books in that language published at Venice and Bucharest. He also learnt Turkish from the same master.

In due course, Schulze became, in the year 1708, a Master of the Pædagogium, and in 1715 was employed as a secretary by the well-known physician Fred. Hoffmann, the Boerhaave of Germany. This accident seems to have determined his errant inclinations ultimately in favour of medicine—though we still find him reading in his intervals of leisure such erudite fathers of the Church as Gregory and Nazianzen, whose works, it is said, he studied completely, adding thereto the greater portion of those of Basil.

Under the guidance of Hoffmann—the Hippocrates of his period—who treated him with no less liberality than Corvinus and Franke had done, in the free and cheerful giving of such intellectual stores as he possessed, and initiated him, moreover, into all the valuable secrets of his art, Schulze felt himself, after two years' labour, strong enough to sustain the theses required for his degree of Doctor. His dissertation on "Athletes, their Habits and Diet," obtained for him permission to practise in medicine. He continued his practice at the University till the year 1720, when he accepted the position of Professor of Anatomy at the University of Altdorf. His old and early patron, Corvinus, had set the crown on the previous benefits bestowed on his favourite pupil by giving him his daughter Johanna Sophia to wife, in the year before his election to the anatomical chair.

Schulze sat in this chair some dozen years, and published therefrom his "History of Medicine," which at once placed him in the first rank among his medical compeers. This work was, however, never finished. In 1729 he became Professor of Greek, and later on Professor of Arabic. These professorships interfered much with his medical duties, and the interference was strengthened by his appointment in 1732 by the Prussian Government to the place of Professor of Eloquence and Antiquities in his old University of Halle. His first exercise in this new department of literary activity was a treatise on the much-debated line in Virgil (Æn. xii, 397):—

"*Mutas agitare inglorius artes*,"

which has caused so great disagreement among the learned.

But still Schulze's circle of study was not sufficiently wide for his own convenience. Numismatics now engaged his attention. He collected a large number—some 3,000—of ancient coins and medals, of which Gottlieb Agnether published in 1746 a *catalogue raisonné* with the title of *Numophylacium Schulzianum*.

Schulze's abnormal intellectual energy can best be comprehended by an allusion to some of his multifarious labours. Taking them at haphazard, we meet first with some philological observations on a Greek verb signifying to worship. Next we have a treatise on the condition of the medical slaves (strange expression in the light of our nineteenth century civilization) belonging to the Greeks and Romans. Then a little talk about the Goddess Victory and a particular altar belonging to her; then a medical lexicon; then a translation of Plutarch; then an essay on the Ancient's Hellebore; and then a literary geography, and so on to the number of 166 separate works.

Schulze joined to extraordinary diligence extraordinary ability. He was continually, as the reader who has gone through this biographical sketch may readily believe, engaged in reading, writing, and studying. His excessive application to his books injured his health. He contracted various diseases, of which has been published a minute and unpleasing description. In the Eastertide of 1744 he died, or, as his German biographer prefers to put it, "changed the temporal for the eternal; a truly unspeakable loss for all who knew him."

BROMIDE ENLARGING AND PRINTING.

MAKING bromide enlargements is a work so popular among photographers at this season of the year, owing to the facility of carrying it on by artificial light, that the record of experiences from various sources is sure to be interesting to our readers. We therefore subjoin extracts from articles on the topic, the first being by Mr. D. G. Milburn, in *Wilson's Photographic Magazine*.

A very practical business method, as practised by a New York photographer for introducing large pictures to the general customer, can here be mentioned, as it usually leads to a sale of a life-size portrait at a handsome figure. Every negative of a fairly good quality, after leaving the retoucher's hands, is brought to the bromide operator, and an enlargement is made from it. This plain print is then inserted in a ready *passepartout*, and when the customer calls for his small picture his attention is called to his enlarged bromide picture. He is informed by the salesman that said picture can be sold plain as it is, or can be finished in crayon, oil, or pastel, and specimens of the different styles are shown him, and, as before stated, a sale is usually accomplished. In case of no sale, the print is removed from the *passepartout*, and all the firm is out is the cost of the print, which is not over 60 cents for an 18in. by 22in. The same *passepartout* will answer for showing any number of enlargements in.

A mistake that often occurs with the bromide worker is over-timing, and then to overcome this mistake the addition of an old developer, or bromide of potassium, is resorted to. This is something all operators ought to be very careful to avoid, for an overtime print will never compare favourably with a print that has been timed correctly.

A very practical way of deciding on the right and proper time of exposure for any sized bromide enlargement is to adjust a small piece of bromide paper on the easel, after having focussed the enlarged image sharply, expose and develop, then use this as a guide for the final exposure. If daylight is the medium used to enlarge with, permit as little time as possible to elapse between the test and final exposure, as the light may change.

In case the enlargement is to be made from an over-intense negative, use less bromide of potassium than the formula calls for. On the contrary, if the negative is too soft and flat, an increase of bromide of potassium in the developer will make the proper contrast. Old developer should not be used for that purpose, as it has a tendency

to leave the print slightly yellow. The oxalate and iron developer has been proven to be the correct developer for bromide paper work, and the writer recommends it above all others. If bromide enlargements are to be made in large quantities, electric light will be preferable, as there is less variation in that light; with it Eastman's extra quick bromide paper will work the best.

Enlargements of sizes over 30 by 40 are best produced with daylight, and Eastman's standard paper is then recommended.

Any amount of crayon, oil, or pastel can be done on a bromide enlargement, and any one used to crayon work will require but very little practice to become proficient. But very little work is required on a good bromide print to make a highly finished picture.

The following is selected from a paper by Mr. J. Howson, read before the East Dulwich Photographic Society, and published in the *Photographic Societies' Reporter*:—

For enlargements each man is bounded by his facilities, and I will only sketch, therefore, the two methods available, leaving each to be guided by circumstances and surroundings which plan he will adopt.

First, daylight work. Here we need a dark room, with a window blocked up by a shutter; this shutter must have in its lowest part an opening the size of the largest negative to be enlarged from. At the bottom of the opening must be a shelf, on which to stand our ordinary camera at full stretch, if the size of our enlargement so needs it. Outside the window, at an angle of forty-five degrees, must be a mirror, or a board covered with white paper, to reflect the daylight inwards. A north aspect for this window is preferable, and direct sunlight very undesirable. Inside the room we want an easel; one of the most primitive kind will do, cabable of being readily moved and adjusted so as to be strictly parallel with the negative. Our lens, with which the original negative was taken, is in position in the camera, and that is all. Pin a piece of plain paper on easel, mark on it the size of enlargement wanted, put the negative in place of focussing screen, film towards lens; change relative position of negative, lens, and easel, until the image covers the size marked; replace the plain paper by bromide, taking care that the latter is well stretched and evenly level, and expose. There are exact rules as to the finding of these relative distances for each size of enlargement, but as they are found in all year-books, we need not discuss them, only mentioning that the farther from the lens the sensitive surface is, the larger the image, and *vice versâ*. In practice, a rectilinear lens gives better enlargements than a single one, and as large a stop as possible is preferable, as it facilitates focussing and shortens exposure; but, of course, the larger the plate proportionately to the lens, the greater the necessity for stopping down. Further, most negatives are wanting in definition at the edges, and also in most cases in interest; it is therefore advisable, in making an enlargement of, say, 12 by 10, to let the image on the screen be an inch or so larger; the resulting picture, on 12 by 10 paper, will be more pleasing and sharper, though not embracing the whole subject on the negative. Then, as to size of enlargements, as compared with size of negative, I think it is admitted that, to obtain most perfect results, we should not exceed three times—that is, a ¼-plate should be enlarged to 12 by 10, and no further. There are other opinions expressed on this point, but I am going with the majority. I ought perhaps to have mentioned before the class of negative to be used—a negative that will give good results on ordinary albumenised paper will give good results on bromide naturally; but I go further than this, and endorse the frequently expressed opinion that bromide is the "salvation of a poor negative," and say that a negative that is too thin to give a decent print on ordinary paper, will give a capital picture on bromide, with ordinary care; and even if you have a hard negative, presuming all detail is present, a very passable bromide print can be got. A negative tending to thinness and full of detail, however, gives the best results. These remarks apply, of course, equally to enlargements and contact prints, and, in the proper place, I shall say a few words as to the methods of correcting in exposure and development the excess or lack of vigour in the negatives from which we may be working. Now, as to exposure. Here we have four points to be considered—the variation of light; the density, or, speaking more correctly, the *printing value* of the negative; the focal value of the stop; and the size of the enlargement. The two first points are matters of pure experience, the third and fourth are subject to well-ascertained laws. As regards the size of picture, if the distance between negative and sensitive paper is two feet, and two seconds is found to be a correct exposure, then, when the distance is four feet, the exposure will be *not* double, but four times as long; the rule is, not proportionately as the distance, but as the square of the distance. As regards the focal value of the lens, this is dependent on the ratio the diaphragm bears to the focal length; a lens of 8in. focus, with a diaphragm of ½in. diameter, would give a focal value *f*/16, because the aperture is one-sixteenth the focal length, and the relative value of light passing through the several apertures is all laid down in the year-books.

Whilst it seems almost useless to attempt to give any standard of exposure, it may help workers to say that one of the 15 by 12 enlargements on slow paper was made at mid-day with a lens stopped to *f*/10, from a 5 by 4 negative, and nine minutes' exposure given. These times may be remembered as a guide for working. I have spoken first of daylight work because it entails the use of fewer appliances and less expense, whilst, at the same time, most of the remarks I have made apply equally to work done by artificial light. For this latter kind of enlarging it is impossible to work without some sort of lantern, or at least a condenser, for securing an equal diffusion of the light over the whole negative to be enlarged.

One prime reason why the best results cannot be always obtained by this method is, that most artificial lights are of a comparatively low intensity, and do not possess sufficient penetrative power to enable them to give the full gradation of tone in a vigorous negative. Therefore, a negative with strong contrasts should be specially avoided when working by artificial light, except unusual care is taken to modify results. In using lanterns for enlarging, it should be borne in mind that the light must be as intense as possible, and the flame not large—in fact, a perfect light for this purpose would emanate from a single point. Then as to condensers, these should be at least half an inch larger in diameter than the longest side of the plate to be enlarged; that is, a quarter-plate negative would need a six, or at least a five-inch condenser, and as these are expensive articles in the larger sizes, a suggestion made by a well-known worker is worth bearing in mind. He has only a four-inch condenser to work with, and therefore reduces his half and whole plates in the camera to lantern size, prints by contact a negative, from which

he enlarges. This is a roundabout way of working, but the plan is one to be remembered in case of need.

The remarks as to exposure which I made in reference to daylight apply here also, and I will, with the same reserve, say that a negative to be enlarged three times will need an exposure of two to five seconds, using Ilford rapid bromide, which is twenty times as fast as the slow kind. In any case, it is unwise to rely on these time standards without experience, and the plan usually adopted is to make tests by means of slips of the sensitive paper. Such a plan will save much paper and much disappointment. I will add only that the process is a comparatively simple one, and any worker who can be fairly certain of producing a decent negative will not find any difficulty in doing good work after a very slight practical experience; and the advantages of being able to reproduce larger pictures from good though small negatives are obvious to all, and need no comment from me.

On the subject of bromide printing, for directions in which inquiries are frequently made, the editor of the *Photographic Record*—the organ of the Amateur Photographic Society—writes the first portion of an instructive article, from which we make the following extract:—

For the amateur, bromide printing possesses many advantages over silver, and although we admit there are disadvantages also, such as the difficulty of combination printing, yet the comparison is greatly in favour of the bromide. One of the most important of these advantages is that it can be worked in the evening by gaslight, and, in consequence, is quite independent of the weather. Winter, with its gloomy days, makes no difference, except that the long evenings are a decided gain, and can be made to yield an additional pleasure. There is no necessity even to use the dark room, which is often a makeshift arrangement, and is cold and cheerless in the winter months, for, with the exception of the final washing, all the operations may be undertaken by the fireside in a sitting-room, or any other convenient apartment. Let us suppose that an ordinary sitting-room is used, which is illuminated by gas in the usual way. All that is required is to allow the fire to burn down to a red glow, to spread a newspaper or sheet of brown paper over the table, and place upon it the few bottles of chemicals, three dishes, and a measure from the dark room. A red lamp will be required on the table. One of the best is obtained by purchasing a small paraffin oil lamp, usually costing sixpence, and painting the glass chimney with two coats of light red oil paint. The light of this can be turned up or down at will. Two jugs, one containing clean water, will also be wanted; the empty jug is to receive the spent developing solutions. It will be an improvement if the gaslight can be placed low down on the table, by means of an india-rubber tube attached between the chandelier or bracket and a standard, such as is often used for reading purposes, but this is not a necessity. When all is ready, pour out some of the clean water into one of the dishes, mix the developing solutions in the measure, light the dark room lamp, and then turn down the gas very low. Place a watch near the lamp to check the exposures by. A sheet of the bromide paper should now be placed in contact with a negative in the printing-frame. The face of the paper is known by its tendency to curl upwards slightly, the emulsion with which it is coated causing a contraction of the surface. After seeing that the stock of bromide paper is carefully covered, the gas may now be turned up and the exposure made. For an ordinary negative, with Eastman or Ilford slow paper, an exposure of 1 to 1½ minutes at one foot from the gas is about correct: but if the negative is very dense it should be held closer, say six or eight inches away. The colour and quality of the negative must be judged prior to the exposure, or a test made by a slip of the paper. A stained negative being somewhat non-actinic, the light has difficulty in penetrating it, and a prolonged exposure is necessary. If the negative is thin and weak all over, as an over-exposed plate usually is, it will require to be placed further from the gas. Three minutes' exposure, at three feet from the light, will often give good results from this class of negative, but at times it is even necessary to considerably exceed this distance and time. A negative which has been under-exposed, and has portions very dense and other parts very thin, will require special treatment. The weak portion must be shaded while the dense parts are being held near the gas; afterwards it should be removed further from the gas, the shading material taken away, and the exposure continued for the thin portion. A piece of paper or cardboard, with a torn, irregular edge, and kept moving during the exposure, is suitable for shading purposes. Vignetting is nicely accomplished by cutting the required shape, slightly reduced, in a piece of cardboard, and, after fixing the negative at the proper distance, moving the vignetter backwards and forwards between the negative and the light. This will produce a soft edge. Daylight is very uncertain, the light being too intense; but with gas almost any variation in colour or density of negative may be successfully dealt with, by reducing or increasing the flame, the distances, or the length of exposure. Even the faint details in a thin negative, which cannot be retained in a silver print, can be shown very presentably by the treatment suggested.

After the exposure, the gas should be turned down till nothing but a small blue flame is seen on the burner; the printing frame is opened, and the paper immersed face downwards in the bath of clean water for about a minute. So that the water shall act evenly and air-bubbles be avoided, the paper should be drawn into the water by the edge, only the extreme edges of the paper being held by the finger ends. It should then be taken out and placed face up in an empty bath. The developing solution is now poured upon the paper, and the bath rocked freely to produce equal action of the developer. The time should be observed, so that an idea may be gained of the correctness of the exposure. Some developers are very slow. This is because the accelerator is weak and restrained, and, in consequence, it cannot be considered an ordinary developer, though it makes a pleasing tone. Something quicker is wanted for general practice if the work is not to become monotonous, and from a half to one minute should be sufficient to start the image. About three minutes should complete the development. The following is a good iron developer giving a purple-black colour free from strong contrasts, and is well under control:—

No. 1.—A saturated solution of potassium oxalate
Ammonium bromide, 3 drops to each 5 ozs. of the above.

No. 2.—A saturated solution of ferrous sulphate
Citric acid, 20 grains to each 5 ozs. of the above.

To make 2½ ounces of the above, take—

No. 1	1 ounce
No. 2	¼ „
Water	1¼ ounces

Nos 1 and 2 should always have a few undissolved crystals at the bottom of the bottles. Whenever any portion of No. 2 is used, the bottle should be filled up with water so as to exclude the air, and from time to time a few grains of citric acid added to prevent the iron from oxidizing.

If the picture shows signs of developing unequally, the dish should be tilted so that the solution may run off the fully-printed portion, and remain on the part which requires the extra development. Another plan is to pour all the solution from the dish before any part of the image is fully developed, and then work out the completion with a camel hair mop dipped in the solution. The dish should be elevated at one end while this is being done. When any part is finished, squeeze the moisture from the brush with the fingers, and pass it over the completed portion so as to absorb the solution on it and stay further action. The remaining parts should have additional solution supplied by the brush until a satisfactory result is obtained. Do not attempt to stop the development with water, or a degraded colour will be produced wherever it is applied.

When the development is complete, the print should be transferred to another dish to be acidified. The removal of a print from one vessel to another is greatly assisted by using the handle of a teaspoon to lift the edge of the paper. Especially if hydroquinone is used will this little help be appreciated, because this developer imparts a slippery feel to the print, and softens the texture of the paper. Care should always be used in handling, so as to avoid any abrasion of the surface.

L'Amateur Photographe is in the habit of saying that an illustration accompanies the number in which the said remark is made; the publishers, with equal regularity, invariably omit the illustration from the copy posted to us, and perhaps to others. This is as economical as the medal system at the Paris Exhibition.

THE ACTION OF ELECTRICITY ON IODINE.—In the course of a memoir on "The Long-continued Action of the Electric Discharge on Iodine," Dr. C. Luedeking, of Leipzig, says :—"In my experiment the disappearance of the element iodine was not due to any other cause than its uniting with the constituents of of the glass. Under the influence of the electric discharge, iodine certainly acquires superior chemical affinities, attacking the substance of the glass, and forming iodides, and, from the disappearance of one-fifth of the volume of gas, I should say also some iodates. To meet this eventuality, I reduced by sulphuretted hydrogen previous to precipitation."

SELF-LUMINOUS CLOUDS.—I am very sorry that I took no notes, some six or seven years ago, on the first and only occasion of my seeing self-luminous clouds, but though I can give neither date nor positions, the following facts are still fresh in my memory. Passing through Bushey Park after dark, I noticed an aurora borealis, and, as I had only recently seen the rather rare phenomena of the rays of the setting sun converging towards a point in the east, I followed the direction of one of the principal beams of light towards the south, when, at a point somewhat south of my zenith, I noticed an equatorial belt of luminous clouds. I found that each cloud belonged to a ray, and faded and brightened with it, but was separated by about 60° of clear sky. This belt of clouds extended down to the western horizon, the eastern one was obstructed by trees, while shortly afterwards small dark clouds appeared on that side, and the sky soon became overcast. The luminous clouds were quite transparent, so that even faint stars could be seen through them when at their brightest. I have heard from Scandinavian captains that these luminous belts are sometimes seen in northern latitudes, and are sure signs of bad weather. I have written these few remarks in the hope that those of your readers who may have the chance of seeing an aurora borealis, will also look out for these clouds, and if possible determine their position.—C. E. STROMEYER, *Strawberry Hill, Jan. 4th.*

PHOTOGRAPHIC SURVEY OF WARWICKSHIRE.*

BY W. JEROME HARRISON, F.G.S.

Society Excursions Utilised.—Everybody knows the routine of an ordinary excursion of a photographic society. Some well-known spot is selected, the further away the better, as North Wales, Dovedale, and Haddon Hall. If the day is fine, twenty or thirty members attend, and they go round the place in a crowd, occupying themselves to a large extent in getting in, and out of, one another's way.

I would suggest that the excursions be made local, and that a routine of work be drawn up beforehand, in which each detachment of three or four members should be assigned some particular task to accomplish. Thus, in a half-day excursion to Warwick, suppose twenty camera-carriers present themselves; let this number be divided into five sets of four members each, the tasks being as follows:—(1) The Castle and Grounds; (2) St. Mary's Church, including the Beauchamp Chapel; (3) the Leycester Hospital; (4) the Town of Warwick generally, its two gates and old buildings; (5) Guy's Cliff. Given a fine June afternoon, and the work of the survey for that town might be accomplished very rapidly on this plan. But it supposes that a full programme, showing the work of each section of the party, be drawn up beforehand and distributed.

Utilisation of Work already done.—There are probably in existence already some hundreds, or even thousands, of photographic negatives which would be of service in the history of Warwickshire. It must be part of our task to draw up a list of such negatives, showing their subjects and their owners. Some of them may, perhaps, be acquired by gift, loan, or purchase. A separate record book should be kept for those negatives which are already in existence; and a circular asking for information on this subject might be addressed to the professional photographers of the county.

Documents, &c., Copied by Photography.—We must photograph not only places, but things—old documents, seals, plans, maps, various objects of antiquity, rare fossils, &c. All these will provide food for the camera, and will add interesting pictures to our stock. One advantage of photography in this direction is that it enables us to *bring together*, for purposes of comparison, a series of objects which may be scattered in many collections. The facsimiles of documents obtained by photographic processes, are far more valuable than copies by hand can be, since they must be literal and unbiassed; errors in copying are avoided, and the evidence of the photograph is practically as good—sometimes, indeed, it is better, because clearer—than that of the original.

Size of Photographs to be taken.—I fear it will be impossible to bind ourselves down to any definite size of negative. Perhaps it would be best to make the whole-plate size (8½in. by 6½in.) our standard. By the recent substitution of celluloid films for glass plates, the weight of the photographer's equipment has been greatly diminished; so that a whole-plate camera with films weighs no more than a half-plate camera with glass plates.

By the use of cases or boxes to hold separately mounted prints, the difficulty of variety of sizes is largely avoided. If albums are made up, they could be of such a size as to hold one whole-plate print, or two half-plates, on each page.

* Concluded from page 31.

For hand-camera work the usual size is the quarter-plate (4¼in. by 3¼in.); and for pictures of this size separate albums might be provided, or they might be mounted four on a page of the larger albums. It must be remembered, however, that it is easy to enlarge or reduce negatives, so that they could all be brought to one uniform size if that were thought desirable. Or it is even easier to enlarge or reduce the prints as they are made from the negatives, if we use bromide paper for printing upon.

How other Societies (Literary, Artistic, and Scientific) can Aid in the Work of the County Photographic Survey.—I trust that it may be assumed that the three photographic societies already in existence in Warwickshire, viz., the Birmingham Photographic Society—Hon. Secs., Mr. J. H. Pickard, 361, Moseley Road, Birmingham, and Mr. A. J. Leeson, 20, Cannon Street, Birmingham: Leamington Amateur Photographic Society—Hon. Sec., Mr. F. M. Gowan, 20, Beauchamp Square, Leamington; Coventry and Midland Photographic Society—Hon. Sec., Mr. F. W. Dew, The City Studio, Coventry, will do all they can for the work of a photo. survey. But very valuable assistance can be rendered by several other societies within the county, whose aim is the furtherance of literature, science, and art. Among these I may name the Vesey Club, Sutton Coldfield—Hon. Sec., Mr. C. H. Marston; the Archæological Section of the Birmingham and Midland Institute—Secretary of the Section, Mr. Alfred Hayes; the Birmingham Natural History and Microscopical Society—Hon. Secs., Mr. W. H. Wilkinson and Mr. W. P. Marshall, M.I.C.E., The Mason College; the Birmingham Philosophical Society (1876)—Hon. Secs., Prof. J. H. Poynting, F.R.S., 11, St. Augustine's Road, Edgbaston, and Prof. Windle, Queen's College; the Birmingham and Midland Institute Scientific Society—Hon. Sec., Mr. W. E. Weaver, 221, Broad Street (this Society has a Photographic Section); Birmingham Microscopists' and Naturalists' Union (1880)—Hon. Secs., Messrs. Collins and White, Broad Street Corner; Birmingham Architectural Association (1873)—Hon. Sec., Mr. H. R. Lloyd, A.R.I.B.A., 26, Corporation Street; Birmingham School Natural History Society, King Edward's Grammar School; Birmingham Botanical and Horticultural Society, Botanical Gardens, Edgbaston—Curator, Mr. W. B. Latham; Warwickshire Field Club (1858)—President, the Rev. P. B. Brodie, M.A., F.G.S., Rowington Vicarage—Headquarters, The Museum, Warwick; Tamworth Natural History, Geological, and Antiquarian Society—Hon. Sec., ——; Royal (Birmingham) Society of Artists, New Street—Secretary, Mr. Jonathan Pratt; Kyrle Society—Hon. Sec., Miss Gittins, 87, Hagley Road; Association for the Preservation of Open Spaces and Public Footpaths—Hon. Sec., Mr. Grosvenor Lee, 18, Newhall Street; Art Circle—Hon. Sec., Mr. E. Chamberlain, Burlington Chambers, New Street; the Midland Arts Club—Hon. Sec., Mr. W. H. Vernon (meetings at Grand Hotel, Colmore Row): Municipal School of Art, Edmund Street—Head Master, Mr. E. R. Taylor—Secretary, Mr. E. Preston Hytch.

How Antiquarians, Scientists, and others, can Aid in the Work of a County Photographic Survey.—Now, although we photographers may know *how* to photograph, we do not always know *what* to photograph. We want the historian and the antiquary, the literary man, the artist, and the scientist, to aid us in this. We want these students of the past and the present to draw up lists of places and objects in each square of our map which they consider ought to be recorded; and we want them to tell us all about them, so that the pictures we secure may be of interest to us as well as to them.

Assistance from Landowners, Residents, and others.—The nature of our work ought to secure assistance from occupiers in all parts of the county. Armed with an introduction, stating the object and plan of this survey, the photographer may hope to be afforded facilities for his work which he would otherwise scarcely venture to ask for. Those who occupy historically interesting or beautifully situated places, will certainly be willing to aid in such a task, which may really be called national; while to the guardians of our churches—the clergy—our scheme should appeal with special interest.

Required Funds to be Obtained by Subscriptions and Grants.—In the work here proposed, it is thought that all the workers will be willing to help, not only by paying their own travelling expenses, purchase of dry plates on which to make negatives, use of apparatus, and so on, but also by subscribing to raise the funds which will be necessary for the purchase of maps, albums, cases, and the defraying of the cost of printing in platinotype, and making lantern slides.

It does not seem unreasonable, however, to ask for subscriptions from all who are interested in such a survey. Our own Society will, it may be hoped, make a grant in aid; and, doubtless, if a portion of the work is done as a sample, and well done, assistance will not be wanting.

The End of a Photographic Survey.—In the way of work to be done, there could be no end. Every day sees some change, something of the old order is blotted out, something new is introduced. A railway is made across our pet landscape, and we must photograph the trail of black smoke from the engine, if it be only to send the picture to Mr. Ruskin. How rapidly the features of our towns are changing must be obvious to the most careless observer, and anyone who has been absent from the new city for but a few years has good cause to sing the old song, "I can't find Birmingham!"

But the term "end" may also be considered in the sense of "object." What shall be done with our photographs when we get them? Well, this Society should retain at least two complete sets—a working set, and one for reference. Complete sets ought also to be prepared for our Municipal Reference Library, for the British Museum, and for any other public institutions who desire a set and are willing to pay for it.

Our schools would value highly a selection of large photographs, and enlargements might be made for this and other special objects—as for exhibition on the walls of our free libraries, for teaching and for lecturing and other purposes.

Further, it appears to me that the pursuance of a task such as I have attempted to sketch out would unite the members of this society as only men are united who have a definite object in view, and who work for a common end. It would attract, it may be hoped, new workers to join our ranks, and would add to the status of the Society in the eyes of the public. Much energy which is now frittered away would be diverted into a useful channel, and, although it may be said that the main benefits of our work will be reaped by a posterity "which has never done anything for us," yet I feel confident that we shall derive as much pleasure from *doing* the work, as our descendants will from its *study* and *examination*.

PHOTOGRAPHING THE BABY.

BY JOHN WIEDERSEN.

You want something practical for your magazine. That's just what all you editors write; you can supply the theoretical, and the amateurs, I suppose, the artistic. They have elevated photography, don't you know, to a very high standard of art, for which we professionals ought to be so thankful. Wish they had elevated the prices while they were about it. "More price, less art," is my business motto; I do good work, but don't call myself "artist;" no, I assure you. Well, you want something practical, you say, and nothing about art. I see you don't take down all the æsthetic fellows say about posing and composition, or perhaps your subscribers are crying out, "Hold, enough!" Well, I shall not give you anything artistic: I buy my back-grounds from the dealers, and don't build up any of the poetic groupings—genre pictures, as you call them. I am always consistent—that is, make my figures and my grounds congruous; that's a degree in art, I suppose. As I shall not or cannot give you anything artistic, will you have something artless?

I have considerable reputation as a photographer of babies from knee-high to a bumble-bee up; though it is giving away my trade I shall not be stingy, as I have learned many a good practical hint from your magazine which some other generous fellow has given to the public free, gratis, for nothing.

My method with the little ones (recollect I am not a father, and therefore have no fatherly feeling towards them) is as follows:—

The secret of success is in gaining their attention—to get their little minds away from self-consciousness. I remember that one of the writers in your journal gives this as the key for successful portraiture. His language is flowery, and I suppose he is an amateur, but for all that there is a good deal of common sense running all through his paper, but I did not get my idea from him; I have photographed babies, some of whom are now grandmothers. To divorce the mind from self-consciousness is the way to succeed with babies of all ages. Your writer tells how to secure this desideratum in the grown folks; I shall tell you how to secure it with babies.

Suppose we have one of those crying, wriggling youngsters, about two or three years old. You know how the minute they get in the chair the commotion begins; from sunshine to storm instantaneously. Have about you a number of noisical toys—not necessarily musical.

Begin at once to blow one of your penny trumpets. The result is a stare, an inquisition from the little soul whence came that sound, a desire to investigate; for all children not idiots are "newsy." Do not blow again on the trumpet, but ring immediately a bell. A new arrangement of the features takes place. Follow them up with a chuckle, then a run down of the scale on a mouth organ. It is the quick succession of events which engages the mind of the child, and by the time you expend your energies on four or five differently sounding instruments, you will be rewarded with a smile; then press the bulb and secure the impression. With larger children who are intractable I always have a lively conversation, sometimes a gentle dispute with them; telling them I don't believe they know what they are talking about. Doubt the story of Jack the Giant-Killer. Now anyone bold enough to say that the story of the redoubtable Jack is a fabrication will receive the gentle anathemas of the little ones for his scepticism. The result is a most animated expression. Sometimes the telling of a fairy tale in a way that conjures up expectation is just the best way.

It requires tact to get along with children. I sometimes try similar dodges on grown-up babies who are so dreadfully self-conscious that they mar everything in the way of good expression.

You don't tell them fairy tales, I hope! I think I hear you say. Oh, no; not exactly, but then I have a way of getting them out of themselves.

I first of all place on the upright, towards which I direct them to look, not a black mark that can be shoved up and down, but an interesting picture, full of incident, about which they are sure to ask you something concerning the topic. I begin work, the story progresses, and when I am ready I direct attention to a certain figure or object in the picture which has direct reference to what I am talking about. Of course interest is excited; the picture is at the right height on the pole for the eyes, and, moreover, the eyes, instead of being fixed staringly at one blank spot till they wink and water, can wander over a limited field without actually moving. This kink gives the means for securing the best expression possible. Some people tell me, of course, that I have taken them unfairly, and that the expression must be perfectly horrible. The proof is sent, and a good order follows; not only from themselves, but from their uncles, sisters, and aunts.

The use of the spot on which to fix the eyes is an invention of the Inquisition. It is a painful operation for a strong eye, and excruciating for tender eyes. In fact, I have known people to be almost put in a hypnotic state by gazing too long on a spot.

Now, as I wind up—or, as a photographer should say, cap my talk and put in the slide—I would like to know if you think this paper practical. If not, I shall add a string of formulæ, which neither I nor anybody else ever thought of trying, and I don't believe the men who send them to the magazine ever tried.—*American Journal of Photography.*

THE subject at the Camera Club for Thursday, Jan. 23rd, is "English Church Architecture as a subject for Photography," when a paper will be read by the Rev. T. Perkins, M.A.

PROPOSED LANTERN CLUB.—As will be seen from our Correspondence column, a project is on foot to establish an association of those interested in the work of photographic optical lanterns. We refer readers interested to the letter in question.

THE TOTAL ECLIPSE OF DECEMBER 22ND.—Misfortune has attended the double expedition sent by the Royal Astronomical Society to observe the total eclipse of December 22nd. In Africa observations were made impossible by bad weather. Observations were secured off the coast of French Guiana, but at a cost which is deeply to be deplored—the death of Father Perry. The telegram received from Demerara is as follows:—"101 corona American Perry dead dysentery." With regard to the part of this telegram which needs explanation, the *Times* of January 6th says:—"101 is resolvable into the factors 2, 4, and 13, of which the first number means that the weather was only moderately good; the second that successful exposures were made with the Abney 4-inch lens, but that the development was not carried out, owing either to unfavourable climatic conditions, or, possibly, to the illness of Father Perry; and the third, that successful photographs were obtained with the 20-inch mirror, but again the development was not completed. The words corona American signify most probably that the corona was of the same form as that seen on January 1st, 1889, when a total eclipse was successfully observed in California, and the form was then that now generally ascribed to a period of minimum sun-spots, elongated at the sun's equator, and radial but short at the poles."—*Nature.*

Notes.

Photographers who read the *Globe* of Saturday last must have rubbed their eyes when they saw a statement therein gravely intimating that photography must have been known in the thirteenth century. Mr. John Smyth, who is now ship's corporal on board H.M.S. *Impregnable*, was serving, to quote the *Globe*, exactly "$\frac{1}{4}$5 years" ago in the *Royal Adelaide*, and posted a letter containing a photograph to his mother. That letter reached its destination only a few days back. It appears it got into a crevice of the ship's letter box, where it has lain undiscovered "since 1274" (!) But this is not the only wonderful part of the story, for our contemporary adds: "On being opened the photograph was found to be in a good state of preservation." Clearly the discovery of this photograph, which must have been produced in the reign of Edward I., had a paralyzing effect on both the compositor and the writer. The "$\frac{1}{4}$5 years" of the first may thus be accounted for, and so also the astonishing information of the second, that the photograph was "opened," just as though it had been a mummy!

To enquire too curiously into this astonishing paragraph might be hazardous for our own brains and those of our readers, and to prevent any further catastrophe let us at once suggest that the figures may be misprints, the "$\frac{1}{4}$5" being probably intended for 15, and the "1274" for 1874. But taking this hypothesis as correct, the statement is yet sufficiently curious. Fifteen years' exposure of a photograph to the influence of sea air at times charged to excess with moisture, and the photograph still to be in "a good state of preservation," is a marvel indeed. We have always been under the impression that if anything was calculated to try the temper of a photograph, it was a sea voyage. This wonderfully tough specimen ought really to be tried by a jury of experts, and if found to justify the description of the *Globe*, to be hung up in some public place as a refutation of the popular impression that photographs are not enduring.

Photography has been the subject of a good many puns, but it is now squeezed perfectly dry. This is evident when so expert a master of word play as Mr. Burnand fails to extract a joke from it having the least scintillation of freshness. A photographer's studio and a photographer play an important part in the new burlesque "Tra la la Tosca," but, except to lead up to the droll mock execution when half a dozen photographers take aim with their cameras at the prisoner, it is not easy to find out the reason why photography is lampooned. Perhaps Mr. Burnand's faculty for parodying names may have had something to do with it. "Count Cameradossi" is a happy hit.

Who is the inventor of the latest instantaneous photographic apparatus, and of what does the latest apparatus consist? The question is rather an important one, because new instantaneous photographic cameras are being invented at the rate of at least one per week. Whoever the inventor in question may be, we are interested in reading that last week he had the honour of displaying his invention to the German Emperor and Empress at the New Palace, Potsdam. The society journal which chronicles this information says, "The inventor claims to be able to take photographs from life in a manner bordering on the incredible, and surpassing all expectations. As a proof of the power of the machine, the inventor took two portraits of their majesties, with which they were greatly pleased." Is it such a proof of "power" of an instantaneous camera that it is able to photograph Royalty?

A correspondent raises a nice point. He wishes to make some lantern slides from the pictures in *Punch*, but is troubled over the copyright question. Is he infringing the Act by copying them and exhibiting the slides on the screen, he would like to know? In the absence of any precedent, we should fancy there is nothing to prevent him copying the pictures, but he must not attempt to sell the slides. It is also a moot point whether the exhibition before an audience who have paid money to see the lantern entertainment might not constitute publication. Permission probably would be accorded by the proprietors of *Punch*. We know a case where an application was made by a professional maker of slides to the proprietor of another comic journal, and consent was obtained on condition that the words "by permission of the proprietor," and the name of the paper, were on each slide so as to be seen by the audience.

Dr. Vogel, in an article in the *Bulletin de l'Association Belge de Photographie* on the jubilee of photography, points out the influence which photography has had upon the art critic. He contends, and with perfect justice, that photography has given to the public a more profound knowledge of nature, which enables it not only to appreciate, but to judge of the works of painters much more accurately than was possible years ago. Painters, on the other hand, have been compelled to work according to the light which photography has thrown upon the conventionalties of art now shown to be errors. As for the power of reproduction, photography has worked quite a revolution, and added materially to the earnings of the artist. Dr. Vogel gives an example of a painter who sold his picture for 1,500 marks, the reproduction of which brought in at least ten times as much.

But in Germany the reproduction of pictures has grown into an industry of vast dimensions. In England not only artists, but buyers, have occasionally a curious prejudice against their pictures being reproduced by photography. How rarely does one see any of the hosts of pictures hung every year in the Academy, the Institute, and the other galleries reproduced by photography! Yet one would think it would be easy to create a market for photographic scraps of current art. If it were the custom for

painters to have their pictures photographed, the public would eagerly buy copies. But the latter must be sold cheaply to make the demand. It has been urged that if photographs of a picture were sold at a low rate the sale of engravings would be injured, but we fail to see any force in the argument, as the classes of buyers are totally different.

We are not quite sure whether it needs an Archbishop Whately to prove that half a dozen photographs identical in every respect are exactly the same, but we fancy it would puzzle even a logician of Whately's keenness to convince ordinary persons that any number of similar photographs are collectively one, and *vice versa*. This sounds like one of Mr. W. S. Gilbert's topsy-turvyisms, and we had better hasten to explain what we mean, which, fortunately, we are able to do from a case which recently came before the Surrey magistrates. A lady residing at Richmond had occasion to dismiss her servant summarily. After the goods and chattels had been packed up and sent away, it was discovered that a photograph belonging to the maid was missing. The bereft owner thereupon took the summary course of walking into her former mistress's house, and coolly removing a photograph similar to the one she had lost from a frame in the drawing-room, and carrying it away. For this she was charged with larceny, and the case was taken to the Quarter Sessions. There was no question as to the facts, nor was it disputed that the girl knew the photograph she took was not hers, yet the grand jury, directly they heard that the photographs were similar, threw out the bill

---

There is something very droll in this, and either both the girl and the grand jury considered there was no difference between one and a dozen or more photographs from the same negative, or that anybody has a right to look upon a photograph as umbrellas are regarded—common property. Certainly, in the first case, a wide field for speculation is opened up as to any one photograph possessing any identity over another photograph from the same negative, and a very pretty casuistical discussion might be raised on the point by any photographic society hard up for a subject.

Mr. Muybridge gives the palm to Meissonnier for correct drawing of the horse. This is not to be wondered at, for a more conscientious worker does not exist than the great French artist. He pays large sums every year to his models, but he is most exacting. It is said that desiring to paint a horse in a rearing position, he had one forced to assume the attitude every morning until he was satisfied he had got the drawing correctly. The picture was a triumph, but the unfortunate horse was ruined through its enforced exertions. Rosa Bonheur, Mr. Muybridge considers to be the worst painter of animals, and ridicules the drawing in the "Horse Fair." It would be interesting to have his opinion of Mrs. Butler's "Roll Call," which at the time of its exhibition excited so much discussion in regard to the position of the horse's legs.

THE PACKAGE OF PHOTOGRAPHS FOR POST.

BY C. BRANGWIN BARNES.

WHEN a client lives at a distance beyond which it is possible to forward his or her portraits by messenger, it is usual to make use of either the book or parcels post as a means of transmission. Photographs so sent are, as a rule, received with dispatch and in good condition, although, unfortunately, there are exceptions to this rule, and, strange to say, these exceptions always take place with regard to the most important parcels. Having recently had occasion to complain to the postal authorities of damage to several packages of photographs during transit, I was informed that every possible care was taken of such parcels, but unless they were marked "fragile," no exceptional measures could be taken. Two or three of the packages in question consisted of, in some cases, six, and in others twelve cartes-de-visite, enclosed in cardboard postal wrapper, and marked on the outside "photographs only," yet these packages were not damaged in a slight degree, but broken right across the centre, every carte being completely spoiled. In other instances the prints have been so rubbed as to be worthless, and I am sorry to add that in a few cases, where twelve portraits have been forwarded, only eleven have been delivered. All parcels sent by book post are liable to be opened by the authorities in order to see that they contain no written matter of the nature of a letter, and although the package may have been securely and properly arranged before such opening, it is very rarely fastened up again in the same style; it is not to be supposed that the examiner understands the necessity of preventing photographs from rubbing against each other, and even if he does, he very rarely seems to take any steps with that end in view. It is usual for photographers to pack their clients' portraits face to face, which helps to prevent rubbing of the albumen surface; but after the examiner has done his work, he usually re-arranges all this. The only way out of the difficulty that presents itself to my mind is to send all carte and cabinet pictures by letter post, and all larger sizes by parcels. It may be urged that the difference in the rates of postage, between book and letter, would materially affect the petty cash account in the course of a year; but I should say any difference would be more than rectified by the additional satisfaction given to our clients, and by the fact that we should have less damaged prints to produce over again. If the margin of profit is too small to allow of the additional expenditure, then why not charge the postage to the sitter, as many firms do already? The portraits should then be packed in a perfectly fitting envelope, so as to allow no room for their rubbing together, face to face, with a slip of tissue paper between each pair, and a plain card at each side of the whole, as otherwise the outside pictures will bear a vivid impress of the sorter's zeal in the shape of a deeply indented postmark. A dozen cartes packed in this manner would cost three-halfpence or twopence for postage, as against one penny by book post.

The larger sizes should be first packed face to face and wrapped in thin paper, technically known as small hand, then placed between two pieces of thin wood (back boarding), one of which should be cut the reverse way of the grain to the other, and the whole packed in thick brown paper and securely tied. I recommend wood in preference to strawboard for two reasons: firstly, because it is cheaper; and secondly, because the contents are far less liable to damage. The reason for the wood being the two different

ways of the grain is not far to seek, as it increases the strength of the package at least four-fold. The address may be attached on a luggage label, which should also carry the stamps to defray postage.

Unmounted prints should be rolled, albumenized surface outwards, on a thin wooden roller, and enclosed in a strawboard music roll; so packed, they cannot be damaged, unless maliciously, and to prevent any intermeddling with the contents, letter post, or if the package is heavy, parcel post rates should be paid.

Negatives, opals, or opalines should be packed in a wooden box containing hay or bran—I personally prefer hay, as it keeps the contents more steadily in one position—and under no circumstances should the address be written or stamps stuck upon the box or its covering, the sudden jar of the stamping machine being often sufficient to break the negative inside, without damaging the box.

In conclusion, there is no necessity for marking the parcels as containing photographs, as the word seems to convey little or no meaning to the postal employés: in its place the word "fragile" should be substituted, it being of far greater necessity to impress upon the minds of those whom it may concern that the contents of the parcel are capable of receiving injury, than to inform them of the exact nature of those contents. While on the subject of packing, it may not perhaps be altogether out of place to mention the package of framed photographs, more especially as so many come to grief during transit. All photographs in frames should be first encased in a good covering of soft paper, and then again in thicker, and tied firmly between two boards; or, if the frame be a large one, it is sometimes advisable to pack it in a box. When such is the case, care should be taken to thoroughly fill up the interstices between the frame and the sides of the box with plenty of old waste paper, the softer the better, and, in the case of a very heavy frame, it will be found of advantage to put a couple of stout screws through the bottom of the box into the back of the frame itself, which will prevent it from moving and chipping.

PHOTOGRAPHING THE HANDS.—We owe a new and interesting application of photography to M. Bertillon, the well-known director of the Identification Department at the Paris Prefecture of Police. M. Bertillon has been devoting himself for some months to the study of the physical peculiarities engendered by the pursuit of different occupations. The police have frequently to deal with portions of bodies, and it would greatly aid their investigations to be able to determine the calling of the murdered person in each particular case. The hand is as a rule the part naturally most affected by the occupation, and M. Bertillon has taken a very large series of photographs, each one showing on a large scale the hands, on a smaller scale the whole figure of the workman at his work, so that one may see at a glance the position of the body, and which are the parts that undergo friction from the tools in use. From the hands of the navvy all the secondary lines disappear, and a peculiar callosity is developed where the spade handle rubs against the hand; the hands of tin-plate workers are covered with little crevasses produced by the acids employed; the hands of lace-makers are smooth, but they have blisters full of serum on the back and callosities on the front part of the shoulder, due to the friction of the straps of the loom; the thumb and the first joints of the index of metal-workers show very large blisters, whilst the left hand has scars made by the sharp fragments of metal. Experts in forensic medicine (Vernois among others) have before drawn attention to the subject, but this is the first time that an investigation has been carried out on a large scale, and in M. Bertillon's hands it should lead to the best results.—*Nature*.

VAPOUR DEVELOPMENT.

BY T. H. LUDERS.

THE use of vapours in picture making was one of the first methods. The polished silver plate being exposed to iodine vapour to make it sensitive, and after-exposure to that of mercury to develop the image, was the process of early days. Since then there does not seem to have been any use of vapour, except for fuming silvered albumen paper.

In the use of ammonia vapour, I have found by a few crude experiments that the modern dry plate may be developed by soaking for a minute or so in a plain solution of pyro in water, and then exposing to the fumes of ammonia, again returning it to the pyro bath, followed by the ammonia vapour, thus alternating until sufficient density is obtained. There does not seem to be much difference when the vapour is used before the bath—of course first wetting the plate—though more careful experiments may show an advantage. I find that a plain, strong pyro solution acts most rapidly, but too powerful a vapour acts too strongly, and is liable to produce red and green fog.

I think that a solution of pyro with any preservative that could be used with ammonia as the alkali, might also be used with ammonia vapour, and the alkali having kept separate from the pyro, it might be used repeatedly, as the action goes on mostly while under the influence of the vapour, and it seems to be necessary only to swab the plate with the pyro solution.

Perhaps the most valuable quality of this process is the ability it gives to localize and control development, as any part of a plate may be built up while other parts are left nearly or entirely undeveloped. By holding the plate film side down over an open bottle of ammonia, which may be warmed a little to increase the vapour, the image is slowly or rapidly developed, according to the distance above the mouth of the bottle. Four or five inches high diffuses the vapour sufficiently for uniform action over a five by seven plate, and for local action down to half-inch, according to the strength of the vapour. An open dish can be used, and probably a small hose from the mouth of the bottle would work for local development with film upwards. The above process is equally applicable to intensification with bichloride of mercury solution, and the action can be carefully watched, so that only those parts needing extra density need have full exposure to the fumes. It seems necessary that the plate should be evenly wet or damp all over to get uniform action, but I found no difficulty about that.

The advantages seem to be especially the local action without hard lines, and the pyro does not darken even in plain solution nearly so quickly as when the alkali is mixed with it, and probably by the use of a swab or brush, without immersing the plate in the solution, it could be preserved and used over and over again.—*American Journal of Photography*.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.—An International Photographic Exhibition will be held in the Central Exchange Art Gallery, Newcastle-on-Tyne, from April 18th until May 3rd. A supplementary exhibition of photographic apparatus and appliances, and photo-mechanical printing processes, will be held at the same time and place, under the auspices of Messrs. Barkas and Son, Art Gallery, Newcastle-on-Tyne, to whom application for space in this section must be made. Further information may be had from the Hon. Secs. Photographic Exhibition, Art Gallery, Grainger Street, Newcastle-on-Tyne.

THE EXHIBITION OF THE WEST LONDON PHOTOGRAPHIC SOCIETY.

LAST Friday and Saturday the Exhibition of the West London Photographic Society was open at the Addison Hall, Addison Road, near Uxbridge Road railway station, and was of an interesting description. This Society of professionals and amateurs was founded in December, 1888, and principally by Messrs. G. F. Blackmore, T. B. March, L. Bennett, and J. A. Hodges. A preliminary meeting was held at Chiswick, and the subsequent meetings at Addison Hall. A new president is appointed for each year, and the retiring president is not eligible for re-election. The first president was Mr. William England, and the present president is Mr. Charles Bilton, B.A. The Society has about seventy members.

Last Saturday evening, Mr. Chang, of the Chinese Embassy, took four flash-light pictures of the assembled company. On the platform he had two small cameras, one on a stand, the other attached to the back of a chair by a camera clip. The top of a step ladder on the platform he covered with tufts of gun-cotton, and on this explosive area of nearly a foot square he distributed a considerable quantity of magnesium powder out of a bottle; the flash was necessarily of a magnificent description, and left behind some little residual bonfires of blazing magnesium.

THE JUDGES' REPORT.

We, the undersigned, beg to state that our awards in the 1890 Photographic Competition between members of the West London Photographic Society are as follows:—

Division I.—Class 1. Frame of six Dutch landscapes (first medal), W. L. Coolls; set of three, "Eventide," "Romney Lock," "Silver Lining" (second medal), G. F. Blackmore; set of three, "Conway Quay," "A Quiet Pool," "On the River Ogwen" (third medal), J. A. Hodges. This is a very well contested class, and we have had pleasure in awarding some of the medals withheld in the other classes. Amongst other pictures in this class, we would draw attention to "A Grey Morning, Dovedale," H. Selby; "Blowing up for Rain," J. Wilson; "A Coming Storm," C. Garner Richardson. Class 2. One photo of set of three, "Bridge and Stream," Walter L. Coolls, medal. Some discussion took place as to any award at all being given in this class. Class 3. Set of three, "Conway Castle," "Reception Room and Refectory," Plas Mawr (medal), J. A. Hodges. A very admirable series. Class 4. Exeter Cath. Choir (medal), Chas. Whiting. Class 5. Whilst withholding any award in this class, we would indicate that the "Sister and Brother," S. S. Chang, is considerably the best exhibit in the class. Class 6. No award. Class 7, 8, 9, 10. No award. Note.—In Class 8, "Greywell Tunnell" and "In Cassiobury Park," Dr. F. H. Low, show good technical work; "Kew Bridge," Dr. F. H. Low, being the best pictorially, though not held of sufficient merit. In Class 9, the only distinctive genre picture is "Spinning the Top," by J. A. Hodges; but it is rather a painting than a photograph. Of the rest, we would refer to "Watching the Amateur," by L. C. Bennett. *Lantern Slides.*—Class 12 (landscape), no award; the set marked "Bennett" is noted as the best. Class 13 (marine). Chas. Whiting, medal. Class 14 (architecture), Chas. Whiting, medal. Class 15 (instantaneous), withheld. Class 16. The judges prefer to leave this exhibit to a judge with the requisite technical attainments.

Signed, G. DAVISON, F. P. CEMBRANO, F. M. SKIPWORTH.

The annual *conversazione* of the Society was held at the Exhibition last Friday.

Mr. CHAS. BILTON congratulated the Society upon the Exhibition; he also congratulated those members who had been fortunate enough to gain medals, at the same time reminding those who had not been so successful that their failure on that occasion should stimulate them to greater efforts in the future. He then read the report of the judges, and informed the members that the names of the competitors were not disclosed to the judges until after the awards had been made.

The medals were then presented to the successful competitors by the president.

Dr. F. HARRISON LOW, in proposing a vote of thanks to the judges, remarked that curiously enough the awards upon the present occasion seemed to have met with universal approbation.

The motion having been seconded by Mr. Bennett, and adopted,

Mr. DAVISON, responding on behalf of the judges, said that although it was generally held that the task a judge had to perform was a thankless one, yet he was glad to find, from the manner in which the awards had been received, that such was not the case invariably. There was, however, a thought far back in the inner recesses of his own mind that there might be some dissatisfaction at the number of medals withheld. Although he did not then propose to justify the circumstance, he had not the slightest doubt but that the exhibitors would, on calm reflection, feel convinced that the action of the judges was justifiable. They went through their task with great care, going over some pictures again and again, and when a discussion arose as to whether a medal should be awarded or not, a decision was arrived at by a fair system of give and take. The Society was to be congratulated on the appearance of Class 1, landscape, half-plate, and under. Considering the size of the collection as a whole he did not think he had ever seen a better class. Although they had given two extra awards in that class, there were still three other exhibits well worthy of mention; they were photographs which would bear examination, and although, perhaps, defective in some respects compared with the winning pictures, yet still possessed considerable merit; not merely technical merit, but something approaching "the pictorial and complete." The architectural class, half-plate and under, was also an exceptionally good one on account of the excellence of some of the exhibits, among which he would refer specially to Conway Castle, Refectory and Reception Room, and Plas Mawr, a set of three platinotypes by Mr. Hodges charming in colour, well chosen and beautiful in subject, and technically of great perfection. Also in Class 1, he would specially refer to the three medalled pictures by Mr. Blackmore, which were of high artistic merit, and speaking for himself he would say he hoped to see much more work from Mr. Blackmore at future exhibitions.

The members and their friends then inspected the pictures and lantern slides exhibited. Light refreshments were provided by the president, and the tables were presided over by Mrs. Low and Mrs. Hodges. A musical programme, in which Messrs. M. Morgan, H. Selby, Syckelmore, and Pilgrim took part, contributed to the pleasure of the evening.

The next meeting takes place on Friday, 24th June, when an adjourned discussion on "Hand-Cameras" will be concluded. The competition slides will also be shown by means of the lantern.

A TENACIOUS SOLDER.—An account is given in the *Berliner* of a soft alloy which adheres so firmly to metallic, glass, and porcelain surfaces that it can be used as a solder, and which, in fact, is valuable when the articles to be soldered are of such nature that they cannot bear a very high degree of temperature, the composition consisting of finely pulverized copper dust, which is obtained by shaking a solution of sulphate of copper with granulated zinc. The temperature of the solution rises considerably, and the metallic copper is precipitated in the form of a brownish powder—twenty, thirty, or thirty-six parts of this copper dust, according to the hardness desired, being placed in a cast iron or porcelain-lined mortar, and well mixed with some sulphuric acid having a specific gravity of 1·85. To the paste thus formed are added seventy parts by weight of mercury, with constant stirring, and when thus thoroughly mixed, the amalgam is rinsed in warm water to remove the acid, and then set aside to cool; in ten or twelve hours it is hard enough to scratch tin. On being used, it is heated to a temperature of 375 degrees centigrade, and when kneaded in an iron mortar becomes as soft as wax. In this ductile state it can be spread upon any surface, to which, as it cools and hardens, it adheres with great tenacity.

Specifications Published.

494.—*January 10th*, 1889. "Photographic Apparatus." CHARLES WINTER, London, Manager to Messrs. Mawson and Swan, 33, Soho Square, London.

The principal object of this invention is to provide a photographic apparatus in which a number of plates or sensitized surfaces are placed in succession in position for receiving the photographic image, and are afterwards returned to a receptacle, in which they are retained without opening the camera or exposing the plates or surfaces to light otherwise than in taking the picture.

According to my invention, as applied to photographic purposes, I provide a suitable closed box or camera in which there is a lens provided with a shutter. Inside this camera, opposite the lens, is a rotary device, into which the sensitized plates or surfaces are introduced one after the other from a box, and from which rotary device they are liberated and received into another box after the picture has been taken thereon. This rotary device constitutes the "slide" of the camera, and is hereinafter referred to as the rotary slide.

The said rotary slide has one end of its axis projecting from the camera, and is provided with a milled head or other means for giving rotary movement to it. The box which contains the unexposed sensitized plates or surfaces, and the box into which the plates or surfaces are received after exposure, are situated inside the camera, preferably occupying the space above and below the lens.

The box from which the plates are supplied to the rotary slide is provided with means by which, when the rotary slide is operated, the undermost of the plates is moved from off a support and falls into a position before a slot in the box, through which the plate can fall or be moved into grooves or guides for receiving it in the rotary slide. These means may consist of a piece which is operated by a projection or recess on the rotary slide, which projection or recess, when movement is given to the slide, causes the said piece to move inwards a pusher bar or the like, which dislodges the undermost plate, and causes it to take up a position in which it can leave the box, and be received in the grooves or guides for it in the rotary slide. A rotary movement is then given to the slide, and thereby the sensitized side of the plate is presented in position to receive the photographic image, and when the shutter is opened the plate or sensitized surface receives the said image; and when, thereafter, the shutter is closed, the rotary slide has a further movement of rotation given to it, which brings the guides or grooves containing the plate into line with the box which is to receive the exposed plates. This preferably consists of a box with an opening in it to admit the plate, and provided with pushers, which are operated by the rotary slide, to press the plate into the box until it is received and retained under retainers, when the pushers return to thir normal position. It is preferred to make the rotary slide with two sets of grooves or guides, so that when one is in line with the box from which the unexposed plates are to be discharged, the other is in line with the box into which the exposed plates are to be received. The plates may be moved from and into the boxes respectively by being caused to fall by gravity, or there may be an endless band or carrier, or other device for the purpose, operated by the rotary slide. The shutter may be arranged to be set either by hand or by a movement derived from the rotary slide, the movement liberating the shutter for the exposure or uncovering of the lens being actuated by hand. Thus, in the arrangement wherein there are two receptacles for plates in the rotary slide, the said slide is brought into a position to receive a plate from the box containing the unexposed plates, and in this movement a plate is brought into position for passing from the box into the rotary slide as aforesaid. When the plate is received into the rotary slide, a quarter turn is given to the said slide, and the plate is then in position for exposure. After exposure a further quarter turn is given to the rotary slide, when the plate which has been exposed is brought into line with the box for receiving the exposed plates, the other guides in the slide then being in position for receiving a fresh unexposed plate, and so on. The axis of the rotary slide, or the head or handle by which it is operated, may be provided with a catch or spring bolt engaging with retainers, so that the slide is kept in proper position, the positions being suitably marked outside the camera, so that the position of the rotary slide can be readily ascertained. The portion of the said slide upon which the plates rest when in position for exposure are made movable, and are operated by a cam or other suitable device, so as to move free of the plate when it is to leave the rotary slide.

Although I have mentioned plates, the invention is of course not limited to the glass plates known as "plates" in photography, as other sensitized surfaces may be used.

504.—*January 10th*, 1889. "Apparatus for the Display of Illuminated Transparencies." CHARLES NORMAN MORRIS, of 36, Red Lion Street, Holborn, London, W.C., Designer and Draughtsman.

This invention has reference to an improved means for the display of illuminated transparencies, such, for instance, as theatrical notices, scenes from plays which are, at the time, being performed, trade notices, and the like, as also for recreational and other purposes.

The device or appliance, according to the invention, comprises an enclosing case of any suitable size and material to serve as a lantern, within which is arranged a gas burner, oil lamp, or other means of illumination, a suitable reflector being provided for the purpose of concentrating the light. In the roof of the lantern, immediately above the illuminating medium, is suspended a wheel formed of a number of vanes or wings disposed within a ring or hoop, which wheel is caused to rotate by an upward current of air set up by the heat of the illuminant. Upon two sides of the hoop above referred to are arranged segmental racks which engage with pinions formed upon two spindles carrying rollers for the purpose hereinafter to be described. During the rotation of the wheel above referred to, the spindles rotate therewith until the last tooth of the first segmental rack has passed beyond the pinion, when both pinions stop; the wheel, however, continues to rotate until the second segment becomes engaged with the pinion. During the interval when the first segment leaves the pinion, and the engagement therewith of the second pinion, the tendency of the revolving wheel would be to rotate with greater speed; this, however, is checked by a spring which comes into action at the proper moment, and, pressing upon the rotating wheel, regulates the speed thereof.

Upon the rollers, above referred to secured to the spindles, is mounted a web or band of paper or cloth, rendered transparent by any of the well-known methods, upon which is

printed, painted, or otherwise delineated, facsimiles of theatrical notices, scenes from plays or operas, trade announcements, posters, and the like ; or, if the improved apparatus is to be employed for recreational purposes, I may cause to be painted, lithographed, or otherwise produced upon said web or band, landscapes, seascapes, or other scenes of interest, such as illustrations of domestic, political, historic, and other episodes. In the representation of theatrical notices, I prefer to surround such notice with a border, illustrating some of the characters of the cast, as also scenes emblematic of the play ; or, if desired, said border may be simply ornamental, either mediæval, antique, modern, or in any other attractive style.

The web or band above mentioned being fixed to the rollers is, when the revolving wheel is in motion, rolled upon one roller and unrolled from the other, each scene dwelling a limited time determined by the distance between the two segmental racks upon the wheel aforesaid, and the speed at which the wheel revolves. Suitable guide-pulleys are employed to keep the web or band from sagging whilst the latter is moving.

When the winding of the web or band upon either of the rollers has been completed, the mechanism will cease to operate, but the current of air impinging against the wheel will cause the latter to move to the opposite side, where the segmental racks would engage with the pinion of the roller from which the web or band had been previously unrolled, setting it in motion and thus causing the web or band to be rewound upon the last-referred to roller. In the employment of lanterns for the display of large transparencies, wherein greater power would be required than in the case of small lanterns, is employed a hot air chamber, by means of which may be obtained any degree of pressure upon the wheel suited to the size and the special requirements of the lantern ; but the inventor does not confine himself to the automatic working of the mechanism by the pressure of a current of hot air, as under some circumstances, the same purpose can be effected by mechanical means or other source of power.

With a view to the protection of the transparency from injury from the heat of the illuminant, there may be interposed between a sheet of thick, clear glass, and in order to guard the web or band from becoming wet from rain when the appliance is employed in the open air, the whole is covered with a sheet of glass fitted into a suitable frame, ornamental or otherwise, as may be desired, the two sheets of glass forming a chamber between which the transparency is caused to move.

17,436.—*November 2nd*, 1889. "Discolouring Tannic Acid Solutions." HERBERT JOHN HADDAN, of the firm of Herbert and Co., Patent Agents, of 18, Buckingham Street, Strand, London, Civil Engineer. A communication from JULES LANDINI, of Grimm No. 6, Hamburg, in the empire of Germany, Manufacturer.

The object of this invention is to discolour solutions derived from wood, plants, and leaves used in tanneries, in order to be able to obtain transparent and clear liquids. The principal part of the invention consists in treating such solutions with nitrate of lead, and subsequently with the addition of alum and borax. The solutions, according to their respective strength, are mixed with suitable quantities of nitrate of lead, then heated or boiled until a complete discolouring has taken place. During this process samples are withdrawn from time to time, and the addition of nitrate of lead is increased until the discolouring is completed.

As an example of the practice of this process it may be mentioned that new decoctions of tannic acids are treated with about 2 kilogrammes of nitrate of lead for each thousand litres of liquid.

It is convenient to use a diffusion battery during treatment of the tannic acids into which the solution is introduced ; then make the above-named addition of nitrate of lead, and boil the mixture for some 25 minutes ; then decant the solution into a vessel or drum provided with some stirring device into which steam is admitted of about $\frac{1}{2}$ atmospheric pressure. After stirring for about 20 minutes a sample is withdrawn and a further supply of nitrate of lead is added should this be found necessary, and the stirring continued until the desired degree is attained. The solution is now withdrawn, cooled down, neutralized, and filtered.

17,708. *November 6th*, 1889. "Photographic Cameras." THOMAS RUDOLPH DALLMEYER, of 25, Newman Street, Oxford Street, London, Optician, and FRANCIS BEAUCHAMP, of Hope Cottage, Whalebone Lane, Chadwell, Romford, Essex, Engineer.

The inventors claim :—

1. A photographic camera, the extensible portion of which is built up upon a wire support.

2. The extensible portion of a camera built up upon a continuous wire support.

3. The support formed of a series of sections or frames.

4. The improvements relating to the manufacture of the extensible portions of cameras described and illustrated.

Correspondence.

REPRODUCTION AND COPYRIGHT.

SIR,—Mr. Ralph W. Robinson's letter has elicited replies which seem to establish two new facts hitherto, I fancy, unsuspected by the majority of photographers, yet of great value to them.

In the first place, your "Notes" show, what few seem to have known, that the right to reproduce a photograph by way of engraving for the use of illustrated papers is worth a certain sum of money, and that one firm, at least, demands and obtains ten shillings for the right to reproduce a portrait in *one* paper, and that they demand a further fee if other use is to be made of the block. Hitherto, the newspapers have patronisingly and doubtfully repaid the photographer by mentioning his name. This concession had to be forced from the papers.

The other fact is of still greater importance. It has been the opinion of the photographic authorities from the beginning, and stated nearly every week in answers to correspondents in one or other of the photographic journals, that if a print of a photograph was sold before it was registered, the copyright was lost. Nobody seems to have doubted the verdict until Mr. Robinson asked the question, which has drawn an authoritative legal reply from Mr. C. Fleetwood Pritchard, who, I believe, is not only a barrister, but also an excellent amateur photographer. He shows us that our trusted leaders have misled us for once, and that a photograph can be effectually registered at any time, with the drawback, however, that the registration is not retrospective, and cannot protect from piracies that have preceded the act of registration.

The photographic world is a gainer for this addition to our stock of knowledge, and it is to be hoped that now photographers know there is a money value in the right to reproduce, they will insist upon getting it, always remembering that they can protect their property *for the future* by registering at any time.

A. D. L.

SIR,—In my letter under the above heading I perhaps dwelt too exclusively on the case of photographs "which are intended to be pictures," as it is from that point of view the subject of right to reproduce has chiefly affected me. However, in the case of a great many, probably the majority of portraits used for reproduction in newspapers, the principle is the same.

You say that the cases you have in your mind are those in which the photographer has already been paid for making the negative. In that case the photographer has no copyright, and therefore no right himself to reproduce, or to give permission to others to do so. The necessary permission in this case, as I understand it, can only be obtained from the sitter. In the majority of cases the sitter has been invited to sit, and the portrait has been produced simply for publication purposes, and in this case it is only reasonable that the photographer should exact a fee from anyone who wishes to use the portrait for reproduction.

The principle is the same as charging two shillings or so for

a published cabinet portrait. It surely would not be contended that it would be for the good of the profession in the long run to publish cabinets at threepence each; yet a photographer cannot have any better advertisement than the spreading abroad of good work bearing his name. It appears to me that any of those means of advertising which tend to cheapen photography in the eyes of the public are detrimental to the best interests of the profession. RALPH W. ROBINSON.

FORMATION OF A LANTERN CLUB.

SIR,—Will you permit me to call the attention of your readers to a step which I trust now to see taken, viz., to bring together, either by means of a club or association, in a practical form, those who are interested in the work of photographic optical lanterns.

I will not here detail the advantages that may possibly accrue from such an association, except to suggest, (*a*) the development and improvement of the lantern itself, (*b*) to help in popularizing it generally, (*c*) to enable those who are fond of so delightful and scientific an amusement to become known to each other, and thus develop their common pursuit, (*d*) to hold in London and the country periodical exhibitions, (*e*) to facilitate the interchange of photographic slides, and (*f*) generally to promote lantern work.

The basis of such an association and its rules remain to be formulated. Meanwhile, I wish to put plainly through your columns a very pointed but respectful request, viz., will all those who are favourable to the idea forward to me at 46, Chesilton Road, Munster Park, S.W., or to the Hon. Slingsby Bethel, at Chelsea Lodge, Chelsea Embankment, their names and addresses, in order that they may be invited to a meeting, or informed of any proceedings that may be taken.

46, *Chesilton Road, Fulham, S.W.* T. H. HOLDING.

ISOCHROMATIC PHOTOGRAPHY AT THE PHOTOGRAPHIC SOCIETY OF FRANCE.

SIR,—Will you kindly allow us space for a few words in protest against M. Leon Vidal's unjust criticism of the prints from negatives on isochromatic and ordinary plates, which, by invitation of the president, M. Davanne, we recently presented to the French Photographic Society.

M. Vidal says in his report, which appears in the last number of the NEWS, that the photographs were "defective as examples," those on the ordinary plates being "taken in a bad light," while those on the isochromatic plates "were more directly lighted." As a matter of fact, both negatives in every case were taken under precisely the same conditions, as could easily be seen by the most cursory examination of those parts where the object was of a neutral tint, and which, not being affected by colour-sensitiveness, were rendered of equal value in both negatives.

We can quite understand that anyone not conversant with the subject would, at first sight, imagine that the great difference shown in some of the proofs could not be produced by colour-sensitiveness alone; but surely M. Vidal should know better. His insinuation that the negatives were dodged in the lighting does not do him credit, and would seem to show that he is ignorant of the progress which has been made in isochromatic photography.

We shall only be too pleased to afford M Vidal the means of testing the matter to his own satisfaction, should he desire further investigation. We are sending to the President of the French Society conclusive evidence that the specimens shown by us were not unfairly manipulated in any way, and we trust that M. Vidal will avail himself of the opportunity of making us the *amende honorable*.

It is unfortunate that as soon as any real improvement in photography is introduced, there are always to be found individuals who, failing to understand the matter by their own light and knowledge, are ready at once to say, "It is not true." These same persons a little later, or, as in this instance, almost in the same breath, rarely fail to raise the cry, "It is not new, we knew it all along."

We opine that M. Vidal will find few to agree with him that a process which has been worked out with infinite pains and at great cost by an individual should belong to the community as soon as it is found to be useful. If this principle were carried out, it would constitute the greatest barrier to progress which it is possible to conceive. It is precisely to prevent such a result, and to encourage research, that the patent laws have been adopted in all civilised countries. In the present instance it is extremely probable, except for the wisdom of the legislature in recognizing and protecting the commercial rights of inventors, which M. Vidal so coolly ignores, that isochromatic or colour-sensitive photography would now be numbered among the lost or forgotten processes of the art.

At the expiration of the existing patent, the process will be free to all the world; until that time arrives we are prepared to defend our rights in this country by all legal means, and at any cost. B. J. EDWARDS & Co.

The Grove, Hackney, London, January 13th.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

AT the meeting of this Society, held on the 14th inst., the President, Mr. JAMES GLAISHER, F.R.S., occupied the chair.

A paper was read by Mr. Chapman Jones, F.I.C., F.C.S., "On Control in the Density of Negatives," in the course of which the author stated that in consideration of the difficulty of exactly deciding upon the density of a negative whilst developing, he considered it best to keep the intensity rather below than above what was finally required, and complete that part of the work in a good light after fixation. Then, as to the process to be used for giving intensity, it was better to take for the normal process one that increased the deposit in proportion to the silver already forming the image. There were processes that did not do this, and for special cases they might be preferable; but, starting with the normal requirements, he had found it most satisfactorily fulfilled by the method of using solution of bichloride of mercury, followed by one of ferrous oxalate. The solutions he used were:—First, a saturated solution of bichloride of mercury to which hydrochloric acid was added in the proportion of three minims to every two ounces of solution. After bleaching with this solution, the negative must be thoroughly washed—an operation for which an hour to an hour and a half with frequent changes of water was not too long. It was then treated with a ferrous oxalate developer composed of one part of saturated solution of sulphate of iron mixed with six parts of saturated solution of oxalate of potash. This developer was made slightly acid with oxalic acid—if considerably acid it was much slower in its action. A process that had been much recommended—that with mercury, followed by solution of sulphite of soda—he could not advise, except when only a very limited amount of intensity was required. It might, however, be used as a starting point, and the negative would be found to be in as good a condition for taking other methods afterwards as if it had not been used. The actual constitution of the image after the use of sulphite had, he believed, not hitherto been shown. He had found that the silver and mercury were both of them dissolved to the extent of one-half by the sulphite, but yet the resulting image was one which generally gave more density than at first. A claim that had been made for this method, that a plate might be treated repeatedly with the solutions, gaining intensity each time, was one that his experiments did not support. The process with mercury and oxalate he could recommend as being clean, having no tendency to frill, even with repeated operations; having freedom from choking up of the shadows, and preserving the gradation of the lights.

Mr. W. E. DEBENHAM considered it very useful to have the *rationale* of a process worked out, as had been done by Mr. Chapman Jones, with the mercury and sulphite process. He had never used that process, except experimentally, as the intensifying power was so limited, and there were others that he considered better. It had been stated that the sulphite pro-

ess might be used to start with, and, if found insufficient, other processes might be employed without the previous use of the sulphite being in any way injurious. As, however, it had been shown that half the original silver had been dissolved away in the sulphite, he put it as a question whether that did not leave the plate in a more unfavourable condition as a basis for intensifying on, than if the whole of the silver were present.

Capt. ABNEY confirmed what Mr. Debenham had said as to the inutility of the sulphite method of intensifying. Very foolish things had been written about intensifying processes, this with sulphite amongst others; and he thanked Mr. Chapman Jones for working out the *rationale* of it. His own predilection was for the cyanide of silver intensifying process, next to which he liked the one with mercury, followed by ferrous oxalate, as recommended in the paper.

Mr. ATKINSON asked Captain Abney whether he thought as perfect gradation was obtainable with the cyanide of silver process as with the ferrous oxalate following the mercury.

Capt. ABNEY replied that it was, and continued, that there was a great convenience in the process, in the facility with which too great intensity could be let down just to the desired point.

Mr. CHAPMAN JONES replied that what he meant by saying that there was no harm in beginning with the sulphite process, was that the image left was just as amenable to intensifying by other processes as the original plate had been. Half the silver was gone, certainly, but the mercury which had replaced it was in the condition to form a basis for intensifying by any known method.

Sir DAVID SALOMONS then read a paper on "The distance beyond which all objects will be in focus with any given lens." He had constructed a table, taking as a basis that any object was in focus when the circle of confusion did not exceed the $\frac{1}{150}$ of an inch. French photographers had adopted a different standard, and took about the $\frac{1}{250}$ of an inch as the standard of definition; but, he said, we cannot have detective cameras if the French measure is adopted.

Mr. DEBENHAM was afraid that the paper might tend to perpetuate a fallacy about lenses which some photographers appeared to entertain. He had even read in the photographic papers about the advantage of a lens with a fixed focus—an absurdity, as no lens could possibly have a fixed focus. The assumption on which the paper was based, that a lens was in focus when there was a circle of confusion of $\frac{1}{100}$ of an inch, was an assumption and not a fact. Taking the example worked out in the paper of a lens of 10-inch focus, it came out that an object which, to be in true focus, required racking in the instrument the $\frac{1}{4}$ of an inch, was still in focus without that adjustment—a proposition which he thought most practical photographers would recognize as not being true, even with the diaphragm of *f* 12 mentioned. As to the statement that if the French measure of permissible confusion was adopted, detective cameras could not be used, that would depend upon the question of the length of focus of the lens. A lens, say, of 3 or 4 inches focus might, while keeping to the French standard, work as rapidly and with as little proportionate confusion for equi-distant objects as the one of 10-inch focus supposed by the paper when giving confusion to the $\frac{1}{100}$ of an inch. Curvature of field such as generally, if not always, existed in detective lenses, was another element in connection with the amount of loss of definition in objects at varying and at equal distances—a loss of definition which might considerably exceed that due to the difference of distance referred to in the paper.

Mr. T. R. DALLMEYER said that the calculation made by Sir David Salomons formed a continuation of those made by his late father, and upon the same basis. If the $\frac{1}{100}$th of an inch was considered too much confusion to be tolerated, calculations might be made adapted to the French or any other standard.

A paper from Mr. W. K. Burton upon "Eikonogen as a Developer in Practice" was read in summary by Mr. Chapman Jones. The writer said that he had found the keeping quality of a plain eikonogen solution to be less than that of a plain pyro solution, but when mixed with sulphite of soda and an alkali the case was reversed. He found that an image developed with eikonogen came up more slowly than when pyro was used, but that eventually more detail was obtainable, probably 25 to 30 per cent., and that might be considered as so much gain in the exposure.

Mr. WARNERKE thought to get the best results, eikonogen and pyro must be treated differently. He found that he got the best effect with caustic alkali when using eikonogen, and that then it was better than pyro. He used:—

Water	100 parts
Sulphite of soda	10 ,,
Eikonogen	20 ,,
Caustic potash	20 ,,

He made up the solution with boiling water, not merely for ease in dissolving, but because the air was thereby removed. This strong solution he diluted with from three to ten parts of water, the former proportion when great vigour was required, and the latter for softer pictures.

Mr. WOLLASTON had not succeeded in getting such intensity with eikonogen as was wanted when copying line work, and enquired whether Mr. Warnerke had not found this to be the case.

Mr. WARNERKE had found the contrary.

Mr. LAWRENCE remarked upon the great strength of Mr. Warnerke's solution, and said that when he had made a solution of only sixteen grains to the ounce, some of the eikonogen had afterwards crystallised out.

Mr. DEBENHAM said that it was understood that eikonogen dissolved much more freely in alkaline solution, and that Mr. Warnerke's formula fulfilled this condition.

It was mentioned that nominations for the approaching election of members of council must be sent in by the 21st inst. The auditors for the year were appointed—Messrs. Seamell and Samuel; and scrutineers of voting papers, Messrs. Seamell, Freshwater, Chas. Sawyer, and Atkinson.

Messrs. H. G. Sheppard, E. E. Corke, and Rajmongee Chuer were elected members of the Society.

CAMERA CLUB.

January 9th.—Bedford Street, Strand, London; Sir GEORGE PRESCOTT, Bart., in the chair.

Mr. W. H. WALKER, who attended to read a paper about the new rollable celluloid film, said that his memoir was something like Artemus Ward's lecture on "Nineveh," which contained nothing about Nineveh in it. He then went into the history of film photography and roller slides, and when speaking of stripping films, said that 25,000 negatives per week were developed and stripped for those who had exposed them, by the Eastman Company, and that ninety per cent. of these were fairly good, if not superior, printing negatives. Those who failed with the stripping-films were persons who did not adhere closely to the instructions issued by the Company, or who, in some cases, used inferior materials, such as bad india-rubber solution. Sheets cut from the new rollable film are not recommended, since no known device will hold them perfectly flat in the focal plane; they should be used in a proper roller slide. The film will not endure great tension in the direction of its length, and when old Eastman roller slides give too great tension for use with them, that tension can readily be reduced by the possessor of the slide by simple means which the speaker described. The film should not curl in the developing solution, but to keep it quite flat, the Eastman Company had devised a new developing dish. The quantity of liquid required to develop a negative was then surprisingly small; still, he doubted whether those dishes would be necessary. To dry the negative, it should be pinned to a board by one or more corners; should it curl, it should, when dry, be wound in the opposite direction round a cylinder. He did not recommend the use of glycerine in this country to reduce curling, but in the dry atmosphere of some parts of the United States, where the furniture can be heard snapping and cracking like pistol shots, the conditions are different. The films are not yet upon the market in this country, but the Company is pushing forward its English factories with all speed. The speaker then exhibited specimens of the new film, coated and uncoated, also some film

negatives; he likewise exhibited various forms of old and new roller slides. He then stated that the new film had some peculiarities which, so far as he knew, were not understood. It sometimes presented markings like branches springing from a central point, and they seemed to be due to some electrical condition; such markings were rare. Also, users would occasionally find what appeared to be a lap or joint of two lengths of the film; it was not really a lap, but was due to the method of manufacture, and Mr. Eastman believed that this drawback would be corrected in the near future.

Mr. FRANCIS COBB wished that Mr. Walker had exhibited in its roller slide a film upon which 10 by 8 inch negatives could be taken; he had never seen a film of that size which, between the rollers, would keep perfectly flat in the focal plane.

Dr. LINDSAY JOHNSON had experienced the want of some very perfect transparent celluloid to mitigate the affliction known as conical cornea, a defect which prevents the sufferer from seeing anything clearly. A properly shaped piece of transparent celluloid laid upon the eye with a drop of oil between was of considerable advantage in such cases, and helped to throw a sharper image on the retina. With an English and French chemist he had been working at the improvement of celluloid, and had succeeded in producing specimens more perfect than that composing the films before them.

Mr. D. P. RODGERS had been taking photographs upon the new film, and found it fairly strong. Out of eleven negatives, he had found the branch-like markings in three. He was not a shareholder in the Company, but he thought that they all ought to be very grateful for what the Eastman Co. had done, and he would prefer to have three faulty negatives out of twelve, rather than to undertake the manipulation of stripping-films.

Mr. E. R. SHIPTON had found that the film, when of whole-plate size, did not lie quite flat in the slide; but the general results were very favourable as compared with the use of glass plates. Could not the Company mark where the laps would come? He also was not a shareholder in the Eastman Company, but was very grateful for what it had done.

Mr. H. STURMEY had been experimenting with a 10 by 8 roll, and had found no unevenness; his difficulty was to wind the film straightly off.

A member remarked that if the films were left to dry for twelve hours—that is to say, until they were far beyond the stage of being apparently dry—they did not curl. He thought that the branch-like markings did not seem to appear when the films were exposed upon wet days.

Dr. C. S. PATTERSON wished to know whether the films would preserve their flexibility when kept for a long time upon the rolls.

Mr. LYONEL CLARK said that the branch-like markings differ in appearance from what might be expected in stress-marks, and that they are distinctly in the film itself, and not in the celluloid. He thought that they were produced absolutely by an electrical discharge. When a celluloid comb is drawn rapidly through the hair, in dry weather, electrical sparks are sometimes produced. The electricity is not present at the outset either in the hair or in the comb, but is the result of friction; in fact, the mechanical energy put forth by the muscles is transformed into electrical energy. To avoid the production of electricity it is well, therefore, to exercise as little mechanical energy as possible, so before exposing the last half of the length of celluloid in his roller slide, he took care to unwind that portion with the greatest slowness; the result was, that the last negatives taken on his length of celluloid were almost entirely free from the branch-like markings. He thought that many photographers would like to expose the new film in double dark slides as usual, rather than to use a roller slide.

Mr. A. PRINGLE condemned the use of glycerine when developing negatives in this climate. Mr. Clark had the advantage of him in being able to perform the comb experiment. He thought that photographers did not want miniature thunderstorms inside their roll-holders.

Mr. S. BOURNE thought that the markings might be due to a kind of fungus in the film.

Mr. WALKER, in the course of his reply, said that Mr. Eastman did not at present intend to put larger films than 12 by 10 inches upon the rollers; he (Mr. Walker) did not know wherefore. Mr. Eastman and those working with him believed that they had so far surmounted all difficulties as to have reached a point where they see that they will be able to turn out a perfect film. Personally, he (Mr. Walker) had had nothing to do with the invention of the film; it was the outcome of the investigations of Mr. Eastman and Mr. Reisenbach. He believed that the films were permanently flexible, for otherwise Mr. Eastman—who had been working at them for a year—would not have put them on the market. He thought the branch-like markings to be electrical, and that they could be avoided by some changes in the mode of manufacture. He believed these films to mark the dawn of a new era in photography, the end whereof no man could see.

The CHAIRMAN thought that the invention would be of the greatest possible use to photographers in the future.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting on the 2nd instant Mr. W. E. DEBENHAM occupied the chair.

Mr. A. COWAN showed a mixture of powdered eikonogen and sulphite of soda that had turned quite black in colour. The powder contained the following proportions: eikonogen 10 grains, sulphite of soda 40 grains. After mixing, the powder was put dry into a stoppered bottle. The next day it had turned quite black. Mr. Cowan said this tended to confirm the opinion of many photographers who questioned the preservative nature of the sulphite. On another occasion a mixture of eikonogen, sulphite, and an alkali and sugar in powder the next day turned to a pasty mass.

Mr. A. HADDON criticised the opinions expressed at the last meeting as to the cause of the cloudiness on the inside of the cover glass of a transparency, more especially the statement that it was due to the mercury left in film from toning attacking the lead in the glass. He said if such were the case it was a fact unknown to chemists and physicists. In his own experience he had never seen any erosion produced from mercury when in contact with glass. Mercury was in constant contact with the glass tubes of thermometers and barometers, and as far as he knew no case was known of its having caused any erosion of the glass. In his opinion the injury to the slide was caused by heat acting upon aqueous vapour imprisoned between the two glasses. He was cognisant of three instances where heat had caused a frostiness similar to that produced on the slide in question. In one case it appeared in a retort after heating over a spirit lamp (retort shown); in another a similar effect was produced in placing a chimney glass over a burner; and in the third instance a bottle, after washing, was placed in an oven to dry. The inner surface of the bottle became curled and wrinkled. He believed the cover glass referred to contained no lead at all. Glass makers would not employ expensive ingredients in cheap sheet or bottle glass. Mr. Haddon then read an extract from Watts Dictionary in support of his statements, and, as a farther proof, he held the neck of the retort already referred to over a spirit lamp, which at once caused a frosted appearance.

Mr. P. EVERETT asked how Mr. Haddon accounted for the cleanness of the cover-glass of the transparency in contact with the mask. Why was not the inside attacked equally all over?

Mr. HADDON said in all probability the paper mask had, by absorbing the aqueous vapour, prevented the heat to which the slide had been subjected in India having the same effect upon the glass.

A Member asked why the outside of the cover-glass had not equally been affected by heat and moisture.

Mr. HADDON said these conditions did not apply equally to the inside and outside of the slide. Heat and moisture were never going on simultaneously on the outside of the glass.

The HON. SEC. believed the binding of a great many slides was done before they ware thoroughly dry. In his own practice, he almost baked his slides before binding.

Mr. T. E. FRESHWATER had seen many field-glasses returned from India with the large lens attached inside, but not on the outside.

Mr. J. B. B WELLINGTON showed two sets of transparencies, the exposure of the plates in each set being 20, 40, 60, and 80 seconds respectively. In one case the plates were taken out of the dish immediately the development was complete, showing a range of tone from a warm colour to a black. The other set was left in the developer until the last one was developed; these developed all one colour.

The CHAIRMAN said this guide proved his contention, that a warm colour was due to an early stage of development.

Mr. WELLINGTON also exhibited a cover-glass of a slide that had been in contact for some time. It showed, when breathed upon, the opening of the mask very clearly. No amount of rubbing or polishing seemed to alter this condition of the glass

---

At the meeting on the 9th inst. Mr. L. MEDLAND occupied the chair.

Mr. CONRAD BECK showed two lenses—one having brass mounts, the other aluminium; the latter being about half the weight of the brass-mounted lens. Mr. Beck said originally aluminium was expensive, but was now much reduced in price. Mr. Beck also exhibited a camera for general out-door work. Two advantages were claimed for this camera—very great rigidity, and simplicity in setting up, two motions only being necessary for this purpose. The front of the camera is fixed, the focussing being accomplished by a rack-and-pinion adjustment to the back.

The CHAIRMAN showed a negative having a curious geometric marking over the whole of the surface of the film. The plate after development was bleached with bichloride of mercury and intensified with ammonia, when the markings appeared. The plate had been thoroughly washed several times without producing any effect upon the markings.

Mr. T. E. FRESHWATER, referring to the discussions at the two previous meetings on the erosion of the inner surface of cover glasses of transparencies, had separated the glasses of some slides of the Paris Exhibition, 1878. They had only been through the lantern once, and had been shut up in a box for ten years. A clouding of the inside of the cover glass had taken place. This, however, unlike those exhibited at a previous meeting, yielded readily to rubbing with the finger. A coloured French slide, twenty-five years old, when separated, showed a distinct outline of the picture on the inner surface of the cover glass. Mr. Freshwater said in his experience French glass was much more susceptible of discolouration than English. He also passed round three prints taken by Mr. England's flash-light lamp.

Mr. A. COWAN showed a series of transparencies developed with a formula given in the current issue of the *Photographic Review*, copied from the *American Journal of Photography*:—

Water distilled	1 fluid ounce
Tartrate of sodium and potassium ...	25 grains
Sulphite of sodium	25 ,,
Carbonate of lithium	1 grain
Pyrogallol	2 grains

He had found it the most powerful developer in his experience. The solution remained perfectly colourless after several plates had been developed.

This being a lantern night, the remainder of the evening was devoted to the exhibition of members' slides; Messrs. H. D. Atkinson, F. C. Kellon, L. Medland, and T. E. Freshwater, each contributed a series of transparencies.

HACKNEY PHOTOGRAPHIC SOCIETY.

A MEETING was held on Thursday last, with Dr. GERARD SMITH in the chair.

Mr. FRED. H. EVANS read his promised paper on "Photo-Micrography" before the members on Thursday last; after which, over one hundred slides illustrative of the paper were shown through the lantern, the most interesting being a series of subjects taken with dark ground illumination, foraminifera, polycistina, wood sections, whole insects, corallines, and ectinus spine sections. The physiological slides were also regarded by medical members present as of special value. The usual specimens of insects and parts of insects were clear and sharp. A formula for development of which the lecturer spoke highly was a modification of one given by Mr. J. B. B. Wellington, and consisted of:—

A.—Quinol	462	grains
Meth. spirit	3½	ounces
Sulphurous acid	3½	,,
Brom. potass.	84	grains
Water to make	10½	ounces
B.—Sodium hydrate fused	261	grains
Potash ,, ,, ...	261	,,
Sodium sulphite pure	462	,,
Water to make	10½	ounces

30 minims of each to 8½ drachms of water.

Messrs. S. H. Barton and J. Reed were nominated members.

The SECRETARY announced that the album, first year's working, was ready for inspection, and that on the 23rd, Mr. F. W. Hart had promised to give a flash-light demonstration.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

A MEETING was held on the 9th inst., at the Club Rooms, Grand Hotel, Birmingham, Mr. E. H. JAQUES in the chair.

It was announced that the council had given an order for the Society lantern, which is not to exceed thirty guineas; also that the annual exhibition would be open to the public on the 21st and 22nd inst., at the Temperance Hall, Temple Street, Birmingham.

Mr. C. J. FOWLER than gave his paper on "Notes on the Summer Excursions," illustrated by a large number of lantern slides made from the negatives taken by the lecturer and members.

Mr. W. J. HARRISON exhibited some slides made on the new celluloid film.

BATH PHOTOGRAPHIC SOCIETY.

January 8th.—Mr. W. PUMPHREY, president, in the chair.

Mr. Archibald C. Coke was elected a member of the Society.

The HON. SECRETARY drew attention to a parcel of photographic journals and books presented to the Society. Circulars relating to the forthcoming Exhibition at the Crystal Palace were also laid on the table.

The CHAIRMAN welcomed Mr. Sumner Gates, of the Cambridge (U.S.) Camera Club.

Mr. GATES, after thanking the Society for the kind way in which they had received him, spoke on the subject of flash-light photography. He had had some experience with magnesium flash-light exposures in America. As a rule, they worked with a larger flame than appeared customary here, and more magnesium was used; but the light so obtained was diffused through a screen. By this means the shadows were less heavy. The Scovill Co. also issue the powder in the form of a cartridge, which is very effective. Some pictures done in this way he had already sent to the States for, and the Society might see them at a future meeting. He hoped to return the hospitality to some members of the Bath Photographic Society.

The CHAIRMAN thought it desirable to say a few words in connection with flash light work before experiments were made. In the first place, the process is the complement, though somewhat reversed, to what is usually regarded as instantaneous photography. Instead of the work being controlled by the rapidity of closing the camera, it is the rapidity of the light one has to deal with, as it commences and ceases with an instantaneous flash. Such a light we find in the combustion of the metal magnesium. The ordinary form used to be exhibited as a thin ribbon of the metal, but there was this disadvantage—that the light came almost from a point; thus some portions must be badly lighted or be in deep shadow. The present plan is to spread the metal in the form of powder over a larger surface, and for a shorter time. The powder, which should be fine, is burnt in a spirit flame, and, instead of proceeding from a point, it has a broad and a powerful light.

About a dozen cameras were then brought into requisition, and successful negatives were made of the Chairman and others,

Mr. A. Spurge manipulated the flashing apparatus during the evening, and a convenient dark room was fitted up for those who desired to use it.

The SECRETARY exhibited several large photographs lent by Mr. Rosen, of the Autotype Co. These illustrated the various coloured tissues in use for carbon printing, and comprised sepia, ruby brown, terra cotta, blue, and engraving black. Examples of collotype, auto-carbon, and auto-crayon were also handed round for inspection.

LEWES PHOTOGRAPIC SOCIETY.

AN ordinary meeting was held on January 7th, with Mr. J. TUNKS in the chair.

The balance sheet of the Lewes and Sussex Photographic Exhibition was read, showing a balance in hand of £9 16s. 1d., and was adopted.

At the conclusion of the usual business, the remainder of the evening was devoted to the making of lantern slides by contact; slides were exposed and developed by Mr. A. H. Webling, and the Hon. Secretary.

It has been arranged to offer certificate for competition amongst the members, once a quarter, for various subjects: the first competition will be for lantern transparencies.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

January 9th.—Mr. J. MATHEWSON in the chair.

The slides of last month's lantern slide competition were exhibited by the lantern. The variety of tone and range of density of the sets of slides was interesting, each set having been made from the same negatives.

Various detective camera pictures were exhibited. Fallowfield's "Facile" and Talbot and Eamer's "Diamond" detective cameras were on exhibition, and their working was explained.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

A MEETING was held in the Mayor's Parlour, Old Town Hall, on January 8th, Mr. S. S. PARTRIDGE in the chair.

One member was elected, and one proposed for ballot at next meeting. Letters of resignation were read from Messrs. Toller and Ellery, which were accepted with regret.

The election of officers was next proceeded with, the following being the result:—*President*—Mr. S. S. Partridge; *Vice-President*—Mr. J. T. Cook; *Treasurer*—Mr. W. Sculthorp; *Secretary*—Mr. H. Pickering, High Cross Street; *Committee*—Messrs. Sculthorp, Wilson, Pierpoint, Porrett, Leeder, F. Brown, Blackwell, and Bankart.

It was decided to offer the following medals for competition among the members for the ensuing session:—Silver and bronze medals, by the Society, for the two best sets of six lantern slides; silver and bronze medals, by the Society, for the best and second best six prints whole plate; silver and bronze medals, by the past President, for prints under whole plate; and silver and bronze medals, by the President, for quarter-plate prints. It was arranged that the competitions take place as follows:—Lantern-slide competition, at the February meeting; enlargement competition, at the March meeting; print competition, at the April meeting.

RECEIVED.—"Tylar's Practical Hints and Photographic Calendar for 1890" is a skilful combination of useful information, handy for reference, and a comprehensive trade catalogue; it contains as frontispiece a specimen of Bemrose's photo-tint, reproduced from a negative by the Rev. F. C. Lambert, of the Chapel of St. John's College, Cambridge.——"The Photographer's Diary and Desk Book for 1890" is issued by the proprietors of the *Camera*, and, like its predecessor, is a handy quarto diary, interleaved with blotting-paper, and intended specially for the use of photographers. The formulæ are printed in a size of type that can be read without much difficulty under red light.——Another diary is the little pocket monthly forwarded by Messrs. Mawson and Swan. Spaces for daily notes and memoranda are interspersed with pages of price lists; this diary is to be obtained gratuitously on application to the firm.

Answers to Correspondents.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

T. C. SELWYN.—To sensitize your rough paper for gas-light enlargements, coat it with gelatino-bromide emulsion, or try one of the papers already in the market, such as Eastman's or the Ilford bromide paper. See advertisements at page lxvi, and at the end of the YEAR-BOOK.

J. A. C.—The sulphuric acid test for bromine. Your failure is attributable to the fact that you operated directly upon the bromide paper, instead of charring this first to destroy the organic matter and concentrate the material. It would be well also to add a grain or two of black oxide of manganese to the vitriol, and instead of starch paper use starch paste at the end of a glass rod. The paragraph from *Nature*, on page 487, describes the fluorescein test, which is not so easily put in practice. Fluorescein is a phthalic acid and resorcein compound (containing no fluorine), and this body gives a pink eosine when submitted to the vapours either of bromine or iodine; it will not therefore distinguish between them, but only enable you to prove that one or the other is present. Pure nitrite of potash and fluoresceein are procurable from Messrs. Hopkin and Williams. We accept your thanks; no expenses were incurred.

E. L.—Mr. W. T. Wilkinson's little manual of "Photo-engraving and Photo-lithography," which treats also of the collotype and heliotype, is published by Messrs. England Bros., 25, Charles Street, Notting Hill, W. A new edition or a reprint is just now in course of preparation.

V. W.—The instruments named (the tachyscope and leucoscope) are not used in photography, but we will endeavour to get you the information asked for.

A. READ.—1. The camera mentioned (No. 2 Kodak) is just the size for lantern negatives, and contains the adjustments you require. 2. There is no doubt about the new celluloid films bearing enlargement quite as well as glass.

J. C.—We fail to see what advantage, even in weight, the new mode of extension would possess over the ordinary leather bellows action in cameras. As a temporary adjunct for enlarging, your idea would, perhaps, be of most service. The sketches are returned by post.

A. M. M.—For removing silver stains from the hands, there is nothing better than painting with a solution of iodine in iodide of potassium, and following up with a fairly strong hypo solution. A second application may be necessary in some cases.

W. R.—1. It is unfortunate that their interests are opposed, but we do not think that you should supply B without consent of A. Fuller particulars by letter. 2. Husnik's new enamel transfer paper is not yet offered for sale here.

GRAIN.—Set up a square of wire-gauze, and photograph that to get the reticulated screen required.

BLUE PRINT.—For working formulæ and full particulars, see the NEWS of 20th September last, and if you want further information, get a copy of "Modern Heliographic Processes," a manual of instruction for engineers, architects, and draughtsmen, by Ernst Lietze (New York: Van Nostrand Company).

J. M.—Varnish for gelatine negatives. Dissolve in the cold an ounce of orange shellac in a pint of methylated spirit, and after a day or two shake up with a small quantity of kaolin or prepared chalk (crushed whiting) to help to clarify the varnish. Allow to settle, and filter. Some operators use more shellac, but a thin varnish is all that is required to protect the negative, if care be taken to dry the paper well before printing.

A. W.—If you wish to exercise your privilege of nominating officers and members of council to serve for the ensuing year, remember that Tuesday next, 21st inst., is the last day for accepting letters addressed to the secretary, at 5A, Pall Mall East, S.W. The notice appeared in the December issue of the Society's *Journal*, at the foot of page 38.

C. S.—There is much truth in the remarks about British Art and the Processes of Reproduction, in the current number of the *Nineteenth Century*; but some error when the author asserts that all the photo-mechanical work is being done abroad.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1638.—*January* 24, 1890.

CONTENTS.

PURPOSE IN PHOTOGRAPHIC WORK.

MANY photographers have purpose enough in their work, namely, those who are engaged in the art-science professionally, so have their well-defined daily duties to the public before them, and are sometimes limited in those duties more than is pleasant to themselves by the uneducated taste of a considerable portion of the populace.

The photographer without a purpose is usually the professional or the amateur who takes out-door views occasionally, say of an attractive building or picturesque landscape, with no more deeply rooted object in view than that of obtaining a pretty picture. An accumulation of his photographs soon grows large enough to tire both himself and his friends, however well they may be executed.

This class of worker will discover that he has a higher mission in life when he has a definite object in view in his photographic work. An example has been set by Warwickshire of a method of utilising these photographic loafers—a word here used in its respectful sense—by setting them to work to make systematic historical pictorial records of the county in which they live. There is no reason why every photographer should not carve out such a line of action for himself. Those who live in London and its suburbs would in most instances be surprised to discover the wealth of historical subjects ready for photographic delineation to be found at their very doors. In the British Museum Library the historical information in relation to all parts of London and its outlying districts is abundant, and extends over many centuries, so that the photographer who goes there to read up the history of the district within a radius of one mile of his own homestead—or rather the homestead in which he is a temporary lodger under a lease—will discover that his immediate surroundings possess an interest unknown to him before, and as he perseveres in his reading and in his photographic work relating thereto, he will find himself gradually becoming the oracle of the neighbourhood in all matters of local history. Such relics of the past as modern improvements have not yet removed, he will photograph ere it is too late, and feeling the absurdity of trying to render his pictorial records more permanent by means of albumenised paper prints than the original objects themselves, he will plunge into higher branches of photography, such as relate to ceramic, platinotype, and carbon pictures, thereby doing service to the public, and building for himself a lasting reputation.

The tourist photographer can also go to work with a purpose. Instead of traversing a country and merely taking prominent architectural and other views which others have taken before him, he may devote a portion of his time to historical reading, and afterwards set to work to illustrate a particular subject, about which he will be able to tell a tale whenever he exhibits the pictures. For example, instead of bringing home a miscellaneous collection of scenes bearing no relation to each other, and the history which he does or does not pick up from guide-books, and soon forgets, he might resolve to follow in the footsteps of Joan of Arc, and photograph the scenes devoted to her history. First would come her birthplace, the little village in the Vosges, of Domremy sur Meuse, with its quiet woods and the ugly little church so different to the church imagined by the artists who paint theatrical scenes relating to her adventures; but many a tale could be told about the interesting interior of the ugly building and its time-honoured contents. He could visit Chinon and its magnificent ruined castle, in which she first met the king, and could photograph the portion of the ancient town which is rotting with age below the cliff on which the castle stands, the ancient buildings being preserved as much as possible by the French Government as national monuments. Then there is Orleans, baking under a summer's sun, with the broad and shallow Loire babbling over its stony bed. The city contains a museum all relating to Joan of Arc, but the objects in it, though ancient, are all ideal and of later date than her time. Then there is the Cathedral of Rheims, the most magnificent specimen of Gothic architecture north of the Alps, in which she crowned the king; and lastly, there is the picturesque city of Rouen, in which she was burnt, as popularly believed, though historical criticism has thrown some doubt upon this point. A series of photographs like these would be of abiding interest to the photographer and his friends, for children of older and younger growth always prick up their ears and brighten in the eyes, when he who shows them beautiful pictures has also a tale to tell.

THE ROYAL INSTITUTION.

IV.

BEFORE quitting the subject of the photographs brought under the notice of the Royal Institution by Thomas Wedgwood in 1802, it may be well to give some biographical particulars about that photographer himself.

He was the third son of Josiah Wedgwood, the world-renowned improver of English pottery manufacture. Josiah was born in July, 1730, and after he commenced business as a potter, by experimental research was enabled to produce new descriptions of earthernwares and porcelains, of studied forms and chaste style of decoration, so that after a time, England, instead of importing the finest goods of this class, began to export them largely. In 1786 he was the founder of an early Chamber of Commerce, which bore the name of "The General Chamber of the Manufacturers of Great Britain." His useful life closed January 3rd, 1795, in his sixty-fourth year. He had been for many years a Fellow of the Royal and Antiquarian Societies.

Nearly all that has hitherto been published about the life of Thomas Wedgwood will be found in Miss Julia Wedgwood's article published in these pages on the 20th of December last, in the second volume of Miss Eliza Meteyard's "Life of Josiah Wedgwood," London, 1866, and in another book mentioned farther on by the same authoress.

Miss Meteyard says, in the 1866 book, that Thomas Wedgwood was born in April, 1771, and named after his paternal grandfather, uncle, and cousins; he was the fifth Thomas Wedgwood in direct line. She had no particulars of his infancy. From the first he seems to have been in delicate health, derived probably from both his parents, who prior to his birth had been in impaired health. These seeds of organic disease subsequently rendered the life of Thomas Wedgwood an indescribably weary burden. At first he was a merry little fellow, full of fun, and the life of the household. Later on he became the hardest of students, and with his father's chemist (Alexander Chisholm) rendered the laboratory at Etruria a place at which, for scientific reasons, the *savants* of our day cast back their gaze to penetrate, if possible, some of the mysteries of the photographic art carried on there. His passion for abstract studies was unbounded, even at the age of sixteen. He studied mathematics under John Leslie, afterwards Professor in the University of Edinburgh, and he often worked far into the night, causing his father on several occasions to deplore that "Tom is hurting himself." Whilst health lasted he joined in athletic pursuits, and he formed one of a body of young men known as "The Staffordshire Bowmen," who met for regular drill and exercise with the bow, and wore a handsome uniform. By instruction under Webber, he became a skilful draughtsman.

Miss Meteyard continues that from love of art he paid brief visits to Germany, Florence, and Venice, and at home for a time he seems to have been skilful as a potter. He designed new patterns, and his scientific researches led to the invention of what is known as "silvered ware," namely, a pattern of dead or burnished silver upon a black earthenware body. The earliest record of this ware is dated February, 1791. Nitrate of silver was sent down to him from the Apothecaries' Hall at the time of these experiments, and its properties led to the discovery of the method of taking photographs nearly forty years before the announcement of the discoveries of Nicephore Niepce and Daguerre.

The most detailed biographical particulars extant of Thomas Wedgwood are in Miss Meteyard's "A Group of Englishmen" (Longmans: London, 1871). In it she sets forth that Thomas Wedgwood was born in May, 1771; he was considered "the humourist" of the three sons. In 1779 he went as a boarder to the school of the Rev. Phillip Holland, Unitarian minister, Bolton. In 1788 a project to send him to Rome was abandoned, and throughout 1789 Thomas Wedgwood appears to have pursued his studies at home at Etruria. In 1790 Leslie, the mathematician, resided in the house for some time as his tutor. In his sixteenth year Thomas Wedgwood sent to London for a copy of "Newton's Optics," for he began to be interested in the subjects of light and heat, and Priestley encouraged him in his researches by letters written in 1791-2. The results were the two papers about light and heat, by Thomas Wedgwood, which were read before the Royal Society, and appeared in "The Philosophical Transactions" for 1792. Miss Meteyard says: "It is curious to observe how much the experiments narrated in the earlier paper were made with substances used in his father's manufactory, or arranged in his collection of fossils." About this time he was in correspondence with Richard Lovell Edgeworth about the improvement of prisons in the matter of sanitary arrangements. Thomas Wedgwood passed some portion of 1796 or 1797 at the Pneumatic Institute at Clifton, for he was nearly always in bad health, and in 1797 he resided occasionally with his brother John, at Cote House, Westbury, Wiltshire; in fact, he sought relief from his ailments by change of scene and of society, and in this year he made the acquaintance of Humphry Davy at Penzance. In 1798 he was, for a time, at Stowey, in companionship with Coleridge and other poets, and in the same year he and his brother Josiah offered Coleridge an annuity of £150 a year, to relieve him from the necessity of employing himself as Unitarian minister; this offer was accepted. In 1799 he bought an estate near Bridgewater, one portion of which, upon which he resided, was known as Castle Fleury, where he gave a little attention to agriculture; he also this year bought more landed property at Gunville, near Blandford, in Dorsetshire. In 1800 he appears to have travelled a little in France, and the same year, in search of health, he went to the West Indies and back; it was probably thought that he would never return, for before leaving England he made his will. He then bought another estate, Eastbury, near Gunville, and about the same time wrote to Mr. Howship, in York Street,

London, to buy for him a book translated from the German, "The art of preserving feeble life under incurable diseases." In 1801 he visited Paris. In the beginning of 1802 he was at Gunville, and in March the same year, about the time when his photographic discoveries were made known at the Royal Institution, he was in London for the purpose of consulting Dr. Baillie and arranging a fresh trip to the Continent, for both the hypochondriacism and *tedium vitæ* from which he suffered had increased, and alarming symptoms had begun to show themselves. Writing at the close of March to his brother, he says:—"God knows what will become of me at present, but I suppose I shall be driven to travel. I have had many painful conflicts of mind from imagining that I had only to forget that I was an invalid to be like other people, and get well. I now know that my body is seriously damaged; my feelings and views are undergoing a change in consequence." During this visit to London he spent his time occasionally at his club, which met at the "Crown and Anchor" in the Strand. He seems to have taken little interest in those photographic discoveries which will for ever render his name famous; in fact, we do not know of a single utterance of his own about them, unless he took part in the writing of the paper on the subject which was read at the Royal Institution, but the probability is that all the writing and speaking on this subject were done by Davy. Wedgwood left London May 7, 1802, for the Continent, and was four hours in crossing to Calais; thence he went *via* Bruges and Ghent to Brussels. On May 17th, 1802, he wrote a long letter about his experiences there, and a few days later he wrote, in much better spirits, from Mons. Afterwards he seems to have been in Paris and Switzerland, and to have returned to England in the autumn of the same year. He travelled much on horseback; indeed, constant motion, whether on the sea or on horseback, seems to have given him more relief from his ailments than anything else.

James Watt visited Etruria in 1790, and afterwards, in the course of a letter to Mr. Josiah Wedgwood, said:—"Thank you for your directions for the silver pictures." This may either be the first written record relating to Thomas Wedgwood's early photographs, or may bear reference to pictures upon pottery, produced by the aid of silver salts.

There is no record that Davy and Thomas Wedgwood met in 1802, but as Wedgwood was in London when Davy made known his photographic discoveries in that year, the assumption is that they saw each other on the subject, especially as Wedgwood was then well enough to be frequently riding or driving about town.

At the end of 1802, Wedgwood was travelling in South Wales, and buying more landed property; the latter habit seemed to be a kind of mania with him when his malady was at the worst. This malady was more of a mental than a bodily nature, and in 1803 he wrote to Humphry Davy to try to obtain for him some Indian hemp, fortunately without success. Davy, in the course of his reply, dated Royal Institution, February 12th, 1803, said:—"I have always looked forward with hope towards a time when your health would permit you to act upon the public by truths which cannot fail to enlighten and to be useful to all classes of men. I trust that time will yet arrive. Believe me, I always look back to the few hours that I have spent with you with feelings of pleasure, of gratitude, and of regret. Your opinions have been to me as a secret treasure, and they have often enabled me to think rightly, when perhaps, otherwise, I should have thought wrongly."

In 1803 Wedgwood was again on the Continent for a short time, and may have reached Italy, but was soon back in London, and at the end of the year was exceedingly ill at Cote, near Bristol. In the following April he sought relief by taking opium.

He died at Eastbury July 10th, 1805, at the age of thirty-four. Miss Meteyard says that by his death "all the anxieties of many friends and many men on his behalf were at an end for ever. Dr. Darwin, of Shrewsbury, had long anticipated that his life would close in frenzy or paralysis. The last was the merciful ordination. In an instant the brain was stricken. He ceased to all outer volition and consciousness, and calmly died no long while after."

He is described as having been tall, thin, pale, and sickly, moving feebly by the aid of a stick about the grounds at Eastbury; staying occasionally to watch with interest his brother's children at play, and remarking as he did so that he would give half his fortune if he could possibly partake of their health and buoyancy of spirits.

There is no evidence that Thomas Wedgwood did anything in photography before producing the pictures to which he drew Davy's attention in 1802, but he and his father made use of the camera obscura, as others had done, before that time. Miss Meteyard, whose utterances are of no scientific value, says in a letter read at a meeting of the Photographic Society, November 3rd, 1863, "You may with safety refer the first experiments in photography to as early a date as 1790 or 1791. In the latter year I find Thomas Wedgwood (third surviving son of Josiah Wedgwood) sending his camera to Birmingham to be mended." She does not give her authority for this statement, and it would have had no bearing on the subject had she done so.

At the meeting, the two photographs said to be by Wedgwood were passed round, and the official report of the Society says that one was "about 8 by 6, a view of a breakfast table, having much the appearance of a faded silver print; and another similar in appearance, a small reproduction of a drawing." In the discussion, "Mr. Foster asked by whom the date 1791 had been written on the frame of the Wedgwood pictures. It was somewhat singular, if these were produced in 1791, that Wedgwood should write in 1802 that no means of fixing sun pictures had then been discovered." Mr. Malone remarked at the meeting, "These pictures certainly, or at least one of them, appeared to be a photograph, and reminded

him of some of Mr. Talbot's early pictures; indeed he had seen some of them with just the same objects. So far as he could see, there was nothing to connect the pictures with the early date assigned to them. . . . Iodine was not discovered until after the alleged date of these pictures."

At another meeting of the Photographic Society, held January 5th, 1864, the secretary exhibited a print which he had found at home, and executed by Mr. Fox Talbot, which was very similar to that exhibited at a former meeting as "The Breakast Table at Etruria Hall," by Thomas Wedgwood, photographed in 1791. He had written to Mr. Fox Talbot on the subject, who, in the course of a reply dated Milburn Town, Edinburgh, November 10th, 1863, said:—"I beg to inform you that I *did* make a photograph of china, knives and forks, &c., disposed upon a round table, which is seen very obliquely in the photograph. It was an early attempt, about 1841 or 1842. The view was taken out of doors, on the grass-plot in the centre of the cloisters of Lacock Abbey. I have no doubt I have copies of it still left in my collection at Lacock. Wedgwood, in his memoir of 1802 (Journal of the Royal Institution), says that he had thought of the possibility of making the photographic views with a camera, but that, on trying the experiment, he had found that no length of time sufficed to make any visible impression. Therefore, if any ancient photographs should be discovered, they will not be his production." In a later letter from the same place, he expressed the belief that he had the negative of this picture at Lacock Abbey. At the same meeting of the Photographic Society, Mr. Malone "produced a collection of photographs done twenty years ago by Mr. Talbot, amongst which was a print which appeared to him to be identical with that picture shown before as having been produced by Thomas Wedgwood. That was the only one of the paper pictures he before believed to be a photograph; and he was now able to settle the matter of its production as belonging to Mr. Talbot."

Altogether, there is no doubt that the two pictures described in Miss Meteyard's books as early photographs by Wedgwood were not such. They condemned themselves, for they were positives and not negatives; moreover, any photographs taken by his method and unfixed, could not last long. The breakfast table picture was published in her "Life of Josiah Wedgwood," and the man with the bagpipes picture as a frontispiece to her "Group of Englishmen." The latter was a positive copy of an engraving, and probably not a photograph at all.

Thomas Wedgwood wrote but little for publication. His first paper, read before the Royal Society, relates to phenomena of light, phosphorescence, and fluorescence, so is appended hereunto in full.

*Experiments and Observations on the Production of Light from Different Bodies, by Heat and by Attrition.**

BEFORE I begin to state the experiments which are the subject of this paper, it may not, perhaps, be improper to give a very compendious history of the discoveries which have already been made relative to phosphoric bodies; omitting, however, the electrical phosphori, and such as are evidently consumed or decomposed in the emission of their light, as these are well known, and are too numerous and important to be slightly noticed.

Pliny was well acquainted with the luminous appearance of rotten wood and of the eyes of dead fish. From this time I find nothing relative to the phosphorism of bodies till the beginning of the sixteenth century, when Benvenuto Cellini, in his Art of Jewellery, mentions his having seen a carbuncle shine in the dark like coals nearly burnt out, and relates a story of a coloured carbuncle having been found in a vineyard, near Rome, by its shining in the night.

About the year 1639, Vincenzo Cascariolo, of Bologna, discovered, by accident, that when a certain stone, found in that neighbourhood, was calcined in a particular manner, it acquired the remarkable property of absorbing the light of the sun, of retaining it for some time, and of emitting it in the dark; subsequent experimenters found it to do the same with the light of a candle.

In 1663 Mr. Boyle observed a particular diamond to give out a light almost equal to that of a glow-worm, when heated, rubbed, or pressed, and investigated very fully the nature of the light of dead fish, flesh-meat, and rotten wood.

In 1677 Baldwin, of Misnia, discovered in the residuum of a distillation of chalk and nitrous acid, a phosphorus similar in its properties to the Bolognian, but not possessing the phosphoric virtue in so eminent a degree.

In 1705, Mr. Francis Hawkesbee found that glass rubbed on glass, in common air, in the vacuum of an air-pum, or under water, "exhibited a considerable light."

In 1724, M. Du Fay discovered that almost all substances which could be reduced to a calx by fire, or after solution in the nitrous acid, absorbed and emitted light like the phosphorus of Cascariolo and of Baldwin; and that some diamonds, emeralds, and many other precious stones emitted light in the dark after being exposed to the rays of the sun.

About the same time Bucaria, of Turin, found almost every body in nature to be luminous after a similar exposure; he added, too, this very important discovery, that an artificial phosphorus exposed to the light in a coloured glass vial emits, in the dark, rays of the identical colour of the vial. Mr. Margraaf, by an analysis of the Bolognian stone, shows that it contains vitriolic acid united to calcarious earth, and that al gypseous stones treated like the Bolognian, provided they are pure from iron, become phosphorescent. About the year 1764, Mr. Canton made a phosphorus of sulphur and oyster-shells calcined together, and distinguished himself by many curious experiments made with it. He found that his phosphorus might be made to shine by heating it after it had ceased to be luminous of itself, but that the same heat would have this effect for a certain time only. Heat has been observed by several of these philosophers to promote the emission, and to shorten the duration, of the light of phosphori. Fluor has been long known to give a fine, bright light when heated. D. Hoffman discovered that red blende and feldspat were luminous when pieces of either were rubbed together. Pott extended this discovery to all pure flints and crystals, and to porcelain. Keysler found glacier mariæ to be luminous when heated. M. de la Mitherie has observed some neutral salts and calcareous earths to be luminous in the same way. The Count de Razoumowski, in a memoir of the Physical Society of Lausanne, shows that quartz and glass give out light when struck by almost any hard body, and that some few other bodies are luminous when pieces of the same kind are rubbed upon one another. He finds quartz to give out its light under water.

This brief account includes, as far as I am able to collect, the chief discoveries which have been made concerning luminous bodies. I was led to make the following experiments from observing the light which proceeds from two quartz pebbles rubbed against each other. I searched for this property in many other bodies with success, but met with two soft stones, which did not afford any light upon the most violent attrition, conceiving the

* By Mr. Thomas Wedgwood. Communicated by Sir Joseph Banks, Bart., P.R.S. Read December 22nd, 1791.

heat might probably be the cause of the light emitted by quartz from attrition. I attributed this failure to a want of sufficient hardness in these friable stones for producing the necessary heat. Accordingly, sprinkling some of their powder on a plate of iron nearly red hot, I had the satisfaction to observe it emitting a considerable light. Extending this mode of trial, I found that the phosphorism of almost all bodies might be made apparent either by heat or attrition. I shall therefore divide the subject of this paper into two parts :—1. On the light produced by heat. 2. On the light produced by attrition.

I.

The best general method of producing the light by heat is, to reduce the body to a moderately fine powder, and to sprinkle it, by small portions at a time, on a thick plate of iron, or mass of burnt luting made of sand and clay, heated just below visible redness, and removed into a perfectly dark place.

The following is a list of such bodies as I have found to be luminous by this treatment, arranged according to the apparent intensity of their light.

1. Blue fluor from Derbyshire, giving out a fetid smell on attrition.

2. Black and grey marbles, and fetid white marbles, from Derbyshire. Common blue fluor, from Derbyshire. Red feldspat from Saxony.

3. Diamond, oriental ruby, aerated barytes, from Chorley, in Lancashire, common whiting, Iceland spar, sea shells, moorstone, from Cornwall, white fluor from Derbyshire.

4. Pure calcareous earth, precipitated from an acid solution —argillaceous earth (of alum), siliceous earth,—new earth, from Sydney Cove, common magnesia, vitriolated barytes, from Scotland. Steatites, from Cornwall, alabaster, porcelain of Cornwall. Mother of pearl, black flint, hard white marble, rock crystal from the East Indies. White quartz, porcelain, common earthenware, whinstone, emery, coal ashes, sea sand.

5. Gold, platina, copper, iron, lead, tin, bismuth, cobalt, zinc. Precipitates by an alkali from acid solutions of gold, silver, copper, iron, zinc, bismuth, tin, lead, cobalt, mercury, antimony, manganese. Vitriolated tartar, crystals of tartar, borax, alum (previously exsiccated), sea-coal. White paper, white linen, white woollen (in small pieces), white hair powder, deal sawdust, rotten wood (not otherwise luminous), white asbestos, red irony mica, deep red porcelain.

6. Antimony, nickel, oils, lamp, linseed, and olive, white wax, spermaceti, butter (luminous at and below boiling).

The duration of the light thus produced from different bodies is very unequal ; in some the light is almost momentary, in others it lasts for some minutes, and may be prolonged by stirring the powder on the heater. It soon attains its greatest brightness, and dies away gradually from that point, never appearing in a sudden flash, like the light of quartz pebbles rubbed together. If blown upon, it is suddenly extinguished, but immediately re-appears on discontinuing the blast.

The light of bodies is, in general, uncoloured ; there are, however, some exceptions. Blue fluor, of that kind which gives out a fetid smell when rubbed, first emits a bright green light resembling that of the glow-worm so exactly that when placed by the insect, just as it has attained its greatest brightness, there is no sensible difference in the two lights, either of colour or intensity. This bright green changes into a beautiful lilac, which gradually fades away. Fetid marbles, and some kinds of chalk, give a bright reddish or orange light ; pure calcareous earth, a bluish white light ; Cornish moorstone emits a fine blue light ; powder of ruby gives a beautiful red light of short continuance.

The most phosphorescent marble is soft and friable, of a coarse crystallized grain, and a fetid odour when rubbed ; black and grey marbles are generally more luminous than the white.

Most of the common white marbles are hard, and of a fine grain, and they are not very luminous, nor is their light of an orange colour. Different chalks vary as much as different marbles in the intensity and colour of their light when no difference of external structure is perceptible. The most phosphorescent chalk loses the brilliancy and redness of its light by being dissolved in an acid, and precipitated by caustic fixed vegetable alkali—by being confined with vitriolic or fluor acid—by calcination by heat, or being combined with the aerial acid in the pellicle formed on the surface of lime-water. Marble would probably be affected in the same manner. The most phosphorescent blue fluor gives the same light after being united to the vitriolic acid, though gypsum is far less luminous than fluor, and its light is colourless. Argil precipitated from alum by an alkali, and magnesia, when combined with fluor acid, give out the same light as before.

Bodies emit their light when immersed in boiling acid of vitriol, or in boiling oils. Small lumps of fluor or of marble make a singular appearance in the acid, as they are moved up and down by its action, and rendered brightly luminous by the heat. They seem equally luminous in pure, fixed inflammable or atmospheric air.

Feldspat, the fetid fluor, and probably all phosphorescent bodies, dropt in moderately fine powder, into a flask containing a small quantity of boiling oil at the bottom, emit a copious flash of light as soon as the powder touches the surface of the oil. When the particles of the body have lain at the bottom of the heated fluid for about a minute, they become but faintly luminous ; if the flask be then agitated so as to raise some of these particles out of the oil, and lodge them on its sides, they suddenly rekindle into the same brightness as at first, and preserve this reassumed lustre for some time ; and even after being washed down again into the oil, they may be readily distinguished from the particles which have remained at the bottom. This experiment is extremely beautiful, and is not at all obstructed by the faint light of the oil ; it succeeds best with the stinking blue of Darbyshire.

Powdered marble, and probably every other body, when spread upon the heater in the receiver of an air-pump, is equally luminous during the exhaustion and readmission of the air.

Bodies are by far the most luminous the first time they are treated, but cannot, perhaps, be entirely deprived of this property by any number of heatings, nor by any degree of heat. Chalk, fluor, and feldspat, give out a very faint light on the heater, after having been exposed to a smart red heat in an open crucible, in small quantities, and kept frequently stirred for several hours ; the feldspat was equally luminous when laid hot upon the heater, or first cooled, and then laid on. Chalk and fluor were not tried in this particular. A bit of glass, melted in a heat of 120° of my father's thermometer, and as soon as it is cold reduced to powder, gives out light on being thrown upon the heater below redness. Quartz, from the same original piece, is equally luminous when the *powder* is directly thrown upon the heater—when it is previously made red hot, and then cooled and thrown on—or when a *fragment of some size* has been made red hot, then pounded and thrown on.

For the most part, the softest bodies require the least heat to become luminous ; marble, chalk, fluor, &c., give a faint light when sprinkled on melted tin just becoming solid. As the temperature of the heater is raised, they continue to give out more and more light.

Vitriols of iron, copper, and zink previously exsiccated, when thrown on earthenware or metal made nearly red hot, give minute flashes of light of momentary duration, such as appear from some of the metallic precipitates, particularly zink, on a similar treatment ; with this difference, however, that the light of most of the precipitates is of a reddish hue.

The light of the metals is white, and exactly similar to that of some earths.

White paper, when dipped in a solution of sal-ammoniac, and slowly dried, becomes black upon the heater, and then gives out much less light than common paper.

If a lump, of the size of a small bean, of fluor, marble, feldspat, or any other of the most phosphorescent bodies, be laid upon the heater, the light proceeds gradually upwards from the part in contact with the heater, till the whole mass is thoroughly illuminated. If the same piece be heated a second time it is much less luminous ; nor if it be broken are the

fragments at all more luminous, either then, or after having been exposed for a month to the light and sunshine.

A little boiling oil at the bottom of a glass flask, when agitated in the dark, illuminates the whole of the flask. The light of boiling oils proceeds, probably, from some kind of inflammation, as it is scarcely discernible unless the vessel be agitated; and, if a little oil be thinly spread on the heater, a subtle lambent flame of a bluish hue instantly arises. The same thing takes place if horn, hair, saliva, or any animal matter be laid upon the heater.

II.

The experiments on the lights produced from different bodies by attrition were chiefly made by rubbing in the dark two pieces of the same kind against each other. All that I tried, with very few exceptions, were luminous by this treatment. The following is a list of them, arranged in the order of the apparent intensity of their light, and as the lights are either white or some shade of red, I have affixed figures to denote these differences. (0) Denoting a pure white light; (1) the faintest tinge of red or flame colour; (2) a deeper shade of red; (3) and (4) still deeper shades.

1. Colourless, transparent, oriental rock crystal; and siliceous crystals (0).
2. Diamond (0).
3. White quartz, white transparent agate (1).
4. White agate, more opake (2); semi-transparent feldspat from Scotland (2).

Brown opake feldspat from Saxony (4)

Chert, of a dusky white, from North Wales (3).

5. Oriental ruby (4).
6. Topaz, oriental sapphire (0).
7. Agate, deep-coloured, brown and opake (4).
8. Clear, blackish gun-flint (2).
9. Tawney, semi-transparent flint (3).
10. Unglazed white biscuit earthenware (4).
11. Fine, white porcelain (2).
12. Clear, blackish gun-flint made opake by heat (3).
13. Flint glass (0).
14. Plate-glass, green bottle glass (0).
15. Fine, hard loaf sugar (0).
16. Moorstone from Cornwall (1); Corune, semi-transparent, from the East Indies (1).
17. Iceland spar (0).
18. White enamel (2); tobacco pipe (3).

White mica (0).

19. Unglazed biscuit earthenware, blackened by exposing it, buried in charcoal, in a close crucible to white heat (4).
20. *Black vitreous mass, made by melting together 5 of fluor, 1 of lime, and some charcoal powder (4).
21. Fluor, aerated and vitriolated barytes, white and black Derbyshire marble, calcareous spar, crystals of borax, deep blue glass, mother-of-pearl.

Rock crystal, quartz, flint glass, and many other hard bodies, during attrition, emit now and then reddish sparks of a vivid light, which retain their brightness in a passage of one, two, and even three inches through the air.

A piece of agate applied to the circumference of a wheel of fine grit revolving at a moderate rate, becomes brightly red, even in daylight, at the touching part; if the wheel revolve at a quicker rate, the touching part emits a pure white light. In both cases glowing sparks are continually emitted, some of which are not extinguished before they have passed twelve or fourteen inches through the air; they explode gunpowder and inflammable air, and burn the skin; their brightness is not sensibly increased by passing into pure air. The corner of an angular piece of window-glass being applied to the wheel in motion, a full eighth of an inch of the glass above the point of contact becomes, apparently, red hot, and retains the redness for a second or two of time after its removal from the wheel. During the attrition, large red sparks are continually emitted, and a mixture of softened glass and the sand of the stone wheel is collected about the touching point.

Quartz, transparent agate, rock crystal, and window glass, give nearly the same flashing light when rubbed against the stone wheel, or in the ordinary manner. Excepting the tinge of red in the former, which it receives from the light of the grit, the transparent agate becomes red hot for a little way about the part in contact with the wheel, and is thus deprived of its transparency as it would be if made red hot in a common fire; porcelain is heated to redness by the same treatment. The red sparks which are emitted by all these bodies during their attrition are heated particles about the magnitude of grains of fine sand, broken off by the friction.

Bodies give out their light the instant they are rubbed against each other, and cease to be luminous when the attrition is discontinued. Colourless, transparent, and semi-transparent bodies emit a flashing light, their whole masses being for a moment illuminated. Opake bodies give little more than a defined speck of red light, and are not luminous below the part struck. The greatest apparent quantity of light is produced by hard, uncoloured, transparent, and semi-transparent bodies, whose surfaces soon acquire an asperity by rubbing together, as quartz, agate, &c. From an examination of the table it appears that white lights are emitted from colourless transparent bodies; faint red or flame-coloured from white, semi-transparent bodies; deeper red from more opaque and coloured bodies: and the deepest red from opaque and from deep-coloured bodies. Extremely faint lights, such as those given by fluor, marble, &c., are of a bluish white: quartz, very lightly rubbed, gives a very faint light of a bluish hue; when rubbed a little harder, it emits a flame-coloured light; when rubbed with violence, its light approaches to whiteness. Opaque red feldspat gives a deep red light by attrition: exposed to a strong heat in the furnace, it becomes white, and somewhat transparent; and when cool, gives out, on attrition, as white a light as quartz. Clear, blackish flint, made opaque by heat, gives a redder light than before; deep-coloured glass gives out a red defined light without any flash, whilst clear, uncoloured glasses emit a white flashing light of some brightness.

Bodies are not luminous by simple pressure; the fragments rubbing on each other produce some light. Mr. Boyle, indeed, found a particular diamond to emit light when pressed by a steel bodkin, but the diamond is phosphorescent in so many ways, and is so curious and singular a body, both in properties and constitution, that it can scarcely be expected to exhibit the same appearances as the common class of earthly bodies.

Alum, indurated by having been kept long in a state of fusion, and being then much harder than loaf sugar or borax, both which are luminous from moderate attrition, gives no light, though rubbed with much violence.*

If two pieces of glass or quartz be strongly rubbed against each other, and then applied to the fine down of a feather, the down is not sensibly affected; if the same glass be rubbed on woollen cloth, and placed near the feather, the down is immediately attracted.

Rock crystal, quartz feldspat, white, unglazed earthenware, Derbyshire black marble, and probably all phosphorescent bodies insoluble in water, give out their light on rubbing them under water, as copiously as in air. Hard, white sugar from the outside of the loaf gives out its light when rubbed in oil. Bodies seem equally luminous in atmospheric, pure, fixed, and inflammable air.

All hard, earthy bodies emit a peculiar smell on attrition. The most remarkable for this property are chert, quartz, feldspat, biscuit earthenware, and rock crystal; this smell does not differ much in kind, though it does considerably in inten-

* Some of this mixture, taken out of the crucible before it was perfectly fused, gave out when rubbed, a strong smell like phosphorus of urine, and on throwing some of it pulverised on a plate of iron, heated just below redness, it was very luminous, and presented every appearance of burning phosphorus.

* The Count de Razoumowski has investigated the luminous property of bodies in a way which appears to me very unfavourable for the discovery of their true lights. He rubbed, not one piece against another of the same body, but all of them against quartz or glass. He finds several metals luminous from this treatment, and attempts to draw some curious conclusions from the colour of their lights. I tried these metals in his own way, and found that no light was emitted, except when the violence of the blow shattered the quartz or glass. A piece of the indurated alum will excite light from rock crystal, but this is the light of the fragments of the crystal rubbing on each other, and not of the alum.

sity. Many of the softer bodies yield the same smell, but in a less degree, and probably none are entirely without it. It appears to be strongest where the friction is greatest; it has no dependence on the light produced by attrition, as it is often very strong when no light is emitted.

Rock crystal, quartz, feldspat, white biscuit earthenware, and probably all such hard bodies, produce this smell under water.

Quartz stones, violently rubbed upon one another for a few minutes in a cup of water, communicate this smell and a peculiar taste to the water. The taste is probably derived from an impalpable powder, which floats in the water for many days.

Derbyshire black marble, and the stinking blue fluor, give out, on attrition, a strong smell peculiar to themselves, both in air and water; they lose this property by being once made red hot.

Quartz produces the smell equally strong in fixed, pure, and common air.

Having now stated all the facts relative to phosphorescent bodies which I have as yet been able to discover, I shall beg leave to offer a few reflections, tending to show that heat is the probable cause of the light produced from bodies by attrition.

The powders of all earthly bodies emit light when heated a little under redness. Now, when two bodies are rubbed upon each other it is probable that heat is always generated on their surfaces; may not then the light which they yield upon attrition be attributed to a sudden heating of particles in their surfaces? For these particles will be affected in the same way as if they had been equally heated by any other means; they will, therefore, give the same light as if they had been laid upon the heater of an equal temperature.

The shining sparks which hard bodies send out during attrition prove that particles in their surfaces are heated at least to more than 600° of Fahrenheit, for the powders of hard bodies are not luminous on a heater much below redness. The heat generated by soft, friable bodies is probably but little, as the minute particles in their surfaces are not much crushed by each other, but merely disjointed from the masses; nor can this little be easily appreciated, for, as the surfaces continually crumble away, the heated parts are carried off before they can warm the masses, and are themselves very quickly cooled by the surrounding air. But as many soft bodies emit a faint light on the heater at the low temperature of about 400° of Fahrenheit, and as it is not a stronger light which they yield on attrition, little heat is required to render the particles in their surfaces luminous. It must be observed, too, that though the absolute quantity of heat generated by one rub be but inconsiderable, the effects of it may be very striking; for just on the instant of attrition its action is confined to the minute colliding points of the surfaces, and will, consequently, operate upon them as much as a greater quantity would on larger points.

The light emitted by bodies in attrition is of momentary duration, wheras a powder on the heater continues to emit light for some minutes; this difference is easily explained. In the latter case the particles are constantly heated; in the former they are instantly cooled by the subjacent mass to a temperature in which bodies are not luminous, *i.e.*, a little under 400° of Fahrenheit.

When the uneven surfaces of bodies are rubbed upon each other, a flashing light is produced at frequent intervals by the collision of the more prominent parts; this, in colourless, transparent, and semi-transparent bodies is copiously reflected from the whole of the masses, and forms an appearance very different from what is ever exhibited by bodies on the heater. It may be well illustrated in the upper part of a candle, by repeatedly nearly closing and quickly opening the snuffers about the burning wick, or by sprinkling some powder of fluor, or marble, on a mass of glass heated just under redness.

Powder of crystal, quartz, agate, &c., is but faintly luminous on the heater under redness; accordingly, if the stones themselves be gently rubbed a faint light is emitted, resembling that which their powders give on the heater. Marble and fluor give about the same light on the heater of the temperature of 100° as they do when rubbed; and, probably, attrition heats some particles in their surfaces to that degree.

It may, at first, seem an objection to the opinion of heat being the cause of the light produced from bodies by attrition, that they yield their light when rubbed under water; but the water acts differently to the air only as being a stronger conductor of heat, and can nowise impede the actual generation of the heat. Now, as bodies emit their light on the very instant of their being heated, the water cannot cool the hot particles before they have given their light.

It is easy to see why bodies emit light *instantly* when rubbed, for they often send out sparks as soon as the attrition commences, which proves that particles in their surfaces are instantly heated to redness by attrition.

Since hard bodies may be heated to redness by attrition, we have an excellent method of discovering the lights they give out at that temperature, which could not be effected by sprinkling their powders on a red hot heater, as the light of the powder would be mixed with that of the heater. In some cases of attrition bodies are raised to a temperature beyond visible heat. The corner of an angular piece of window glass being applied to the circumference of a revolving wheel of fine grit, part of its mass is worn away; but a larger portion, lying just above the abraded part, is heated to redness. Now, as all the heat which is there collected, and a great deal more which is carried away in the abraded part, and conducted off by the air and by the glass lying up to the red hot portion, has once occupied a smaller space in the part worn away, it follows that the abraded portion, or aggregate of heated surfaces, has been heated to a degree exceeding redness by all the heat remaining in the red-hot part, and by the quantity of heat conducted off by the air and adjacent glass; and, consequently, that each surface has been heated by the attrition to a degree as much exceeding redness.

I am aware that this reasoning is founded, in part, on the supposition that the heat is generated on the surface or outermost coat of the body; some of it may undoubtedly proceed from an agitation of the parts under the surface, but the emission of red hot sparks at the *instant* of attrition proves that a great heat is generated on the surface; and as the friction, or apparent heating cause, is so much greater there that the parts are forcibly broken and disjointed, whilst just beneath there is no perceptible alteration in the body, we may venture to conclude that the heat generated beneath the surface is but inconsiderable.

After all, it remains entirely problematical, in what manner heat operates to produce light from bodies; the air does not seem to have any concern in its production, as bodies are equally luminous in almost all kinds of air, and when immersed in liquids. The phosphorism of sugar is probably of a different kind from that of the earthy class; for, although so soft and friable a substance, it produces its light very copiously upon gentle attrition.

In speaking of the attrition of bodies upon the stone wheel, I have said that they became *red hot* about the touching part; I should not have made use of this expression if the luminous sparks which issued from them had not kindled gunpowder and inflammable air, and thus proved that the part from which they came was raised to a temperature at least equal to what is usually termed a red heat; for, till the temperature of the part touching the wheel had been thus ascertained, I attributed the whole of the light emitted to the common phosphorism of bodies. If the velocity of the wheel be much increased the touching part of the body applied emits a bright, white light, much more vivid than any which powders ever give out on the heater, and, probably, the temperature of the luminous part is equal to what is usually called a *white heat*.

Having thus made incombustible bodies red-hot without the aid of fire, I once conceived that all the light which they emit when heated to redness in the fire, proceeded from their great phosphorism, for I could not suppose that they absorbed light from the burning fuel and emitted it again at the same time, and during a continuance of the same circumstances. It appeared, however, equally inexplicable why a stone put into the fire should continue to shine from its own light with

undiminished lustre as long as the fire is kept up; for it has been shown that if a phosphorescent body remain long upon the heater, of any temperature between 400° of Fahrenheit and a red heat, its light diminishes more and more till at last it is scarcely perceptible; and then an increase of heat is necessary to render it more luminous.

APPENDIX.

After a considerable part of the above paper was printed, I repeated the experiment with boiling oil, as previously related, with every possible precaution; I poured the powder into the flask through a funnel which reached to the bottom, so that none of it might be lodged on the sides; for, not having attended to this circumstance before, I was apprehensive that the experiment was delusive, and that the agitation of the hot oil might have washed down some fresh particles which had not been before heated; then slowly pouring in a little oil, I boiled it for a few minutes and removed it into a dark place. When the powder had become but faintly luminous upon agitation, the experiment succeeded exactly. I then boiled and agitated the oil for six or seven times successively with the same result, except that the light of the powder grew something fainter each time. If anyone has the curiosity to repeat this singular experiment, he may attend to the following directions:—Upon each removal from the fire, stop the neck of the flask with a cork having a small hole pierced through it; wrap the neck round with tow, agitate the liquor by quickly raising and lowering the flask.

The spark which leaves the surfaces of hard bodies during attrition may be exactly imitated by burning a bit of dusty paper; the particles of dust are carried by the current of air through the blaze, and are made red hot in their passage.

THE BEST PHOTOGRAPHER.

BY FRED. HART WILSON.

THAT to a great many people the photograph gallery is a place "hedged about with terrors" is unfortunately indisputable. Over its door might be written, "All hope (of looking natural) abandon, ye who enter here." The reception room may hold gorgeous carpets, and red velvet and black walnut galore, but is filled and covered with photographs, photographs, nothing but photographs. There may be waiting-rooms, full of frames and albums, and neat little dressing-rooms, "replete with every convenience," as a new hotel; but the spirit sinks and sinks till, when the gallery, dreadfully bare and business like, in cold blue and white, is reached, it touches bottom with a bump. I remember one reception room, very full one busy day, which was far more abominably desolate than any funeral I ever saw. The victims sat solemnly around the walls, every woman, of course, accompanied by two others nobly standing by their suffering sister in this crisis, occasionally giving her a little pat or pull till her turn came to appear. It was a sad hour.

It is unreasonable, and in a way a severe exposure of poor humanity's vanity and self-consciousness, this photographing state of mind. But it is undoubtedly vastly helped by the mechanical and strictly professional appointments of many galleries, and the semi-surgical manner of the operators.

Of course, a man, especially when a busy and nervous photographer, cannot always be the pink of smiling courtesy. It is well to bear in mind, nevertheless, that people expect to be idealized to a certain extent in the operations of photography, and a little of it before the lens does its work may save a great deal of it afterwards. Easy, unhurried motion, and a calm confidence that everything is going to come out all right, will impart themselves to the sitter, and a natural expression will replace the nervous flutter or the defiant glare, whichever his constitution may have led him to assume. If, in addition, there is a stock of good temper and untiring patience, we have the ideal photographer. Such a one studies the face in its different aspects in various lights, gets an idea of the best effects, and sure, then, of the material part of the picture, turns to the spiritual. Quietly talking, or simply waiting, he persuades the mind of the subject away from himself, until self-consciousness gradually disappears, the happy moment comes, a couple of seconds' pause, and it is done.

Not everyone can do this; but if one cannot change the furniture of his mind, he can that of his reception room. Galleries like those of Rose or Sarony may not be within his reach, but he can sink the shop a little, and make his rooms a pleasant place to be in. A well-chosen few of the innumerable fine reproductions, artistically framed and hung; a few jars, and screens, and mirrors, if he can go so far; anything to make the place less like a shop, and more like an abode of the arts. Let him suppress the photograph just a little, and endeavour to make the place artistic.

For the photographer, especially in the smaller towns, has a very considerable responsibility in that respect resting on him. He can do a great deal, if he will, in quietly educating the people in art. Let him get simply examples of the best photography, and of the reproductions that are now so inexpensive, and hang them, changing them when he can, in his rooms and windows. Let him take a few art journals, and try to read a few art books. It will advantage him, for he will be at the same time educating himself, and the results will be certain to show in his work; and let him coax his patrons on to the appreciation and demand for this—a demand he will be sure to find in time, for it is the peculiarity of the really good thing in art, as elsewhere, to stand wear, to endure and grow upon us. He will find himself forging ahead, and will learn that to be the artistic photographer of his community means not only to be the most skilful and intelligent but also the most appreciated and the best paid.—*Wilson's Photographic Magazine*.

PHOTOGRAPHIC CLUB.—Wednesday, Jan. 29th, annual lantern and musical entertainment. Subject for discussion Feb. 5th, "The Intensification and Reduction of Negatives."

DAGUERRE AND TALBOT.—At the Boston convention it was resolved to organise a one dollar subscription for the purpose of erecting somewhere in Washington a monument or memorial to Daguerre. We could have wished that in this matter the name of Talbot could have been associated with that of Daguerre; as, although each wrought independently of the other, their discoveries were given to the world almost simultaneously; and although for a time the beautiful Daguerreotype carried all before it, in something like a dozen of years it became little more than a memory, while the process of Talbot, in many modifications, no doubt, remains with us.—*The Beacon*.

SOAKING BEFORE DEVELOPING.—Photographers are sometimes advised to soak their plates in water before developing. Speaking from experience we certainly counsel them to do no such thing. This preliminary soaking has a tendency with most plates to make the high-lights flat and dull-looking, whilst it veils the shadows and half-tones in a most exasperating way. It is a great mistake also to imagine, as some photographers do, that a large quantity of developing solution in any way helps to produce a good negative. The finest negatives we have yet seen were developed with the smallest amount of solution that could be used; and we were assured by the artist by whom they were made that to this "kink" he attributed their best qualities. Try it.—*Wilson's Magazine*.

TABLE OF SIZES OF PRINTING AND WRITING PAPERS.

THE following useful tables of papers have been drawn up, with others, under the direction of Col. H. R. Thuillier, R.E., by Col. J. Waterhouse, assisted by Mr. W. H. Cole, M.A., and Mr. T. Archdale Pope, for the Survey of India Department:—

Notes.

Congresses, whether photographic or otherwise, have a disagreeable knack of not letting well alone. Some faddist has a pet idea which he trots out, and if no vital principle is involved, sometimes carries, very often to his own intense surprise. Something of this kind seems to have happened at the International Photographic Congress at Paris, where, at the discussion on "terminology," resolutions were carried which strike at the very basis of photography, as the public understand the term. Thus the first impression, whether on glass or any other material, whether negative or positive, is to be called the "phototype." The proofs from the "phototype" are to be designated the "photo-copies." The simple and familiar word "photograph" appears to have been extinguished.

The *Moniteur de la Photographie*, discussing the question, expresses dissent from the conclusions arrived at, and points out that in England the word "phototype" is already utilized for a particular process of reproduction. The word "photo-copy" pleases our contemporary even less, and it pertinently inquires if the want of the word has ever been felt. Have we ever desired to say, "Give me a photo-copy of your portrait?" or to exclaim, "Here is a beautiful photo-copy!" In speaking of a "photograph," everybody knows what is meant, and "photo-copy" is a confusing and an unnecessary innovation. Besides, to be consistent, other words would have to be revised. Why not "litho-copy" instead of lithograph, or "tele-copy" in the place of telegram? But we in England need not disturb ourselves over the matter. Congresses may come, and Congresses may go, but the word photograph is likely to go on for ever.

One of the oddest characteristics of photography is the facility with which men of equal ability and of equal manipulative skill, in trying the same process, arrive at totally opposite opinions. For the thousandth time, more or less, this was exemplified at the last meeting of the Photographic Society, when Mr. L. Warnerke was loud in his praises of the eikonogen developer, while Mr. S. G. B. Wollaston had not been able to succeed so far as obtaining density was concerned. It is puzzling why there should be these differences, but they bring with them their consolation, for if every photographer had exactly the same experience, where would be the necessity for photographic societies, and what would photographers find to talk about? This latter contingency, we are inclined to think, would be worse than the former.

The Russian authorities have placed a new tax upon travellers. New passport regulations came into force last week, and travellers will now be bound to carry their photographs annexed to their passes. It has been sarcastically suggested that ladies must be careful not to exhibit photographs taken ten years previously, while gentlemen must not be eccentric as to sudden changes in the hair on their faces. To save inconvenience, the *bureau* where the passport is granted should be provided with a photographic studio. This would prevent no end of trouble, as to be obliged to have your portrait taken (supposing you have not a photograph—no unlikely thing) just before starting on a journey would add a new terror to life.

But this is just what the authorities have not done; and the only consolation is, that the photographic profession in Russia will reap the benefit. But even here, what the Government have given with one hand they have taken away with the other; for after having created a trade by forcing people to be photographed, they proceed to lay a stamp duty of about 2d. on every carte-de-visite. Such at least is the expressed intention, and if so, photographers will not gain much, for though they may make more negatives, they will probably print less copies.

Illustrated journalism—if we may use the phase—is full of pitfalls. The journalistic artist is but mortal, and liable to err; but if he does make a mistake, and draws the wrong man, the consequences are far more awful than when a reporter puts words into the wrong man's mouth. The *Daily Graphic* last week had to apologise for a blunder of this kind at an illustrated report of a concert; but this was not so bad as a possible catastrophe in connection with another illustrated, averted only because the editor happened to know the originals. It happened over the blackmailing case, which has excited so much interest in the city. The case, though a criminal one, was heard at the Court of Queen's Bench, and the three defendants were not placed in a dock, but sat beside their solicitors. An artist who was sent to sketch the scene could, owing to the crush, only get admission to the public gallery, and therein made his notes. He was correct in spotting two of the defendants, but for the third drew the face of a highly respectable solicitor instead! Fortunately the editor, knowing the man, was able to put matters straight by cutting out the wrong one; but what would have happened had the block gone in? Surely a gross libel would have been committed!

One would almost think that Major Wissmann, the pioneer of German "colonization" in East Africa, had been to see Mr. Burnand's "Tra la la Tosca," and had taken a hint from the execution scene, which, as we described last week, consists of the prisoner being photographed. Major Wissmann—who, by the way, appears to be a military martinet of the school dear to the heart of Frederick the Great—subjected Bushiri to much the same torture as that gone through nightly at the New Royalty. After catching him, we read, Wissmann dressed him in rags and chains, and then in holiday clothes, and photographed him in each costume. He was to have been shot, but he behaved so treacherously that shooting was considered too good for him. The inference is clearly that by being photo-

graphed he was subjected to a punishment more ignominious than that which bullets would have inflicted! We hardly know whether photographers will feel pleased or annoyed at this.

Knowledge last week gave a full-page reproduction of a print from a pinhole negative taken by Professor Pickering. It represents the rear of the observatory of Harvard College, and though the sun was setting when the photograph was taken, the exposure was only six minutes. The photograph was taken from the roof of a cottage to the north-west of the observatory, and it is noticeable that the slates of the roof, the wires, and other objects in the immediate foreground, with the exception of the fir trees, which probably moved with the wind during the exposure, are equally as sharp as objects at a distance.

Mr. Bignell, the artist who has been selected to make the latest portrait of Mr. Gladstone, will not have a very easy task. Mr. Gladstone has sat so many times to painters and photographers that he is heartily sick of the operation, and has "struck." He flatly refuses to accommodate himself to a formal sitting, but has given Mr. Bignell permission to make himself at home in his library and catch the likeness the best he may, while Mr. Gladstone writes, or reads, or performs his many duties. After all, this is the best way of catching the true expression, but it makes great demands on the ability and quickness of the artist.

Gradually a photographic outfit is being recognised as a part of any traveller's outfit, whether he intends to write books or make pictures. Mr. W. H. Mallock, who has been rambling among Hungarian castles, will write an article on the subject in next month's *Scribner*, illustrated by photographs taken by himself. Mr. Herkomer is off to Cairo, where he will make sketches and take photographs for future use; while Sir John Millais has recently been on a journey, when his daughter acted as the photographer. The one man who, it would be thought, should have been among the earliest to practise the art, has not touched it—we mean the descriptive reporter. If the *Daily Graphic* succeeds—of which, by the way, we have doubts so long as it is conducted on its present lines—he may see the necessity.

Photography is the barometer of popularity. When anybody attains the rank of celebrity, the photographic print dealers are soon made aware of the fact. Major Serpa Pinto is the latest lion, not in England, but in Portugal, and the Lisbon dealers are worried to death because negatives of the intrepid and patriotic explorer, or marauding fillibuster, according whether you are Portugese or English, are scarce. Photographs are, indeed, at so high a price that an old trick, which used to be practised at Berlin in regard to the present Emperor's grandfather, has been imitated in Lisbon, and it is said that a person resembling Major Pinto has been hired to sit, in order to supply the needed negatives.

PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

FORMIC ALDEHYDE AND ITS COMPOUNDS—A NEW FLASH-LIGHT—THE PHOTONOM—QUINOL INTENSIFIER—COMBINED TONING AND FIXING BATH—HARDENING GELATINE PRINTS.

The Use of the Formic Aldehyde and its Compounds in Photography.—An invention has of late been patented by Mr. York Schwartz and Dr. Mercklin, of Hanover, consisting of the use of formic aldehyde and its compounds for photographic purposes. The sodium oxymethyl-sulphonate or formic aldehyde sodium bisulphite works well, especially with carbonated alkali; if added to the gelatino-bromide emulsion it accelerates the ripening, and imparts vigour and clearness to the negatives; also if added to the ferrous oxalate as well as to the pyrogallic and hydryquinone developers, it has a preservative action, accelerates development, and prevents fog. The keeping qualities of these developers are materially improved by the addition, and only about a quarter the usual quantity of iron is necessary to obtain equally good results. The sensitising action of the formic aldehyde and its compounds depends without doubt upon the energy with which they absorb bromine or iodine.

A New Flash-Light.—Professor Max Müller, in his excellent manual on the use of the magnesium light for photographic purposes, published a few weeks ago by Mr. K. Schwier, of Weimar, gives the formula of the flash-light composition with which he has obtained the beautiful cave pictures which were so much admired at the last Berlin exhibition. The original formula of Gaedicke and Miethe, who at first introduced the flash-light in its present form, contained, it will be remembered, crystallised trisulphide of antimony: 1 part of trisulphide of antimony, 3 parts of magnesium powder, 6 parts of potassium chlorate. The trisulphide of antimony, which has the function of accelerating the combustion of the composition, is a very dangerous mixture. For this reason Professor Müller replaces it by *perchlorate of potash*, which contains a larger quantity of oxygen than the potassium chlorate, and causes more rapid combustion without, he asserts, the production of a similarly dangerous explosive composition. His formula is the following: potassium chlorate 3 parts, perchlorate of potash 3 parts, magnesium powder 4 parts.

The Photonom.—This is the name of an ingenious new instrument constructed by one of our most eminent amateur photographers, Ritter von Staudenheim, of Fild-Kirchen, which was exhibited at the last meeting of the Photographic Society of Vienna. This instrument, forming part of the objective, has the function during the exposure of distributing automatically the light coming from the object into the lens, so that, in the case of landscapes, the sky receives a much shorter exposure than the foreground. The whole arrangement is fixed upon the lens tube, directly before the diaphragm slit, and it consists substantially of a shutter, which is moved by clockwork, and which can be regulated in its rapidity by means of retarding winged screws. The shutter moves downwards before the aperture of the lens, covering at first the sky, then the middle of the scene, and lastly the foreground. If, for instance, a plate is to be exposed in all for five seconds, then, by use of the "photonom," the sky, the air, and distant mountains may be exposed for only one second, the centre of the landscape for two seconds, and the foreground, in addition to the three seconds it has already re-

ecived, two seconds extra. The landscape photographs taken by means of this instrument are of excellent clearness, and show plenty of detail.

Quinol Intensifier for Collodion Negatives.—Prof. Eder publishes in the *Correspondenz* a formula for a hydroquinone intensifier which has been communicated to him by Captain Baron Hübl. This experimentalist endeavoured to find a trustworthy physical intensifying method for collodion negatives to replace the mercurial intensifier, and he succeeded by the use of quinol-silver intensification, which acts in the same manner as the well-known pyro-silver intensifier, possessing, however, the advantage that it not only intensifies the wet plate before being fixed, but that it perfects any imperfect details in the negative by continued development. Captain Hübl dissolves 10 grammes of hydroquinone in 1,000 c.c. of water, and adds so much of an acid that the solution, with one-third of silver nitrate solution, 1 : 30, remains clear for five minutes. The intensifier has been tried by Prof. Eder, and the results obtained were excellent. The formula used was the following :—

Solution No. 1.

Hydroquinone	10	grammes
Water	1,000	c.c.
Citric acid	6	grammes

Solution No. 2.

Silver nitrate	1	gramme
Water...	30	c.c.

Before use, 3 parts of solution No. 1 are mixed with 1 part of solution No. 2. The intensifier gives as excellent results in the reproduction of line drawings for photolithography as in the case of half-tone pictures for collotype. The wet collodion plates, after being developed with sulphate of iron, are rinsed and covered with the hydroquinone intensifier. When fixed, the negatives are, for the most part, vigorous enough, but, if necessary, they can afterwards be intensified also with mercury. If the negative has been nearly correctly exposed and well developed, the hydroquinone intensifier is employed after fixing ; the clear lines are thereby perfectly preserved.

Combined Toning and Fixing Bath.—Many toning baths have been recommended of late for prints on gelatino-chloride paper, but the following one, given by Herr Jos. Rud. Shauer in the *Phot. Nachrichten*, seems to be of special value, as it contains no alum, but instead thereof acetate of soda, which compensates for the decompositions otherwise taking place in the toning baths. The bath gives excellent tones of great variety. The following solution is made up at first :—

Solution No 1.

Distilled water...	1,000	c.c.
Hyposulphite of soda	250	grammes
Sulphocyanide of ammonium	30	,,
Acetate of soda (crystallised)	25	,,

To this is added a mixture of :—

Nitrate of silver	5	grammes
Chloride of sodium	8	,,
Water	20	c.c.

After this solution has stood for twenty-four hours, milky flakes of insoluble sodium compounds are produced in it, which are removed by filtering the liquid twice. Then the following solution is made up :—

Solution No. 2.

Distilled water...	100	c.c.
Chloride of gold (yellow crystals) ...	1	gramme
Chloride of ammonium	5	grammes

Solution No. 2 is poured into solution No. 1, not *vice versa*, otherwise the bath would be destroyed by the formation of dark brown sulphocyanide of gold. After a thorough shaking and settling, the bath is ready for use. If it is preferred to tone the prints, more Vandyke brown or umbra, also five grammes of pure carbonate of ammonium, should be added to the bath. A bath made up in the described manner, which has been in use for ten months, works still as if entirely unaltered. The procedure is as follows :—Of the above 1,000 volumes, 100 volumes are poured off into a bottle for daily use. The small quantity which is eliminated by toning is always replaced from the stock solution. Should the bath, by toning one hundred cabinets or more, become dark brown, it does not matter ; the precipitate is removed from the prints by means of a soft brush in the washing water, and the bath is filtered several times. Care should be taken that the temperature of the bath is not below 68 to 71° F.

Hardening Gelatine Prints.—The same experimentalist gives a good formula for hardening or tanning gelatine prints. The following solution is made up :—

Distilled water...	1,000	c.c.
Tannin...	1	gramme
Chloride of sodium	10	grammes
Saturated solution of potassium aluminium sulphate	100	c.c.

The prints, if pressed between blotting paper, never stick together, and if squeegeed on to glass plates rubbed with talc, and dried at a temperature of 77° to 86° F., come off after half an hour with an indestructible high gloss. If they have been touched with wet or greasy fingers, it is only necessary to rub them with a dry rag to remove every trace of uncleanness. The whites remain absolutely pure, and prints treated in this manner can easily be retouched without the retouching being perceptible.

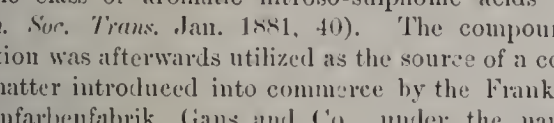
MR. W. DARNELL, writing to the *English Mechanic* about aerial photography, says :—"Being an aeronaut and photographer, I have had the opportunity of exposing a few plates, but have not got them as sharp as I should like. To get good results it requires one to look after the camera, and one to bring the balloon down to the altitude required. In the PHOTOGRAPHIC NEWS there were two plates published on April 2nd, 1886, views of Paris taken from a balloon, which I have by me."

MIRAGES.—The article in *Nature* of November 21st, 1889 (p. 69), recalls to me mirages I saw in March, 1888, while travelling in the East on the steam yacht *Ceylon*. On the 29th we were crossing the Black Sea from Sebastopol. It was a fine, cool day, and quite calm. In the afternoon a false or mirage horizon about 3° above the true one was visible for a few hours. No objects were within range of vision. The mirage disappeared as the sun declined. The next day was very much warmer, and we saw a more marked and interesting mirage in the afternoon as we were steaming across the Sea of Marmora away from Constantinople. In this case it appeared only in the west, and objects were seen reflected in an inverted position. A small conical-shaped island was seen with its inverted image at times distinct from and at times blending with the original. The image was distinctly seen of some land, which was actually below the horizon. The mirage of the reflection of the sun in the sea was, when seen through a glass, especially beautiful. It resembled a glorious cataract of golden water. This mirage lasted till quite the dusk of the evening, and then gradually thinned down and died away. I do not know whether mirages at sea are uncommon ; but as the officers on board did not remember seeing one before, I thought these instances might be worth recording.—ARTHUR E. BROWN, *Thought Cot, Brentwood, December 31st*, 1889.

EIKONOGEN.*

BY RAPHAEL MELDOLA, F.R.S.

IN 1880, when studying the action of nitroso-compounds on phenols, I discovered a nitroso-sulphonic acid of β-naphthol, which at that time was the first known representative of the class of aromatic nitroso-sulphonic acids (*Jour. Chem. Soc. Trans.* Jan. 1881, 40). The compound in question was afterwards utilized as the source of a colouring matter introduced into commerce by the Frankfurter Anilinfarbenfabrik, Gans and Co., under the name of "Naphthol green B." (Ger. Pat. 28,065. January 19th, 1884.) This compound, which was briefly described by Otto Hoffmann (Ber. 1885, 46) is the sodium ferrous salt of the β-naphthol-nitroso-sulphonic acid referred to, and may have the formula—



$$\left(fe = \frac{Fe}{2}\right)$$

according to the view taken with respect to the presence of a nitroso-group or an isonitroso-group in the compound. The colouring matter is of considerable technical value at the present time, and is of interest as being the only known artificial colouring matter which contains iron as an essential constituent, excepting, of course, the well-known iron-cyanogen compounds.

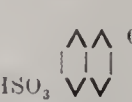
Theory indicates the existence of seven isomeric monosulphonic acids of β-naphthol, of which only four are known at the present time. Only one of these is concerned in the present communication—viz., that modification first discovered in 1869 by Schaeffer, and which is best prepared by heating β-naphthol with twice its weight of strong sulphuric acid to the temperature of boiling water till the naphthol is completely sulphonated. One, if not two other, monosulphonic acids are produced at the same time, together with a certain quantity of isomeric disulphonic acids, but the chief product under the conditions specified is Schaeffer's monosulphonic acid. It is the latter acid, which on a small scale can best be isolated in the form of its ammonium salt, which gives the nitroso-acid under consideration. In order to prepare the latter it is only necessary to dissolve a given weight of the ammonium or other salt of Schaeffer's acid in cold water together with the necessary quantity of sodium nitrite, and then, keeping the solution well cooled, gradually add hydrochloric acid to acid reaction. The nitrosulphonic acid is at once formed and remains in the solution, imparting to the latter an orange colour. The acid can, if necessary, be isolated in a state of purity as a barium or calcium salt (*Jour. Chem. Soc. Trans.* 1881, 44).

By the reduction of the nitrososulphonic acid an amido-sulphonic acid was prepared, which was isolated and analysed and described in the paper referred to (*loc. cit.*, 47). This acid was the first amidosulphonic acid of naphthol ever obtained, and it is the sodium salt of the said acid which has recently been introduced as a photographic developer under the name of "Eikonogen." As the discoverer of the acid I have been urged to give this note upon its chemical history for the use of English chemists, and in doing so, I think it only fair to add that although the easily oxidisable character of the acid and its salts naturally suggested trying it as a photographic developer, I was not at the time engaged in photographic work, and the idea was never carried out till the substance was actually introduced into commerce for this purpose.

Of the advantages of eikonogen as a developer I do not propose to say anything on the present occasion, since its qualities have been thoroughly tested by photographers, and it is becoming very popular for many reasons, which will be found in the papers dealing with its application. (See, for instance, papers by Professor G. D. Liveing, PHOTOGRAPHIC NEWS, September 20th, 1889; John Spiller, in the recently-published YEAR-BOOK OF PHOTOGRAPHY (1890, 124); also Lyonel Clark and H. M. Elder in the PHOTOGRAPHIC NEWS of December 13th, 1889). Some months after the publication of my paper Griess obtained an amido-β-naphtholmonosulphonic acid, which was no doubt identical with the one described by me (Ber. 1881, 2041). He obtained it by reducing the azo-compound formed by the action of metadiazobenzoic acid on Shaeffer's acid. The whole subject has since been thoroughly investigated by O. N. Witt (Ber. 1888, 3468 and 3489), who has not only confirmed and extended my original observations, but has also obtained the three other amidosulphonic acids corresponding to the three β-naphtholmonosulphonic acids made known since the time of my investigations. Witt's amido-sulphonic acids were all prepared by the reduction of azo-derivatives of the respective β-naphthol-monosulphonic acids by means of stannous chloride. There are thus known at the present time:—

1. Amido-β-naphthol-β-sulphonic acid, from Schaeffer's acid.
2. Amido-β-naphthol-α-sulphonic acid, from Bayer's (Crocic) acid.
3. Amido-β-naphthol-δ-sulphonic-sulphonic acid, from Casella's F-sulpho acid.
4. Amido-β-naphthol-γ-sulphonic acid, from Dahl's acid.

Of these four acids the first appears to be the most readily oxidisable, and therefore the most suitable for photographic development. It is possible that some specimens of eikonogen may contain the acids (2), (3) or (4), but I have not yet met with a preparation in which these isomerides could be detected. With respect to the constitution of eikonogen, I am glad of the present opportunity of being able to correct my earlier statement, because more exact information has been obtained by numerous workers during the nine years which have elapsed since my own investigation. The constitution of the amido-sulphonic acid is, in the first place, dependent upon the constitution of Schaeffer's acid, which was practically unknown in 1881. It was not even known with certainty whether the hydroxyl and sulpho-groups were in the same or in different rings. It has now been shown that this acid is a heteronucleal derivative, and the most probable formula is—

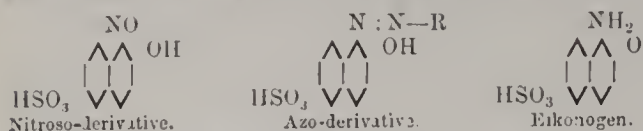


It is true that by the oxidation of my amido-β-naphthol-sulphonic acid I obtained phthalic acid, and this led me to the conclusion that Schaeffer's acid was a homonucleal compound. There is now no doubt, however, that the product of oxidation is β-sulphophthalic acid (Remsen and Comstock, *Amer. Chem. Journ.* V., p. 106; Rée, Inaug. Diss. Bern, 1886), and that the phthalic acid obtained by me from the amido-sulphonic acid was the result of the hydrolysis of this sulphophthalic acid.

It is well known that in compounds which furnish both

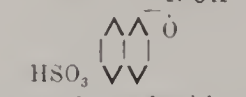
* From the *Journal of the Society of Chemical Industry*, December 31st, 1889. No. 12, vol. viii.

azo-and nitroso (isonitroso) derivatives the azo-group and the nitroso (isonitroso) group occupy the same position in the aromatic ring. In Schaeffer's acid the most readily replaceable hydrogen atom is undoubtedly the α-(ortho)-atom with reference to the hydroxyl, so that the constitution of these derivatives and of eikonogen is as follows :—



Nitroso-derivative. Azo-derivative. Eikonogen.

If the first of these compounds be regarded as an isonitroso-compound its formula will be :—



Eikonogen may thus be made either by the reduction of the nitrososulphonic acid or of an azo-derivative of Schaeffer's acid. By the action of diazobenzene chloride upon this last acid an orange colouring matter is obtained, which is met with in the market under the names of "Crocein Orange," "Brilliant Orange," "Ponceau 4 G.B." &c. It is one of the oldest known azo-colours, having been described by Griess in 1878 (Ber. 1878, 2197.) This compound may be used as a source of eikonogen, using stannous chloride as a reducing agent:—

$$C_6H_5.N_2.C_{10}H_5.HSO_3.OH + 2\,SnCl_2 + 4\,HCl = C_6H_5.NH_2 + 2\,SnCl_4 + C_{10}H_5.HSO_3.OH.NH_2$$

It would seem more economical, however, for manufacturing purposes to revert to the original method and reduce the nitroso-β-naphtholsulphonic acid, which need not even be isolated for this purpose, but can be formed by the action of nitrous acid in the manner previously described, and reduced in the same solution. The use of aniline can thus be dispensed with, and tin replaced by a cheaper reducing agent, such as zinc dust. The raw material is, moreover, practically a waste product, since the azo-colours obtained from Schaeffer's acid are of but little value compared with those obtained from the other monosulphonic acids of β-naphthol, and it is the manufacture of some of the latter that Schaeffer's acid is obtained as a by-product. Owing to the readily oxidisable character of the salts of eikonogen, it is necessary, after the free acid has been obtained, to convert the latter into the sodium or potassium salt in the presence of excess of sulphite.

To the numerous coal tar products which have given to chemical industry such a wealth of technically valuable compounds, we can now add this new photographic developer, which threatens to drive the older and related compounds—pyrogallol and hydroquinone—altogether out of the field.

FOR restoring old papier machè trays a German photographer recommends a double coating of asphaltum, followed by a coat of a solution of 1 part of shellac in 5 parts of alcohol.

TEMPERATURE IN DEVELOPMENT.—Alfred Stuglitz notes in the *Photo. Rundschau* the extreme influence of temperature on developers. He states that a developer used too cold is certain to give hard negatives, while one too warm will give them quick and weak. He recommends a standard temperature at which the developer is to be kept all the year round, about 60° F.; and considers that 10° either way make considerable difference in the action. More especially is this so in the leisurely development which is always advisable when finely graduated soft half-tones are desired in the plate; with very rapidly-working development the effects of temperature are not so noticeable.

Notices of Books.

OUR HOME IN AVEYRON. By C. Christopher Davies and Mrs. Bronghall. (*Blackwood & Sons, London:* 1890.)

THIS book consists of studies of peasant life and customs in Aveyron and The Lot, far down in the south of France, and is illustrated with copies of photographs taken by Mr. Davies. He says that in giving lectures and exhibiting lantern pictures to rural audiences in England, he found that much more interest was exhibited in the simple details of home life, which might easily be compared with one's own modest experiences, than in more ambitious tales of travel. This is true, and were more lantern-slide pictures devoted to illustrating the manners and customs of other nations than ours, and fewer devoted to mountain scenery and large public buildings, their interest to the general public would be increased. The book before us does not exactly carry out its programme so far as the illustrations are concerned; they number but a dozen altogether, and several of these are not pictures representing the manners and customs of the people. What, in this respect, is lacking in the pictures—which, however, are interesting so far as they go—is made up in the letter-press, wherein will be found minute details about life and manners in a French mining village, furnished by permanent English residents, who consequently were well acquainted with the subject in hand. One of the best illustrations in the book represents a religious procession, with the villagers ambling along, and throwing out their legs, with their hands in their pockets, all resulting in a realistic effect such as photography alone would be likely to give, for few painters could or would have grouped their models in such natural and ungainly attitudes.

The out-of-the-way district described by the authors is known as the "Lost Country," the difficulty of access to and egress from it having given it, say the authors, the name of the "Pays Perdu" among distraction-loving Frenchmen. "What will you?" they say; "There is nothing, literally nothing, wherewith to amuse one's self. It is a lost country." On a remark being made to a peasant woman, "This is a beautiful country of yours," she replied, "Oui, mademoiselle, mais il est un peu perdu."

In the schoolroom of the village schoolmaster, who was the mayor's secretary, Mr. Davies one night gave a lantern entertainment to a crowded house. "Never," he says, "was such a thing heard of in that out-of-the-way village before. One woman asked another if a *lantern magique* was like a Chinese lantern. The younger people, like most young people at a half-dark entertainment, indulged in a little flirtation, thus giving the pictures an added charm; while as for the children, they gazed with open-mouthed wonder upon the enchanted sheet where the views and figures appeared and disappeared. When the news got abroad that Monsieur le Directeur (of the local mines) had come, and the entertainment was about to commence, in came the people, like the rats in the castle on the Rhine; they came in at the windows and in at the doors, till the place was literally crammed. The front row knelt, the second stood, the third climbed on the desks, and the rest stood on the window-sills or on the shoulders of those willing to bear the weight.

"The long man of the village bore a friend on his shoulders, and this friend bore another friend. Then these three got unsteady and toppled, in their descent upsetting the belle of the village, who gave the long man a

box on the ear by way of recompense. The audience were delighted with the views shown them of Paris and Switzerland; but when a transparency of their village street, showing a group of familiar figures, was thrown upon the screen, they were uproarious. We finished up with a photograph of the director, under which was written *Bonne nuit*, after which the schoolmaster thanked us for the entertainment, and the people dispersed, thoroughly pleased with their evening's amusement. One poor old woman asked if there would be a collection, and when told No, expressed her astonishment that any one should take so much trouble simply to give pleasure to others. Poor people! they are so money-grubbing themselves, and so used to see those above them money-grubbing also, that they cannot understand that we should wish to give them pleasure and charge nothing for it."

The farmers in France are for the most part proprietors of the land they cultivate, and they turn out vast quantities of dairy produce for sale in England, to the great financial benefit of our Gallic neighbours. Mr. Davies and some of his English friends were one day invited to lunch by a wealthy peasant proprietor, M. Pantillac, an unshaven little man, in a blue blouse and a shabby felt hat. As in those parts flower-pots with a big hole in are fixed in front of the houses, and the birds of the air confidingly build their nests therein, and the young birds are collected and cooked by villagers, an invited guest fresh from England expected stewed nestlings and dandelions on the occasion. "On the contrary," said a friend, "you will get a meal of twenty courses, and most excellent wines. . . . He wants me to buy a bit of his land, so he will give us a grand feast." "That isn't very flattering to us; I would rather think he means to be hospitable." "Ah! that is not the virtue of a French peasant."

France is a great country, and what is true of one portion may not be true of another, just as a description of Yorkshire peasantry would not be applicable to those of Scotland. The description the authors give of the main streets of some of the villages being also the main sewers, all open to sun and air, is not applicable to all parts of France. In the rural districts of that nation will be found many homely, hospitable, genuine people.

The authors of the book are Protestants, as they often inform the readers, and they have much to say about Protestants and Catholics. Some years ago a Government Inspector asked the children at the convent school at Bouillac, "What are Protestants?" and was told that they were black people with tails, and, being little better than the devil, were all damned. At his last visit the children were indignant; they said that they had discovered that the English Protestants then living in the village had no tails, were not black, but were very nice people indeed.

Altogether, the book is an interesting one to photographers and to the general reader. It gives information about the inner life, and customs, and thoughts of villagers in some of the provinces of France, such as could only be given fully by permanent residents in their midst, and not by casual visitors. Hence the photographic tourist, who reads it before starting on his travels in France, can gain a store of useful information, remembering always that portions of it are true only in relation to the particular provinces described by the authors.

RUST spots on lenses may be readily removed by placing the spots in contact with chlorhydric acid diluted with a little water.—*La Nature.*

THE LATE CUTHBERT BEDE AND HIS BOOK "PHOTOGRAPHIC PLEASURES."*

BY W. LANG, JNR., F.C.S.

I THINK we may safely take it for granted that all of us have read "The Adventures of Verdant Green, Freshman at Oxford." Published more than thirty years ago, it still enjoys a world-wide popularity. It is not, however, so generally known that the same author has a work which appeals more especially to us who are interested in photographic matters. The title of this work is "Photographic Pleasures," popularly portrayed with pen and pencil, and I purpose showing you, through the medium of the lantern, some of the more interesting sketches which are to be found in the volume. Before proceeding to do so, however, a few details regarding the author may perhaps be appropriately given. In the first place, we will have thrown on the screen the portrait of Cuthbert Bede, which appears as frontispiece to the volume of "Verdant Green" which I have in my possession, and then we will have the picture which appeared in the *Illustrated London News* of December 28th, 1889. The original is a Meisenbach photo-block from a photograph taken by Messrs. Hill and Saunders, of Cambridge. It is almost superfluous to state the fact that Cuthbert Bede is only a *nom de plume*, our author's real name being Edward Bradley, or, rather, the Rev. Edward Bradley. At the time of his death, which took place on the 12th of December last, he was vicar of Lenton, a village near Grantham. Although his famous work depicts student life at Oxford, he was not himself an Oxford graduate. He received his education at Durham University, where he took his degree. He was ordained in 1850, and was successively incumbent of Bobbington, in Staffordshire (1857), rector of Denton, Hunts (1859), rector of Stretton, near Oakham (1871), and finally he was presented in 1883 to the vicarage of Lenton. "Verdant Green" was published in 1854, and "Photographic Pleasures" in 1855. The following are his other works, with year of publication:—"Nearer and Dearer" (1857); "Fairy Fables and Happy Hours" (1858); "Glenereggan" (1860), this being a record of a visit paid to Kintyre; "Curate of Cranston" (1862); "Tour in Tartan Land" (1863); "The White Wife" (1864); "The Rook's Garden" (1865); "Matins and Muttons" (1866); "Fortheringay and Mary Queen of Scots" (1866); "Little Mr. Bouncer," a sequel to "Verdant Green" (1878). He contributed, also, articles to *Punch* and to the *Graphic*. The above list will show that he was a prolific author, and he not only could write with his pen, but he could draw with his pencil. The illustrations accompanying the letterpress were invariably his own. You will be better able to judge of his success in this direction when you see some of the pictures from his "Photographic Pleasures." Here is the title-page. He dedicates the book, "To all the light-hearted friends of light painting these pages of light literature are with no light regard dedicated."

The book is divided into twelve chapters:—

CHAP.

I. "Photography regarded as a Light Subject."
II. "Photography in a Legendary Light."
III. "Photography in a High Art Light."
IV. "Photography in an Artistic Light."
V. "Photography in a Portrait Painting Light."
VI. "Photography in a Love Light."
VII. "Photography in an Amateur Light."

* A Communication to the Glasgow Photographic Society.

CHAP.
VIII. "Photography in an Aristocratic Light."
IX. "Photography in a Negative Light."
X. "Photography in a Positive Light."
XI. "Photography in a Detective Light."
XII. "Photography in All Manner of Lights."

The illustrations are twenty-four in number, all of them full-page. The picture which forms the frontispiece has for its title, "Portrait of a distinguished photographer who has just succeeded in focussing a view to his entire satisfaction." The first illustration in the body of the book shows a possible contingency which might happen to the unhappy possessor of a photographic tent: the letter-press underneath is as follows:—"An enthusiastic photographer tries a tent of his own invention. He is disagreeeably interrupted in the pursuit of science by the entry of a wild Irishman, who forthwith is carried back in imagination to the pleasures of Donnybrook Fair, and is unable to resist the temptation that the tented head presents." The next illustration represents "A mediæval photographer, from an illumination in the (Gun) Cotton MSS.," and "Monsieur Daguerre introducing his pet to Mr. Bull, with the remark, 'My Sun, sir.'" Both pictures are intensely funny. The toy camera on wheels which the son draws after him is a fine touch of humour.

I may just refer to one or two of the more outrageous jokes in the chapter, "Photography in a Legendary Light." You have had from myself lately a little of the history regarded seriously: we will see what Cuthbert Bede has to say on the matter from his point of view, which we may safely call the comic side of the question:—"Porta was the gate that indirectly led to photography. It was in the sunny land of Italy that a philosopher, Baptista Porta by name—a Porta who thought no small beer of himself—invented the camera. He inhabited an apartment to which (owing, probably, to the oppressive nature of the window tax) the light was admitted through a small aperture. The whole of the discovery was owing to the hole, for, as it was of a lenticular shape, the ray of light that passed through it painted upon the wall, in cheapest of frescoes, pictures of all that was going on on the outside. The philosopher saw the ray, cried 'Hurrah!' and constructed the camera, that Pandora's box in which photography lay concealed." Speaking of Sir Humphry Davy's attempts, he says, "His plates were like the hearts of flirts, the images impressed on them were but faint, and could not be fixed." Our author is a little mixed when he says, "Daguerre's pictures were fixed on paper impregnated with nitrate of silver; those of M. Niépcè were upon glass, silver-plated copper, and polished tin." But let that pass. He gives Daguerre a side thrust when he says the Frenchman delayed the execution of the official document, viz., the giving over the process to the French nation, until a patent had been secured for an agent in England, "thus being guilty of a deception patent to all." The dispute between Talbot and the Rev. J. B. Reade, as to the use of gallic acid as a developer is thus disposed of:—"The Rev. J. B. Reade addressed to the London Institution an account of a method for obtaining light pictures by a process in which infusion of galls was employed. This led to the infusion of no small amount of gall in a correspondence which took place on the subject between Mr. Reade and Mr. Talbot, the latter having, in an affidavit, denied Mr. Reade's title to the invention he claimed; the moral of all this being that Mr. Talbot had leant upon a reed until it pierced him." Referring to Scott Archer, we are told he "shot himself into the temple of fame by the use of guncotton."

The next illustration in order, entitled "Photographic Tableaux," embodies two pictures. "The Infant Photography Strangling the Serpents," these being Daguerre's and Talbot's patents, and "Photography between Love and Vanity." This is followed by a full-page picture, a simple mode of "levelling" a camera. The picture speaks for itself. The seventh illustration comprises three subjects, and are as follows:—"The Fixing Process," where a bull is seen chasing a somewhat obese individual who has arrived at the wicket gate of the field only to find that he cannot get through; "An Exciting Process" is represented by a man being pushed overboard from a ship only to fall among the sharks who are expectantly waiting for him; "The Sensitive Process" depicts a pair of lovers in the conventional attitude, with the motto, "He to lips that fondly falter presses his without reproof."

(*To be continued*).

THE DAGUERRE MONUMENT AT WASHINGTON.

MR. H. MCMICHAEL writes, on behalf of the Daguerre Memorial Committee:—The memorial will be placed in the Smithsonian Institution at Washington, at the opening of the next convention, which will be held in that city some time next summer. A report will be made at the next convention of the amount raised by each house, and the name of each person who subscribes one dollar will be deposited within the monument.

The Committee, composed of the Executive Board of the Photographic Association of America for 1889, have spent six or eight weeks in correspondence with different artists, with reference to style and price of such a memorial, and have come to the conclusion that the sketches submitted by the celebrated sculptor, J. Scott Hartley, of New York, are the most satisfactory. Mr. Hartley sends four sketches, ranging in price from twenty-five hundred to six thousand dollars.

Nos. 1 and 2 will cost twenty-five hundred dollars each. These designs contemplate pedestals three feet six inches high; No. 1 to be of richly carved oak, and No. 2 of granite with bronze bas-relief; a design of oak or laurel framing the relief on a wood pedestal, shows Daguerre experimenting with the camera. Both pedestals are to be surmounted by a bust of Daguerre in bronze or marble.

No. 3 can be executed for three thousand dollars, and consists of a globe and rough unhewn base in granite; globe polished and map incised and encircled with laurel wreath in bronze and mounted with a cast-bronze bust of Daguerre, the whole to stand five feet high.

No. 4 contemplates something more elaborate, and consists of a pedestal or base in unpolished granite, the name of Daguerre in polished letters. This base is mounted by a globe of polished granite, map incised, with wreath of laurel, medallion portrait of Daguerre and life-size figure of Fame in standard bronze.

The design represents Fame taking the laurel, which encircles the earth, and placing it about Daguerre as a framework. The whole is to stand nine feet high, and would certainly present many unusual art possibilities. There would be little profit to the artist at six thousand dollars, for which he agrees to erect it.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical meeting, Tuesday, January 28th, at 8 p.m., at the Gallery, 5A, Pall Mall East.

Specifications Published.

1365.—*January 25th*, 1889. "Lamp for Photographic Work." WILLIAM JAMES LANCASTER, trading as J. Lancaster and Son, of Colmore Row, Birmingham, Manufacturing Optician.

This invention relates to an improved construction and arrangement of lamps, principally for photographic work, although the same may be employed for other purposes.

The said invention consists 1st, in a double reflector, viz., a primary inside reflector, and a secondary outside one. 2nd, In a means of retaining or holding the said secondary reflector in an adjusted position. 3rd. In double folding panes of ruby light, which open outwardly, and fold inwardly upon each other.

In making a lamp according to my invention, I mount a pyramidal shaped body part upon a base or pierced support, and with the said body part surmounted by a perforated lantern or cowl, through the piercings of which the products of combustion of the lamp outwardly pass.

The open front of the lantern is enclosed by two ruby panes or lights, respectively of about the area of the said open front, and are so arranged that when in use they fold and lie flat light-tight, one upon another.

Thus, the No. 1 ruby light is hinged close to one side of the open front, and folds flat to its boundary edging, whilst the other or secondary ruby light is hinged crank like to the other side of the said open front, and is arranged to fold over upon, and flat to the No. 1 light aforesaid.

To near the top of the open front, the combined reflector and lid is jointed, and moves vertically and flap like over the ruby lights as aforesaid; so that light radiating from the lamp falls upon the reflector, which depends at an angle, and is from thence reflected downwards upon an object as may be required. This overhanging reflector is provided with a stiff joint, so that it may rest when adjusted at any angle.

The affixing after adjustment of the secondary reflector may be accomplished by a forked or slotted arm, directed from the top of it, and embracing the stem of a headed screw which, when turned home, clamps the arm in the said reflector's adjusted position.

The secondary reflector also prevents the rays of light from passing upwards into the operator's eyes in developing or manipulating a photographic negative.

The purpose of the double ruby panes is that an operator can decrease or intensify the ruby light at pleasure.

The primary reflector is mounted upon and at the back of the oil tank or reservoir, which is preferably placed in position by a sliding movement; that the removal of the tank and burner, carried by it, takes away with them the said reflector.

The wick winder axis is connected to the outside by a detachable clutch arrangement, consisting of an outside milled head, whose neck passes inwardly to a clutch or fork, wherein a crutch end of the said winder axis passes when the tank is in position.

Thus, when the tank is removed, the crutch end of the winder axis is taken from the fork or clutch of the turn, and when the tank is placed in position the winder axis and turn are as one, and rotate together.

The back of the lamp is preferably made to slope pyramidally more than the sides, and upon which said back a handles or handles is or are secured.

It may be further observed that the lid encloses the front when closed upon it, and that the primary reflector may be made detachable from the lamp or from the tank, so as to admit of being readily cleaned.

The inventor claims—

1.—Providing or enclosing the open fronts of lamps for photographic work, with two or more ruby and orange coloured panes or lights, which admit of being used independently or collectively for the purpose.

2.—Making the hinged sides of the carrying frames of ruby or orange lights, referred to in the preceding claim, stand away flange or crank like from the sides of lamp, to which they are hinged, so as to admit of the said lights folding upon each other when closed, and opening out, free of the open front of the lamp, or of the frame or frames of the inner light or lights.

3.—Providing lamps employed in photographic work, as described, with a screen reflector, jointed to the top of the lamp, and adapted to be employed as a reflector and screen when open, and as a lid for enclosing the front of the lamp and cognate parts of it when closed.

4.—Affixing the combined screen reflector and lid in a screening and reflecting position, by means of a jointed and slotted arm and clamping screw.

5.—Providing the interior or back inside of the lamp with an upright parabolic reflector, or an upright reflector of the figure of a parabola, in cross section.

6.—Providing lamps as described, with open bottoms, or bottoms partially enclosed by the oil tank, and a platform partition, whereby air for promoting combustion is admitted, and light from the lamp intercepted.

7.—Operating the wick winder spindle from without by a clutch or connection.

8.—The construction and arrangement of the parts of lamps for photographic and other work.

18,444.—*19th November*, 1889. "Appliances for Ascertaining Distances." HENRY SAMUEL SPILLER WATKIN, of the Wilderness, Woolwich, Kent, Major Royal Artillery.

The instrument and appliance consist of three parts:—

a. An optical square fitted with a telescope and hinged flap.

b. A telemeter by which the distances are read off on a drum.

c. A peculiarly constructed cord which forms a base, at the ends of which the instruments are worked.

After describing the apparatus, with engravings, the inventor says: "To obtain ranges of moving objects, all that is required is for the observer with the optical square to constantly obtain coincidence by swaying his body and shifting his position. In this manner the ranges of artillery, cavalry, and infantry in motion have been taken; five or six ranges per minute being obtained, to an accuracy of one per cent."

The inventor claims:—

1. The peculiar arrangement of screw and drum.

2. The arrangement whereby the said screw is applied to form a telemeter.

3. The construction of cord for use with the telemeter.

QUICK WORK.—An unprecedented experiment in photography was tried at the entertainment of the Lynn Camera Club, whereby the audience was shown to itself. During the first part of the meeting, Mr. G. D. Milburn, of Rochester, took a flash-light picture of the audience from the platform. During the entertainment he developed the negative, made a lantern slide, and, while the speaker, Mr. Walter G. Chase, was describing some instantaneous pictures the view of the audience was suddenly thrown on the screen without previous notification. The effect upon the individual members of the audience, as each one recognized himself or herself—for every face was distinct—was somewhat startling. The flash-light exposure, development of negative, and the exposure and development of the lantern slide, including washing of both negative and slide, consumed less than one hour."—*Wilson's Magazine*.

Correspondence.

ORTHOCHROMATIC PHOTOGRAPHY.

SIR,—Mr. B. J. Edwards's proposition that but for the patent law, "colour-sensitive photography would now be numbered among the lost or forgotten processes of the art," appears to me to be not only so baseless, but in such direct opposition to the facts, that I think it should not be allowed to pass unchallenged.

Mr. Edwards complains of M. Vidal for ignoring Tailfer, whilst his own proposition ignores the labours of Waterhouse, Vogel, Ives, Obernetter, Abney, and others; labours which have established colour-sensitive photography. Not only is this so, but it is the work of one of these inventors that has put it within the possibility of a patentee, M. Tailfer, to endeavour to monopolise one of the principal processes.

In another letter, Mr. Edwards has spoken of the "eosinated silver bromide process patented by Tailfer," an expression that might lead to the inference that eosinated silver bromide itself is claimed in the patent, which, however, is strictly limited to the use of ammonia with eosine, eosine as a colour-sensitiser having been some time before discovered by Waterhouse.

Any who may desire to practise orthochromatic photography, and do not wish in their own persons to defend public rights at the risk of threats, at all events, of legal proceedings, may remember that, according to several experimentalists, eosine and erythrosine may be used with effect without ammonia, whilst chlorophyll, cyanine, chinoline, and azaline, and other sensitisers, are substances that not even the most partisan scientific witness can be found to class as eosines.

W. E. DEBENHAM.

SIR,—Mr. B. J. Edwards has, perhaps, not exactly caught the sense of my observations relative to his presentation to the French Photographic Society. I by no means intended to criticise the nature of the results obtained upon his orthochromatic plates; I merely said that amongst the proofs submitted there were some which had been reproduced *a jour frisont* (those on ordinary plates), whilst the compared image on an orthochromatic plate had been obtained with another lighting. That is a simple statement of fact which does not relate to the results, well recognised and appreciated by me, obtained on orthochromatic plates.

If Mr. Edwards maintains that he has not operated with different conditions of lighting, I am constrained to avow that I do not understand it at all; but I do not the less persist in finding it astonishing that upon ordinary plates there should be effects of reflections that do not exist on the orthochromatic plates.

I recognize that my ignorance is great upon such matters, for up to the present I believed that orthochromatism only modified the tonalities obtained, without having anything to do with the reflections. To my judgment, as to that of all who saw the proofs, it appeared evident that they were the result of different lightings. I intended to say nothing more than that, and I am not of those who would place a barrier in the path of progress, from wheresoever it may come, and whatever may be the means employed to realize it.

Paris, 18th January, 1890. LEON VIDAL.

THE "ROLL CALL."

SIR,—One of your "Notes" in yesterday's issue treats of Mr. Muybridge's approval of the manner in which Meissonnier draws horses in motion, and you remark, "it would be interesting to have his (Mr. Muybridge's) opinion of Mrs. Butler's 'Roll Call,' which at the time of its exhibition excited so much discussion in regard to the position of the horse's legs."

It was my pleasure to listen to Mr. Muybridge at the Associated Soirée held in Liverpool on the 8th inst. The subject of his lecture was "The Science of Animal Locomotion in its Relation to Design in Art." During the course of the lecture, reproductions of a picture by Meissonier representing Napoleon and his staff on horseback, the "Horse Fair," and "Ploughing," by Rosa Bonheur; and "The Roll Call," by Lady Butler, were projected on the screen. Whilst severely criticising the manner in which Rosa Bonheur expresses motion in the animals she paints, Mr. Muybridge had nothing but words of commendation for Lady Butler and Meissonnier, both of whom, he said, had, in the face of adverse criticism, portrayed the walk of a horse with absolute fidelity to nature. It must be pleasing to all photographers to know that their "art-science" has been the means of vindicating the artistic perception of a great English woman.

J. H. SPENCER.

36, *Bridge Street, Chester, January 18th*, 1890.

BASKET-WORK IN PHOTOGRAPHY.

SIR,—I am pleased to see that you are taking up the question of basket cases for photographic baggage, and I feel assured that it will be to the benefit of tourists to adopt this means of packing their apparatus in place of the usual leather cases.

I must, however, disagree with your opinion that palm leaf baskets will be generally adopted by photographers as those best suited to their requirements. Lightness is the chief reason of the photographer for using a basket at all. Now, strength for strength, the weight of a basket properly made of willow will be only one-half that of a palm leaf basket. As to appearance, my ideal photographic basket is covered outside with waterproof cloth, is lined inside with baize, the wicker-work is not visible, and is merely a skeleton frame-work giving the needful strength and rigidity. A handle of bamboo would do excellently, and need *not* be covered with leather, bamboo being smooth, and affording a good grip. If it be thought desirable for the wicker-work to be visible, a basket of willow can be made so closely worked as to be practically waterproof. This would add slightly to the weight and cost.

Palm-leaf baskets could never be made so closely as to be waterproof or weatherproof of themselves. I am sending for your inspection a half-plate case made with a skeleton of wicker-work, and respectfully invite your criticism. Your wide experience will doubtless suggest improvements in an article as yet imperfect.

Referring to the concluding paragraph of your article, photographers may possibly not concern themselves as to who makes their apparatus and accessories, but quality and price being equal, I venture to think English photographers will employ English workmen.

W. SCALING.

Bushford, Nottingham, January 18th, 1890.

CAMERA CLUB EXHIBITIONS.

SIR,—Will you kindly allow me to announce that the exhibition of Rejlander's photographs at the Camera Club will close on Thursday, January 30th. Until that date the Exhibition will be open to visitors, on presentation of card, from 10 a.m. to 5 p.m.

On and from Tuesday, February 4th, there will be an exhition of photographs by members of the Amateur Photographic Field Club.

This Society is known as one of the earliest devoted to landscape work. A part of the exhibition will be given up to showing results of the older processes. The collection will be open to inspection for about six weeks, under the usual conditions.

G. DAVISON, Hon. Sec.

HACKNEY PHOTOGRAPHIC SOCIETY.

Sir,—Below is our programme for February, 1890:—

Thursday, 13th—"Retrospective Photography." Mr. G. H. SLIGHT.

Thursday, 27th—"Exhibition of Members' Work and Apparatus."

Each member is expected to send on apparatus and work, to reach Morley Hall by 6 p.m. on the 27th.

W. FENTON JONES, Hon. Sec.

12, *King Edward Road, Hackney, N.E.*

Proceedings of Societies.

THE CAMERA CLUB.

ON Thursday, January 16th, Mr. R. TINDALL gave an address upon the "Plane Polarization of Light." Mr. H. M. ELDER occupied the chair.

Previous to the lecture the Secretary handed round some interesting silver prints sent to him by Mr. W. K. Burton, and he announced that Mr. Burton had contributed a paper, which would be read hereafter at the Club.

An apparatus called the "Hibbard Flash Lamp," sent by Messrs. Fry & Co., was also exhibited, and later in the evening experimental flashes were made by it. The light afforded by it appeared to be unusually brilliant, and two or three flashes of about equal intensity were obtained with one charge.

Mr. Tindall's lecture was illustrated throughout by the aid of a lantern polariscope.

At the conclusion of his paper Mr. Tindall handed round two cloud negatives—subject, blue sky and white clouds—one taken in the ordinary manner, and the other with a Nicol prism before the lens; an orthochromatic effect was alleged to be thus obtained.

On Thursday, January 30th, Mr. T. R. Dallmeyer will read a paper "On some Practical Deductions from the Law of Conjugate Foci."

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting on the 16th inst., Mr. J. L. BRIGINSHAW occupied the chair.

Mr. T. E. FRESHWATER passed round two lenses that had been sent from India to be repolished, being useless from atmospheric action on the surface of the glass.

Mr. A. COWAN had continued his experiments of the previous week with the developer published in the *American Journal of Photography*, using alternately acetate, citrate, oxalate, borate, phosphate, and tartrate of soda; twenty-five grains to the ounce were used in each case; pyro, hydrokinone, and eikonogen were severally used also in conjunction. With the exception of borate, all gave excellent results; with this developer he was unable to obtain the least trace of an image. Ordinary commercial plates were used, registering about 19 on the sensitometer, with an exposure of five seconds, three feet from a gas burner.

Mr. COWAN said the degree of density in each case was entirely at the will of the operator. The results of the experiments—in all, twenty-three half-plates—were exhibited; among them was a plate developed with pyro and sulphite of soda only. This, Mr. Cowan said, tended to disprove the accepted theory that sulphite of soda was a restrainer. All the plates were fixed in hyposulphite, to which bisulphite of soda had been added. Of the various developers used, the oxalate in connection with pyro was found the most energetic. Mr. Cowan said it was his intention to repeat the set of experiments with variations of the several developers, promising to lay the results before the members as soon as complete.

Mr. A. HADDON spoke about the importance of the various salts used in the developer being as nearly neutral as possible, and the desirability, in experimenting, of testing each salt separately. He believed in the set of experiments before them free alkali in the sulphite of soda to be the developing agent, and he questioned whether the other salts played any part at all in the development of the image.

Mr. E. B. LAWFORD showed two bromide prints of a sepia tone. After washing and fixing, he had placed them in water to which a few drops of an intensifier sent out by the Platinotype Company had been added, which changed the black into a sepia tint. (It was remarked that the whites had also become discoloured.) Mr. Lawford believed the paper used was not a pure white previous to placing the prints in the back referred to. He intended to repeat the process with pure white paper.

A question from the box was read:—"Does reversal of image take place when collodio-bromide is over-exposed in the same manner as it does in the case of gelatino-bromide?"

None of the members present had experienced any reversal of image in using collodio-bromide.

EAST DULWICH AND PECKHAM PHOTOGRAPHIC SOCIETY.

ON Friday, Jan. 17th, the President, Mr. F. W. EDWARDS was in the chair, and the following new members were elected:—Messrs. B. Lyon, E. Cann, and Robert Burch.

The subject was "Cameras, Stands, and Shutters"; among the shutters on view were Watson's snap, Kershaw's, Guerry's, Mayfield's, and Newman's. Mr. Cadett sent three specimens of his shutters, in one of which all chance of vibration was exeluded by the use of a velvet sleeve for attaching the lens to the shutter. Specimens of the optimus three-fold and four-fold stand were also shown by the members using them. One of Pumphrey's metal stands was also on view.

The discussion on shutters and stands occupied the eveniug, so the subject of cameras was postponed.

Mr. W. RICE drew the members' attention to a specimen of Messrs. Perken, Son, and Rayment's new wide angle euryscope saying that it worked at F. 9·50.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Committee of this Association met on the 17th inst.

Mr. Lambert and Mr. Bird, of Bath, and Mr. R. Keene, of Derby, were elected members.

The Committee considered two applications for assistance; in both cases grants were made.

Messrs. W. T. Coventon, F. Haes, H. Newson, and T. Samuels were appointed arbitrators.

Friday, February 14th, was fixed for the annual general meeting.

Mr. H. J. Beasley was elected honorary secretary, and will take up his duties on the above date.

A special committee meeting was then held, and the proposed new rules formally passed; they will be submitted to the general meeting for confirmation.

ABNEY CAMERA CLUB.

AT the weekly meeting of the above, held Jan. 17th, after the discussion of the questions in the box, the Sec., M. F. H. LEEDS, A.I.C., read a paper entitled "The Chemistry of Photography," in which he discussed, from the theoretical point of view, most of the ordinary processes of photography. The chemical symbols and equations employed were illustrated by means of a blackboard.

The discussion was postponed until Jan. 24th.

MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY.

THE monthly meeting of the Manchester Amateur Photographic Society was held in the Athenæum on Tuesday eveniug, last week; Mr. FLOWER presided. Six new members were elected. The President stated that the annual exhibition of the Society would be held in the Manchester Athenæum in the middle of February

Mr. M'KELLEN exhibited his latest detective camera and a plate magazine. The magazine is an ingenious piece of mechanism, fitted inside the camera without increasing the size of it. A dozen plates can be stored in the camera, and by moving a small lever each plate is dropped into a receptacle after having been exposed, and the next put in position. The movement of the plate is caused by a small spring, which makes it impossible for more than one plate to be displaced at a time. There is no fear of there being two exposures on the same plate. The whole twelve could be changed in less than a minute. Each plate is put into a thin shield which is lined with non-actinic paper, thus saving the trouble of backing the

plate. The camera when closed is focused for anything beyond twenty feet, and can be fixed at will to any distance within that. There are three speeds to it, and the shutter, working by a reversible motion, obviates all danger of exposing the plate while being adjusted. Time exposures could also be made by means of a small lever in front, which draws another shutter (inside the camera) across the lens, and thus does away with the cap. Mr. M'Kellen stated that now he never thought of using a tripod for outdoor work. Several of his friends had sent him specimens of some excellent work done with this camera. By means of a "finder" he could take a picture as well carrying the camera under his arm, or holding it in front of him.

Three lime-light lantern exhibitions followed. Messrs. Davenport and Seed showed a large number of familiar views taken in Manxland. Mr. J. W. Wade illustrated his "Scamper in Holland," starting with sea views and a picture of the busy river Maas at Rotterdam, following with pictures of the quaint streets of that town, scenes from the canals, the large arcades, and quaint bits of Dutch life about the quays. He took his audience through the parks, along the railroad to Dort, paying special attention to the old city of Delft, with its cathedral, a heterogeneous pile of conflicting architecture, and showed various phases of Dutch scenery. Mr. Wade strongly recommended photographers to pay a visit to Holland. The country afforded more subjects for a quarter-plate than even Switzerland and Norway. It was void of mountainous scenery, but it was full of picturesque views enriched by river and canal and ancient buildings. Following the "Scamper in Holland," he exhibited his "Loiterings in Lakeland."

GLASGOW PHOTOGRAPHIC ASSOCIATION.

THE third general meeting of the session was held on the evening of Thursday, 16th January, in the rooms of the Philosophical Society, 207, Bath Street, Mr. Wm. LANG, junr., F.C.S., President, in the chair.

Four new members—Messrs. James Gardner, Alf. H. Cade, Andrew Gibson, and Andrew Boag—were elected.

MR. JOHN ANNAN then showed two volumes of Calotypes printed in 1844-45, and several of the original negatives from which the prints had been made.

Mr. FRED. MACKENZIE gave a demonstration of timing the speed of a drop shutter by means of a tuning fork.

Mr. W. LANG, junr., read a communication about the late Cuthbert Bede and his book on "Photographic Pleasures." The whole of the various sketches in the volume by the author were shown by means of the Society's lantern.

Mr. T. N. ARMSTRONG afterwards exhibited his new illuminating chamber for photographs at night by means of coal gas.

Copies of Mr. Lang's paper, "Fifty Years' Photography, 1839-89," communicated last session, and printed at the request of the Association, were afterwards distributed to the members present; also tickets for forthcoming popular evening "Paris and its Exhibition," by ex-Provost Clark, of Paisley.

DERBY PHOTOGRAPHIC SOCIETY.

THE annual meeting was held at the Rooms in Derwent Street, on the 14th inst.; Mr. A. B. HAMILTON presided.

Mr. T. SCOTTON read a paper on the "Early History of Photography," concluding with a few practical hints to beginners on the more modern photographic processes.

A discussion followed, in which Messrs. F. Cooper, Cope, Hamilton, B. Cooper, and Hart took part.

THE 13th annual exhibition of bicycles, tricycles, and accessories, which this year takes place at the Crystal Palace, opens to-day. Not only is the entire floor of the Palace and courts covered by exhibits, but this year the large Concert Hall has had to be thrown open to this use.

A LAHORE paper mentions as an instance of the advance of civilisation that Abar Khan, chief of Lalpoora, who recently sent for a photographer from Peshawar, has signified his intention to learn phosography, and has detained the photographer for the purpose.

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

J. A. R.—Slow toning of ready sensitized paper. This is a common experience attributable, as you say, to the use of citric acid in the final stage of preparation. Add a trace of ammonia to the last washing water before removing the prints into the toning bath. 1. The ultimate effect of the gold solution would be the same, whether the reduced silver was derived from darkened albuminate or chloride, but the first usually takes longer to work the change because of the surrounding organic matter. 2. The complete interchange of gold for silver is possible, but not desirable, for then we get the blue-black or greenish tints of overtoned prints, and the cost would be much greater without any compensating advantage.

W. B. (Reigate).—We shall be glad to hear the result of your comparative trials, and particularly would like to know how it suits your special style of work.

G. SHAW.—Your welcome letter to hand. We thank you for giving the desired permission to publish.

T. W. (Blackburn).—The card mounts are very good, and the printed address at foot quite unobjectionable. The edges are done with pure gold.

C. T. C.—The altered time of meeting will be less convenient to us, but we hope to be present.

OLD PHOTO.—Zerr's Reliefs in Gelatine. Specification No. 16,677, A.D. 1888. These are moulded in plaster of Paris, very much in the same way that Mr W. B. Woodbury did them in 1867, for his process of uniero-photo-sculpture described at the Dundee meeting of the British Association in that year, at which specimens were shown.

LIGROINE LAMP.—We have not yet seen any announcement offering for sale the new incandescent lamp described at page 170 of the YEAR-BOOK, but we are enquiring about it of our friends in Vienna, asking whether there is an agent prepared to deliver them in this country, and will let you know later on.

J. & B. DODSWORTH.—Received a sample of your new unbleached blotting-paper, which certainly bears out all you say regarding it, perfectly free from sulphates and chlorides, very absorbent, and yet immensely strong in the fibre, giving off no fluff to adhere to the prints.

T. E.—Old sulphate of iron crystals. It is doubtful whether they would be worth the trouble of re-crystallizing, but very often the ochrey incrustation is only superficial, in which case they could be rapidly washed with ice-cold water on a sieve or cullender, well drained, and once more dried.

L. A. M.—There is no fund for the purchase of historical specimens and apparatus, but an effort is being made to form such a collection, and provide for their safe custody. The Photographic Society of Great Britain put out a circular with this intention on the 24th of August last.

ART-PHOTO.—The exhibition of Rejlander's works is still on view at the Camera Club, Bedford Street, Covent Garden, and will well repay a visit. Admission is granted on presentation of your address card.

A. LANGWORTHY.—We never heard of any such process. Be so good as to repeat the leading details, some of which are not fully intelligible.

PRINTER.—The addresses of *all* photographers in the United Kingdom are not yet got together in any single directory, but you would be able to start with the Post Office London Directory, and those for the larger provincial towns, in order to get the names of professional photographers, and then work from the published lists of members of the Photographic Society, Camera Club, &c., to pick up some of the amateurs. Or, finally, make friendly arrangements with the principal dealers and publishers.

E. J. WALL.—Consult Reimann's "Hand-book of Anilines," *Chemical News* Office, Boy Court, Ludgate Hill; Watts's "Dictionary of Chemistry," vol. iv. pp. 465-473, "Aniline Dyes;" also Slater's "Manual of Colours and Dye Wares," Crosby Lockwood and Co.

CONTENTS.

MAGNESIUM LAMPS.

MESSRS. SAMUEL FRY & Co. have sent us for review a little magnesium lamp, which, with its store of powdered metal, is not much larger than half an average cigar box, when all the parts are packed in their card-board case. A peculiarity of it is, that it will give from one to three or more flashes at will of nearly equal intensity; this is due to the magnesium required for immediate use being held in a small test-tube, out of which it cannot be blown all at once by a single compression of the pneumatic ball. The lamp, which is said to be highly popular in America, requires no stand, but is held in the hand, and fired off near the ceiling when it is used in an ordinary room. It gives a horizontal flash of large area, because it is so constructed as to throw the powder out in a fan-shaped blast, and the metal is then ignited by means of a large flame. In some experiments tried with it, it was found that with suitable management it is tolerably easy to obtain full length portraits without hard shadows.

Magnesium lamps require more scientific study than they have yet received. Nearly all of them allow some powder to escape unburnt; especially, of course, is this the case when the powder is blown through the flame at right angles to the longitudinal axis of the latter. Even when the powder is blown upwards through the flame, complete combustion of the magnesium is not necessarily secured—a fact which has been experimentally proved in public. When the powder is blown out by a short, violent puff of air, there is a reduction of the amount of ejected metal burnt, because it then passes more rapidly through the flame, and with most of the present lamps it may be wise to incur this loss sometimes to shorten the time of exposure. Schirm's lamp attracted some attention in Germany, because of its alleged economy in the use of magnesium; in this lamp, which was pictured last year in these pages, the magnesium was first made intensely hot, and then blown upwards through a long flame. While Schirm's lamp was in the hands of our Photographic Society, it would have been well had its action been submitted to a series of thoroughly scientific tests. The bringing together in one instrument of the best features of the Schirm and Fry lamps, particularly the abolishing of the stand used with the former, might possibly result in the advent of an advanced type of useful magnesium light.

When magnesium first mentally and physically dazzled the world, by being produced otherwise than as an extremely costly chemical curiosity, gelatino-bromide plates were unknown, and in those revered good old wet-plate days we tried some of the earliest experiments in photographic portraiture by the magnesium light. The lamp invented by Mr. Henry Larkin answered best, in which sand was mixed with magnesium powder, to carry the latter downwards rapidly from a kind of funnel into a flame below; it was then found best to do away with the neck of the brass funnel and to enlarge the orifice thereof, to obtain a flame of shorter duration, and to reduce it, if necessary, to a rapid flash. Another objection to the neck of the funnel was, that the vapour of water produced by the combustion of the flame employed to set fire to magnesium, had a tendency to condense inside the metallic neck, and by wetting the mixed powder to choke the tube, thereby stopping the action of the lamp. Mr. Larkin, when obliged to keep up a continuous light, as on the occasion when he lit up Guildhall Yard by means of gigantic magnesium lamps, overcame this defect by means of a "pricker" driven by clockwork. This pricker was a needle which vibrated longitudinally in the tube of the funnel. The modification above described of this lamp, to make it give a light of brief duration, might be useful at the present time, because the large size of the flame tends to prevent sharp shadows; indeed, it is easy to produce a flame two feet long. The greater the proportion of magnesium powder to the sand, the larger is the flame. The duration of the flame is governed by the size of the orifice through which the powder falls. The sand gets intensely hot during its descent, and will char or set fire to wood if allowed to fall thereupon if much magnesium be used.

In those early days a lamp was invented and publicly described for burning magnesium ribbon continuously, yet carrying the smoke away from the face of the flame by an air-draught from the front. This principle, with mechanical improvements in addition, has been

used in a lamp which Mr. Warnerke purchased somewhere on the Continent, and which will go on burning for a long time nearly as steadily as a candle. With proper appliances for carrying off the smoke, this instrument might prove a formidable rival to the electric lamp in commercial work in the photographic studio, the electric light being so costly.

When magnesium riband was first made it was rotten, and broke easily when handled; this defect was overcome by alloying it with a trifling proportion of zinc. As zinc gives a bluish-white light when burnt, it might be worth while to try experiments for the production of a large and brief flame of burning zinc at will, to find out what can and what cannot be done with it in photography. The photographic value of the combustion of excessively rare and costly metals yielding the more refrangible rays of the spectrum might also be tried, for it might be possible to turn out those metals cheaply now that the electric furnace and other modern inventions have placed such great powers in the hands of metallurgists, and now that more about the chemistry of high temperatures is beginning to be understood.

OBTAINING THE CRITICAL FOCUS UPON FINELY-GROUND GLASS SCREENS.

BY F. H. VARLEY, M.I.E.E., F.R.A.S.

In my article upon grinding glass focusing screens, published in your issue of November 8th, 1889, I pointed out the desirability of a finely-ground surface being obtained. The purpose of the present communication is to further develop that idea, and to show a method by which the exact or critical focus can be obtained with facility and precision.

The present method of employing a dark cloth to exclude extraneous light from the focussing screen is at its best but a fairly efficient expedient. To me it is one far from being satisfactory. First, as my eyesight is getting weaker, I require a reading lens to see the image distinctly or otherwise: secondly, to view the image at a distance of 16 inches from the screen, when I find it difficult to clearly discern special minutiæ of detail with any degree of confidence that it is in correct focus.

The employment of a lens between the eye and the surface of the ground glass is also fraught with dangers, unless the ground surface of the glass be kept distinctly focussed during the whole time of racking in or out the camera lens. When the reading lens has to be employed, it is quite possible to obtain a sharp image which is not coincident with the ground surface; it may be formed either behind or in front of the screen, according to the relative distances between the lens and the screen and the eye from the lens.

In a landscape there is always one part of the picture which it is desirable should be in critical or precise focus, and from which the foreground and distances may be more or less perfectly focussed, but not absolutely sharply defined. To obtain this critical focus I have devised a special form of the Ramsden or positive eye-piece, which insures perfectly precise focussing. This is shown in fig. 1. A is the field lens, B eye-lens, C centre of ball and socket movement, D face of the socket to be held close to the polished side of the glass screen, E clamping screw to fix the eye-lens when it is correctly in focus with the surface of the ground-glass screen, F the eye-cup for excluding extraneous light. The two lenses are plano-convex, with their convex sides turned towards each other.

The field lens should be of about 2 inches focal length, and about 1 inch to 1¼ inch in aperture.

The eye-lens three times the focal length of that of the field—viz., 6 inches. The distance between these lenses is somewhat less than two-thirds of their combined foci, say 5¼ inches. The final adjustment of the eye-lens depends upon the distance that the ground surface of the glass is from the field-lens. This arrangement forms a

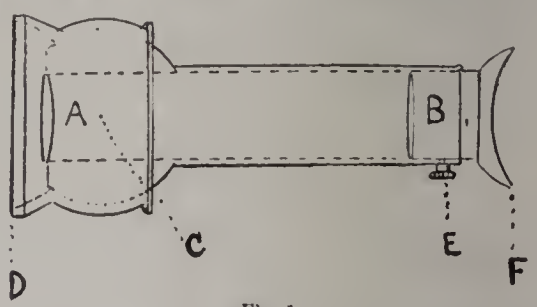

Fig. 1.

low-power aplanatic microscope on the one hand, by which the critical focus of the ground glass is obtained, and becomes at the same time a positive eye-piece for viewing the image formed by the camera lens; by this the exact coincidence of the critical image with surface of the ground glass is readily determined.

Fig. 2 illustrates its application.

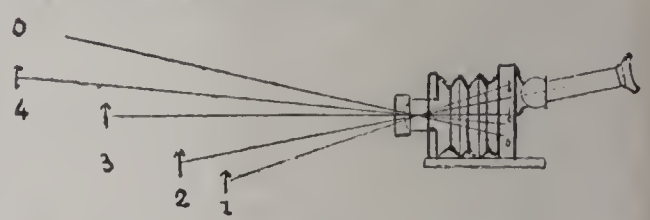

Fig. 2.

The arrows 1 to 3 represent the landscape, whilst all above may be distant mountains or sky.

The arrow fig. 2 is intended to represent that portion of the landscape which it is desirable to have in critical focus.

The use of the ball-and-socket movement is then apparent, as it enables the eye-piece to be inclined at such an angle to the ground glass as to render its optical axis coincident with the ray of light reflected from the arrow 2; this insures a greater brilliancy of illumination, and although by so tilting the eye-piece the distance of the field-lens from the surface of the ground glass is increased, this is readily corrected by sliding in the eye-tube until the ground-glass surface is in focus at the centre of the field.

The advantage gained by securing the critical focus at any desired part of the picture, I think, will be more fully appreciated as small cameras and enlarging processes come more extensively into favour; whilst the facility of focussing afforded by the positive eye-piece, I think, is worthy of the best attention of camera makers and opticians.

THE JOURNAL OF THE PHOTOGRAPHIC SOCIETY.—The last number of this journal exhibits a great improvement, which will probably render it more attractive to the public, in the shape of a great number of small paragraphs giving practically useful novel information, culled from recent photographic and other periodicals all the world over.

EIKONOGEN AS A DEVELOPER IN PRACTICE.*

BY W. K. BURTON.

IT may seem presumptuous in me to write from the other end of the world on a subject that the members of the Photographic Society of Great Britain have a much better opportunity of forming an opinion on than I have, and on a subject that will perhaps have been thoroughly threshed out before this paper can be read; but when I consider for how long new developers have often been in use before any actual comparative experiments with them and old developers have been made, or at least before the results of such experiments have been made public, I am encouraged to think that what I have to tell may not be so very much behind time after all. Moreover, the changes that may be rung on a developer by varying the proportions of the ingredients are so endless, that every experimenter working on lines laid down by himself is likely to cover some new ground, however much may have been covered already.

There have been numerous expressions of opinion as to the value of the new developer. It has been declared "as good as" and "better than" pyro. and so on. Now I quite appreciate the value of such opinions when they come from men of experience; but, after all, they are of less value than an actual detailed account of experiments undertaken for the sake of making a comparison.

There fell into my hands what I believe to have been the very first box of eikonogen that came to Japan, and I set about to compare its working with that of pyro at once, and with the most practical object that I could have—namely, to determine whether or not I should adopt it instead of my old friend in actual practice. It may take a little time to detail the principle of the experiments that I have made, but I think that if this paper is to have any value, it will be by detailing what I have done before I give the conclusions that I have drawn.

The eikonogen came into my hands carefully done up in one of the original tin boxes, on the outside of which were instructions not to open it in the presence of ammonia fumes, but in a dry, pure atmosphere. These instructions were duly attended to. There were no instructions as to the method of using it, but I had read enough in the English photographic press to know at least pretty fairly what to do with it. Briefly, this is what I understood to be claimed for it. It was intended to be used as a substitute for pyro, and was said to be quicker and more energetic in its action. The alkali recommended was carbonate of soda, and some had stated that either only very little of this should be used, or that some restraining bromide should accompany it, otherwise there was a danger of fog on account of the excessive energy of the developing action. The eikonogen was found to be a somewhat heavy, coarse powder, of a rather dirtyish pinkish colour, readily soluble in about thirty times its weight of cold water, and giving a yellow or light brown solution, which rapidly darkened in the air from the absorption of oxygen. It was neutral to test papers.

Here, at the very beginning, a series of experiments was made to test, as well as it could be done without waiting a long time, the keeping qualities of the solution. The following were the results:—In aqueous solution without any preservative eikonogen darkens much more quickly than pyro. If the eikonogen be dissolved in a solution of sulphite of sodium instead of water, the colour is light green instead of yellow. If sulphite of soda be added to an aqueous solution before it has darkened much, the colour will be changed immediately from yellow to green. This "sulpho-eikonogen" solution seems to be very permanent, and does not stain the hands. It is not necessary to neutralize the sulphite of soda with acid to get a permanent solution. The sulphite of soda that I used was a fairly good commercial sample, and was distinctly alkaline to test papers. The addition of alkali to the aqueous solution accelerates the discolouration, but not to nearly so marked a degree as in the case of pyro solution. Even when made strongly alkaline the "sulpho-eikonogen" solution discolours very slowly. A solution that had been used for development, and that was put on one side in a measuring glass, was of a very light brown colour only at the end of several days. Even the alkaline solution does not stain the hands. If an aqueous solution has turned deep brown by exposure to the atmosphere, it will change to a comparatively light brown by the addition of sulphite of soda.

The first set of experiments with pyro and eikonogen were intended merely as "feelers," so that I might get some idea of the action of the substance I was working with. I made up a one per cent. aqueous solution of eikonogen in water, and a ten per cent. solution of each of sulphite of soda and common carbonate of soda in crystals. The first developer that I tried was made up as follows:—

Pyro	...	...	...	...	2 grains
Sulphite of soda	...	...	...	10	,,
Carbonate of soda	...	...	...	10	,,

to each ounce of water. Another developer was made up with exactly the same proportions, but replacing the pyro with eikonogen.

Exposures were made two at a time in the camera, the subject being chosen to show great contrast and full gradation. A table covered with ornaments was selected, and over two vases standing side by side was thrown a black velvet cloth and a white table-napkin. The first two plates were purposely much under-exposed, the second two received a little shorter than the first exposure, the third pair a full exposure. A pair of plates was placed in dishes side by side, and at the same moment the two developers were poured over the two plates. The results were as follows:—In each case the image under pyro began to show considerably before the other, and development was complete, or had gone as far as it would go, when the plate under eikonogen was not half developed. The development under eikonogen went on steadily, however, and eventually there came out, in the first case, apparently the same amount of detail as with pyro; in the second, little more; in the third case, the eikonogen plate had the appearance of being somewhat over-exposed, the other of being just rightly exposed.

Experiments were tried with the carbonate increased by twice, and eventually by three times, but the results were exactly the same as in the first cases, except that, both with pyro and with eikonogen, the development was a little quicker. In every case the eikonogen proved much the slower developer, but on the whole there was in the finished eikonogen-developed plates a very little more detail than in the case of the others. There was no appearance of fogging with eikonogen (or with the pyro either), even when the largest amount of carbonate was used, and the colour of the image was excellent, whether the alum bath was used or not.

Further experiments were tried to see the effect of developing several plates in succession with the eikonogen

* Read before the Photographic Society of Great Britain.

—in all the experiments already described a fresh solution had been mixed up for each plate. The development became slower and slower, but on the whole the eikonogen compared favourably with the pyro, inasmuch as it appeared to become exhausted more slowly, and certainly became discoloured much more slowly. In fact, by the time that a pyro developer had become of the colour of stout, the eikonogen developer showed little or no discolouration at all.

The net results of these experiments was to show that eikonogen had at least as powerful a developing action as pyro, but that it was a great deal slower. Now I am myself in favour of slow development, and would not consider the tardy action of the eikonogen to be a drawback, but I know that no developer that is much slower than pyro with carbonate of soda will find general acceptance. My next series of experiments were therefore to determine what was the quickest modification of the eikonogen developer that I could find. I mixed a stock solution containing 2 per cent. of eikonogen and 10 per cent. of sulphite of soda. All the following developers had the same amount of eikonogen and of sulphite—namely, 2 grains of the former, and 10 grains of the latter to each ounce, the alkali and restrainer only being varied. The subject chosen was a landscape, including dark green foliage and a gate painted a glaring white, a great range of contrast being again got. A number of plates were exposed in quick succession, an exposure a little less than what I should consider "normal" being given.

The first plate was developed with the following developer:—

Pyro	2 grains
Sulphite of soda	10 ,,
Carbonate of soda (crystallized)	20 ,,

My idea in taking this as a standard with which to compare eikonogen was that, although it is a slower developer than any common ammonia developer, it is pretty quick as developers with alkaline carbonates go. I consider that a developer is not likely to become generally popular unless it will work as quickly as does this one. The plate was watched in this developer, and it was found that the image made its appearance in 20 seconds, and that development was finished in 3 minutes. I set myself then to find, if possible, an eikonogen developer that would work as quickly as this one. I tabulate the results, it being understood that the eikonogen and sulphite of soda were, as stated above, constant:—

	Developer.	Image Showed.	Development Finished.	Remarks.
	Eikonogen and sulphite without alkali.	1 min. 30 secs.	20 mins.	Full detail, but thin image.
1	Carbonate of soda, 5 grains ...	30 secs. ...	6 mins. ...	Very good quality.
2	,, ,, 10 ,, ...	30 ,, ...	5 ,,	
3	,, ,, 20 ,, ...	30 ,, ...	4 ,, ...	Image rather thin and foggy.
4	Carbonate of soda, 20 grains; bromide of potassium, 2 grains. ...	1 min. 30 secs.	15 ,, ...	Very good quality.
5	Carbonate of potassium, 5 grains ...	30 secs. ...	6 ,, ...	Very good quality.
6	,, ,, 10 ,, ...	30 ,, ...	4 ,,	
7	,, ,, 15 ,, ...	25 ,, ...	3 ,, ...	Image rather thin and foggy.
8	Carbonate of potassium, 20 grains; bromide of potassium, 1 grain. ...	40 ,, ...	4 ,, ...	Very good quality.
9	Liquid ammonia, 2 minims; bromide of potassium, 1 grain. ...	2 mins. ...	10 ,, ...	Thin image, with both chemical and colour fog.

All quantities are in grains to the ounce.

The only conclusion deducible from these experiments is that eikonogen will not work as quickly as pyro. It will be seen that in every case but No. 8, where the rapidity of development came up to, or even nearly up to, that of the pyro developer, the image was thin and foggy. Farther than that, with the above exceptions, the best negatives were distinctly those that took a considerable time to develop. It will be seen that of the developers tried, the quickest contained 20 grains of carbonate of potassium and 1 grain of bromide of potassium to each ounce, and that this did not come very much short of the pyro developer in the rapidity of its action. On the whole, as in the first set of experiments, the eikonogen appeared to bring out a little more detail than the pyro.

The colour was in all cases—except that of the ammonia developer—good, but I do not think that it was any better than that given either by hydroquinone, or pyro with sulphite and a carbonate, using the alum bath. The gradation of density—or "tonality," to use the slang of artists—was certainly somewhat different from that given by pyro, but I do not think I am able to judge whether it was better or worse. There certainly is a certain softness about the eikonogen developed negatives that must be an advantage in the case of some subjects.

It will be seen that one plate was developed without any alkali, except that due to the slight alkalinity of the sulphite of soda. The fact that this was possible induced me to try the following experiment:—Three solutions were made; they were as follows—(1) Eikonogen 2 grains to the ounce of water; (2) Sulphite of soda 10 grains to the ounce of water; (3) Eikonogen 2 grains, sulphite of soda 10 grains to the ounce of water. Three plates were flooded with these three solutions at the same moment; the results were as follows:—In the case of (3) the image appeared in two minutes, and development was finished in twenty minutes. In the case of (1) the image appeared in two minutes, but at the end of two hours little more than the high lights had appeared, and the solution was much discoloured. In the case of (2) no trace of an image had apppeared at the end of two hours.

A rather curious thing came out of this last set of experiments. I mixed (1) and (2), and with the result that a great part of the colour was at once discharged, and flowed the solution over the plate that had been under the sulphite of soda solution for two hours without being affected. I intended to see what would be the result in the way of development, but forgot all about the plate for two days, when I suddenly remembered it.

I expected to find nothing but a mass of fog, but, to my no small surprise, I found in the dish a fully developed and fixed negative. I suppose the fixing was effected by the sulphite of soda.

I ought to observe here that all the plates used so far were of about average rapidity—as so-called rapid plates of the present day go—giving something about twenty on the sensitometer, and that they were of a very "robust" kind. That is to say, they gave, with any ordinary pyro developer, very clear shadows, and would stand "any amount of forcing." I wished to try the new developer on an entirely different kind of plate, and I had by me a kind that is very common amongst commercial plates, and that is excellent for many kinds of work; I mean a very rapid plate, giving density easily with pyro, and giving a full, round image, with good gradation, under a moderately strong, or fairly restrained, developer, but fogging more or less with a developer strong in alkali unless duly restrained. I found that with such plates, using two grains of eikonogen and ten grains of carbonate of soda to the ounce, but no restrainer, I could get nothing but thin images, or, if I prolonged development, foggy plates. A corresponding pyro developer gave excellent results. It was evident that with such plates and eikonogen a restrainer must be used, and I tried bromide accordingly. I, however, thoughtlessly used bromide of ammonia, forgetting for the moment that in the presence of sulphite of soda free ammonia would be produced, and that ammonia does not agree with eikonogen at all. The images came up finely, and in the developer apparently boldly and strongly, but on fixing I had the most beautiful sample of almost ruby-red fog that I have seen. I do not think that it would have been possible to get red fog with these plates, using pyro. With pyro they would have given grey fog (if any), and it is my experience that grey fog, whether due to over-exposure or to forcing, and colour fog, do not appear at the same time under pyro. The substitution of bromide of potassium for bromide of ammonium gave quite satisfactory negatives, but the development was very tedious. The restraining action of bromide appears to be greater with eikonogen than with pyro, so that only a little need be used. In this case I found one grain to the ounce sufficient.

My next experiments were with the sensitometer. I do not intend to give these in detail, for I fear that I have been intolerably tedious as it is with all the details that I have brought before you. It will be sufficient to say that I tried many different kinds of plates, and tried over again all the developers that have been described above, with the result that it was certainly possible to get out a little more with eikonogen than with pyro. I think that perhaps there is an advantage equal to about 20 to 30 per cent. in the matter of exposure in the case of eikonogen, that is to say, the exposures might be shortened in the ratio of 6 to 5, or possibly as 4 to 3.

Here, however, came in quite a new element. I had not before tried the use of the preliminary bath of hyposulphite of soda, recommended as an accelerator. I tried it now, using a solution of 1 part of hypo in 1,000 parts of water, and merely allowing the plate to rest in this whilst I was mixing up the developer. The result when the developer was poured on the plate was startling. The image flashed out with astonishing rapidity; but I found that development soon came to an end, and that not only did no higher figure come out after the preliminary bath of hyposulphite of soda, but that it was not possible to get out quite so much as without it. The difficulty of quick development, however, was solved, and I went back to the development of plates exposed in the camera. I now found that with a preliminary bath of hyposulphite of soda, and with a developer containing two grains of eikonogen and ten grains of carbonate of soda to the ounce, the image began to show in fifteen seconds, and development was complete in three minutes—that is to say, the rapidity on development was up to the arbitrary standard that I had set up.

This finished the experimental work that I have done up till the present, and it will be expected that I give the deductions that I have drawn from it. I am tempted to do so by taking an advertisement of eikonogen that sets forth its wonderful properties under ten headings, and to set opposite each of these the conclusion that I draw from the experiments that I have just described. I put the statements of the advertisements and my own conclusions in parallel columns:—

Superiority of Eikonogen.

1. One of the principal features of eikonogen is the fact that the exposure in the studio can be reduced to half the time required for hydroquinone or pyro.	This is not the case. The exposure cannot be reduced by more than about 25 per cent.
2. Eikonogen gives a bluish-black colour covered by a very delicate precipitate, which will bring out the finest details to a degree that is not even approached by any other developer.	The colour is good, but not better than that given by some other developers.
3. It makes the task of judging a negative a very easy one, as its black colour shows the contrast and grades of light and shade much better than a negative of any other colour.	I think that it is a little easier to judge of density in the case of eikonogen than in that of other developers, not for the reason given, but because the density seems to go off less in the fixing bath.
4. A solution of this developer can always be kept on hand ready for use, and will keep over a month. The developer can be used several times, as it does not discolour in the air.	This is true.
5. Eikonogen packed in boxes will keep for years, while hydroquinone and pyro in time deteriorate greatly in quality.	Eikonogen may keep for years, although it is rather difficult to see how this has been established as yet. It is not my experience, however, that pyro, if properly packed, deteriorates. I believe that hydroquinone does.
6. Eikonogen is the cheapest developer, not only in price, but also because it possesses more developing power.	Possibly it is.
7. By using an old developing solution till all the details have appeared and then taking a fresh one, those much-desired high lights will be easily obtained. The old developer may be used in this way three or four times.	This is not very comprehensible. Is it intended to indicate that "those desirable high lights" cannot be obtained working in the ordinary way? If so, it is difficult to see where the advantage comes in.

8. It is unnecessary with this developer to maintain a certain degree of temperature in winter time.	Low temperature certainly does not retard development so much as with pyro.
9. When plates are under-exposed, they should be put for half a minute in a preliminary bath containing some hyposulphite, and details will be obtained which neither pyro, nor hydroquinone nor iron can give.	A preliminary bath of hyposulphite of soda hastens development, but does not bring out more detail than can be got without it.
10. The greatest over-exposure can be compensated by using old developer and sodium bromide, or by diluting fresh developer with two or three times the quantity of water and a little sodium bromide.	There is certainly great power of compensating for over-exposure.

Just as I have written the above it seems very dogmatic, but I wish it to be distinctly understood that I am not laying down what I write as established facts, but merely as the results of my experience gained from experiments that have certainly been numerous, and that have been carried out with due care, but that have all been done with one sample only of the substance in question. I think, however, that it is quite fair to take one sample as typical, because if it be pleaded that that particular sample was inferior, the plea will hold good on either one or other of two assumptions only, namely, that eikonogen is variable in its efficiency, or that it is liable to deteriorate.

After all, I have not answered, even to myself, the question that I started with, namely, shall I prefer eikonogen to pyro for general work? It will be seen that I consider that the claims that have been put forward in its favour are extravagant. On the other hand, it has certain advantages. One of these is its extreme cleanliness. This will probably have more weight with most people than with myself. Then, it is hard to part with old friends that you do, or at least fondly believe that you do, quite thoroughly understand. On the whole, I intend to stick to pyro for at least a little time longer, and this especially considering that I have, I believe, used up the whole of the store of eikonogen that there is in Japan, and that it will be several months before I can get a further supply.

POSTSCRIPT.

Some remarks that I read in one of the photographic journals since the time that my paper on eikonogen was written remind me that in the comparative experiments that I made I omitted almost the most important of all comparisons—namely, that of the difference in effect produced by varying the quantity of the eikonogen itself. I was led to this omission by having my mind too much bent on the action of pyro. It is well known that in the case of this substance the effect of the increase of quantity is not to accelerate development either in the matter of time that it takes for detail to appear, or in the matter of the eventual amount of detail that can be got—that is, working within pretty wide limits. It did not strike me that it might be quite different in the case of eikonogen.

I first set myself to establish the statement made above with regard to pyro, which I had in my mind only as a general impression, not as the result of any comparative experiments. Several plates were exposed for the same length of time in quick succession, and a set of developers was made up, each precisely the same except in the matter of the quantity of pyro contained. This was varied from two to ten grains to the ounce. The plates were placed side by side, and were developed by pouring the different solutions simultaneously over them all. Those images which were under the strong pyro appeared to come out a very little before the others. Perhaps there was a difference of five or six seconds between the one and the other end of the row of five plates. After a little time, however, all appeared to be at about the same stage; that is to say, so far as the eye could judge, the same bit of detail appeared on all plates at just the same time. The plates were removed from the solutions at the same time and fixed together. When they were fixed, those that had had the greatest amount of pyro were the densest, but the difference was much less than I expected. Those that had had the most pyro also had the appearance of having had less exposure than the others, but this was due rather to a certain harshness of gradation than to the actual absence of any detail that was visible in the others. The few experiments that I could make with eikonogen immediately showed that with this substance the effect of increasing the strength of the solution is quite different from what it is in the case of a pyro solution. Increase in the quantity results in very great increase in the rapidity of development. Unfortunately, by the time that I had reached this stage, I had too little eikonogen left to enable me to make a set of thoroughly comparative experiments. The results I did arrive at, however, were that increasing the quantity of eikonogen to 5 grains to the ounce, I got with the same quantity of alkali the same rapidity of development as with a pyro development. With pyro developer, however, 2 grains to the ounce gives as great a speed of development as does 10, and gives more satisfactory negatives. I therefore conclude that it takes about 5 grains of eikonogen to equal 2 of pyro, and this especially as negatives developed with that amount of eikonogen showed no tendency to hardness. It will be seen that this knocks on the head the idea of the comparative cheapness of eikonogen, unless the manufacturers reduce the price to less than half that it is at present. I could not make out that the strong eikonogen had any advantage over the weak in the actual amount of detail brought out.

THE next annual dinner of the Photographic Society of Great Britain will take place at the Café Royal, Regent Street, on February 10th, at 6.30.; tickets, six shillings each. Early applications for tickets should be made to Mr. W. England, 7, St. James's Square, Notting Hill, W.

PRINTS AND DRAWINGS.—Those who are interested in the Egyptian mummy, or the Roman urn, or in the mysteries of ancient manuscripts and rare prints, will be glad to know that some instructive lectures upon these subjects as exemplified in the British Museum, will be delivered in the coming month at the Steinway Hall, Portman Square, by Mr. Louis Fagan, of the Department of Prints and Drawings. The first lecture will treat of the origin of the Museum collection, through the bequest of Sir Hans Sloane, nearly a century-and-a-half ago, of its gradual progress, and of the Egyptian, Assyrian, and Babylonian antiquities; and the second and third lectures will deal with the Greek and Greco-Roman antiquities, the library, manuscripts, and prints, and the character and constitution of the Museum. Photographic reproductions of the objects described, by the oxy-hydrogen light, will be exhibited, so that subsequent reference to them may be facilitated. The history of our national collection in Bloomsbury is one of decided interest to students of art and science. No inconsiderable part of it existed under the designation of the British Museum for more than three-score years before the building which now contains it was commenced.—*Daily News.*

EIKONOGEN.

BY LYONEL CLARK.

It is, perhaps, beyond the bounds of reason to expect that every new production should be presented to us only when it has attained a condition as nearly approaching perfection as is obtainable by mortals, but still one may be permitted to express a very decided wish that it might be so. The series of somewhat exhaustive experiments that I made on the behaviour of the newest claimant to popular favour as a developing agent were hardly finished, when a new form of this same salt is introduced that is manifestly superior to the old. Wishing, however, was of no good, and there was nothing else to do but to start again, and repeat in a form simplified by experience the previous experiments.

In appearance the new sample of eikonogen presents a great superiority over its more ancient rival; whereas the latter was in the form of a palpably discoloured, sand-like powder, the former is in pure and well-formed crystals of a slightly yellowish colour. Its behaviour when in solution is also distinctly different. The old sample, when dissolved in water without the addition of any sulphite, instantly decomposed, turning of a deep port wine colour, that rapidly thickened; whereas the new sample only slightly discolours the water—a similar difference is apparent, even when sulphite is used, the old sample forming a deep green-coloured solution, whilst the new one gives a faintly yellow one. It is quite evident from these facts alone that the discolouration of the older sample was due to an incipient oxidation of the crystals themselves, which became more apparent when in solution, and was no doubt the cause of its so soon becoming muddy, and losing its clearness.

The amount of solubility of the new does not appear to vary very much from that of the older sample; as a matter of fact, it is not very easy to determine the amount of solubility very accurately, as it varies according to the temperature; in boiling water a large amount is taken up, but on cooling down to 60° F. or so a large amount crystallises out. On the whole, I should consider about fifteen grains to be the maximum amount that can be dissolved in one ounce of water to which thirty grains of sulphite of soda have been previously added.

However, my practice at present is to make up a solution of a less strength than this—that is, one of ten grains to the ounce—to which I add twice the weight of sulphite of soda and an equal weight of carbonate of soda; I make these up with boiling water, in which I first dissolve the sulphite completely, and then add the eikonogen. I use boiling water, for by this means all air is expelled, and there is less discolouration of the solution from the absorption of the oxygen of the imprisoned air, for a developer so made up is complete in itself, and will equally as well oxidize at the expense of the air as it will at the expense of the partially reduced silver haloid of the negative.

In my first experiments I found that the developing action of eikonogen lay entirely in the salt itself—that is to say, that it did not require the addition of any alkali to cause a reduction of the silver, although, at the same time, the rapidity of its action was increased when either the fixed or the caustic alkalis were added. But the gain was not very great, and, beyond a certain point, a further increase of alkali made but little difference; indeed, if the added alkali were in a somewhat dilute solution, owing to the general weakening of the developer, a loss of density followed, instead of an increase in rapidity of development.

It is this behaviour that so markedly defines eikonogen from the alkaline pyro developers, and makes it much more analogous to ferrous oxalate. The developing power lies in the eikonogen almost entirely. If this be present in large quantities, the development is very rapid, and great density is obtainable; if the eikonogen be present in small quantities, it develops slowly, and no density at all is obtainable by it; but in both these oppposite cases it will be found that the same amount of detail will be brought out, if time be unlimited. With pyro, on the contrary, an extremely rapid developing action can be set up, even with a minimum amount of this salt, and, indeed, a further addition of it will actually tend to slow the development. We can undoubtedly prepare eikonogen developers that shall be suitable for any class of work, but they must be prepared beforehand; they cannot, like an alkaline pyro developer, have their character totally and instantaneously altered by very small additions. This is doubtless due to the insolubility of the salt itself. If we could only add it as we can pyro in the dry state, its power might be vastly increased; but, as it is, we have to make up solutions beforehand, and we can only modify their action in one direction, unless we resort to the somewhat bulky expedient of having several baths of different tendencies.

I think, therefore, that for that class of work where the exposure, although ample, has been more or less of a hazard, or where the general scale of lighting has been unsatisfactory—that is to say, for the best class of landscape work—eikonogen will not displace the alkaline pyro; but for that class of work which is usually termed *instantaneous*—that is to say, where the exposure has been so short that every part of the plate has received the minimum of exposure, and yet every detail must be forced out, and at the same time, every effort be used to obtain density—for this class, eikonogen presents most marked and useful advantages over any other system of development with which I am acquainted.

To begin with, it is absolutely free from all tendency to cause green fog, with its unpleasant iridescent stains; even when used as strong as possible, no discolouration of the gelatine is perceived. Secondly, a greater amount of intensity may be given to the slightly exposed portions by eikonogen than by any method of pyro development. I satisfied myself of this fact when experimenting with the older sample, and with the newer one I find it still more accentuated. Lastly, eikonogen has a peculiarly sedate way of going about development: it never seems to start things with a rush, causing streaks and stains, but builds up the silver image as quietly and as surely as the coral insects build up their atolls. I have had a good experience of its behaviour in this respect lately, having had to develop in great haste a spool of the new rollable celluloid film, containing some sixty exposures. I manipulated them as if they were prints being toned, putting half a dozen of them into a dish at once, and simply turning them over from time to time; half the spool was developed in this way with pyro and ammonia, and the other half with eikonogen. No difference is observable in the results as regards either the amount of detail brought out, or its density; but whereas the pyro-developed negatives are marred by green fog and local stains, those developed with eikonogen are all equally clean and clear. When one considers the careless and hasty way in which they had to be treated, this fact speaks very highly for this new developer.

The developer that I used in these trials, and the one I have now generally adopted for short exposures, was compounded as follows:—200 grains of sulphite (crystallized) were dissolved in ten ounces of boiling water; when dissolved, 100 grains eikonogen (crystallised), 100 grains carb. sod. (recrystallized), and 5 grains of bromide of potassium were added. On cooling, no precipitate should be formed, the solution being of a clear yellow colour. This clear yellow shade gradually gave way to a reddish claret colour when a negative was developed in it, and subsequently darkened to a full port-wine colour, remaining, however, clear and free from muddiness. On the following day some more negatives were developed, but the bath then began to lose its power; but on the addition of a little fresh saturated solution completed its task, and was then thrown away. From the results obtained—for the whole lot of negatives were hand camera work taken at the beginning of the present month, when the light was extremely feeble—I feel convinced that no better developer for such work is at present known; and, considering the number of negatives developed, it works out by no means a costly one. As I have before now pointed out, when used for solitary negatives, eikonogen is at least three to four times as expensive as pyro; but when a batch of similarly exposed work is to be done, its cost is considerably and proportionally diminished. A developer like the above can be prepared in large quantities, and if stocked in small bottles filled up to the brim, and tightly corked, it should keep indefinitely.

The quantity of sulphite used is small, being only twice the weight of eikonogen present; but since, when kept protected from the air, it does not appear to go wrong, and remains sufficiently clear during development, I failed to see the use of adding more. Of course if it were desired to keep the once-used developer for subsequent use, a greater amount might perhaps be advantageously added; but I can never advocate such a system, as it is impossible to guage the strength of a spent solution, and its use degenerates development from a science to simple chance. The only other solution that I can tolerate would be a saturated one—that is, dissolve about 300 grains of sulphite in 10 ounces of water, and add as much eikonogen to the boiling solution as it will take up, and also about 150 grains of potash, and let the excess crystallize out on cooling. Such a developer may be reserved for the most under-exposed cases, and if it will not give them printing density, I really do not know what will. At the same time, should—from the light having been better than estimated—the negatives begin to show signs of hardness, this may be remedied by diluting the developer with a solution of carbonate of soda, say of a strength of ten grains to the ounce, as much as an equal amount or less of which may be added to the normal developer as the appearance of the image dictates.

In generally comparing the new and the old samples, I may say shortly that the new, being clean and free from oxidation, an equal weight has greater developing power; and this freedom from oxidation renders practical, what I found with the old sample impossible, namely, the preparing and keeping of stock solutions in an unaltered and unweakened condition. It was this proneness to oxidation, coupled with its great insolubility, that compelled me to relinquish with regret the use of the old sample, for I had already recognised the great power that the developer had of giving full density to very slightly exposed plates; but the superiority of the new sample now obviates this, and I shall certainly have recourse to it for all hand-camera work, although I do not feel disposed to replace pyro from its use with my larger and more carefully developed work.

AMATEUR PHOTOGRAPHY IN PARIS.

THE *Daily Telegraph* says:—"The camera, the sensitive plate, and the developing chamber now reign supreme in Paris. A certain foreign Count has succeeded in resuscitating the long-languishing method of executing photographic portraits of the carte-de-visite instead of the album size; while yet another Count, Primoli by name, said to be a descendant of Lucien Bonaparte, has, after making a brilliant photographic conquest of the salons of Rome and Florence, descended on those of Paris, armed with an apparatus for taking instantaneous light-portraits. "Le revolver-camera" has already been heard of; but Count Primoli appears to be the first amateur practitioner who has made the invention fashionable.

"Enterprises of a more exalted artistic nature, however, are spoken of in connection with the magic art of Daguerre and Fox Talbot. The Baroness Adolphe de Rothschild has installed a photographic studio on a superb scale at her Château on the banks of the Lake of Geneva, where she has produced a series of portraits not only as photographically life-like, but as artistically vigorous and refined, as those for the painting of which in water-colours the Princess Mathilde Demidoff, *née* Bonaparte, has acquired such bright celebrity.

"Naturally the sculptors and the aquarellistes feel little satisfaction at this new development of practical art among the 'grandes dames de par le monde' in France. A very few lessons will convert any person of average intelligence into a tolerable amateur photographer; indeed, with the aid of a lucidly written manual and an efficient apparatus, the craft is one which can be self-taught. On the other hand, the studio of Madame de Rothschild on the Lake of Geneva may be regarded as a wholly exceptional experiment, and one not more likely to injure either professional painters or professional photographers than M. Mollier's amateur circus is to shut up the cirque once known as Franconi's."

ON the first of January, 1888, there were 110 members on the rolls of the Photographic Society of India; now there are 205, an average increase of eight members per month for the whole year. Twenty-six have been enrolled since November last, so the average monthly increase is now not less than 13. Three new members every week is a criterion of the growing popularity of the Society.

NATIONAL PHOTOGRAPHIC EXHIBITION.—With the intention of securing for this Exhibition a thoroughly national character, the directors of the Crystal Palace Company have decided to offer a valuable challenge cup, to be retained for the current year by that Photographic Club or Society which, in the opinion of the judges, sends the best collective exhibit of not less than fifty pictures. The following are the conditions:—(1) All pictures entered in this competition will be subject to the general rules of the Exhibition, as published, where applicable; (2) There will be no entry fee charged for the club challenge cup competition; (3) The pictures included in a joint club exhibit are equally eligible for awards in their several classes, but a separate application form must be filled up by the individual exhibitor, and, in the case of professionals, the stipulated fee enclosed; (4) The challenge cup will be handed over to the Mayor or other public functionary of the town or district in which the head-quarters of the successful Society are located, to be held by him, in trust, for a period of one year, at the expiration of which it shall be returned to the Crystal Palace Company; (5) the name of the successful Society will be engraved upon the cup or pedestal, with the date of the award; (6) The challenge cup shall be confined to Societies within the United Kingdom, and provincial makers and dealers, it is said, will be more fully represented this year than upon previous occasions, and the Exhibition is accordingly expected to be more generally interesting.

THE LATE CUTHBERT BEDE AND HIS BOOK "PHOTOGRAPHIC PLEASURES."*

BY W. LANG, JNR., F.C.S.

In the next picture we find photographic processes still further gone into. As each drawing has its title underneath, you will be able to extract the humour without the aid of any explanation of mine.

A "Photographic Fix" is our next subject. "Mr. Jones, being on his way to the lakes, embraces the favourable opportunity of calotyping some fishing boats on the Ulverstone Sands, Morecambe Bay. The tide unexpectedly comes up during the time that his head is beneath the hood; disagreeable position of Mr. Jones on emerging from the hood."

Then we come to a series of photographic fancies:—Applying the black varnish, best black varnish (a copy of "Uncle Tom's Cabin"), applying an exciting fluid, &c.

The following illustration is entitled "To secure a pleasing portrait is everything. Daguerreotypist to cheerful sitter: 'The process will commence as soon as I lift up this slide. You will have the goodness to look fixedly at one object, and call up a pleasant expression to your countenance.'"

Another page of photographic facetiæ is to be found in the twelfth illustration, where we find a photographic bath, photographic abstraction, developing solutions, all portrayed from the Cuthbert Bede point of view.

In the chapter entitled "Photography in a Love Light," we find our author has one or two passages which are extremely pathetic, and I may be permitted to quote them.

The picture which we find interpolated in the chapter we have already quoted from, viz., "Photography in a Love Light," is representative of "one of the pleasures of photography," visiting country houses and calotyping all the eligible daughters, and the picture in question you now have thrown upon the screen.

Another illustration of photographic facetiæ comes after the foregoing, and we will leave it on the screen for some little time, so that the details may be studied.

Perhaps one of the most humorous sketches in the book is the one entitled "A Photographic Positive." The picture, which, if I mistake not, appeared in *Punch*, is self-explanatory.—Lady Mother (*loquitur*): "I shall feel obliged to you, Mr. Squills, if you would remove these stains from my daughter's face. I cannot persuade her to be sufficiently careful with her photographic chemicals, and she has had a misfortune with her nitrate of silver. Unless you can do something for her, she will not be fit to be seen at Lady Mayfair's to-night."

The appearance of the lady amateur with her mottled visage is a fine bit of humour, and is portrayed in a manner worthy of Cruikshank. I fancy our professional members will rather enjoy this hit at the amateur dabbler in photography, and perhaps some of them may be going the length of saying, "Serve her right!"

The next picture to be thrown on the screen, as you will see from reading underneath, is called a photographic picture. Here you see a man focussing, and an old lady, who appears suddenly from round a corner, and who is not used to these new-fangled notions, is made to say, "Please, sir, don't for goodness' sake fire, sir!"

In his preface the author refers to the fact that four of the pictures in his book had appeared in *Punch*, but he does not, I am sorry to say, indicate which particular ones these are. I rather think I have seen the one which I am now going to show you in the journal in question. It has for title, "What it has come to, and, What it may come to." In the former we find a young hopeful addressing his father, an ardent amateur, you may take it for granted. "Oh, pa! me and baby have emptied out all your bottles, and have cleaned them so nice!" and in the latter, What it may come to; or, the British nursery in 1865, a nurse is found asking the child in its chair, "Did it want its camera then?" and the reply, "No, I don't; I want to go and print off my negatives! Boo! hoo! hoo!"

Passing on, we come to the method prescribed by Bede for procuring a photographic negative. He says, "Take any village, and in its vicinity select a field through which there is a public way. Focus your view, and make all ready for the negative. While the process is going on take your seat upon the next stile—the more distant the better—and lose yourself in the leaders of the *Times*. You will thus be giving an opportunity to children of a speculative turn of mind to solve their doubts as to what your camera really contains. At the expiration of twenty minutes, shut up your *Times*, and return to your camera. When you take out your slide you will find that you have secured a most excellent negative!"

Photographic faces comprise the following: Brown sees his face in the glass, and thinks he is rather an agreeable looking fellow; Brown sees his face in the negative, and his second thoughts are by no means the best. Portrait of a very beautiful lady, who has had the misfortune to sneeze at the moment of the removal of the cap. Portrait of a very unsteady gentleman. Lady, with hood, time of Elizabeth, and camera, with hood, time of Victoria. Phœbus Apollo, portrait painter to General Earth.

Exciting for the sensitive, has the accompanying letterpress. Outraged protectionist (whose ideas have not been developed in proportion with those of the photographer): "Ho, you there! 'illo! I'll teach you what it is to bring your theodderlite 'ere, and come a measurin' for railroads on my land."

Photographic people are next hit off. Fancy portrait of Dr. Diamond. A sitting with Beard. Portrait of Dr. Diamond in his calico bag. Look on this picture, The Hon. Miss Haggis, from the portrait by Chaldon, R.A., and on this, the Hon. Miss Haggis, from a Daguerreotype. Gems from the Blackguards' Photographic Portrait Gallery. Brown is, of course, naturally anxious to see how Smith looks in the camera. Mr. Wedgwood, from a photograph by himself. Photographer: "Be pleased to look straight at me sir!" Sitter: "Why, dang it, I've been a-doing it these ten minutes!"

We come now to a picture which Mr. Bell will no doubt appreciate, the photographic detective, and photographic focussing and hocussing. Mr. Priggins as he appeared before the "Beak," Mr. Priggins as he appeared before the camera. I'm afraid the conditions are now reversed, and Mr. Priggins will not now look so amiable.

A Photographer Astonishing the Natives.—"Come along, Betsy Jane, do, and look at the man with the Peep Show." This picture, the author tells us in a footnote, appeared in *Punch*.

The last sketch in the book is entitled "The Present Attitude of Photography," and in the concluding chapter we find the question asked, "What is there that our friend camera will not do?" and I may be permitted to quote the last paragraph or two, and it will be a matter of especial interest for us as an association to find therein an allusion to a former president. I refer to Mr. Kibble.

* Concluded from page 72.

Notes.

A French professor of physiology (Dr. Verdin) has compiled a sort of code of human expression, his theory being that for every weakness or vice there is a corresponding cast of feature which affords an infallible index to the character of the man. Dr. Verdin is trying to do what Lavater failed in. Physiognomy is true enough where broad generalities are concerned, but when minute subdivisions are made, two professors of the science are as likely as not to differ. Still experiments in connection with the human face are always interesting, and this theory of Dr. Verdin's is one where composite photography is likely to prove useful. If we mistake not, Mr. F. Galton's composite photographs of criminals were made from the faces of prisoners taken indiscriminately. If it be really possible to localise a vice or weakness, it would be necessary to classify somewhat minutely.

Thus, we might get the typical expression of the pickpocket, the burglar, the forger, the poacher, the "smasher," and a host of others. Murderers in England are not numerous enough to afford material; they therefore must be left alone. So also must the individuals which the *Echo*, in commenting on this subject, wishes to be distinguished. If Dr. Verdin can help us, says our contemporary, to distinguish an honest company-promoter from his dishonest brother, or a well-meaning "outside" stock-broker from his disingenuous fellow-labourer in the vineyard of finance, humanity will be grateful. Doubtless; but we are afraid Dr. Verdin protests too much. At present it would be certainly unsafe to rely upon subtle distinctions of the kind we have referred to.

At the last meeting of the Royal Astronomical Society, Mr. Maunder incidentally stated that there was a work about to be begun at Stonyhurst which was certainly much wanted, seeing that we are entering upon a new solar period. The work referred to is the regular photography of sun-spot spectra. A photographic record of sun-spot spectra will have a great advantage over eye records, in that it can be referred to afterwards; and if there is any difficulty or doubt, the question can be settled by reference to the photographs. Mr. Maunder mentioned, as an instance, that in the earlier observations made at Greenwich of the spectra of sun-spots, he saw that lines were broadened over the spots, which were mostly those of well-known and well-marked Fraunhofer lines. As time went on, he found the broadened lines were lines which could not be ascribed to any element, nor could they be even seen on the general disk. At first Mr. Maunder thought there must be a mistake on his part; but he found that precisely the same observations had been made at the same time at South Kensington, so there could be little doubt that there was a genuine change in the character of the spot-spectra. But if his observations had stood alone, it would have been very possible to have accounted for them by supposing that, when fresh to the work, he had naturally been attracted to the more conspicuous lines, but that afterwards, when he had had more experience, he had been able to observe less important lines. "If we have a photographic record," observed Mr. Maunder, "we can consult old photographs, and no doubt whatever could arise."

Photographs have over and over again formed an important element in the evidence in divorce cases, but rarely in so novel a manner as in a Scotch divorce case trial last week. The respondent, in accordance with Scotch law, had been cited to appear, but she took no notice of the order, and a photograph was put in for purposes of identification, and to show that the order had been duly served upon the right person. To this photograph the respondent's counsel took an initial objection, and after the evidence had been heard, contended that the Court should find the case "not proven," on the ground that the photograph was not sufficient. Lord Trayner, however, held that the photograph was admissible, and not only so, but that the photograph of the co-respondent, who did not appear, should be admitted, and pronounced for the petitioner. It is not every judge who is such a believer in the faithfulness of photography. Cases might be cited where the judge absolutely refused to receive photographs as evidence of identification. A good deal, perhaps, depends upon the photograph.

If Mr. Brudenhall-Carter's assertions at the Society of Arts, as to the fallacy of the tests in use to determine whether a person is colour-blind or not, be correct, the sooner an exhaustive series of experiments be made the better. Dr. Carter points out that a man may have learnt by experience that the light which appears to him dull green is called "red" by the majority, and when that colour is shown he promptly gives a correct description. But the uselessness of this test appears with calamitous results sometimes when the true green light is blurred by atmospheric conditions. The truth seems to be that really very little is known about colour-blindness. The two colours, green and red, are selected as the most important for accurate observation, as green and red are the danger signals generally in use; but may it not be that there are just as many people unable to distinguish between blue and orange as between green and red? We have also never seen it recorded what was the experience of a person, whose eyes were insensible to the red rays, when shut up in a photographer's dark room. Would he see green?

It is rather amusing, after visiting the Exhibition of the Humorous in Art, to find "Atlas," in the *World*, indignantly protesting against the length to which caricature is carried now-a-days. To look at Gillray, Woodward and Rowlandson, and Cruikshank, and compare their gross perversions with the productions of

"Ape," "Lib," and "Spy," the drawings of the latter appear absolutely refined. It is by no means certain that photography has not rather injured caricature, though whether this is to be regretted we need not enquire. When a comic artist has to caricature a public man, he buys his photograph, and makes a sort of fancy distortion. This is not caricature, for the essence of caricature is truth, but truth, of course, exaggerated. The older caricaturists made their drawings from the life, and only after much study—hence their force. The coarseness was that of the age, and neither added to nor detracted from the truth of the exaggeration.

Photography has made the work of the lecturer far more interesting to his audience than used to be the case. In former days, all that the lecturer could do when he had any specimens illustrating his lecture, was to invite the audience to step on the platform at the conclusion of the proceedings and make an inspection. As a rule, about half a dozen persons used to respond to the invitation, and all the rest hurried away in order to catch their tram or omnibus. We manage things better now-a-days by having photographs made wherever it is possible, and throwing these on the lantern screen. The advantage of this plan was admirably shown this week at a lecture on the history of printing delivered at the City of London College. The accuracy and facility with which manuscript and printed books can now be photographed render such objects peculiarly suited for lantern slides, and the whole audience were enabled easily to see what, in the old days, would have been visible only to a few. The photographic lantern slide plays the same part in a lecture as illustrations do in a book; it enables a larger number of people to take an interest in subjects which otherwise might seem dry and repellant.

The "Photographic Union" of France, described as a Mutual Help Association, and corresponding very much to our Photographers' Benevolent Association, has started very well. Before even the objects were formularized, and the basis of the society established, subscriptions began to flow in, and though the members are fully conscious that much cannot be done until a permanent fund has been created, a very respectable nucleus has been got together. The Association is founded on the system originated by Baron Tayler, who created so many associations of a kindred nature, all of which are now rich and prosperous. The main principle of this system is essentially sound, as it involves the inalienability of the capital, all help being derived from the revenue. At a meeting held recently the scheme was explained by M. Vidal, and it was stated that, after an appeal had been made to the photographic profession generally, steps would be taken to bring about a public recognition of the utility of the association. Already subscriptions to the amount of 4,000 francs have been announced, and these will doubtless be followed by others.

SELECTING FOCAL DISTANCE WITH DETECTIVE CAMERAS.*

BY W. E. DEBENHAM.

THE expression forming the title of this paper may be used with two significations: involving either the choice of the focal length of lens that it is desirable to use; or, when the lens is decided upon, the use of it either at the distance from the plate which corresponds with its focal length for objects in the extreme distance, or at some distance which shall bring into more exact focus some object which is nearer.

There seems to be a good deal of misapprehension, not, perhaps, amongst the members of this Society, but amongst those who derive their principal impressions about photography from the statements of dealers, and from their happening, in their occasional reading, to come across what may be called pseudo-scientific papers, concerning the capabilities of a photographic lens for focussing simultaneously objects at different distances. Here it may be well to remark that, owing to curvature of field, almost any lens will focus simultaneously objects at different distances, if such objects fall upon parts of the plate, some nearer and others farther from the centre of the field of the lens. What, however, is meant is the capability of focussing at the same time, objects which are either on the same part of the plate, or at an equal distance from the axial line of the lens. As an illustration of the misapprehension referred to, may be cited a statement that has been the subject of comment at this Society, as to the advantage of some lens which was supposed to have a fixed focus. Another absurdity is that of setting up some standard of a permissible amount of confusion, such as that of $\frac{1}{100}$ of an inch, and then proceeding on the assumption that all parts of the picture in which that amount of confusion is not exceeded, are in focus. The falling off of focal sharpness is gradual, and there is no definite line of demarcation where sharpness begins, whether at the $\frac{1}{100}$ of an inch, or at any other limit. If, on the one hand, there were such a distinction line of demarcation; and if, on the other hand, we were able in general work to avoid photographing all distances where confusion due to want of focus exceeds such limits—if both these conditions were fulfilled, a table showing distances with particular lenses where sharpness could be secured would be very useful. As a matter of fact, neither of the conditions is fulfilled. Sharpness does not begin at any measurable limit, and we are constantly meeting with subjects where any such attempted limit must be exceeded in some part of the picture. We must minimise our loss of sharpness as much as the particular circumstances will permit. There is, of course, a limit to the defining power of lenses, as well as, perhaps, to the power of the photographic film to register minute details, and of human observation to appreciate such details when registered. When these limits are reached, and any two objects, however much they may differ in distance, are rendered simultaneously upon the plate with such definition that no deficiency is discoverable in the one when the other is focussed, they may be said to be both in focus.

This apparent equality of focus of objects at widely different distances is always reached if the nearest of such objects is only removed sufficiently far. There is no photographic lens in the world—I am, of course, not speaking of telescopic objectives—which will show any differ-

* Read at the London and Provincial Photographic Association.

ence of focus for objects, the nearest of which is a mile, whilst the others may include the moon at a distance of some hundreds of thousands of miles, and the planets at many millions, or the fixed stars at still greater distances. If a lens of twelve-inch focus could be made of such perfect defining power as to show a difference of adjustment required when focussing between these limits—that is, at a mile, and at the greatest conceivable distance respectively—the adjustment necessary would amount to about the $\frac{1}{1000}$ of an inch. As, however, that amount of racking in or out makes no discoverable difference in the sharpness of the image given by such a lens, objects not requiring more than that adjustment may be considered to be in focus. When, however, we come to distances which have been mentioned as those beyond which all objects are in focus, such as 100 feet, 50, 30, 20 feet, or even less, the case is very different. With a lens of 5-in. focus, the difference of adjustment for objects at 20 feet and beyond will amount to about the $\frac{1}{60}$th of an inch—a difference which, as a very slight amount of practice will suffice to show, produces a very appreciable difference of distinctness in the focus.

Since we cannot hope to focus truly at the same time near and distant objects upon the same part of the field of the lens, the question becomes, how shall we proceed so as to reduce the indistinctness due to imperfect focus to the smallest amount? What length of focus shall we choose for our lens, and shall the instrument be set so as to truly focus the extreme distance, or some nearer point? In answer to the first part of the question, both long and short focus lenses have been advocated, and each with reason, if a particular class of subject is in question. The principal argument in favour of long-focus lenses for a given size of plate, is that as the field of definition is always more or less curved, and the longer the radius—which means the less the curvature—the nearer to it will be the flat surface of the plate. Another argument, relating to a consideration not now under discussion, is that with a long focus lens any selected object will appear of larger size, and assume greater importance in the picture. For the short-focus lens, it may be argued that objects differing in their distance from the instrument, will be represented as less removed from the focal plane than with the longer focussed instrument.

This is a very significant consideration, and one which is of the greatest importance in detective camera work for the most part. Let an object at, say, 20 feet distance, be included in a view taken with two lenses, one of 3-inch and one of 6-inch focus, each stopped to the same rapidity, and each focussed for some object in the extreme distance. The blurring of the near object will be double with the 6-inch lens than it will be with that of shorter focus. It is not merely that the blurring with the lens of shorter focus will be reduced to smaller proportions because the whole photograph is smaller, but that when both are enlarged to one size, the enlargement from the short-focus lens will show only half the blurring that the other does—that is to say, the representation will be as distinct as if the longer focussed lens had been racked half the distance required to suit the particular object.

Here, then, is a great advantage for the short focus lens, against which must be set the disadvantage for the particular plate, but not for one of proportional size, of want of focus towards the margin, owing to curvature of field. There will also be further want of definition towards the margin from other optical causes; but taking the curvature of field alone, that may sometimes be turned to a positive advantage.

The most common case in which this is seen is in photographs of interiors, which are not generally detective work, and in street scenes, and such similar cases, where the side objects are much nearer than those occupying the centre of the field. The curvature of field of the lens is a matter that I think photographers, especially those who go in for detective work, would do well to study. If we are obliged to put up with the drawbacks attendant upon curvature of field, let us take advantage of any possible help which it may occasionally render. It will be found then, with any ordinary detective lens, that as we approach the margin of the field, an object to be in the best obtainable focus must be much nearer to the instrument than the distance which has been focussed at the centre of the field. Suppose that we have a lens of 5-inch focus used with a quarter-plate. We may find that when it is focussed for the distance at the centre, an object occupying a spot 1½-inch distance from the centre of the ground glass will be in focus, when only about twenty-five or thirty feet off. If we are capable of judging distances tolerably, and have either previously noticed on the ground glass or with the finder what part of the scene will be occupied by an object which comes 1½-inch from the centre of the plate, we may succeed in catching a near object of interest when in focus, without disturbing the general focus for the distance. This case is put as an illustration of what may be done. We may, for instance, note a place in a line of roadway along which vehicles travel, and by getting a horse, dog, or foot passenger there when passing a spot at a certain distance from the centre of the plate, get it just at the focus for that part of the plate, although at the centre it would be decidedly out of focus.

We now come in conclusion to the consideration of whether it is desirable for general detective camera work to have the lens focussed for the extreme distance, or some point at the distance, as near as may be, at which it is anticipated that objects of interest will appear.

Of course the object of special interest should not be decidedly out of focus, and therefore it would be better to focus for that, if there is a ready means of adjustment, or if that probable distance is known beforehand. If such object come in the centre of the plate, the lens must be racked out, and the distant background will be out of focus. It has, however, been shown that with a short focus lens and tolerable wide angle of view, it is possible to get a rather near object in focus without movement of the lens, provided it is not very near the centre of the field. When it is desired to obtain objects of a certain size on the plate, and to cover a plate of given size as sharply as may be towards the edges, then a lens of long focus will be selected; but, in this case, if near and distant objects are both included, one or other must give way in the matter of focus. When, on the other hand, actual size is not important, and it is desired to get objects at different distances all as nearly focussed as possible without diminishing the speed of the instrument, this will be accomplished by using a lens of short focus. The power of yielding a sufficiently magnified image may, however, as suggested before, be limited by the capability of the film of registering, without interference due to structure or coarseness of grain, details beyond a certain degree of fineness.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

WE have received from the Committee, through Mr. H. Harland, secretary, a request for the insertion of the subjoined report and statement of the future policy of the above-named Association: —

Your Committee, in submitting their Report for the past year, consider that it is desirable on the present occasion to give something more than the customary abstract of receipts and expenditure. It would be idle to contend that the Association has, at any period of its existence, completely fulfilled its mission, and the problem which has at several previous epochs of its history confronted its management has, during the past year, again presented itself and appealed for solution.

It will be within the knowledge of all but recent members that in 1885 the roll of membership had become reduced to such meagre dimensions that the Association became unworkable under the then existing system, and it was thereupon resolved to reduce the subscription to 2s. 6d. per annum, with a view to encourage the poorer members of the profession to join the Association. At the end of the following year the number of members had certainly increased, but the greater part of the increase consisted of persons who would never be likely to require assistance from the funds. At the Annual Meeting in 1887 two notable alterations were made in the Rules: —Amateurs were allowed to become members, and the Committee was empowered to consider applications for relief from non-members if the case had been recommended by a donor of £1 1s. Under the new conditions the number of members rapidly increased, but a vast majority of the increase consisted of amateurs, who were never likely to require aid, even if they were eligible to receive it; the class which the Association was designed to benefit still held aloof, and practically ignored its existence. One of the chief difficulties your Committee has to contend with is the fact that the good effected through the Association is of necessity very little known, those who receive benefit being, perhaps, naturally the last to talk about it. Many recently acquired members seemed to have taken a mere passing interest in our benevolent aims, and have suffered their subscriptions to fall into arrear, or, perhaps, have never really looked upon themselves as permanent subscribers at all. Owing to these circumstances the success of the Association has been materially hindered; and, although it will be recognised that this is no new difficulty, one of the first points your Committee had to determine was whether it was worth while, for the sake of a score of members who practically constitute the Association, to carry it on almost solely for their benefit? They have come to the conclusion that something more than this is expected from them, and that they should rather seek for powers to enable them to extend its scope and sphere of beneficence still further in the direction of such as have not hitherto been in a position to contribute to the funds. The old members, who have all been consulted on this point, are quite willing, for the general good, to sink their individual claims, and your Committee have now formulated a new set of rules embodying the principle on which they propose that the Association should in future be conducted. This, while reserving to old members a preferential claim on the funds, will afford a larger discretion in administering assistance to any deserving cases of distress, irrespective of membership, and will consequently give your Committee a better standpoint when appealing for funds for the general purposes of the Association. The serious attempt now for the first time made to initiate an independent Annuity Fund will be kept prominently in view, and it is with some confidence anticipated that it will before long very largely exceed the sum of £250, at which the new scheme will start it.

It has, from time to time, been brought as a reproach against the Association that the expenses of management have been too heavy in comparison with the amount expended in relief. Your Committee fully recognise the justice of this contention, and it has several times been considered whether the work might not be efficiently performed by an Hon. Secretary; but while they could reckon upon retaining the services of Mr. Harland, whose energy and experience have been of material service to them in the past, they have not thought it expedient to recommend so radical a change. Mr. Harland has, however, now seen fit to resign his office, and in response to an appeal which was thereupon inserted in the photographic papers, a gentleman has come forward and proffered his services as Honorary Secretary to the Association, and your Committee have, without hesitation, accepted his generous offer. They confidently trust that a new era in the affairs of the Association, marked by economy as well as efficiency of administration, will thus be ushered in, and they hope that the time is not far distant when the Association will take its proper position as the recognised channel for the benevolence of the profession.

Referring to the balance sheet for the past year, it will be seen that the funds show the substantial increase of £67 5s. 1d., and now stand at £375 12s. 11d. Members' subscriptions show a considerable falling off, being £20 19s., compared with £30 11s. for 1888; this has been already alluded to. The donations amounted to £71 18s. 5d., fully £10 more than in 1888, but of this sum £34 16s. 11d. was transferred from the abandoned Orphans' Fund. The exhibition of the P. S. G. B. produced £12 5s. 6d. against £14 3s. in 1888. The grants by way of relief, which in 1888 amounted to £38 14s., during the year under review amounted only to £18 4s., and this is the fact which has given your committee most reason for proposing to re-consider the position of the Association with a view to extending its sphere of usefulness; and the result of the long and anxious consideration they have given to the subject has been embodied in the new draft of rules which they now intend to submit for your approval.

A copy of the proposed new rules may be seen at the office of Mr. W. Benham, Hon. Solicitor to the Association, at 4, Great James Street, W.C.

THE CALCUTTA PHOTOGRAPHIC EXHIBITION.

THE *Journal of the Photographic Society of India* just received is full of interesting information. The best Photographic Exhibition ever held in Calcutta is over, and the judges who awarded the prizes were Sir Comer Petheram, Chief Justice; Col. Waterhouse; and Mr. W. H. Jobbins, Superintendent of the School of Art. The decision of the judges was not handed in before the close of the Exhibition, but the delay was unavoidable. Colonel Waterhouse did not return until after the Exhibition was open, and then, what with arrears of work and other calls upon his time, he was prevented from doing anything towards the judging until after Christmas week. By that time Sir Comer Petheram had gone to Darjeeling for the Christmas holidays, but he, at great personal inconvenience, came down to Calcutta and met Colonel Waterhouse and Mr. Jobbins at the Exhibition.

The following is an abridgment of the report of the judges, and contains the names of all the successful candidates: —

The special gold medal presented by His Highness the Bara Thakur Bahadur of Tipperah for the best platinotype by an amateur, irrespective of class or section, was awarded to Mr. F. M. Sutcliffe, for No. 164, and high commendation to his other pictures.

Class I.—Section 1 (Landscapes, Architecture, and Interiors). —Gold medal presented by Sir C. Petheram: Mr. R. Keene, for his series of landscapes and interiors. Society's silver medal: Mr. F. P. Cembrano. The award of an extra medal recommended to Mr. J. P. Gibson for his landscape views. Honorable mention: Messrs. Bourne and Shepherd, Bremner, Austin, J. S. Gladstone, Lala Deen Dyal, Pancoast, H. P. Robinson, Lyddell Sawyer, and Sutcliffe.—Section 2 (Portraits, Groups, and Studies).—Special medal, presented by H. E. the Viceroy: Messrs. Johnston and Hoffman. Society's gold medal: Mr. W. W. Winter, for "My Mammy," platinotype print. Society's silver medal recommended to Mr. Lyddell Sawyer,

Honorable mention: Messrs. J. E. Austin, G. M. Elton, J. P. Gibson, Robert Hotz, Kapp, Klier, Lala Deen Dyal, P. Nicholson, Lyddell Sawyer, Sutcliffe, and Miss Clarisse Miles.—Section 3 (Genre Pictures, Animals, and Still Life).—Gold medal, presented by H.H. the Maharajah of Kuch Behar: Mr. J. E. Austin, for his pictures of animals and studies. The Society's silver medal: Mr. R. S. Redfield. Extra medal recommended for the series of little wayside studies exhibited by Mr. M. H. Harding. Honorable mention: Messrs. D. Barnett, F. Bremner, Rev. F. C. Lambert, Miss Miles, Messrs, A. Nicholson, H. P. Robinson, F. M. Sutcliffe, and J. Walker.—Section 4 (Instantaneous Photographs).—Gold medal, presented by the Nawab of Dacca: Messrs. West and Sons, for photographs of yachts. The Society's silver medal: Mr. F. Bremner. Extra medal recommended to Mr. W. Parry for instantaneous views. Honorable mention: Messrs. C. R. Pancoast, Lyddell Sawyer, and Sutcliffe.—Section 5 (Combination Pictures).—Silver medal, presented by Col. J. Waterhouse: Mr. F. Whaley.—Section 6 (Stereoscopic Pictures).—Messrs. G. W. Wilson and Co.

Class III.—Section 12 (Photographs on Wood, Glass, Linen, or China).—Society's silver medal: Mr. Robert Hotz, for his porcelain pictures.—Section 13 (Reproductions and Enlargements).—Society's silver medal: Messrs. Kapp and Co., for group of the Naval Volunteers. Honorable mention: Messrs. Johnston and Hoffman, Messrs. Bourne and Shepherd, and Mr. Robert Hotz.

Class IV.—Section 14 (Miscellaneous Processes).—Certificate: Messrs. Kapp and Co.—Section 15 (Heliotype, Photo-Engraving, &c.).—Certificate: Mr. J. E. Dumont.—Section 16 (Photographs taken by Artificial Light).—Certificate: Mr. Robert Hotz.

INDIAN AMATEURS ONLY.

Class I.—Section 1 (Landscapes, Architecture, and Interiors).—Society's silver medal: Mr. E. W. Stoney. Extra medal recommended to Mr. T. D. La Touche. Honorable mention: Mr. G. J. Apcar, Mrs. Currie, Messrs. G. Ewing, S. J. Leslie, Col. Rogers, His Highness the Bara Thakur Bahadur of Tipperah—some of whose views in platinotype were specially commended—and Claude White, whose No. 18 was also of considerable excellence.—Section 2 (Portraits, Groups and Studies).—Society's silver medal: Mr. G. J. Apcar. The judges mentioned the general excellence of Mr. Apcar's pictures in this and other sections. Mr. Pope's group of survey officers, enlarged and printed in heliogravure, is deserving of notice, and some of the portraits exhibited by His Highness the Bara Thakur Bahadur of Tipperah are also good.—Section 3 (Genre Pictures, Animals, and Still Life).—Society's silver medal: Mr. A. G. E. Newland, whose pictures in this and other classes, though not so effective as they might be as photographs, show considerable originality and skilful grouping. Honorable mention: Messrs. Apcar and Stoney.—Section 4 (Instantaneous Photographs).—Society's silver medal: Mr. E. M. Showers. Honourable mention: Messrs. Apcar, Stoney, Newland, and Leslie.

Class II.—Section 8 (Micro-Photography).—Certificate: Mr. W. M. Osmond.

Class III.—Section 13 (Reproductions and Enlargements).—Society's silver medal: Mr. A. L. H. Palmer.

The awards for lantern slides are postponed until the pictures have been tried in the lantern.

THE ROYAL INSTITUTION.—Last Friday the first evening lecture of the session at the Royal Institution was delivered by Professor Dewar, with Sir Frederick Abel in the chair. The lecture dealt with the life and discoveries of Joule, and in the course of it Professor Dewar exhibited an experiment in which pieces of ice were melted by the heat produced by their friction against each other. They were rubbed against each other in the exhausted receiver of an air pump, and over strong sulphuric acid, two conditions by which water can be frozen, so that the melting was proved to be due to heat produced by friction, and not to the temperature of the theatre.

PHOTOGRAPHY IN SWEDEN.

IN the first number of the present year's issue of the Swedish *Photographic Journal for Professionals and Amateurs*, published at Stockholm, we meet with an interesting description of a reunion of the Photographic Society, communicated by the secretary, Alexis Hasselquist. The reunian was held on the 4th of January, 1879, and forty members of the Photographic Society attended. Dr. Wolff, the well-known astronomer from Heidelberg, honoured the assembly with his presence.

After Herr Palmgren, who presided at the meeting, had welcomed those ladies and gentlemen who were in the room, with suitable forms of speech, he took occasion to refer in terms betokening poignant regret to the great and grievous loss which the Society had lately suffered by the death of its former much-loved and well-esteemed president, Professor Herr Heymans.

Herr Palmgren then spoke in well-chosen phraseology, and at some length, of the important advantages which had been derived from photography by science, art, and industry, and added that photography's valued aid was by no means the least among the many aids which had of late years been offered to education. He was anxious those who were there present should know, and that by their means others interested in this matter might be given to understand, that photography in the hands of the amateur was no mere idle toy, insignificant plaything, or harmless amusement, but had its essential use and purpose in furthering the interest of the art student and the scientist, the physician and the astronomer.

The president concluded his speech, which was heard with the deepest attention, by a few interesting remarks about the rich and valuable collection of the products of photographic art which the members of the society saw before them, and might afterwards examine at their leisure.

Herr Roosval, the editor and publisher of the Swedish *Photographic Journal*, in succession to the president, addressed the meeting, and gave an account of the beginning of photography, of the early years, so to speak, of the art's childhood, when it was as yet scarcely able to walk alone. From this he passed to its present matured growth, speaking very highly, by the way, of the greatness of the art, and the noble inventions of our own time which had so much in them due to modern photography. His remarks were copiously illustrated by a large collection of Daguerreotypes, paper negatives, glass, and wax cloth pictures, which he said were fashionable in the year 1840 before paper pictures were invented. But the most interesting object in the whole collection for those assembled at this Swedish reunion was a Daguerreotype taken after nature at Copenhagen in 1840, for it represented the world-renowned sculptor Thorvaldsen. The plate, of the size of 18 by 24cm., was in excellent preservation, and is the property of the photographer, J. Jæger.

After the admission of many new members, and the transaction of the usual business of the Society, the visitors busied themselves with the inspection of the various objects of photographic interest which had been collected for their amusement.

Among the most noteworthy specimens of artistic work exhibited at this Swedish reunion may be mentioned several interiors and landscapes by Major Adelsköld; transparencies and landscapes by Doctor Aspelin; pictures from Panama by Herr Bowallius; heliogravures by Herr Börtzell; oil-coloured photographs and magnesium flash-light pictures by Herr Carleman; genre pictures by

Herr Cedergren; negative pictures of moon-eclipse and stars by Doctor Charlier; a rich collection of large photographs of the environs of Stockholm, also of places in Germany and Spain, by Professor Curman; instantaneous pictures by Herr Feychting; negative and positive pictures of star groups, lightning flashes, &c., by Professor Hasselberg; pictures from Gotland and Karlsöarne; interiors and enlargements on bromide of silver paper by Lieutenant Hasselquist; large panoramas from Stockholm and interiors, mostly taken with wet plates, by Herr Jæger, photographer; a few portraits taken thirty years ago by Herr Palmgren; some platinum pictures by Herr Roosval; landscape and pictures from Visby by Herr Stenquist; instantaneous pictures, taken with Stirn's camera, by Herr Strindberg; two photographs of pictures of Carl Larsson and Zorn, by Herr Ostlin; enlargements on bromide of silver paper, together with large and small landscapes, and instantaneous pictures of running horses, vessels under sail, &c., by Herr Blom; landscapes and genre pictures by Herr Carl Johansson; landscapes and instantaneous pictures of sea waves and breakers by Herr Kallstenius; photogravures by Herr Lagrelius; instantaneous pictures, landscapes, interiors, photographs of pictures and busts, with enlargements on bromide of silver paper, and photographs copied on aristo-paper by Herr Siljeström; and genre and instantaneous pictures of vessels under sail by Herr Smitt.

THE DISTANCE BEYOND WHICH ALL OBJECTS WILL BE IN FOCUS WITH ANY GIVEN LENS.*

BY SIR DAVID SALOMONS, BART.

THE author found a simple formula for ascertaining the distance beyond which all objects will be in focus with any given lens—it is $f + 100 f^2$ R inches—where f and R have the same meanings as usual. This formula is very useful to ascertain the most suitable lenses for detective cameras, and for other purposes. It is assumed that if points in the object are represented in the image by circles having diameters of $\frac{1}{100}$ inch and less, the picture will be sharp.

A special instance will be given to show its use:—$100 f^2$ R inches may be written $8\frac{1}{3} f^2$ R feet, since 100 inches = $8\frac{1}{3}$ feet. The addition of f in the formula may be neglected, being small compared with $100 f^2$ R. Most of the rapid landscape lenses work at $\frac{f}{8}$, so the formula reduces itself to f^2 feet approximately. This shows that, with any lens $\frac{f}{8}$, all will be in focus after a distance expressed by the square of its focal length in feet. Putting the formula in words, $100 f^2$ R inches reads:—100 multiplied by the ratio, multiplied by the square of the equivalent focal length of the lens, expresses in inches the distance beyond which all objects will appear in focus. To give an example:—After what distance will all objects be in focus with a lens stopped $\frac{f}{12}$ (*i.e.*, $\frac{1}{12}$), the equivalent focus being 10 inches?

Answer—

$100 \times \frac{1}{12} \times 10 \times 10 = \frac{10000}{12} = 833\frac{1}{3}$ inches = 69 feet $5\frac{1}{3}$ inches. To be strictly accurate, add f (= 10) to this, and distance becomes 70 feet $3\frac{1}{3}$ inches from optical centre of lens.

It is a good plan to mark the stops for the distance after which all will be in focus, as well as the standard number. In practice this is invaluable, for when a subject is to be taken requiring a particular stop to get the focus right, and it is found that this stop has a number requiring too long an exposure, a plate is saved.

* Read before the Photographic Society of Great Britain.

The following table will be found useful for many purposes: some 1,200 calculations having been made to compile the results given:—

FOCUS TABLE FOR DETECTIVE CAMERAS AND OTHER SPECIAL WORK.

Focus of lens in inches.	Decimal Standard Stop Numbers. 5	10	15	20	25	30	35	40	Ratio Marked on Stops. $\frac{f}{4}$	$\frac{f}{5}$	$\frac{f}{6}$	$\frac{f}{8}$	$\frac{f}{10}$	$\frac{f}{12}$	$\frac{f}{15}$	$\frac{f}{16}$	$\frac{f}{18}$	$\frac{f}{22}$	$\frac{f}{25}$	Focus of lens in inches.
	Numbers of feet and inches after which all in focus.								Number of feet and inches after which all in focus.

Specifications Published.

1,543.—29*th January*, 1889. "Photographic Camera Shutters." WILLIAM JAMES LANCASTER, trading as J. Lancaster and Son, of Colmore Row, Birmingham, Manufacturing Optician.

This invention relates to photographic camera shutters, or apparatus for obtaining instantaneous or protracted exposure within certain limits, whereby light is allowed to pass momentarily, or otherwise as aforesaid, through the lens, or exposure aperture, at the will of the operator—thus, the shutter may be made to act instantaneously, or may be made to acquire varying speeds, according to the length of exposure required.

The apparatus consists, first, of a double shutter arrangement, which, for instantaneous exposure, acts in unison, but for protracted or varying exposure they act independently of each other; secondly, in shutter-holding means; thirdly, in shutter-releasing means; fourthly, in suspending and operating the shutters; fifthly, in clock or running-down mechanism, which operates a short arm, and removes the holding catch of the secondary shutter, after a period of time has elapsed since the raising of the primary shutter; sixthly, in time stop mechanism and other accessory parts in connection with the apparatus.

In carrying out my invention, I take a rectangular box-like frame, with an exposure aperture made through it; and sliding and working within guides contained within the said frame, I arrange two shutters, viz., a primary shutter and a secondary shutter, which alternately come in front of the exposure aperture.

The primary shutter works in juxtaposition to the inside back of the front of the enclosing casing, and with its upper end connected to the outer end of a flexible cord, whose inner end is connected to a hollow or box pulley, wherein a coiled spring is enclosed—this spring is the motive power for raising the shutter from before the aperture on exposure.

The primary shutter is held in position by a spring catch, working upon and through one side of the framing, in a manner that the bolt part of the said catch takes within a like notch or cut away part in the side of the shutter; so that on the shutter being lowered, or brought in front of the aperture, the catch is moved away by an incline, and then snaps into the notch.

The spring catch of the primary shutter is cranked at its lower end; and between it and the end of a releaser conducting tube, a small flexible bellows is enclosed; so that by pressing a pneumatic releaser, in the form of a flexible tube and ball, the bellows is expanded, and the catch taken out of action.

The secondary shutter works upon the back, or near the back of the primary one, and is held in position at two points, viz., on the side and at the top, whilst it is taken into its aperture covering position by a flat spring acting upon a stud; and further, it is taken into its raised position by the downward movement of the primary shutter, whose upper end is connected to that of the secondary one by a flexible cord passing over a pulley mounted at the upper end of the enclosing casing.

The side fastening is effected by a tumbler catch, in the form of a bell crank lever, with one arm directed vertically, and the other horizontally; and upon the latter, the time arm which is on the principal axis of the time mechanism comes, on the said mechanism having run down.

The upright or vertical arm carries a knife-edged catch or pivot, which engages with a side notch in the said shutter.

The secondary holding point of this said shutter consists of a spring catch, whose nose and inclined plane protrudes through the outer casing. This catch forms both a supplementary holder for the secondary shutter, and a buffer stop to the primary shutter.

The time mechanism, which consists of a barrel with a volute spring enclosed within it, a ratchet and pawl arrangement, a large toothed wheel gearing with a pinion on another axis, and which pinion axis carries a large toothed wheel, which gears with a second pinion on an axis which carries a third toothed wheel, which meshes with the teeth of a third pinion, and whose axis carries a fourth toothed wheel, with the teeth of which a knife edged stop engages, consisting of a fork-like arm pressed home by a spring, is arranged as aforesaid.

The axis which carries the drum, ratchet wheel, and primary tooth wheel as first named, is the same axis as carries the time arm. Thus, the moving of a turn carries on the said time arm axis through a portion of a circle, winds the spring up to an extent equivalent to a unit of time, which, when released, is allowed to run down only at a certain rate by the reduction gear or train of wheels as aforesaid.

The turn for giving varying speeds to the shutters, or rather to the secondary shutter, is provided with a pointer, which traverses in front of a graduated and set out dial, indicating one, two, three or more seconds, and portions of them.

The action of the apparatus or shutter for instantaneous exposure is as follows:—

The exposure aperture is covered by the pulling down of the primary shutter, which is held by its catch, while the secondary shutter is held by the top catch, which is the buffer stop to the primary one.

When the parts are in the positions as indicated—that is, the primary shutter down, and the secondary one up—the ball end of the pneumatic releaser is pressed, when the bellows at its other end is distended, and the spring catch released from the primary shutter, which now being free, is instantly drawn upwards, by the spring enclosed within the pulley, to which the flexible cord of the shutter is attached.

The rising and striking of the said shutter against the buffer stop catch liberates the said shutter, which is pressed down in front of the aperture by a spring.

For a greater exposure, the time required is fixed by placing the pointer in front of one of the markings on the dial, which determines the exposure required; this is done after the primary shutter has been brought before the aperture. Thus the primary shutter has been pulled down, and there held by its catch, and the secondary shutter pulled upwards, and held by the buffer stop catch; this done, the time for exposure is determined by moving the turn and pointer to the required position, when the secondary shutter holding stop carried by the bell-cranked arm passes into the notch on side of the said shutter, and holds it there.

The affixing of the shutter by the lower and side catch is done by a spring acting upon it when the time arm on the time axis mechanism is removed by the rotation of the turn and finger.

The pressing of the pneumatic releaser distends the bellows, removes the catch from the primary shutter, which is raised by the coiled spring from in front of the exposure aperture, and releases the buffer stop-catch from the secondary shutter, and also takes the knife-edged stop from the teeth of the top wheels of the train of wheels, which now being free, run down at a determinate rate, and bring the time-arm upon the top side of the horizontal arm of the bell crank catch, liberating the secondary shutter, which is now pressed down by the spring,

and comes in front of, and closes up light-tight, the exposure aperture.

It will be thus observed that the secondary plate follows the movement of the first one, after a certain definite period of time, and that the time-stop is released by the primary shutter coming against it.

1,439. *January 26th*, 1889. "Photographic Cameras." JOHN WILLIAM TURNER, Heathfield Street, Liverpool, Photographic Apparatus Manufacturer.

The invention relates to photographic detective or hand cameras, in which a number of dry sensitive plates are stored, are successively submitted to the action of light, and are then deposited in a suitable receptacle until they are required for development.

The object is to so make such cameras that the plates are readily and easily placed therein and removed therefrom, and are with certainty moved into the required positions by simple and efficient mechanism.

The invention consists essentially in providing first, rack or equivalent mechanism by which the plates are fed with certainty and regularity one after the other into position to receive the focussed image; and second, oscillating grippers by which the plates are removed from the focal centre and deposited in a container or receptacle.

A sliding rack operated by a pinion answers well to feed the plates forward intermittently. Each tooth of the rack acts on a plate, and springs are used to assist in moving the plates forward.

Grippers opened and closed by screw spring or equivalent mechanism, and moved in an arc by means of a handle or lever, are advantageously employed for removing the used plates into the container or receptacle.

12,860.—*August 14th*, 1889. "Optical Lanterns." ALFRED WRENCH, 50, Grays Inn Road, London, Manufacturing Optician.

This invention relates to improvements in or applicable to optical or magic-lanterns, whereby both mounted and unmounted slides can be more conveniently and easily exhibited than hitherto, the unmounted slides being automatically registered; by these improvements also a curtain or screen is operated between the exhibition of the slides as hereinafter more particularly described.

In carrying out my invention I form the lantern with two compartments in the stage or receptacle for the slides. One of these compartments is adapted for the reception of mounted slides, and the other compartment is provided with guides in which works a carrier operated by a rack-and-pinion or other arrangement, and adapted to receive and exhibit unmounted slides, and to register such slides automatically. The guides are furnished with spring-lugs, which yield to the upward pressure of the slide, and immediately it has passed them they spring outwards and hold the slide in position for being exhibited.

The said carrier also actuates a screen or shutter in such a manner as to produce the effect of a curtain falling after the exhibition of one slide, and rising to exhibit to view a new picture.

In a modification of my invention, I employ a shifting stage operated by a rack-and-pinion or other arrangement, whereby mounted slides and mechanical slides can be exhibited and registered automatically, in the same way as unmounted slides, and which shifting stage also actuates a screen or shutter to produce the curtain effect hereinbefore mentioned.

PHOTOGRAPHIC CLUB.—The subject for discussion on Feb. 5th will be "The Intensification and Reduction of Negatives"; and on Feb. 12th, "Illuminants for the Optical Lantern."

MESSRS. SMIB, CHURN, DUTT, & Co. seem to carry on a mixed kind of business. In their advertisement in *The Journal of the Photographic Society of India* the first column gives the prices of beers and wines in bottles, and the second column the prices of photographic apparatus. They also mention that they sell oilman's stores and provisions, hardware, and all sorts of tea and indigo garden implements.

Correspondence.

THE 1890 CAMERA CLUB CONFERENCE.

SIR,—I am requested by my Committee to ask your assistance in announcing the following outline of the Camera Club Conference for 1890:—

The 1890 Conference will be held in the Theatre of the Society of Arts (by kind permission of the Council) on Thursday and Friday, March 20th and 21st, under the Presidency of Capt. W. de W. Abney, C.B., R.E., F.R.S.

On Wednesday, March 19th, at 8.30 p.m., there will be a special Smoking Concert at the Club Rooms, and the Members' Annual Exhibition of Pictures will be opened.

On Thursday, March 20th, at 2 p.m., the President will open the Conference and Exhibition of Apparatus at the Society of Arts, and papers will be read from 2 to 5.30 p.m. In the evening a lantern slide exhibition will be given in the Theatre of the Society of Arts, for which special tickets may be obtained.

On Friday, March 21st, the apparatus will be on show from 10 a.m., and at 2 p.m. the Conference will be renewed.

At 7.30 the annual dinner for members and friends will take place.

A complete programme will be issued later and distributed. All photographers will be cordially invited to the Conference.

GEORGE DAVISON, *Hon. Sec.*

Camera Club, 21, Bedford Street, W.C., January 27th.

ISOCHROMATIC PHOTOGRAPHS AT THE FRENCH SOCIETY.

SIR,—We are glad to find that M. Vidal's error in supposing that the photographs on isochromatic and ordinary plates which we presented to the French Photographic Society were lighted in different ways was, as we surmised, simply owing to his want of knowledge in such matters. Had he been better acquainted with the isochromatic process as now employed in copying oil paintings, he would have been aware of the fact that the reflections from the rough surface of the canvas, which show so conspicuously in copies taken by the ordinary process, are usually scarcely noticeable in those taken on colour-sensitive plates. This is one of the peculiarities of the process, and is well recognized by those who practise it.

No alteration in the lighting is necessary to produce results such as we have shown, nor, in this instance, would such a thing have been possible, all the negatives being taken in the National Gallery from the paintings in the positions they occupy, and from which they are not allowed to be removed.

That our every-day results should be received with incredulity by experienced photographers says much for the capabilities of the process, and, except for the suggestion of unfairness which has been made, would have been perhaps the highest compliment we could receive.

We have forwarded to the President of the French Society conclusive evidence in support of our statements, and we shall now trust to M. Vidal's sense of honour and justice to aid us in removing the erroneous impression which seems to have prevailed with regard to the photographs presented by us to the Society.

B. J. EDWARDS & Co.

The Grove, Hackney, London.

CAMERA CLUB NOTICES.—Monday, February 3rd, 8 p.m.: Opening of Exhibition of photographs by members of the Amateur Photographic Field Club; 8.30 p.m.: smoking concert. Thursday, February 6th, 8 p.m.: Paper by Sir David Salomons, "Rule for ascertaining Size of Disc at a Given Distance for Lantern Work"; lantern exhibition of Dutch views by Messrs. Elder and W. A. Greene, and of slides by other members. Thursday, February 13th, 8 p.m.: Mr. Graham Balfour, "Landscape." Thursday, February 20th, 5 p.m.: Annual general meeting; 8 p.m.: Paper communicated by Mr. W. K. Burton, "On one or two of the Tenets of the 'Naturalists,'" with notes in reply by Mr. G. Davison. Thursday, February 27th, 8 p.m.: Dr. C. S. Patterson, "The Camera as Applied to Medicine." Monday, March 3rd, 8.30 p.m.: smoking concert.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

AT the technical meeting of this Society held on the 28th inst., the chair was occupied by Mr. T. SEBASTIAN DAVIS.

Mr. CHAPMAN JONES read a short paper on "Marks on the Plate, due to the Hinges of the Dark Slides." He said that the effect of the near presence of the leather hinge was recognised as sometimes causing fogging, and sometimes a certain amount of insensitiveness. In a case that he had recently met with the effect seemed to be that of increasing the sensitiveness. He had had a plate in a dark slide for about four months, and upon exposing it late one dark afternoon he found the image to be very much under-exposed generally, but opposite the hinge of the dark slide the image appeared to have received two or three times as much exposure as the rest of the plate. The slide in question was one which had some time since been sent to the manufacturers, who had replaced the original leather hinge with one of a material that they now employed instead, and which was jean of a particular kind. They had adopted this material because of the fogging which had so often been complained of when leather was used. The manufacturers assured him that they had never found any evil effect to result from the use of this material, and this was so far confirmed by his own experience, that he had kept plates for two years in slides thus fitted without their sustaining any injury. It might be that instead of the hinge material conferring additional sensitiveness, the rest of the plate had lost that quality.

Mr. A. COWAN believed that the last suggestion was the real explanation of the case. It had been found by the late Mr. Collins that some kind of black—that mixed with oil—caused insensitiveness in the plates.

Mr. A. MACKIE said that turpentine black produced that result; the wood of which some slides were made also had the same effect. He treated such slides with melted paraffin.

Mr. COWAN showed some plates that he had exposed in illustration of the characteristics of a developer recently introduced in an American annual, consisting of 25 grains each of sodium sulphite and Rochelle salt, 2 grains of pyro, and 1 grain of lithium carbonate to the ounce. He expressed his opinion that this formula constituted an advance in pyrogallic development. He had tested it against the standard formula of 2 grains each of pyro and bromide, and 4 minims of ammonia to the ounce. The lithium-developed plate did not come up so rapidly at first as that developed with ammonia, but it afterwards overtook it, and would give a higher number on the sensitomer than could be got with the ammonia plate, unless the latter was so pushed as to lose the clearness of the shadows. It seemed to him that it was not necessary to confine oneself to Rochelle salt, as almost any organic salt of soda or potash appeared to have similar action. He had used acetate, phosphate, citrate, and valerianate with much the same result. He also showed a plate developed with pyro and one grain of lithium carbonate to the ounce without other addition, and this gave a very vigorous image. The use of ten times as much carbonate of potash in place of lithium gave a very weak image.

Mr. A. MACKIE said that Mr. Brooks used acetate of soda in the developer for collodio-bromide. He (Mr. Mackie) had tried it, but could not find that it made any difference.

Mr. W. E. DEBENHAM said that there was another use in Mr. Cowan's experiments, that is, in showing the great variations of density that could be obtained with the same plates and similar exposure. Were the plates used those of ordinary rapidity?

Mr. COWAN replied that they were, and gave 19 or 20 on Warnerke's sensitometer.

Mr. MACKIE, referring to a recent paper on intensifying, by Mr. Chapman Jones, asked the author whether he had tried the method of gaining intensity which consisted of applying a solution of sulphate of iron, slightly acid, before immersing the negative in the hypo bath.

Mr. CHAPMAN JONES thought that the method indicated resembled Mr. Howard Farmer's intensifying process. He had not tried it.

Mr. MACKIE did not think that there was any fresh deposit of silver, as an acid bath completely removed the density that had been gained by the use of the iron solution. As to reduction of intensity by the use of acid in cases where the sulphate of iron bath was not used, he thought that was due to the change of colour of deposit, and might therefore be considerable in the case of a negative developed with pyro, but not with one developed with ferrous oxalate.

Mr. CHAPMAN JONES said that a photographer of great experience had told him that he always reduced intensity by an acid bath, and that he developed with ferrous oxalate. He further stated that a negative originally too dense would become flat if left too long in the acid.

Mr. HOLLYER had never found that the acid bath made any difference in the density of negatives that had been developed with ferrous oxalate.

Mr. W. BEDFORD had found the same absence of reducing power upon negatives that had been developed with hydroquinone.

Mr. MACKIE had seen developed bromide prints reduced considerably by leaving some of the acid wash in them when placed in the hypo fixing solution.

Mr. DEBENHAM suggested that the difference of experience as to the reducing power of an acid bath upon negatives already of a grey or purplish colour might be due to the presence in some cases of a little iron in the acid used.

Mr. J. DESIRE ENGLAND wished to know why the yellow stain that occurred on pyro negatives, particularly when soda was used in development, and that was removed by acid, returned if the acid was thoroughly washed out.

Mr. MACKIE thought that the compound which showed itself as yellow stain was not removed by acid, but changed in colour, and that on the removal of all the acid the original yellow colour showed itself again.

The use of eikonogen as a developer was referred to, and some of the members spoke well of Mr. Warnerke's formula, in which it is used very strong; but Mr. Cowan thought that there was no advantage in using more than five or six grains of this substance to the ounce.

The CHAIRMAN had found great difficulty in getting density with eikonogen. He thought it very useful in practice to begin development with eikonogen, and when the details were well out, to add a solution of hydroquinone to the developer. A very superior quality of image was thus obtained, and density came easily.

Mr. MACKIE complained of the tendency of hydroquinone to start development at one place, and to get density there before the rest of the plate was developed.

Mr. CHAPMAN JONES never liked hydroquinone. He always got more stains with it than with any other developer.

Mr. COWAN said the large quantities of Rochelle salts and sulphite of soda used with lithium in the American formula answered equally well with eikonogen and hydroquinone, as it did with pyro.

THE CAMERA CLUB.

JANUARY 23rd, Bedford Street, Strand, London; the Rev. A. B. WHATTON, M.A., in the chair.

The Rev. T. PERKINS, M.A., read a paper on "English Church Architecture as a Subject for Photography," in the course of which he said that the man who is born an artist will produce artistic photographs, but no man who is not born an artist can be made one by means of rules. Even photographers who are not artists may make themselves useful by taking pictures of Church architecture, which pictures, after the lapse of time, may prove to be very valuable, for almost everywhere the "restorer" is at work destroying beautiful old buildings. He wished that they would erect new buildings instead, but spoiling old ones is cheaper, so memorials of them should be taken and preserved, ere it is too late. Whenever amateur photographers hear that a church in their neighbourhood is about to be restored, they should at once set to work to photograph the old one inside and out, and they should combine with this duty some study of architecture. Before 1018 most of the churches in this country

seem to have been built of wood ; at present only about a hundred of our churches built before the Conquest are to be found, and they represent Saxon work, after which came the Norman period. In photographing churches surrounded by other buildings, a suitable point of view is frequently obtainable from the south-east, and with a lens of moderately long focus, so as not to destroy the perspective, it is then sometimes possible to get in the tower ; people generally do not like to be buried on the north side of a church, hence the graveyard has a tendency to extend to the south-east. He deprecated the use of wide-angle lenses, unless the photographer were absolutely forced to use them ; even interiors were better if taken with narrow angle lenses at the cost of reducing the amount of subject included. He then projected upon the screen lantern pictures of a great number of British churches, including one of a church erected about the year 800 at Bradford-on-Avon, and now preserved as a national monument : he also gave an interesting and architectural description of each church represented.

The CHAIRMAN thought that if photographers gave attention to church architecture as recommended, they would not alone be doing good historical service, but their work might promote the art or science of architecture itself. Their work might also result in many churches being kept open on week days, instead of closed while the photographer went in search of a lazy verger. He had been told of one verger who was asked, "Do not people come sometimes out of service hours to this hallowed sanctuary, for peaceful meditation and silent prayer?" "Yes," replied the official, "I ketches 'em at it sometimes behind a pillar, and tells 'em service hours is eleven in the morning, and half past three in the afternoon." Vergers like that should be improved off the face of the earth.

Mr. GALE remarked that very few churches were built from the time of Henry VIII. to about the time of Wren, and he spoke of some points of resemblance between the towers of Somerset churches, as shown by Mr. Perkins's pictures, and others he had studied in Brittany.

Mr. J. S. WHATTON believed that there was a wooden church somewhere in the eastern suburban district of London, the name and situation of which he should much like to discover.

Mr. AVENT remarked that there was one at Greenstead, near Ongar.

Mr. DAVISON urged that all photographers of a practical bent should devote themselves to some connected work with a definite aim—as Mr. Perkins had done—but he maintained that such work, admirable in itself, led in quite a different direction from that in which the art student would find his development and prosecute his study. In regard to the City churches which had been mentioned, he drew attention to the good work done by Mr S. H. R. Salmon, of East Putney. In treating of the practical points raised, he stated that a lens of focal length equal to the longest side of the plate used, would not give a natural angle ; the perspective would be unnaturally violent.

On Thursday, February 6th, the lantern will be employed to exhibit some Dutch views by Messrs. Elder, W. A. Greene, and others ; some general subjects will also be shown.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting on the 23rd inst., Mr. A. HADDON occupied the chair.

Mr F. P. CEMBRANO passed round a brass binder for lantern slides for use in place of paper strips. He also showed eight negatives, four of which had received a time camera exposure ; the others had been exposed in a hand camera with a quick shutter. Pyro and eikonogen with various alkalies were severally used for development, and similar set of developers was used for each set of exposures. A comparison of the results exhibited showed that for a time-exposure pyro, sulphite, and ammonia proved the best developer, but with the instantaneous exposures eikonogen, sulphite, and carbonate of soda gave the best negative.

Mr. W. H. PRESTWICH had tried eikonogen in comparison with pyro, using the same alkalies in each case ; he found no appreciable difference with either developer.

The CHAIRMAN remarked that eikonogen gave greater transparency in the shadows of a negative than the pyro developer.

Mr. CEMBRANO said that plates developed with eikonogen had a greater tendency to frill than when developed with pyro.

Mr W. E. DEBENHAM read a paper on "Selecting Focal Distance with Detective Cameras" (see page 87).

Mr. F. P. CEMBRANO said that it was not easy to determine whether a long or short focus lens was best for a hand camera. If only one class of work were required, then a lens could be chosen best suited for that work. Both long and short focus lenses had their advantages and disadvantages. He had been using a 6½-inch lens, but he believed a lens of about 5½-inch focus would be more generally useful. He considered that a short focus lens rendered distances more truly, and for general work was most useful ; on the other hand, if pictures of animals were wanted, then a long focus lens was to be preferred.

Mr. W. COLE thought that some means might be devised whereby the lenses of a hand camera could be changed quickly, either by a rotating front or a microscopic nose-piece.

Mr. P. EVERITT said that he held that the rule of using a lens the focus of which was double the length of the plate, applied equally to hand cameras ; this would give for a lantern picture about 5½ inches focus.

Mr. W. E. DEBENHAM said that when used in connexion with a fine film, the advantage lay on the side of a short focus lens ; better definition also was obtained with this lens. If the register were fixed for the principal object in the centre of the field, the curvature of the lens might prove an advantage from the shorter distance of objects on either side.

Mr. J. J. BRIGINSHAW remarked that it was unusual for the principal object of the picture to be placed in the centre.

Mr. P. EVERETT said that with a very round field, would the lecturer fix the register for the centre, or midway between the centre and side ?

Mr. DEBENHAM would fix the register to agree with the principal subject of interest in the picture.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

THE following have been elected as officers for the ensuing year : —*President*—Mr. J. Humphries, F.S.A.; *Vice-Presidents*—Messrs. H. Beckett, W. T. Goodhew ; *Curator*—Mr. F. Davall ; *Council*—Messrs. C. Beadle, F. Cherry, T. C. Lathbridge, W. A. Lavanchy, F. L. Pither, J. Saville, J. Steuart, H. Walker, E. T. Hiscock ; *Treasurer*—Mr. E. Seymour Paul ; *Hon. Sec.*—Mr. Geo. R. Martin, Harringay Park Granary, Green Lanes, Finsbury Park.

On Monday, January 27th, Mr. L. Medland gave a lecture entitled "In Northern Latitudes with a Camera," illustrated by lantern slides shown through the optical lantern ; the slides were made on collodio-bromide by himself, from negatives taken during his tour.

The following have been elected honorary members :—Messrs. S. Herbert Fry, Chas. W. Hastings, and E. F. C. Damaut.

On Monday, February 10th, Mr. Humphries will open a discussion on "Dark-room Illumination," and illustrate by several practical tests. Any photographer having lamps which they consider especially safe while giving a maximum of light, are invited to bring the same for the purpose of experiment.

WEST LONDON PHOTOGRAPHIC SOCIETY.

A MEETING was held at the Addison Hall on 24th January, Mr. CHARLES BILTON in the chair, when Messrs. Frogbrook and Eydmau were nominated for election ; after which the adjourned discussion upon hand cameras was proceeded with.

Mr. STEIN, in summing up his previous remarks, said a perfect detective camera must be unobtrusive in appearance, have some mechanical means of changing plates, and at the same time be as simple as possible ; the shutter must also be a good one, and work without jar or shake. In regard to the lens, he preferred one of short focus. With a 6-inch lens everything beyond thirty feet was in focus, but it was often necessary to get nearer to the object, and with a 3-inch lens everything beyond eight feet was practically sharp. He used in his de-

tective a 3¼-inch wide angle lens, by Wray, and found it worked well.

Mr. LESLEY SELBY, explaining the artist's hand camera, said that it could scarcely be called a detective, because it was not what Mr. Stein had called unobtrusive. However, all he wished to do with it was to get views, and for that work it answered admirably, as it could be very easily and quickly manipulated; moreover, it was light though strong, and would stand rough usage; he had taken it up Seawfell Pike without experiencing any fatigue.

The PRESIDENT announced that Mr. Wyndham Rickford and Mr. Garner Richardson had presented the Society with a lantern and screen, with accessories for using the limelight.

HACKNEY PHOTOGRAPHIC SOCIETY.

A MEETING was held on the 23rd inst., when the chair was occupied by Mr. GRANT.

Mr. HART gave a flash-light demonstration, and prefaced his demonstration by an interesting lecture on "Magnesium and its Use in Flash-Light Photography." Two groups were taken, with a dozen members in each; six lamps were used connected pneumatically. After the demonstration the lamp was described.

Mr. HADDLE then showed a neatly constructed detective camera of his own making. The weight was claimed to be less, and the camera more hidden, than the general run of "detectives," but the great novelty was a self-setting time and instantaneous shutter, which he had patented.

The SECRETARY announced that on the 27th February there would be an exhibition of apparatus.

Messrs. Barton and Reed were elected members.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

A MEETING was held at the club rooms, Grand Hotel, Jan. 23.

The Chairman, Mr. E. H. JAQUES, announced that the president, Mr. J. B. Stone, J.P., had offered a prize for the best set of six views taken within a radius of ten miles round Birmingham.

Mr. GODFREE exhibited a very handy bichromate battery fo producing an electric light suitable for the developing room.

Dr. W. W. J. NICOL then gave his paper on "Iron Printing," which was illustrated with chemical experiments. Mention was made of the different forms of iron printing, the "dusting-on" and blue processes, sepiatype, platinotype, and particularly his new process, the "Kalotype." In this the paper is coated with—

Ferric oxalate	5 per cent.
Ferric tartrate	5 ,,

and in exposure the ferric salt is reduced to the ferrous salt, and is then developed with—

Potassic oxalate	10 per cent.
Nitrate of silver	1½ to 2 ,,
Ammonia	sufficient to clear.

The print is developed by floating the same as platinotype. It is then washed in three baths of—

Ammonia	1 ounce
Citrate of soda	¼ ,,
Water	1 gallon

The advantage claimed for this process is fixing without hypo, thus securing greater permanence.

THE BIRMINGHAM GEOLOGICAL SOCIETY.—Mr. W. J. Harrison, F.G.S., the Science Demonstrator of the Birmingham School Board, has just received intimation from the Secretary of the Geological Society that the Council have awarded him the proceeds of the "Barlow-Jameson Fund," in recognition of his "valuable contributions to geological science," and he is invited to attend the anniversary meeting of the Society on 21st February next to receive the award. The former recipients of the "Barlow-Jameson Fund" were, in 1882, Dr. James Croll; 1884, Baron von Ettingshausen; 1886, Professor Leo Lesquereux; and in 1888, Dr. Johnston-Lavis. The income of the fund is "to be applied every two or three years, as may be approved by the Council, to or for the advancement of geological science."—*Birmingham Daily Post.*

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

PHOTARGUS.—We sympathise with you in your desire to find fairly good water in your island home. For the better purposes, such as the removal of the silver nitrate and last washing of your finished prints, it would seem necessary to use distilled water, the preparation of which is tedious rather than difficult, and there are now several kinds of tin stills to choose from. Instead of using permanganate of potash, which will only remove organic matter, and none of the saline impurities, we should advise you to rely upon a prolonged washing in frequent changes of well water, and then finally remove these soluble salts from the paper by distilled water. The use of permanganate as a test for hypo yet remaining in albumenized prints does not work satisfactorily, because of its ultimate reduction by the albumen. How do you manage to get drinking water on the island; and have you any trouble in finishing off your gelatine negatives?

C. E. E.—The Key camera was exhibited last summer at the St. James's Hall meeting of the Photographic Convention. For a description of it see the NEWS of August 30th last, "Convention Notes," p. 573.

A. and G. T.—The cards are of exceptionally good quality, and there is no bronze powder in the printing ink. Those not used (three) are returned to you by post.

OLD HAND.—Dextro-maltose is very soluble in water, and may answer your purpose. Enquire of the Maubrè Saccharine Company, Hammersmith, W.

W. T. D.—Would like to communicate with Mr. Frederick Winterhoff, who took out a patent last year for a "Process of etching and engraving on glass." The address given in the specification is reported to be merely London, Middlesex. Can any of our correspondents oblige us by furnishing the desired information as to present address?

PHOTOGRAPHER.—Slow toning of ready-sensitized paper. See reply to J. A. R. last week, and try the effect of a last washing with very dilute ammonia before toning. Having tried without success the carbonate and borax toning baths, it might be well to experiment with the tungstate or with the very active chloride of lime toning bath, as prescribed at page 202 of the YEAR-BOOK. Two grains of gold per sheet ought to be amply sufficient.

FLUX.—Reduction of silver residues. The chloride and sulphide precipitates had better be treated separately. For the first, dry well and mix with an equal weight of carbonate of soda, and project this mixture, by small portions at a time, into a clay crucible containing fused carbonates of potash and soda. As oxygen and carbonic acid are given off, be on your guard against loss by frothing. When all is introduced, allow time for tranquil fusion, let cool, and break the crucible to extract the lump or button of pure silver. Gold residues are treated in the same way, but the metal usually contains a little silver, and sometimes enough to whiten the alloy. Paper ashes are also treated like the chloride, but in a more capacious crucible, to provide for lively effervescence. The sulphide of silver residues had better be roasted to get rid of much sulphur, then fused with dry carbonate of soda, and occasional addition of nitre to burn off the rest of the sulphur. Proceed cautiously for fear of the action becoming too violent. Some operators add, finally, a little dry borax, which helps to refine the metal.

T. M. K. (Jersey).—Studio construction. Your sketch gives only the end view of proposed iron building, without details of sides and roof. The window 12 by 6 feet ought to be placed horizontally instead of vertically, for it would be of no use carried down so low to the ground. Why not avail yourself of the full width of the gable wall, and so get more light? You have not indicated the aspect, or given sufficient data to enable us to advise you on several points; in fact, the sketch is altogether too rough to properly represent your ideas.

F. GOW.—Shall we return your money, or send out collotype prints to the value?

VOL. XXXIV. No. 1640.—*February* 7, 1890.

CONTENTS.

LIGHTS FROM EXPLOSIONS OR DETONATIONS.

A GREAT point in taking photographs by bright flashes of light of short duration is, that those flashes shall be short enough to obtain the portrait before the sitter has time to move or to blink his eyes; what he does after the illumination is over is of no moment. In a large proportion of the flash-light photographs from various sources which have been publicly exhibited, the curious appearance of the eyes of the sitters is usually noteworthy, more especially in groups. Excellent flash-light photographs taken in their own homes of single sitters are easily obtainable by giving the subject a book to read, so that the eyelids are naturally somewhat drawn down. In a group of half-a-dozen sitters this plan does not answer, for rarely in real life are so many persons seen all desperately studious at once, and the smirk and other expressions on the countenances of some of them reveal obviously that they are not reading, but being photographed, so the whole picture is grotesque. Single sitters can be trained to steadiness of the eyes under the flash light, but the professional photographer does not desire to use up plates or to give the time necessary for the educating process.

Explosive mixtures containing magnesium were largely experimented with some two or three years ago, to overcome this difficulty, and good compounds effected their object in this respect. They now seem to have been generally abandoned, in this country at least, because of their danger, and some frightful accidents have occurred in consequence of their commercial introduction in other lands than ours. Chlorate of potash is usually the oxygen-imparting substance in such powders, and our Government, fortunately, will not give permission for the sale of any explosive containing chlorate of potash. The would-be introducers of such a new explosive once complained at a meeting of the Society of Chemical Industry of this action of the Government, whose officials had said that the mixture would explode under the glancing blow of a broomstick on a floor. The complainant then industriously hammered away with a wooden mallet at some of it placed on a wooden anvil, and no explosion resulted. Dr. Debus, who was present, quietly remarked that the operator had been careful to strike along and not across the grain of the wood of the anvil. He added that explosives were like horses; they knew when they had a good rider, and might be safe enough in the hands of their scientific advocates. The Government, however, had the duty of considering the safety of the lives of the poor and ignorant who might have to use them.

Our idea is, that the trial of such explosives in photography has been prematurely abandoned, because the materials ordinarily used in them are safe enough when kept in powder in separate bottles, and when a few grains of explosive mixture are wanted, that small quantity alone may be prepared immediately before using, and gently mixed with the feather end of a quill pen. An objection to the light produced by the explosion is that it is small and star-like, therefore throws harsh shadows. Another objection is that the smoke is thrown out at the moment tolerably equally in all directions, so obscures some of the light. Magnesium, however, is now so cheap, that the latter objection is of small importance, even if it be not overcome.

To diffuse the light, suitable translucent screens and suitable reflectors have been used, but with these the percentage of light lost is heavy. The better way of overcoming the difficulty seems to be to fire off several of the little charges at once by means of electricity, so that the light shall come from several different points. The late Mr. Donkin suggested the use of a galvanic battery, to send a current through minute lengths of platinum wire wherever the powder was placed, so that the powder charges should be ignited by the lengths becoming red hot. A simpler and much cheaper method seems to us to be, igniting them by means of a Wimshursts electrical machine, arranged to give sparks at will between disconnected parts of an otherwise complete metallic circuit. Some explosive powders such sparks will scatter and not ignite, but placing a piece of wet string in the circuit usually overcomes this difficulty.

THE ROYAL INSTITUTION.

V.

Dr. Thomas Young's Discoveries and Photographs. The researches and discoveries of Dr. Thomas Young next claim attention. He was one of the early photographers, and held an appointment at the Royal Institution when, in 1802, Wedgwood made known his discoveries there, and Davy took the first micro-photographs. Young was born at Milverton, in Somersetshire, on the 13th of June, 1773, and his parents were members of the Society of Friends. In March, 1872, he was sent to a private school at Compton, in Dorsetshire, and at the age of fourteen was appointed tutor at Youngsbury, near Ware, to Hudson Gurney, grandson of Mr. Barclay. His medical studies began in 1792; he made rapid progress, and after a time he proved why the eye can see distinctly at different distances—namely, "by the alteration of the curvature of the crystalline lens," and his memoir on this subject appeared in the "Philosophical Transactions" of the Royal Society, of which Society he was next year elected a member. Subsequently he continued his medical studies at Edinburgh, and afterwards spent some time in the Highlands, visiting members of the Scottish aristocracy. In 1879 he went to the University of Gottingen to pursue his medical studies, and subsequently received there his degree as doctor of physic, surgery, and midwifery. At Brunswick he was presented at Court, clothed in other than Quaker costume, and he travelled a little in Germany. On his return to England he became a fellow-commoner of Emanuel College, Cambridge, and when he was about thirty years of age began the practice of medicine.

Huyghens first broached the wave theory of light, but the great authority of Newton, who had adopted the emission theory, and considered that light consisted of small particles thrown out with immense velocity by the luminous body, bore down all opponents, so that the emission theory was then most believed in by scientific men. Young favoured the undulatory theory, and on the 16th of January, 1800, sent in to the Royal Society a paper entitled, "Outlines and Experiments respecting Sound and Light." In it he points out some difficulties in the emission theory. The first is the uniform velocity with which light is supposed to be projected from all luminous bodies. How is it, he asks, that whether the projecting force be electricity, the friction of two pebbles, the lowest degree of visible ignition, the white heat of a blast furnace, or the intense heat of the sun itself, these wonderful corpuscles are always projected through the same medium with uniform velocity? Another objection which he urged was the partial reflection from every refracting surface. One of Newton's objections to the wave theory was, that waves, say of water, will go round any opposing obstacle, such as a rock, and be found behind it as well as before. Young's argument was that, "in a medium so highly elastic as the luminous ether must be supposed to be, the tendency to diverge may be considered infinitely small," an explanation now known to be the true one. Lord Brougham also opposed Young's arguments, and abused him unmercifully.

Wedgwood's photographic discoveries were made known at the Royal Institution in 1802, so it may be well here to restate a fact or two, and to show what men of science were engaged on the premises at the time, and we state the position in the words of Professor Tyndall, who says: "The Royal Institution was founded by Count Rumford, supported by many of the foremost men in England. The King was its patron, the Earl of Winchilsea its first president, while Lord Morton, Lord Egremont, and Sir Joseph Banks were its vice-presidents. On the 13th of January, 1800, the Royal Seal was attached to the charter of the Royal Institution. Dr. Thomas Garnet was appointed Professor of Natural Philosophy and Chemistry. During his previous residence in Bavaria, Rumford had ruled with beneficent but despotic sway, and the habit of mind thus engendered may have made itself felt in his behaviour to Dr. Garnet. At all events, they did not get on well together. On the 16th Febuary, 1801, Davy was appointed Assistant Lecturer in Chemistry, Director of the Chemical Laboratory, and Assistant Editor of the Journals of the Institution. The post of Professor of Natural Philosophy was offered to Young, and he accepted it. The salary was to be £300 a year. On the 3rd of August, 1801, the following resolution was passed:—'Resolved that the Managers approve of the measures taken by Count Rumford, and that the appointment of Dr. Young be confirmed.'"

One of the best proofs ever given of the wave theory of light was advanced by Young. Suppose two stones to be dropped at some distance apart into a pond, each stone will send out rings of waves, and the two series of water-waves will meet. If the elevations of one series of waves then tend to coincide in position with the elevations of the other series of waves, increased wave motion will be the result of their meeting; but if the depressions of the one series of waves tend to coincide with the elevations of the other series, as in the accompanying cut, the two actions will neutralize

each other, and still water is the result. So, argued Young, should it be with light; it ought to be possible, by mixing two lights of the same wave-length, to produce stillness or darkness. This can be done experimentally. If two beams of monochromatic light—say the pure red of the spectrum—are made to fall upon each other at a narrow angle, instead of producing an area of unbroken red light upon the screen, the arrangement, when properly made, gives alternate bands of red light and darkness upon the screen, the darkness being due to two series of waves of light neutralizing each other. Young called this "the general law of the interference of light."

(*To be continued*).

PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

STELLAR-PHOTOGRAPHY—LITHO-PHOTOGRAVURE—GELATINE PLATES FOR PHOTO-MECHANICAL PURPOSES.

Stellar-Photography.—One of the most talented and ardent amateur astronomers in this country, Mr. Eugen von Gothard, of Herény, Hungary, has of late produced a number of highly interesting photographs of nebulæ. These beautiful pictures show that it is possible, with comparatively very limited instrumental resources, by the aid of photography, to obtain results which by far surpass what has been gained even with the largest instruments by means of ocular observations. E. von Gothard possesses a ten-inch reflecting telescope of a comparatively short focus (about six feet). Reflecting telescopes are, however, in the case of stellar photography, in many instances superior to the refractors, since, with the former, light-waves of every wave-length are united in one point; whilst with refractors each sort of ray possesses a different focus. With reflecting telescopes it is, therefore, also possible advantageously to make use of orthochromatic plates. The renowned astronomer, Professor H. C. Vogel, of Potsdam, has of late published enlarged lithographic reproductions of some of the photographs of M. Gothard, rendering most exactly the photographic originals, showing, however, at the same time, much more detail than the drawings produced after direct ocular observations. Vogel speaks very highly of these photographs. Especially beautiful is one photograph of the well-known spiral nebula in the "Hunters," which has been taken with an exposure of two hours and thirty-five minutes. It is remarkable that this picture admits a strict discernment between light-knots—*i.e.*, stellar-like condensations in the nebulosity—and stars, the silver deposit on the negative, if examined at high powers, being a materially different one in the case of a star, than in the case of a light-knot. With regard to the very remarkable success with which this photograph of the nebula has been achieved, Prof. Vogel recommends a very special study of it by means of exposures of different lengths of time. Not only that with shorter exposures, by which only the brightest parts of the nebula will be apparent, and exact measuring of their position will be possible, but also a photographic determination of the relative intensities of the different parts of the nebula will be given by a number of differently long-exposed plates. It will be remembered that in stellar photography the inferior rapidity of the instrument is compensated for by a longer time of exposure, which enables the rendering of objects which are too feeble to affect the eye.

Litho-Photogravure.—Herr Ottomar Volckmer, chairman of the Photographic Society of Vienna, gives in the *Correspondenz* an interesting description of a peculiar, very perfect photo-mechanical process, which has been invented by his friend Carl Eckstein, of the staff at the Hague. At first, a lithographic stone of the finest quality is polished with oxalic acid and water, and then covered by means of a roller very evenly with a very diluted asphaltum solution, which is prepared by boiling five parts of asphaltum, six parts of white wax, six parts of stearine, adding to it two parts of soda solution, dissolving the whole, after cooling, in turpentine oil, filtering, and keeping in well-stoppered bottles. Into the thin, light-brownish film are now, by means of a diamond with the ruling machine, scratched very fine lines, from eight to ten to one millimetre (1-26th of an inch), until the stone is all over evenly covered with them. The latter is then provided with a wax border one-fifth of an inch high, and well levelled within a trough. An etching liquid is now poured over the stone, consisting of one-sixth part of chemically pure nitric acid, six parts of alcohol of 36°, and 350 parts of distilled water. After half-a-minute the stone is quickly washed, dried, oiled, the asphaltum washed off with turpentine, and then inked up; it is then ready for being printed from, and forms the so-called mother-stone. Now, one or a number of transfers are made from it on a well-polished, and afterwards with oxalic acid repolished stone, by slightly moistening the back of the print on the transfer paper, squeegeeing it on to the stone, and, when almost dry, by treating it with warm water, until the paper comes off. After well washing with warm water, other transfers can be applied to the same stone, so that the lines cross themselves with the former ones from one to four times. The latter is especially to be recommended for litho-photogravure work. The stone is then dusted with finest resin powder, the surplus removed by means of a camel's hair brush, and the resin melted on to the transfer by ether vapours. A carbon transparency on glass is now produced from a good, clear negative, ordinary pigment paper exposed behind it, slightly moistened, squeegeed on to the ruled stone, and developed with water of 104° to 113° F., until the paper, and afterwards the excessive colour, by constantly rocking the stone in warm water, begins to loosen. The picture is now a negative copy. The stone should then be dried spontaneously with care, which requires from five to six hours. The etching is done with ferric chloride of 40·37° F., 33° and 30° Beaumé, respectively, beginning with 40° and finishing with 30°. This requires skill and practice. The strong solution etches at first through the thinnest parts of the relief, after some time also through the thick ones. The etching fluid of 30° dissolves at last in its water the whole of the pigment film still remaining. As soon as the required depth of etching is attained, the stone is removed to a trough and thoroughly washed in running water, then the asphalt is washed off with turpentine, washed again in several changes of water, and dried. The image is now deeply etched in the stone. Finally, it is oiled, inked up, and treated otherwise as any other engraved stone. Should it be desired to print from the stone in more than one colour, it is at first inked with a local tone—grey, violet, or brown—according to the required character of the picture, and then by marking out the other parts. The single colours are imposed upon the ground tone. A very slight touch will deposit a sufficient amount of colour. As soon as the different colours have been applied, a print can be made at once. The colour effect is excellent.

Gelatine Plates for Photo-Mechanical Purposes.—It is generally known that negatives which are to be used for photographic transfers from line subjects should show the lines quite clear, and the rest of the film very dense and opaque. Many operators suppose that gelatine dry plates are not at all applicable for this purpose, and, therefore, prefer the wet collodion process, which they find to be the best for producing such negatives. Gelatine plates are, however, by no means quite useless for this class of work, for, without mentioning that there are a few manufacturers who produce a sort of slow gelatine plate which gives satisfactory results, there is no doubt that also

ordinary gelatine dry plates may successfully be employed for photo-mechanical work, provided they are correctly treated. In the case of reproductions from drawings and other line subjects, clearness, and especially vigour, is obtained more easily and with more certainty, without intensifying, than with collodion plates, if the following method, as recommended by Herr F. Wilde, be employed:—The plate is exposed twice as long as would be required for ordinary photographs, and to the developing solution is added from the beginning the following iodo-bromide restrainer, in the proportion of 20cc. to 25cc. to each 200cc. of developer.

Solution 1.

Iodine, sublimed	1 gramme
Alcohol	200 cc.

Solution 2.

Potassium bromide	14 grammes
Water	200 cc.

Solutions one and two are mixed, and the mixture is added to the developer in the above given proportion. By prolonged development negatives of such a vigour and density may be obtained, as are very difficult and not always with equal certainty obtainable on wet collodion plates, even with subsequent intensification. If these directions are carefully observed, the gelatine dry plates are decidedly preferable to the wet collodion plates for this special purpose.

THE RETOUCHER'S POINT.

BY JENNIE R. SKIDMORE.

I WATCHED her pencil glide about,
I also watched the hand that hid it,
I paused a moment, half in doubt,
Then boldly asked her how she did it.

She laughed, and gave a gay retort,
As still her fingers kept their pace,
Yet while she crushed my heart in sport,
She deftly rounded out my face.

And cleared my brow of every care,
And put such fire within my eyes!
And squared my chin and smoothed my hair—
I gazed upon her in surprise.

And when 'twas done, I said to her,
"An easy thing 'twould be to live
If shown by some philosopher
That Life is like a Negative."

Then, smiling, cried the pretty maid:
"I'll prove it to you very pat;
There's naught in life but 'light' and 'shade,'
Though sometimes we pronounce it 'flat.'"

"And then again we find it 'sharp,'
Or 'blank' or 'clouded'—men have rhymed
Of youths the gods take to their heart,
And then you see its 'under-timed.'"

"And then—" "I yield the palm to you;
Your doctrine's sound at every joint."
She tossed her head—"That's nothing new;
Retouchers often make a point."

American Times.

PHOTOGRAPHING A DUEL.—A correspondent of the *New York Herald*, in an account of the recent duel between the Marquis de Mores and M. Camille Dreyfus, says:—"I stood a few dozen yards away watching every detail, and from time to time taking instantaneous photographs with the aid of a detective camera stowed beneath my waistcoat. These photographs will be reproduced in the *Herald* within a few days."

ON CONTROL IN THE DENSITY OF NEGATIVES.*

BY CHAPMAN JONES, F.I.C., F.C.S.

IT is universally allowed that the practical density of the deposit obtained in a gelatino-bromide negative is difficult to estimate during development, probably on account of the variable printing value of negatives that have the same apparent densities, and certainly because of the opacity of the film. This last difficulty is increased when the sensitive salt is in suitable quantity to prevent light passing through the film, so as to make the best possible gradation, and avoid the evils of halation.

The photographer who aims at something higher than to simply take what comes on his plate and make the best of it in printing, has a choice of three principles of action in controlling the densities of his negatives. He may get as close as he can to the desirable condition by development, and trust to processes of reduction if his plate is too dense, and to intensification if it is not dense enough; or he may get density at all risks, and endeavour if necessary to reduce his negatives to what he wants; or, lastly, he may take care that the density got by development shall never be too great, so that the error may be corrected by intensification alone. Each method has its advocates, and is doubtless occasionally useful; but the amount of control obtained by the usual processes is so small, and the uncertainty of the various operations so great, that many expert workers prefer to either print from or else altogether reject their negatives as produced by simple development. It is the aim of the author to do away with this uncertainty, and to show how—what is for all practical purposes—a perfect control may be realised in the densities of negatives.

It has been shown by Captain Abney that in all probability the amount of silver deposited in a film by development, after exposures within the ordinary limits, is proportional to the actinic power of the light acting upon the sensitive salt, though the opacity is not strictly proportional. It will be convenient to speak of the gradation in such a negative as "normal." In methods for altering the densities of negatives it is important that the gradation shall remain normal, being either increased or diminished throughout the scale in a proportional manner. An alteration of the gradation may sometimes be good, but it will be allowed by all that a standard process working with exactness is desirable, if only as a point from which departures may be made.

In seeking for methods by which the control of density may be obtained without destroying the normal character of the gradation, it is necessary to remember the very appreciable thickness of the sensitive film, and that in almost every case the reagent employed begins to act at its outer surface. This demonstrates at once that to get with certainty a normal alteration of density, the changes produced must be such as may be allowed to work thoroughly and through the film. A thorough reduction by any of the usual processes would lead to a complete removal of the image, and methods of reduction are, therefore, useless for the normal control of density. It may, perhaps, be possible, by employing a very dilute reducing solution, to get the reagent to work so slowly that it penetrates the film before it appreciably acts, and so by beginning to produce its effect on the whole image at the same time, to work normally; but there can be no guarantee that the action is not irregular. It may, perhaps, in a somewhat similar manner, be possible to get a normal intensification by the use of a reagent that first intensifies and then reduces, but in practical work it is not possible to be sure that the reducing effect has not begun at the surface before the intensification has reached its maximum in the high lights that extend deep into the film. Such irregular processes may have their uses, in which their characteristic irregularities are taken advantage of, but as standard methods of work in which certainty is important, they can only be regarded as treacherous and unsuitable.

It remains, therefore, in getting control of density with certainty, and without producing abnormal results, to take care that the negative as developed is not too dense, and to seek for methods of intensification that shall give increase of density in

* Read before the Photographic Society of Great Britain.

easy stages, and are free from the faults above-named. Taking into consideration also such matters as permanency of result, it appears that, by the use of mercuric chloride, sodium sulphite, and ferrous oxalate, in the manner hereafter described, the control sought for may be realized.

It will be convenient to consider the subject under the following divisions :—Historical references ; chemistry of the changes ; action of mercuric chloride ; action of sodium sulphite ; action of ferrous oxalate ; practical methods.

Historical References.—In a letter addressed to the editor of the Photographic News, in 1878, Mr. J. W. Swan stated that "ferrous oxalate advantageously replaces the nitrate of silver, Schlippe's salts, or other of the chemicals now commonly used for blackening the image after treatment with bromide of copper." In 1881, Messrs. C. I. Burton and A. P. Laurie described before the Edinburgh Photographic Society (Photographic News, XXV., 269) some experiments with intensifiers. After bleaching with mercuric chloride, they sought to blacken the negative by exposure to light, and failed. They therefore used mercuric bromide in saturated solution instead of the chloride, washed the plate, exposed it to sunshine for about a minute at least—the longer the better—and then applied a developer. They preferred ferrous oxalate as developer, but stated that pyrogallic acid was also serviceable. They found that the process might be repeated several times on the same negative. Scolik's method of intensification by treatment with mercuric chloride or bromide followed by sodium sulphite, was introduced in 1884 (*Photographische Correspondenz*, XXI., 265), and Dr. Eder, in the Year-Book of Photography for 1885 (page 100), states that "the white and insoluble mercurous chloride which is deposited upon the plate is rapidly reduced to the metallic state by the sulphite." He says, in addition, that mercury forms a stable image.

Chemistry of the Changes : The Action of Mercuric Chloride.—As mercuric chloride is the first reagent employed, it appeared to be important to discover the change that it brings about. It is generally stated that when mercuric chloride reacts with the silver of the image, silver chloride and mercurous chloride result.

$$Ag + HgCl_2 = HgCl + AgCl.$$

As I have not been able to find any record of a specific proof of the truth of this reaction, I treated a quantity of pure precipitated silver by grinding it with mercuric chloride and water, and repeating the grinding at intervals during a few days. The product was washed, and consisted chiefly of a pure, white powder, but mixed with a coarse, grey powder of probably unacted-on silver. As much of the white product as was deemed advisable was separated by elutriation, dried at steam heat, and found analytically to contain 37·75 per cent. of silver chloride, the amount needed by the above equation being 37·86 per cent. This result was confirmed by other methods, such as the quantity of mercury salt taken up, and the weight of product obtained from a given weight of silver ; therefore there is no room for doubt that the commonly accepted reaction is correct so far as the matter of proportion goes. The properties of the product, however, both chemical and physical, point to the conclusion that it is not a *mixture* of the two chlorides, but a definite double chloride. This matter is still under investigation, but, acting in the light of evidence already to hand, I will, for present purposes, regard the substance as a definite compound, writing the equation that represents its production—

$$Ag + HgCl_2 = HgAgCl_2,$$

and postpone any further consideration of the matter.

The Action of Sodium Sulphite.—The action of sodium sulphite upon mercurous silver chloride is commonly stated to result in the solution of the silver chloride and the reduction of the mercurous chloride to the metallic state. This I believe to be entirely incorrect, though there appears to be sufficient ground for having provisionally accepted the idea. In the quotation given above from Dr. Eder, one would naturally infer that this was the change, and test-books of chemistry very commonly state that sodium sulphite reduces mercurous chloride to the metal. It is also well known that silver chloride is dissolved by sodium sulphite. But the reaction before us is not equal to the result of the action of sodium sulphite upon mercurous chloride and silver chloride separately ; the silver is not dissolved, the mercury is not reduced, and the sodium sulphite apparently does not play the part of a reducing agent.

Concerning the action of sodium sulphite on silver chloride alone, there is little that calls for remark. The silver chloride is dissolved, and there seems no reason to doubt the commonly accepted statement that a double sulphite is produced, or perhaps more than one.

The action of sodium sulphite upon mercurous chloride has been studied conjointly by Dr. Divers and Mr. Schmidzu (*Journal of the Chemical Society*, XLIX, 533). They found that there was at first a transient blackening due to the formation of what they call hypomercurosic sulphite, and formulate thus : — $Hg(SO_3)_2Hg_3$. This formula halved and written empirically becomes identical with mercurous sulphite, Hg_2SO_3, and there appears to be no conclusive reason why the production of this compound should not be expressed by the simple equation $2HgCl + Na_2So_3 = Hg_2SO_3 + 2NaCl$. But excess of sodium sulphite so readily attacks the mercury salt that it cannot be prepared by taking any precautions from mercurous chloride, the final products of the change being mercuric sodium sulphite, which dissolves, and a residue of metallic mercury, thus :—

$$Hg_2SO_3 + Na_2SO_3 = Hg + Hg(NaSO_3)_2.$$

For practical purposes, therefore, the action of sodium sulphite upon mercurous chloride may be stated to produce mercuric sodium sulphite and metallic mercury, and the whole change may be expressed thus :—

$$2\ HgCl + 2\ Na_2SO_3 = Hg(NaSO_3)_2 + Hg + 2\ NaCl.$$

It is important to notice that the sodium sulphite does not play the part of a reducing agent at all, for it is not oxidized ; and that half the mercury is dissolved, the other half remaining as metal. I have confirmed the truth of this reaction so far as identifying the mercuric sodium sulphite in the solution by the properties it is stated to possess, and I have proved analytically that half the mercury is dissolved, and that the other half remains as metal. If, therefore, it were possible to exchange the silver image of a negative for mercury, it would not be possible to increase the amount of metal by the action of mercuric chloride followed by sodium sulphite. The contrary of this has been stated by some writers on photographic subjects.

The action of sodium sulphite upon mercurous silver chloride does not appear to have been investigated. The current and incorrect idea has been referred to above. My investigation of the reaction is not yet so complete that I can give a proved equation to represent it, but it is not likely that further work will discover results of practical interest to the photographer. When sodium sulphite reacts upon mercurous silver chloride, the whole of the chlorine goes into the solution ; three-fourths of the mercury and half the silver are also dissolved, and one-fourth of the mercury and half the silver remain in the metallic condition to form the image. The action may be represented thus :—

$$4\ HgAgCl_2 = \underbrace{3\ HgCl_2 + 2\ AgCl}_{\text{Dissolved by the sodium sulphite.}} + Ag_2Hg.$$

The Ag_2Hg remains to form the image, and the mercuric chloride and silver chloride are taken up and doubtless changed by the sodium sulphite in a way that might easily be conjectured ; but, as I have not yet proved by experiment the compounds that are formed, it is better to leave it an open question for the present. I have also proved that the silver and mercury are actually present in the above proportion in a negative intensified by mercuric chloride followed by sodium sulphite, by an estimation of the metals present in the film. It will be observed that this method of intensification results in an exchange of half the silver of the image for mercury, four atoms of silver (4 Ag) yielding after the action two atoms of silver and one of mercury (Ag_2Hg). This generally results in a slight increase of density, but not always ; it appears to depend upon the physical condition of the film and its image

whether or not the exchange of half the silver for less than its own weight of mercury (216 : 200) will give increased density; but personally, I have found that there is an intensification effect in the vast majority of cases.

There are statements concerning this method of intensification that I have not been able to confirm. First, that by repeating the operation any density can be obtained. This is probably the assertion of a mere theoretician who argued from false premises. I have repeated the process six times on a plate, and the density is greatest where it has received only one treatment. It has been pointed out above that so far as mercury itself is concerned, the action of these re-agents does not increase its quantity. Secondly, that a negative intensified by this process may be reduced by immersion in a solution of sodium hyposulphite. I have never found this to be the case, even by prolonged treatment (one hour), nor can I see any reason to expect reduction under these circumstances.

There is what at first appears to be an anomalous property of the image resulting after the application of this intensifier, namely, that it is invariably darkened to a slight extent by the application of ferrous oxalate to it. As the solution of the chloride of silver in sodium sulphite, as shown in the above equation, is not very stable, it may be that a little silver chloride remains attached to the image, and that this is reduced to the metallic state by the ferrous oxalate, but the fact remains that, even by prolonged treatment with fresh sodium sulphite solution, I have been unable to eliminate whatever it is that leads to this effect.

It may be worth while recording here that if mercurous silver chloride and sodium sulphite are allowed to remain in contact for some days, the residue is chiefly silver instead of Ag_2Hg. This fact has probably no photographic significance.

The Action of Ferrous Oxalate.—In order to make quite sure of the processes that I am about to recommend, I have proved experimentally that a solution of ferrous oxalate reduces both silver chloride and mercurous chloride to the metallic state; and that ferrous oxalate solution removes all the chlorine from mercurous silver chloride and leaves the whole of both the metals as such.

Practical Methods.—The method of getting control in density that I wish most urgently to recommend to those who aim at getting good negatives with certainty is, to take care that in development the density of deposit never exceeds what is required, and then to work up the negative to the best condition by the action of mercuric chloride followed by ferrous oxalate, repeating this process if necessary; or, if the intensification that would be given by these re-agents is conjectured to be too great, following, under certain conditions, the mercury solution with sodium sulphite. The important matter is that every effect shall be thorough, that every atom of silver in the negative may be acted upon in the same way and to the same extent.

I first recommended the use of mercuric chloride, followed by ferrous oxalate, in 1888, in the PHOTOGRAPHIC NEWS (Vol. XXXII., p. 18), and in my "Introduction to the Science and Practice of Photography." During the last two or three years I have had considerable experience in the application of this process, and could have shown many negatives treated by it, but so far as appearance goes it is very doubtful whether anyone could distinguish a negative so intensified from one not changed after development. To illustrate the effect, I have treated various parts of a thin landscape negative, which includes sky, sea, distance, middle distance, and foreground, up to four times.

The solutions that it is advisable to use are—

1. A saturated solution of mercuric chloride, to which has been added two or three cubic centimetres of strong hydrochloric acid to each litre (or half a dram to each pint). No ammonium chloride or other salt should be added. There is no need to use mercuric bromide, as stated by Burton and Laurie, nor is the subsequent exposure to light specified by these gentlemen at all requisite. The operations may be carried on by daylight or gaslight, and, indeed, I have not found it necessary to pay any attention whatever to the light that falls upon the plate. After the mercuric chloride the washing must be thorough, generally about an hour or an hour and a half, with constant changes of water.

2. The ferrous oxalate is conveniently prepared by adding one part by volume of a saturated solution of ferrous sulphate to about six parts by volume of a saturated solution of neutral potassium oxalate. The potassium oxalate may be just acidified with oxalic acid, but acid tends to retard the action of the oxalate. The solution may be used weaker than above, but then it acts more slowly. The action of the ferrous oxalate is retarded if all the mercuric chloride is not washed away from the negative, though the addition of mercuric chloride to the ferrous oxalate solution does not appear to have any appreciable effect. If the action of the ferrous oxalate is made unduly slow, the reduced silver and mercury will tend to whiteness, as is also the case in a very slowly developed negative. The slaty colour of the metals produced in extreme cases, especially at the glass side of the film, may lead an inexperienced operator to consider the action of the ferrous oxalate unfinished, although the reduction is complete.

3. The solution of sodium sulphite may vary as to strength within wide limits; a five to ten per cent. solution is convenient. A little acid should be added to it, preferably sulphurous, until the solution ceases to give a red colour to a dilute solution of phenol-phthalein. Litmus paper is useless in this case. For ordinary work it is sufficient to take advantage of the fact that if a good sample of crystallized sodium sulphite is dissolved with one-thousandth of its weight of citric acid, the alkali in it will probably be neutralized. To be on the safe side, five times this amount may be taken, say half a gram of citric acid to one hundred grams of sodium sulphite, or two and a half grains of acid to one ounce of sulphite. It is a mistake to say that a negative should be only just rinsed after treatment with mercuric chloride when sodium sulphite is to be used. The washing need not be so thorough as in other cases, but the more complete it is the more rapidly will the sulphite produce its effect.

We have already seen that mercuric chloride, followed by sodium sulphite, will not add to a mercury image, the operation leaving exactly as much mercury as there was originally; and as the effect of mercuric chloride, followed by ferrous oxalate, is simply to accumulate mercury upon the original silver of the negative, the intensifying action of the sulphite method becomes inappreciable after two or three applications of the oxalate method. This gives an additional uncertainty as to the intensifying effect of mercuric chloride followed by sodium sulphite; but the small amount of added density given by this method is often valuable, and the process has the advantage that if it does no good it does no harm, for the negative, after a thorough washing, is just as amenable to the mercury and ferrous oxalate as if the sulphite had not been used.

It will be observed that the reducing power (using the expression in a chemical sense) of the image is lessened by the application of mercuric chloride and sodium sulphite, the Ag_2Hg being able to take to itself only three atoms of mercury by one application of mercuric chloride and ferrous oxalate, while the original four atoms of silver could take four atoms of mercury. But the difference in density given by mercury and ferrous oxalate when applied to a negative before and after the use of the sulphite method is not practically appreciable.

I had hoped to have been able to give a more or less exact idea of the densities of negatives as varied by such treatments as have been described, but the visual opacity sometimes proves different from the retardation of printing processes. It appears that this may always be so; but, whether or not, it is wrong in principle to attempt to estimate one effect by the measurement of another, when the two are not of necessity proportional. I have found also that the increase of printing density produced by the same operation varies somewhat according to the conditions under which the changes are effected. It may, however, be stated in practical language that one treatment with mercuric chloride and ferrous oxalate generally about doubles the opacity; that after a second treatment the result is about equal to that produced by the application of mercuric chloride followed by ammonia upon the original negative; and that mer-

curie chloride and sodium sulphite on the original gives a density about half way between the original and that treated once by the oxalate method.

Doubtless, if the manner of controlling density here advocated is adopted, some operators will find troubles; and in order, as far as possible, to forewarn those who appear to have a predisposition to fail, I have endeavoured to discover all the drawbacks that beset the operations. If the plate darkens very slowly under the ferrous oxalate, and the oxalate is not unduly diluted or acid, the washing after the mercury salt has been insufficient. But at the same time it may be remarked that ferrous oxalate is much slower in action than ammonia or sodium sulphite. If the finished negative has a black looking stain upon it, the ferrous oxalate has not been washed away, and a further washing will rectify it. The removal of the excess of mercuric chloride is greatly facilitated if the mercury solution is poured off when the glass side of the film is grey, then a sufficient quantity of the solution is probably in the film to complete the bleaching. It is, however, important to make the bleaching thorough in the end, if a truly proportional effect is sought after.

The minor advantages of the use of the methods recommended might be set out in a formidable list. There is no tendency to frill, even with repeated treatments, the operations are clean, the negative is in no way stained, the shadows are not choked up, and the lights do not lose their gradation. The operations are reliable, and the results are permanent. In order to test this last matter, I heated an amalgam of silver, containing an equal number of atoms of each metal, at the temperature of boiling water for about twelve hours, with occasional weighing, and found that the volatilization of the mercury gave a loss equal to nearly one part in two hundred per hour—indicating a want of permanence. But a part of a developed plate that had been intensified by the mercuric chloride and ferrous oxalate method until it probably contained more than ten times as much mercury as silver, after heating in a steam oven for six days (forty hours) showed no sign of diminished density either on a varnished or an unvarnished part. The density, indeed, seems rather increased by the treatment, and this may be due to a shrinkage of the film brought about by the prolonged heating. Thus the gelatine confers an extraordinary permanence upon the otherwise slightly volatile mercury. It may be noted as a fact, though hardly an advantage, that after intensification by the methods advocated, a negative is as amenable to intensification by many and probably by all other processes as it was originally. But the greatest advantage of all is that these processes enable the photographer to work step by step up to the density he desires, with the full conviction that the character of the gradation of the negative is not altered.

Photographic Club.—The subject for discussion on Wednesday, February 12, will be "Artificial Light for Portraiture"; on February 17, "Lantern Illuminants."

Incandescent Lamp.—*Kuhlow's Review* is responsible for the following curious paragraph:—"It has hitherto only been possible to produce incandescent lamps of a comparatively inferior light-strength, and hence it has not been practicable to use them everywhere, such as in large rooms and open spaces. This disadvantage has now been overcome, as it has been possible to produce incandescent lamps of 3,000 candle power. These lamps, which have been named high candle-powder incandescent lamps, like all incandescent lamps, have a uniform clear, yellow light, whereas the arc lamps, which are at present alone employed in illuminating great spaces, have the well-known unpleasant bluish light, and burn very unsteadily. The incandescent lamps hardly require any maintenance; they burn for 1,000 hours without supervision, and they are therefore much cheaper than the arc lamps, which require constant attention, besides causing great expense for charcoal. The high candle-power incandescent lamps are therefore likely to soon drive out entirely the arc lamps, and the electric light will then become still cheaper and more popular, as the incandescent lamps yield a perfectly natural light, and now also a light in sufficient volume to meet all requirements.—*Invention.*

THE NEW ROLLABLE CELLULOID FILM.*

BY W. H. WALKER.

Fortunately the new film does not require exceptionally skilful manipulation. Probably no radically new product of similar importance was ever more simple in construction, or more tractable when intelligently manipulated: but such peculiarities as do exist require reasonable attention and provision. Without these requirements, the film may be a needless cause of vexation and loss, while a little precaution will enable it to be manipulated with the utmost ease and certainty.

As has been repeatedly stated with reference to the stripping film, a cut sheet is *never* recommended excepting for single exposures with small stops, as no practicable device has yet been produced which will hold a cut or free sheet sufficiently flat within the focal plane; but a roller slide, if properly made and adjusted in conjunction with a proper film, will perform the feat sufficiently well for all practical purposes.

The roller slides sold by the Eastman Company during the past five years vary somewhat in detail, but all have certain fundamental devices, some of which require with the new film *not* alteration, but adjustment, which any one possessed of an ordinary pocket-knife may accomplish in five minutes.

1st. The rollable transparent film does not require and will not endure an excessive tension in the direction of its length, and in some cases, where the resistance-brake is too powerful, the film willl be stretched out of its normally flat condition.

Therefore, to reduce this tension in all the roller-slides—excepting those originally made with the internal metallic frame—spring open the crescent-shaped wire which causes the resistance, by inserting the edge of a knife-blade between it and the circular groove within which it lies, and also place within the groove a single drop of salad oil.

2nd. By far the largest number of the Company's slides are of the wooden frame variety, and have on the outside of the case a brass spring alarm actuated by a projection on the periphery of the indicator dial. This alarm spring is fastened securely at one end of the wood by two screws, while near the dial there is a third screw by which the resistance offered to the revolutions of the dial may be increased by running the screw further into the wood, and the contrary effect obtained by partially withdrawing it.

Therefore, if by any chance the resistance-brake within the instrument case should be *too weak*, and thereby permit the film to slip over the measuring roll (*i.e.*, the roll having the perforating pins at its ends), we obviously have another means of correcting an error.

Development.—Nothing could be simpler than the development of the new film; it is so thin that it should, when properly soaked, adhere to the flat bottom of any ordinary developing-dish; but if for any reason any difficulty occurs, it is evident there are many simple devices which will cause it to remain perfectly flat. For this purpose has been invented a cheap and simple developing tray, which fully answers any conceivable requirement, and which will reduce the amount of developer ordinarily used to such an extent as to more than pay for its cost with the first spool of film used with it.

Development may be conducted with any approved

* From *The Journal of the Camera Club.*

formula, but we must recommend that contained in the printed instructions which accompany each packet.

In drying, we have not found it necessary to resort to any other expedient than simply suspending the negative by one or more of its four corners from ordinary pins. In drying the negatives may curl inwards, but when dry simply roll them, film side out, over any cylindrical surface, and there allow them to remain for about an hour, after which they will remain flat.

In damp climates, like that of England, the use of a bath of glycerine to ensure flexibility is not recommended. When not in use, the films should be kept flat between the leaves of books or in the Company's film negative boxes, which will soon be ready for sale. These boxes will enable many thousands of negatives to be stored within a remarkably small compass, and by a simple classification any one of the series may be obtained without displacing any of the others.

The Company's factory in America, specially designed for the manufacture of this film, is daily increasing its output, which at present is a serious task, as there are fully 25,000 instruments of its production requiring supplies.

The English company, however, are pushing forward with all possible speed their proposed English factories, which will be planned upon such lines as will ensure a continuous supply, while both companies will work in entire harmony with each other other to prevent undue shortage.

In closing, may I say that it is not for one moment assumed that the experience of the future will not be fully as valuable as that of the past, and that the Company continue to rely upon the kind forbearance of its friends to aid it in determining the true cause of any alleged defects, for without this information progress is greatly retarded.

PHOTOGRAPHIC LIBRARY CATALOGUE.—We have received the proof-sheets of the Catalogue of the Library of the Photographic Society of Philadelphia. It is high time indeed that this valuable collection of books had been put in order and classified. The Society having started to accumulate these books in 1862, will account for the numerous antiquated volumes pertaining to early processes that are to be found on its shelves. A large portion of these books may thus be said to be quite obsolete in so far as modern practice is concerned; but they are still interesting historically, and will often be found useful to those closer students of the art who endeavour to trace the growth or development of one process from another. We understand that the present executive committee of the Society intend to make the Library a chief feature of usefulness, and to add numerous treatises and text-books to the collection, besides supplying all the best journals for daily reference. Journals pertaining to photography are now in the table cases, and they may be considered as the representative ones of present times; beside the American and English, there are also the German and one French; the latter being the official organ of the Photographic Society of Paris. The preface to the Catalogue reads as follows: "It is hoped that the following Catalogue will be useful in aiding those who desire to refer to the valuable Library belonging to the Society, its contents being now for the first time arranged in alphabetical order. A noteworthy feature in the Library is the number of complete sets of journals, dating from the earliest days of the art down to the present time. Although separate text-books of the various branches of photographic science are not wanting in the Society's collection, the journals—which detail the progress of the art from day to day—still remain the most useful sources of information."—*American Journal of Photography.*

ERNST SCHERING.

IN alluding to the death recently of Mr. Hugo Schering, the senior member of the firm of Schering and Glatz, of Maiden Lane, the *Oil, Paint, and Drug Reporter* gives some interesting particulars about his uncle, Mr. Ernst Schering, the well-known manufacturing chemist of Berlin, whose death occurred about three weeks prior to that of his nephew. From this account we append an extract.

Mr. Ernst Schering, the celebrated founder of the firm Chemische Fabrik auf Actien (vorm. E. Schering) was born at Prenzlau, May 31st, 1824. After attaining his school education he entered for apprenticeship at Berlin, in 1840. Though this term was to be for four years, he had shown such ambition in the execution of practical chemistry that after eighteen months he was consulted in the production of chemicals when such were contemplated.

The art of photography, originating from the method of Daguerre for the production of light pictures, induced Mr. Schering to devote his attention to the production of the chemicals required therefor, such as iodine and its salts, silver and gold salts, and pyrogallic acid. He recognized that the unsatisfactory results in photographic duplication were in greater part due to the irregular purity of the chemicals used, and consequently devoted his energy to the production of the purest chemicals for photographic purposes. In course of time the number of chemicals produced by Schering's factory continually increased. It was, however, the motto of the owner to keep the qualities of his preparations at the highest possible standard, and never to have them impaired by the manufacture of larger quantities. Encouraged by his successes, Schering undertook, at the first Paris exhibition, in 1855, to show his iodine salts and resublimed iodine, as also some few other preparations, in great purity and beautiful crystallization. The manufacturer, then practically unknown, was honourably rewarded, and from that time on his preparations received considerable attention from all consumers. With the extension of business came the creating of agencies in the principal commercial cities of Europe and also America. The relations with the trade in this country became so important, that Mr. Schering always exercised the greatest care in the preparation of goods for this market. His restless and uninterrupted activity at the laboratory for many years had its evil effects on his physical constitution, and only after the most ardent and repeated suggestions of his physicians could he be induced to seek rest at intervals. After visiting Teplitz, to effect a cure of his ailments, which, however, failed to give the desired results, he concluded to form a stock company whereby he could increase his facilities. This transfer took place October 31st, 1871, when the firm of E. Schering was converted into the Chemische Fabrik auf Actien, vorm. E. Schering, in which he consented to be one of the leading directors.

GESTURES AND SPEECH MECHANICALLY REPRODUCED.—Edison has been developing his great idea of making use of photography as an adjunct to the phonograph in order to bring a speaker's personality before the eye. The result of Edson's experiments has been a wonderful machine. In front of the speaker are placed two small machines, one a phonograph, and the other an ingenious piece of mechanism by which photographs of the speaker are taken in succession with enormous rapidity at intervals of from one-eighth to one-twentieth of a second, and both these machines are at work silently recording both the uttered speech and the personal appearance of the speaker at each fractional part of a second. The results thus obtained may be sent to any desired point, and the photographs thrown on a screen by an ingeniously-contrived piece of mechanism. Thus the exact appearance of a speaker, with all his gestures and play of features, is exactly reproduced, while the phonograph simultaneously delivers the speech. The interval between the successive photographs is so infinitesimal that the screen picture is apparently a living one, moving, gesticulating, and apparently uttering the words which in fact are spoken by the phonograph.—*New York Herald.*

INTERNATIONAL COPYRIGHT.

BY WILLIAM BENHAM.

Perhaps no branch of the law is in a more confused state than the above, as will be seen by the following.

Probably most of your readers are aware that photographs were not protected until 1862, when the Act of Parliament (25 and 26 Vict. 68) was passed which vested in photographers the copyright of their negatives, prints, &c., and the right of reproducing the same during their own lives and seven years afterwards, or for a term of forty-two years, whichever should be the longer. So far a photographic copyright was placed on exactly the same terms as the literary copyright, except that literary copyright was protected in several foreign countries provided certain conditions were observed as contained in two Acts of Parliament which will afterwards be referred to. By the Act of 1862 registration was imperative if the owner of the copyright wished to protect himself against piracies, as he was unable to properly found his action or suit until after registration, which had to be done within three months of the date of first publication.

By Acts of Parliament passed in 1843 (7 and 8 Vict. c. 12) and in 1852 (15 Vict. c. 12), it was enacted that authors in any foreign countries which had by convention or treaty with this country given reciprocal rights to a British author should have a copyright in his literary composition according to the laws of this country. By the before mentioned Act of 1862, the above two mentioned Acts were re-enacted, and the same was to have effect with such countries as should from time to time be named in an Order in Council.

On the 10th day of January, 1852, an Order in Council was published in the *London Gazette* giving British subjects international copyright in their literary works with France, Germany, Belgium, Austria, Prussia, and Spain. It will be seen that the above Order in Council was issued twelve years before the passing of the Photographic Copyright Act, but as this Act re-enacted the two International Acts, it has been successfully argued that the Order in Council was also taken to be republished.

If any readers contemplate taking proceedings for infringement of their photographs, it is first of all necessary to make sure that the same are registered in the country of origin, and that they have complied with the conditions of the Treaty or Convention with the country where the same are being infringed. The usual conditions in all countries are that they should be registered there as well as here within the period of three months from their first production.

The certificate of registration in foreign countries requires to be authenticated by one of its Ministers before it can be given in evidence in a court here. With regard to the remedies in this country, they are threefold: an action for damages, an injunction to restrain the wrongdoer, and proceedings for penalties upon a summons before a magistrate. International copyright in music has by an Act passed in 1888 been much simplified, and now the author or composer of a musical composition or song has only to register in the country of origin; proof of such registration is sufficient to perfect the title for all purposes connected with proceedings in our courts so far as the copyright is concerned.

Developers for Films.—Major J. F. Nott says that soda is the only alkali which can be used with advantage with stripping films. Quinol is an excellent developer, but it destroys the gelatine film.—*Journal of the Camera Club.*

SELF-LUMINOUS TRANSPARENCIES.

Photographers are always on the look-out for something new or attractive, and yet many excellent suggestions are made and immediately forgotten, simply because they fail to reach the eye or ear of the man with sufficient foresight and enterprise to take advantage of them. What, for instance, would be more attractive to, well, a large portion of creation at a certain period of life, and under certain circumstances, not only to have a picture of the loved one that may be gazed upon during the day, but that in the darkness and during the silent watches of the night may be taken from under the pillow, and, self-luminous, every feature of the beloved countenance traced? This, and many other equally useful applications of what was at one time well known, Balmain's paint, may be made by any photographer with profit to himself and pleasure to his customers.

Balmain's paint is a sulphide of calcium or barium, or a mixture of both, and, as is well known, possesses the property of absorbing certain of the more refrangible rays of the spectrum, and continuing to give them off again for a considerable time in the dark. When the material was first popularised by Balmain it was largely employed in coating clock faces, candlesticks, match boxes, and other articles likely to be required in the dark, and, as evidence of the durability of the material, we have a match box on the cover of which is a tablet so coated, that has been in constant use for at least eight years, and which, if exposed to light during the day, is as luminous at night as it was when it came into our possession.

From time to time suggestions to employ the sulphides in connection with photography have been made without attracting attention, and more recently the matter has been taken up by the *American Lithographer and Printer*, which recommends the rendering of suitable lithographs or photographs translucent, and laying them down on a card that has been coated by dusting the luminous powder over a varnished surface.

No doubt fairly good effects may be produced in this way, but we think we can suggest one that for photographs, at least, is very much better. It is to print on glass a transparency of any desired size from a negative, and when dry, coat it on the film side with an emulsion of the sulphide in gelatine or other suitable vehicle. Balmain's paint was at one time, and may be yet for all we know, sold in bottles, in a dry powder mixed with gelatine, so that it was only necessary to add water to the consistence of cream to make it ready for use. We are under the impression that Warnerke, in coating the tablets for his well-known sensitometer, employs melted paraffin, in which case the picture would require to be gently warmed to allow of the mixture being evenly spread.

We think the size of picture most likely to take, and most conveniently made, would be one made on the ordinary lantern slide plate; and in reducing by copying in the camera, the negative should be placed so that the picture will be correct when seen through the glass. They should be backed with some impervious material, or, better still, put into the old-fashioned leather cases, if they are still to be found; and if any of our readers are enterprising enough to make a few from some of their best negatives and show them to their customers, we feel fully warranted in promising them a ready sale and many orders.

Who will be the first to advertise "The new night-blooming photograph?"—*The Beacon.*

Notes.

The general public, ignorant of photographic advance, cannot quite understand the reproduction of photographs in newspapers. They are about as advanced as the illiterate family who, when one of its members with an artistic turn got a drawing accepted by an editor, refused to believe that the drawing was his, because it was in print. These good people had a vague idea that a picture was produced in print very much as the reading matter is, and they could not realize that it had to be drawn first. Reproductions of portrait photographs the public accept without asking any questions as to how the photographs get converted into blocks which can be used in a printing press, but a photograph of a landscape fairly puzzles them.

A case in point occurred the other day. An illustrated paper contained some reproductions by the Meisenbach, or a kindred process, of some instantaneous photographs. One, a bit of river scenery, was particularly charming, and it had the effect of causing the editor to receive several letters asking from what painting the copy was made. This was a great compliment to the photographer, and in addition to illustrating the point we have advanced, shows that the public have not yet fully grasped the fact that a photograph from nature can be as artistic as a painting.

An odd example of combining two hobbies came under our notice the other day. One of these hobbies, we need scarcely say, was photography; the other was a mania for collecting old suits of armour and old weapons. Where the combination comes in, is seen in the album, which the owner exhibits with great pride, containing a number of photographs of himself attired in the various suits of armour forming his collection. The fad is a harmless one, but the duty of looking through the album is rather trying to those with a sense of humour, for although the armour itself is seen to advantage, the wearer possesses a most pacific countenance, while the pose is not in every instance that which one imagines a Crusader would assume.

The insurance offices, so far as we know, still maintain their stolid indifference to the altered conditions under which photography is carried on. Some time ago, we drew attention to the fact that, despite the absence of all danger of fire, photographic studios were classed under the head of "extra risk." There was justification for this charge in the old collodion days, but surely dry plates have now been sufficiently long in use to warrant the premiums being fixed on the ordinary scale. If any photographer has of late made any effort to get his insurance reduced, it would be interesting to know his experience.

No one would wish to lessen the glory of Daguerre by a jot, but is there not rather a tendency to overdo the homage which is being paid to his memory all over the world? In the universal pæan of praise which is being sung, one is apt to forget the name of Talbot. It is no question of rivalry between Talbot and Daguerre which we desire to raise, but rather a reminder that, while Daguerre's process is practically extinct, the germ of the Talbotype yet remains incorporated in our everyday work. The proposal by the Boston Convention to raise a memorial to Daguerre in Washington, by means of a one dollar subscription, has drawn forth a comment similar to that which we have raised above.

Whether from its costliness, or from some practical difficulty, luminous paint has not fulfilled the future held out for it. We now learn that a firm in Austria has discovered a mode of preparation which will lessen its cost of production to about one-sixth of its present price in England. What reliance may be placed upon this statement we cannot say, but if true, a great demand will spring up for the paint, for which there are a hundred uses.

A reaction, it is prophesied, will before long set in against the huge, unwieldy sizes which the majority of American newspapers affect. People, we are told, are beginning to cry out for smaller papers, less padding, less trash. One authority declares that a one cent paper is wanted, somewhat larger than a lady's handkerchief, printed in leaded nonpareil, containing the news up to twelve, one, or two o'clock last night, in two, three, or four line items. He recommends typewriting in nonpareil style of type-writing type, photographing it, and dashing it off in sixty minutes. All this sounds very go-ahead, but the authority omits to say how long the preparation of the photographic block will take. We fancy that when the details are gone into, the old-fashioned way of setting up type will be found the speedier.

The French police are nothing if not scientific. They have now obtained, by means of photography, large cartoons of the hands of various artisans, artists, and professionals, so as to carry out their speculations as to the fact of the hand proving the occupation. This selection does not seem very complimentary to the artisans, artists, and professionals. The latter term, by the way, is rather a wide one; does it include professional thieves? Apropos of the hand, what a pity it is that some student of Desbarolles and D'Arpentigny does not issue a new edition of the former's great work on Palmistry, illustrated by photographs? The hand is admittedly the most difficult member of the body to draw, and the illustrations in these volumes, instead of elucidating the divisions and subdivisions of the subject, rather tend to confuse them. The professor, no doubt, has definite ideas on the distinction he draws between various hands, but when these ideas have to be translated by an artist, we get something very often totally different. Now about photographs there could be no mistake. Any one who has tried to master D'Arpentigny will admit the truth of this.

SOME EXPERIMENTS WITH EIKONOGEN.

BY C. BRANGWIN BARNES.

As the new developer seems to have created some little stir in the profession and to act in an entirely different manner in different hands, it may not be uninteresting to detail some experiments which I have recently made with a view of comparing the qualities of eikonogen as a developer with those of pyrogallol and ferrous oxalate. The experiments in question were made with a sample of what is termed "white crystalline eikonogen" (probably for some reason known to the manufacturer), although in reality it is of a delicate yellow tint. This I received in a capsuled bottle containing one-tenth of a kilo of crystals about the size of peas. In order to give the developer a fair trial, I decided to first follow implicitly the instructions I received therewith, and as I imagined that, even when powdered in a mortar, the solubility would not be so perfect in cold water as in hot, I chose the latter and made up my developer with four parts of sulphite of soda, one part of eikonogen, and ten parts of boiling water. I thoroughly stirred this with a glass rod until the whole of the eikonogen was dissolved, which dissolution occupied about ten minutes, and I now had a somewhat murky liquid of a pale primrose tint, which I poured into a bottle, and proceeded to mix three parts of pure crystallized carbonate of soda with twenty parts of hot water, which I poured into another bottle, and allowed both to cool.

On proceeding to develop a plate, I took three ounces of the eikonogen solution, and added thereto one ounce of the soda, and placed the plate in the mixture without the previous bath of water usually adopted with the pyrogallol developer. In order to compare the time of development, I rocked the bath as with the pyro. The negative commenced to develop almost immediately, and had all the detail out in three minutes, but was sadly lacking in density. I therefore continued the development for another minute and a half, with the result that the plate obtained a good printing density, without in any way fogging or damaging the shadows. I then substituted a second plate without changing or strengthening the developer, and again obtained an equally good result; I then attempted a third, and was again successful, although in this case the development was prolonged to five minutes, and the negative was rather thinner. I fixed in the combined hyposulphite and bisulphite of soda bath without using alum, and found I had three good printing negatives. Between the two first developed there was no perceivable difference, but the third was certainly slightly inferior. Pouring back the used developer into a glass measure I examined it in the light, but failed to find any pronounced signs of oxidation, so put it aside until the following day, when it appeared but a trifle darker in colour, and I again attempted to use it; the result, though not altogether satisfactory, far exceeded my most sanguine anticipations, as it yielded me a negative full of detail, though requiring intensification.

My second experiment was with an opal plate, and here again the new developing agent came out with flying colours. I should have mentioned that the three plates used for the first experiment were No. 1 Derwent rapid, No. 2 Britannia ordinary, and No. 3 Ilford white label.

My third experiment was with an isochromatic plate, which required six minutes to complete development. The result was, however, good, with the exception that there was a slight veiling of the deepest shadows; the detail was fully brought out, and the density all that could be wished for. So far, my experiments had all been conducted with what I have reason to believe were properly exposed plates; the next, however, was one which I knew to be much under-exposed, having been taken with a Stirn's detective camera on a not over-bright winter's day, the exposure being about one-tenth of a second. To my surprise and gratification I was enabled to develop out a considerable amount of detail, far in excess of that which I obtained on another plate exposed under identical circumstances and developed with pyro and ammonia. The difference between the two was most marked, the eikonogen yielding a negative with a fair amount of detail, but needing intensification, while the pyro gave me one without any detail whatever, only the high lights developing at all. An attempt to develop an over-exposed plate resulted in failure, although it might undoubtedly have been saved by the addition of a little bromide to the developer; but this was not tried, as my intention was, on this occasion, to test the merits of the developer according to the formula issued therewith, and having done so, I proceeded to conduct further experiments with an altered or modified developer. In the first place, I substituted ordinary washing soda for the pure crystallized carbonate, and must confess that I was unable to distinguish between the resulting negatives. I next attempted the use of ammonia as an accelerator, but do not consider it necessary to detail the individual trials, as it did not seem to yield such good results as the soda, although the time occupied in development was materially shortened. Such being the case, I again reverted to the first or published formulæ, with the exception that I added half a dram of bromide of potassium to the eikonogen in solution, which has the effect of prolonging the development and lessening the detail.

In conclusion, I must give my vote on the side of the friends of eikonogen, as I find it, in conjunction with soda, to be a quicker developer than pyro and soda, though, perhaps, a trifle slower than pyro and ammonia; the addition of bromide is very rarely required; the minute detail is more marked, the half-tones are better, and, to crown all, the colour, which closely resembles that obtained with ferrous-oxalate, is such that at least one-third the time is saved in printing as compared with the old and still popular pyro and ammonia. So far as cost is concerned, I must confess I can see very little difference between the two agents, though if one is cheaper in the long run I should opine it is eikonogen, added to which there is no doubt the present price will decrease as the demand increases. It is, perhaps, an additional advantage that the new developer does not stain the fingers, and that the dishes and measures are far more easily kept clean.

The foregoing notes merely represent my experiments up to the time of writing, but I am still engaged in a further comparative series.

Mr. Stanley, writing to a friend some particulars of his forthcoming book, which he hopes will be ready in May, states that he has a number of most interesting photographs of scenery, and sketches of interest, and that maps will be a prominent feature.

Royal Institution.—The Rev. Canon Ainger will begin a course of three lectures on "The Three Stages of Shakespeare's Art" on Thursday, the 13th of February; and Lord Rayleigh will begin a course of seven lectures on "Electricity and Magnetism" on Saturday, the 15th of February.

A PHOTOGRAPHIC FIEND.

WHILE we were sitting at our desk working hard to get out a leader for the front page of the *Pirate*, a timid rap sounded on the door, and at our yelling "Come in!" the most comical specimen of humanity that ever drifted into our sanctum appeared. How he ever managed to walk through the street from the Puma Hotel to the *Pirate* office without being riddled with bullets is more than we can understand. The boys must have all been sitting in a game over at the Dew Drop Inn at the time. He was tall, thin, and homely, with hair the colour of a ripe carrot, and on his long, narrow feet were a pair of yellow shoes that might have been called handsome in the effete East, but they looked very ratty in our town. On his head he wore a little tourist's cap with a fore-and-aft visor, and on his lower limbs he wore a pair of short pants, which were held up by a yellow and black bandage which encircled his stomach. We endeavoured to be polite, but little Pete, our office boy, fell into a fit at sight of the freak, and we were obliged to stuff an exchange into our mouth to keep from laughing in his face.

"I beg pawdon, deah fellaw," said the man, as he entered and looked us all over through a little round piece of glass, "but I am er-aw-a tourist, don't ye know."

Of course we were glad to see him; we had to be, as it was our place.

"A tourist, did you say?" we asked, not knowing what else to say; and Pete had another fit, during which he pied a galley of solid nonpareil.

"Er, yaws, I'm travelling through the country, don't yer know, securing photographs of natives; and having heard that you had some particularly romantically dressed charactaws of the cow-boy type in this place, I thought I would see what success I would have in securing a few negatives."

"Well," said we, "the town is full of queer characters, and all that is necessary to bring them forth is to fire off a gun in the street."

"Why, how perfectly *odd!*" exclaimed the man; and stepping outside, he brought in a box and a bundle of sticks, which he set up inside of three minutes, and there had as pretty a camera as one could wish for. When we saw this our respect for the man rose several degrees, and we began to get interested. At first it was our intention to let the boys have some fun with him, but now we changed our mind, and decided to warn him.

"Aren't you afraid to aim that at some of these rough men?" we asked. "You see, they are liable to take you and your machine for a target, and indulge in a little revolver practice."

"Well, er, aw, to tell the truth, ye knaw, I am *rawther* timid, but I always awsk one's permission, don't ye knaw, er, before taking their photo."

"Well, take the advice of a friend and be careful," said we, as we sized him up again, and thought of the risk he was running.

"Thanks, er, awfully," said he; and carrying his camera to the door, he stepped out on the walk, and reaching into his hip pocket, pulled out the ugliest gun that it was ever our lot to behold. He aimed it into the air, and a report like a small cannon followed. Hardly had he replaced the revolver in his pocket when the boys came pouring out of the Dew Drop Inn, and, when their eyes rested on the tourist, they looked at each other, first in surprise, and then mischievously. Locking arms, they all faced the party with the abbreviated pants, and commenced to march on him. On they came, keeping perfect time, walking straight at him, and almost any other man would have turned pale and run, but not so with the dude. He pulled out a cigarette, lit it, and, after taking a few puffs, commenced to mark time. We could see plainly that the crowd were a trifle staggered at the man's nerve, and did not know whether to keep on and walk right over him, or try some other scheme to frighten him. Finally they decided to stop and hear what he had to say for himself, and they were not kept long in suspense.

"Gentlemen," said the dude; "if you don't mind, there being so many handsome fellows among you, I should like to take youah photographs." This knocked the boys all in a heap, but Col. Jno. Watkins was the first to collect his senses, and said:

"All right, pardner, bring out year photygraffin machine, an' we'll try ter look pleasant." At this the dude stepped inside the office, and, opening a valise which he had previously brought in, he took out another camera, laying it tenderly on a chair while he removed the one from the tripod. "I find," said he, as he glanced out of the window, "that in case the crowd is *very* rough, that, er, in ordah, aw, to successfully get their pictures, it is first necessary to thoroughly frighten them. Now, they will undoubtedly fire at the camera the moment it is aimed in their direction, and I must, er, aw, fool them, don't ye know. Observe me, and you will see how it is done."

Thereupon, he took up the camera which he had handled so carefully, and screwed it on to the tripod, and, going out into the road, aimed it at the crowd, who were patiently waiting with drawn revolvers.

"Aw, are you ready, gentlemen?"

"We are," they replied in chorus.

"Then wait one moment, till I, aw, return, and I will take your photos."

Hastily entering the office, the man commanded us to lie down flat upon the floor. We did as we were ordered, gazing through a knot hole in the wall the while, and we must own that what followed startled us. Col. Jno. Watkins gave the order to take steady aim at the camera, and at the word fire, twenty bullets entered the box, which exploded in its turn, tearing up the ground for twenty feet, and shattering every window within the block.

"That, aw, was twenty-five pounds of dynamite," coolly explained the dude, as he lit a fresh cigarette. Taking another tripod from his valise, he fastened it to his camera, and going out on the side-walk, addressed the frightened gang.

"Gentlemen, aw, you were very unwise, er, don't ye know, to risk your lives in that mannaw, and I would advise you not to fire at this one, as it would blow up the whole town." Every mother's son in that crowd turned pale at this, and Col. Jno. Watkins was upon the point of running away. "One moment, er, deah boy," said the dude, as he observed the colonel's action, "I desire youah photograph." Then pulling out that ugly gun, which had a bore nearly big enough for a jack rabbit to crawl into, he said: "Gentlemen, I want you, aw, one at a time, don't ye know, and as I point this aw, little revolver at a man, I, aw, want him to come forward and look pleasant." In this manner every one in the crowd was photographed, and told to skip a soon as the operation was over. The dude left that night on the stage, but we have since learned that he is a member of a private detective agency, and would warn our good citizens to be in constant readiness to take to the sage bush.—*American paper.*

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The annual meeting will be held on Tuesday next, February 11th, at 8 p.m., at the Gallery, 5A, Pall Mall East.

COPYING DRAWINGS.—A new method for copying drawings which may be found of service is described by *Building*. Any kind of opaque drawing paper in ordinary use may be employed for this purpose, stretched in the usual way over the drawing to be copied or traced. Then the paper is soaked with benzine by the aid of a cotton pad. The pad causes the benzine to enter the pores of the paper, rendering the latter more transparent than the finest tracing paper. The most delicate lines and tints show through the paper so treated, and may be copied with the greatest ease, for pencil, Indian ink, or water-colours, take equally well on the benzinised surface. The paper is neither creased nor torn, remaining whole and supple. Indeed, pencil marks and water-colour tinting last better upon paper treated in this way than on any kind of tracing paper, the former being rather difficult to remove by rubber. When large drawings are to be dealt with, the benzine treatment is only applied to parts at a time, thus keeping pace with the rapidity of advancement with the work. When the copy is completed the benzine rapidly evaporates, and the paper resumes its original opaque appearance without betraying the faintest trace of benzine. If it is desired to fix lead pencil marks on ordinary drawing or tracing paper, this may be done by wetting it with milk, and drying in the air.

DANGERS OF FLASH-LIGHT COMPOUNDS.*

BY JOHN G. BULLOCK AND CHARLES L. MITCHELL, M.D.

Within the last two years the community of Philadelphia has been startled by a series of fatal accidents occurring during the manufacture of magnesium flash-powder, a compound well known to photographers, whereby in all five human lives have been lost. On three several occasions explosions have taken place, each with fatal results, the last and most recent of all resulting in the death of three persons. As a natural consequence considerable attention and inquiry have been attracted to the subject of flash-powders and their probable dangers, and the writers of this paper were requested at a recent meeting of the Photographic Society of Philadelphia to prepare a report upon the subject.

The composition of the particular powder which was the cause of this disastrous loss of life is understood to have been powdered magnesium, chlorate of potash, picric acid, and bichromate of potash. No one of these ingredients is in itself explosive except under extraordinary circumstances, and may be considered as safe; but the moment that they are mixed an element of danger is introduced.

Many finely-powdered metals are prone to rapid oxidation; give them the oxygen and the reaction takes place rapidly, and is frequently accompanied by heat and flame. Powdered magnesium and powdered zinc have been known to become sufficiently hot to ignite material in contact with them, on being wet with water.

The addition to magnesium of a chemical rich in oxygen, or holding oxygen loosely, so to speak, increases its susceptibility to rapid change.

For instance, a match applied to some of the powdered metal will fail to ignite it, or occasions a mere glow from slow ignition; but let the magnesium be mixed with chlorate of potash or nitrate of potash to furnish it with oxygen, and the whole mass will flash with almost explosive violence. Again, mix with the magnesium and chlorate of potash some carbon, and under some conditions a dangerous explosive will be formed. For instance, oxygen gas is made safely from the heating together of chlorate of potash and oxide of manganese; allow some carbon to be accidentally mixed with the two ingredients and heated, and a violent explosion will probably ensue. The rubbing together of chlorate of potash and some organic substances is accompanied with a crackling noise and frequently explosion, as instanced in the combination with sugar or tannin.

Such compounds as we have spoken of are known as explosives, as typically illustrated by gunpowder—a mixture of nitrate of potash, carbon, and sulphur. Another and more dangerous class of chemical compounds which may be formed under some circumstances are known as detonators; that is, compounds the component parts of which are held together under so strained a condition of high tension, that a very slight cause, such as a light, sharp blow, will occasion them to fly apart violently with a sharp, loud report; in other words, they detonate. The force of an *explosion* is felt at a greater distance than that of a *detonation*, but the disruption of surrounding bodies is greater and more complex with the detonation than the explosion. An explosion is generally accompanied by fire and smoke; a detonation is not.

Many detonating compounds may be heated and burned until consumed without discharge, whereas the detonation or snapping of a common pistol cap in contact with or near them may detonate the entire mass; such is the method adopted in the explosion of mines, &c.

Picric acid is, in itself, we might say, perfectly safe, as it can be burned without danger, and will detonate only when confined. In compound, however, with some other bodies, it produces a class of very dangerous substances, notably picrate of potassium, picrate of sodium, picrate of barium, picrate of strontium, picrate of magnesium, and picrate of lead. These substances are extremely unstable in character, and liable to explode with slight percussion or friction with the liberation of immense volume of gas. Sarran states the relative force of picrate of potassium, when exploded, as compared with gunpowder, is as 1·98 to 1·00—almost twice as great. A mixture of 0·5 kilograms of potassium picrate and 0·5 kilograms of potassium chlorate evolves through its combustion 352 litres of gases. One kilogram of gunpowder evolves but 200 litres under the same circumstances.

Picrate of magnesium is, when dry, one of the most unstable of its compounds, and therefore highly dangerous to handle. It may be made in a wet way by double decomposition, or by the intimate mixture of the powdered ingredients. Time is, of course, an important factor in the latter process of manufacture, but a microscopical examination of the mixture, after long standing, will show that the metal has entirely disappeared, and the explosive compound been formed. There is no doubt but that this combination may be greatly assisted by the presence of atmospheric moisture. Powdered magnesium is quite hygroscopic, and has a tendency to cake together in loose masses, or adhere to the sides of a bottle, if exposed to a moist atmosphere. Picric acid, when powdered, is also rather sticky in character, and it can be readily seen how, if these two substances existed together in a mixture, they would be attracted to one another; then, given the elements of time, moisture, and perhaps some slight warmth, and a chemical combination would inevitably occur. That this is not simply theory, but fact, can be substantiated by a fact lately mentioned to one of the writers of this article by Prof. Henry Leffmann, of this city, in a personal conversation. He stated that some time previous, while microscopically examining a sample of flash-powder which contained picric acid, he was surprised to notice an entire absence of metallic magnesium, the yellow crystals of picric acid being alone prominent. On dropping the powder into water, however, an abundant sediment of metallic magnesium was deposited, showing its presence, and a closer examination of the powder showed that the particles of magnesium were completely enveloped in a yellow coating of picric acid. Of course these circumstances afforded a most fruitful opportunity for the conversion of these two substances into the explosive picrate of magnesium.

Here is the probable explanation of the late calamity at the laboratory of Wiley and Wallace. A bottle containing in the neighbourhood of several pounds of flash powder, made, after the before-mentioned formula, some eighteen months previous, was being emptied into a drain for the purpose of getting rid of it. No fire or other chemicals were known to have been present. Water had been thrown upon some of it to aid in its being carried down the drain. Experiments subsequently made proved that the presence of water would not occasion sufficient heat to ignite it. The most reasonable supposition is, therefore, that a small portion of the powder was detonated by an

* Read before the Photographic Society of Philadelphia.

accidental blow, and from thence the entire mass was detonated. No smoke or burns appeared upon the bodies of those killed, or surrounding objects, thus proving the absence of fire. For the preceding disasters by the same powder another theory must be advanced, as they occurred at the time of the mixing of the ingredients, and previous to the probable formation of the picrate of magnesium. In the first case there was an explosion during the process of grinding the material; in the second case, while the powder was being sifted. In the first case it can readily be seen that an explosion would be the natural sequence. In the second case it is probable that some clogging of the sieve occurred during the mixture of the materials. The loss of these five lives is a terrible caution against the use of the especial compound which caused the explosion, and a sufficient reason to regard with suspicion any powder the formula of which is not made public and known to be safe. This especial formula produced a compound which was alike unsafe to make, to use, or to keep. To sell such an article, therefore, for ignorant and unskilled persons to use, or to induce anyone to attempt its manufacture, places a fearful responsibility upon those who knowingly undertook such a risk.

It is much to be regretted that the formulæ of most of this class of preparations are not published, and it is highly probable, in many cases, that their ingredients have been combined with but little regard to their chemical properties and the chemical reactions which might occur from their admixture. The fact that the compound may bear a label proclaiming it "safe" is but a very slight guarantee when its composition is altogether unknown.

It seems hardly necessary now, in view of all that has been said, to raise a note of warning in regard to the use of all these flash-powders, but the statement has been already made that while this one particular compound was unsafe, other compounds are harmless. The writers wish to state, therefore, that they consider *all forms* of flash-powder dangerous, the difference between them being only in the degree of danger involved. As has been said, they are all composed of substances liable to rapid decomposition when in contact with each other: they are liable to form new compounds often possessing dangerous and unknown properties, their combustion is attended with an intense degree of heat, involving risks from severe burns, and they are liable to spontaneous explosion or ignition. This danger is greatly augmented when they are made or kept in mass, and the probable reason why a greater number of fatal accidents have not occurred is because the powders have mostly been made in comparatively small quantities and put up in separate packages, each containing but a few grains of the mixture. They contain, in most cases, chlorate of potash, bichromate of potash, permanganate of potash, ferrocyanide of potassium, nitrate of potash, amorphous phosphorus, and other highly organized compounds, the very purpose of their admixture with the magnesium being to increase its inflammability and the rapidity of its combustion. This can only be done by making the combination more unstable, and thus introducing at once a large element of danger. A simple mixture of magnesium and chlorate of potash, which has been claimed to be harmless, if placed in a confined situation, as in a pistol, and discharged by a cap, will detonate, and there is probably no compound of this character which does not possess some elements of danger.

Since the introduction of the different forms of the magnesium lamp, in which pure metallic magnesium can be burned with absolute safety, there seems to be but little reason why the use of flash-powder should be continued, and as the only possible advantage in their use over that of the lamp is that a slight amount more of speed may be obtained, the question may well be asked whether the possible advantages to be gained are worth the additional risk involved in the use of the flash-powder.

In conclusion, the following quotation from Eissler's work on "The Modern High Explosives" may well be cited here, more particularly in reference to combinations into which chlorate enters:—

"In mixing these compounds great danger is attendant, and too much circumspection cannot be used. They explode instantly upon any violent stroke, very often by friction alone; sometimes spontaneously, as when in a state of rest, and no known cause for their combustion can be assigned. Many are deluded as to its safety by so-called experiments with freshly-made powder. Manufacturers of the compound may attempt to show its safety by hammering it and cutting it, and similar tests; but let the powder be exposed to the natural atmospheric action, attract some moisture, then get dry, and the least friction or blow will cause an explosion."

The writers hope that the knowledge of the dangers attending the use of flash-powders is now so diffused that no farther accidents will result from their use, and that their manufacture will eventually be abandoned.

THE first number of the *Art World*, a weekly art newspaper, is announced for February 22nd. It is to be devoted chiefly to the pictorial and plastic arts, and to the interests of artists of all denominations. It will not be illustrated.

NEXT Monday, Mr. Douglas Freshfield will give a full account before the Royal Geographical Society of the search expedition undertaken by Mr. C. Dent and himself, which solved the problem of the fate of the two English mountaineers, Mr. Donkin and Mr. Fox, who were lost in the Caucasus in 1888. Mr. Freshfield's paper will be illustrated by photographs taken by Signor V. Sella, one of several travellers who succeeded last year in the ascent of Mount Elbraz, and by Mr. H. Woolley, who accompanied Mr. Freshfield in his search expedition.

THE following experiment showing how primary colours produce white is of interest. Cut a circle of pasteboard nine inches across, pencil it into four parts, then again each of these into seven. With bright, clear water-colours paint these narrow, pie-shaped slips with red, orange, yellow, green, blue, violet, indigo, in this order; then begin, and do this in each quarter. Put a round, smooth nail or pin through the centre of the disc where the points of the colours meet; drive this into a heavy board edge, and whirl it around as fast as you can. The colours disappear, and you see a round but rather dirty white circle. If the colours were pure it would be pure white; if they were really prismatic you would have a little shining white moon of light.—*Invention.*

MESSRS. PERKEN, SON, AND RAYMENT.—Our attention is drawn to the subjoined extract from the *London Gazette* of January 28th:—"Notice is hereby given that the partnership heretofore subsisting between us the undersigned, Louis Edmond Perken, Frederic Louis Perken, and Arthur Rayment, carrying on business as Manufacturers and Importers of Optical and Scientific Instruments at No. 99, Hatton Garden, and elsewhere in the County of London, under the style or firm of Perken, Son, and Rayment, has been dissolved by mutual consent, as from the 31st day of December, 1889. All debts due to and owing by the said late firm will be received and paid by the said Frederic Louis Perken and Arthur Rayment, who, with Edgar Theodore Perken, the younger son of the said Louis Edmond Perken, will continue to carry on the same business at No. 99, Hatton Garden aforesaid, in partnership, under the same style or firm."

A CAMERA WITH THE LUSHIA FIELD FORCE.*

BY TOM. DE LA TOUCHE.

We left Calcutta on the eve of a cyclone, and the weather was so gloomy that no pictures of the embarkation of troops or views of the river were possible; but as these have been often photographed, perhaps it was just as well not to be tempted to waste plates on them. Arriving at Chittagong, let us draw a veil over the events of the intervening two days. I tried a picture of the I. G. S. *Dalhousie*, which had brought us across; but having just before been showing off the beauties of the camera to some friends on board, and having left it on a skylight for a short time, one of these friends had taken the opportunity to set the lever that keeps the shutter open, and consequently, on releasing it, the shutter stuck halfway. The result was a picture that showed the *Dalhousie* as she might have appeared in the height of the cyclone, and which even a hardened sailor could hardly have contemplated without its bringing on an attack of sea-sickness. A view of the shipping in the river with boats in the foreground preparing to embark troops turned out better; but away from the river Chittagong is uninteresting, and does not lend itself well to the camera. Proceeding up the river, the little station of Rangamati, built on a ridge high above the river, makes a fairly good picture, but below this place and for a long distance above it the banks are monotonous, low hills covered with dense jungle to the water's edge extending for miles. At Burkul, however, two days above Rangamati, where the river cuts through a lofty range of hills, and is broken by a series of rapids, the scenery becomes finer, and several good views may be obtained. This is a grand place for fishing, and a rod should be included in one's kit, but the strongest kind of tackle, especially hooks, will be required. All the fish that I hooked broke away, sometimes straightening out the hooks or bending them into a ring. Above Burkul there is another long stretch of still water, and few good subjects for pictures are met with till Demagiri is reached, where one or two fine views may be obtained, especially of the rapids and falls above the station, and the rod may again be used with effect. There is a Kulsi village on the heights opposite Demagiri; and if one does not object to a steep climb of about 1,000 feet, a group of the inhabitants and their bamboo huts will repay the trouble of getting to it.

As far as Demagiri the journey is easy enough; and, as a police post has been established there for several years, it may be visited at any time. A steamer leaves Chittagong for Rangamati once a week, and, beyond this, dug out boats are easily procurable, which are fairly large and comfortable, and may be slept in at night, but a mosquito net is indispensable. Beyond Demagiri it would not be safer to proceed, at any rate for the present, without an escort; but in a few years, let us hope, these hills will be as free to the seeker after the picturesque as any part of the hills of Assam.

Camp Demagiri; 20th December, 1889.

PHOTOGRAPHIC COMPETITION WITH OTHER PICTORIAL ARTS.

The *Daily Telegraph* says:—There is no great probability, fortunately, of any development of the art, or rather scientific craft, of photography doing any harm to water-colour painting. What harm photography has been capable of inflicting on art has already been perpetrated, and it must be confessed that the mischief effected has been prodigious. It has killed lithography—the chalk branch at least; chromo-lithography has escaped, and will enjoy immunity until the secret of producing photographs in colour is discovered. It is killing the beautiful craft of drawing upon wood, and, allied with all kinds of electro "processes," it is killing the art of wood-engraving itself. It has nearly slain the art of portrait-drawing in crayons; although a good many French and a few English portraitists are fighting a valiant fight in the production of drawings in charcoal, and in "sanguine" or red chalk; while the enterprise and taste of Sir Coutts Lindsay have succeeded in giving fresh life to the beautiful, but almost moribund, art of pastel. Photography, however, has utterly and, it is to be feared, irrevocably slain the art of miniature-painting. The names of Carpenter, of Mee, of Margaret Gillies, of Thorburn, of Ross, of Karl Schiller, seem almost to belong to ancient history, and at the summer exhibitions of the Royal Academy miniatures have become almost as rare as enamels. Yet it is questionable whether the good deeds done by photography have not very far surpassed the artistic evil which it has undoubtedly wrought. The services it has rendered to the cause of archæology and architecture have been immense. Photography has lightened the labours of the botanist, the ornithologist, the comparative anatomist, the decipherer of manuscripts, the entomologist, the aeronaut, and the meteorologist. It has given material assistance to those whose calling is the detection of crime. It has been literally the traveller's joy and the solace of those who have never been able to wander to far-distant lands, of the scenery of which they are able, through the medium of the camera, to view exact and picturesque transcripts. Photographic portraiture, again, as a means of pleasant intercommunication between widely separated kinsfolk and friends, and as an agent for the cultivation of the domestic affections, has been productive in degree of comparatively as much social benefit to the community at large as cheap postage itself. Who are so poor and lowly, "so accursed by fate, so utterly desolate," as not to have been able to afford at some time or another a photographic portrait of themselves or of those they have loved, even though the counterfeit presentment has been taken for a few pence on the sands at a watering-place?

* From *The Journal of the Photographic Society of India.*

Correspondence.

PHOTOGRAPHY AND ILLUSTRATED PAPERS.

Sir,—My attention has just been called to a paragraph in your "Notes" of January 24th, in which you remark, referring to photography, that "The one man who, it would be thought, should have been among the earliest to practise the art, has not touched it; we mean the descriptive reporter." And then, referring to the new venture of the *Daily Graphic*, you add, "He may see the necessity."

Now, sir, I have seen the same, or similar assertions, made repeatedly in the photographic press; but, from personal experience, I feel bound to dissent from them. I happen to be on the staff of one of the leading trade journals, and some years ago, seeing the importance and usefulness of learning the art of photography, I did so, and although my work with the camera, and also with the "detective," has become my chief hobby, and I have so improved myself that no branch of the art comes amiss, yet I find it of no use whatever; certainly, for our own journal, I sometimes take a photo for reproductive purposes, but although I have offered my services to most of the leading papers, including the *Daily Graphic*, I am met with the stereotyped reply that they prefer pencil artists, who are capable of making rough sketches. As to my descriptive powers, they are fully appreciated by some half-a-dozen periodicals that I contribute to, but whenever photography is mentioned it is pooh-poohed. Practically, the only use I have as yet been able to put it to has been the illustration of some of my own stories; but for the newspaper proper—daily or weekly—it has as yet failed to grasp the use of descriptive writer and photographer combined.

I merely write this letter to give you the experience of one who has endeavoured to push himself forward on the lines you recommend for some years past, but finds there is no opening.

George Brown.

25, *Sturgeon Road, Walworth, S.E., February 1st.*

Manchester Amateur Photographic Society.—A Photographic Exhibition will be held at the Manchester Athenæum on Thursday, Friday, and Saturday, February 13th, 14th, and 15th. Open Thursday, 6 to 10 p.m., Friday and Saturday, 10 a.m. to 10 p.m. The Council have arranged for a lantern exhibition at 8 o'clock each evening.

Specifications Published.

2,623.—*14th February*, 1889. "Flash Lamp." JOHN LEISK, 169, Commercial Street, Lerwick, Shetland, Merchant.

My invention relates to a new or improved form of flash lamp, for the rapid or instantaneous combustion of magnesium powder applicable to photographic or other purposes, whereby the powder is propelled by centrifugal force outwards, equally all round, from the surface of a circular horizontal rapidly revolving disc, into a suitable flame or flames completely surrounding the said revolving disc, thus securing the total combustion of the metallic powder under conditions favourable to obtaining the maximum of incandescence, the result being an instantaneous flash of actinic light circular or globular in form and many inches in diameter, which, from its large area and diffusive power, is eminently suitable for photographic purposes. All in contra-distinction to the methods heretofore used of projecting the magnesium powder by means of an air current into a suitable flame, either horizontally, obliquely, or vertically, by which mode, in some instances part of the metallic powder passes through the flame unconsumed, and in all the cold air introduced into the flame tends to disturb the same, lowers the temperature, and prevents the maximum incandescence of the magnesium powder used.

By one arrangement my invention may be constructed as follows :—

A bed plate of metal or other suitable material, and which may be five inches square, is prepared, and on each corner of the same is erected rigidly a stout pillar one and a quarter inches high. A second plate, of same size as the first, is now placed on the top of these pillars, to which it is attached by screws or otherwise.

Pivoted to the centre of the lower or bed plate, and rising perpendicularly through an opening in the centre of the upper plate, is an arbor or spindle, about three inches long, on the upper end of which is rigidly fixed, at right angles by its centre, a circular metal disc about one and a half inches in diameter, the said arbor being fitted so as to revolve easily, and being provided with the necessary collars or shoulders to prevent it leaving its bearings.

To the lower part of the said arbor is attached a coiled spring for revolving the same, and also a ratchet wheel and suitable detent for stopping the spring when wound up.

By another method an india-rubber band may be substituted for the coiled spring.

There is also attached to the bed plate a suitable trigger arrangement, brought by pneumatic or other means under the control of the person using the lamp, by which the detent can be instantly removed from the teeth of the ratchet wheel when a flash is required to be made.

Resting upon the upper plate is a circular spirit lamp or burner, made of metal in the form of a flat, hollow ring two and a half inches in diameter, one and a quarter inch broad, and one eighth of an inch or more in thickness. The wick of this lamp, preferably of asbestos, protrudes from the upper open edge of the ring aforesaid, the other edge being closed and resting upon the plate, while a small capped reservoir at the side, connected to the ring or burner by a short tube, supplies the wick with spirit. This circular lamp or burner is attached to the upper plate in such a manner that it shall surround equidistantly the circular disc and arbor before mentioned, with the surface of the wick at a level one half of an inch below the upper surface of the said circular disc, the part of the top plate thus enclosed being freely perforated so as to admit a free current of air from below between the circular disc and the spirit lamp wick. An annula cap for extinguishing the spirit lamp is also provided.

By another arrangement a circular Bunsen burner or circle of gas or other flames may be substituted for the spirit lamp in conjunction with the revolving mechanism before described for igniting magnesium powder and producing a flash.

To use a flash lamp as before specified : the lamp is first filled with methylated spirit. The spring is then wound up by turning the circular disc at the top of the arbor. The charge of magnesium powder, which may be three grains or more, is then spread on the upper surface of the aforesaid disc, and the spirit lamp lit ; the detent is now withdrawn from the ratchet wheel, when the coil spring thus suddenly released, causes the arbor and disc instantly to rapidly revolve on its axis, and by the centrifugal force thus generated to scatter the charge of magnesium powder into the adjacent flame of the lamp, thereby producing an instantaneous flash of maximum size and brilliancy with a minimum of powder used.

Having thus described my invention, the chief feature of novelty of which consists in utilizing centrifugal force to project the magnesium powder into one or more suitable flames, the mechanism here described for carrying out that principle may be somewhat varied in details or size ; the measurements before given being merely relative, must be varied to suit other sizes of flash lamps.

When used for taking photographic portraits a suitable reflector and diffusing screen should be used in conjuction with the lamp herein described.

2,723.—*February 16th*, 1889. "Controlling Exposures when Using-Flash Lamps." FREDERIC WILLIAM HART, 8 and 9, Kingsland Green, London, Manufacturer of Scientific Instruments.

The object of this invention is for controlling the exposure of the sensitive photographic plate or plates. in lighting single or grouped objects to be photographed by flashing light or lights ; it has been found that some persons and lower animals involuntarily move either the body or more frequently close the eyelids very shortly after the flash commences ; to render this movement of little or no moment I employ a stop-cock with two separate ways, or two separate stop-cocks actuated simultaneously by one lever or turnkey ; each way is connected with a separate air chamber in which is air or gas under pressure : one conducting tube for air goes to the flash-lamp, and the other to the pneumatic release of an exposing shutter ; their relative times of discharge are so adjusted that the shutter exposures take place at the early part of the flash or combination of flashes, and according to the volume of light provided so the actual exposure of the plates may be reduced to a very small fraction. It has been found impracticable for many to accomplish the double movement for flash and shutter by simple hand pressure on balls at the right instant of time. It has also been suggested to connect the exposing shutter-release with the same air-ball or chamber that discharges the magnesium, but as the air does not escape at the shutter's release, but exerts pressure, and

on the other hand the tube to the flash-lamp is practically open, it is seen that such an arrangement could exert no practical pressure at the shutter-release.

The inventor claims :—

1st. The combination of a two-way stopcock, pneumatic release-shutter, and flash-lamp or lamps.

2nd. The combination of two air or gas chambers and stop cocks in line, the discharge ports of the plugs being adjustable one to the other by means of a graduated disk and index.

3rd. The combination of a two-way stopcock with separate air chambers, valves, and air compressing balls or pumps.

4th. The combination of two separate air chambers, each with stopcock and their plugs in line, their axes connected through a prolongation and set screw, or the stopcocks placed parallel, and worked by an intermediate tooth wheel.

15,289.—28*th September*. 1889. "Shutters for Photographic Apparatus." Newnham Browne, 73, Cheapside, London, Fellow of the Institute of Patent Agents, communicated from abroad by Richard Kindler, Friedrich Str. 29, Dresden, Mechanician and Optician.

The invention relates to shutters for photographic apparatus, which contain two plates, one placed over the other, and capable of longitudinal motion with reference to one another, each plate having an aperture, and which two plates in their positions at the end of their stroke close or cover the lens, whilst when the plates travel from one extreme end of their motion towards the other, they uncover or expose the lens for an instant at the time when the apertures in the two plates are coincident.

The improvements relate partly to the mechanism and adjusting devices causing and controlling the motion of the shutter-plates, and partly to the arrangement of the plates themselves, whereby the manner in which the exposure is effected is controlled.

Mr. E. Muybridge will, we understand, shortly give a second lecture in Manchester on "Animal Locomotion."

Specimens of the late Mr. Rejlander's photographs can be obtained made up in albums from Mrs. Rejlander, 2, Waverley Villas, Bruce Grove, Tottenham.

A contemporary says that a mother whose sons were tending cattle on her estate, named the estate "Focus," because, she said, it is where the sons raise meat.

A light basket-case for a half-plate camera has been received for inspection. Shortly we shall return to the subject of basket-work for photographic purposes, to bring forward some fresh points.

The annual dinner of the Photographic Society will be held on February 10th, at 6.30 p.m., at the Café Royal, Regent Street, London. Tickets, six shillings each, may be obtained from Mr. William England, 7, St. James's Square, Notting Hill, London. Evening dress optional. Ladies will be present.

In our last number, we stated, in a paragraph about illustrated journalism, that *The Daily Graphic* had to apologise for a blunder in regard to one of its illustrations. We find that this statement is not correct, and accordingly express our regret at its insertion, and offer to our contemporary our sincere apology.

Proposed Lantern Club.—Mr. T. H. Holding, whose letter respecting this project appeared in our issue of January 17th, writes as follows :—"Permit me to notify that a meeting will be held in the Upper Regent Saloon of the St. James's Hall Restaurant, (Regent Street and Piccadilly), on Thursday, February 20th, at 8 p.m. I have to ask those who can attend to send in their names either to the Hon. Slingsby Bethell, Chelsea Lodge, Chelsea, or to myself, before that day. Possibly there are those who will have engagements, and, nevertheless, are in sympathy. We shall be glad also to have a word from them before the 20th, as it will be useful. Any suggestions which any gentleman may have and will embody in a brief letter, shall be put before the meeting.—T. H. Holding, 46, *Chesilton Road, Fulham, S. W., 7, Maddox Street, W.*"

Proceedings of Societies.

The Camera Club.

On January 30th, Mr. T. R. Dallmeyer read a paper entitled "Practical Interpretations of the Law of Conjugate Foci." Mr. Lyonel Clark occupied the chair.

The Hon. Secretary handed round a matt surface silver print, sent by Mr. Quick, in which the note paper on which his letter was written had been sensitised and printed upon with good results.

Mr. Dallmeyer showed a graphic method of illustrating the equation representing the law of conjugate foci, by the properties of lines drawn within the circumference of a circle. He also showed applications of the law of conjugate foci, whereby the purposes of a view-meter were served, and also to give indications of the object focussed for being actually in focus. These included one by Mr. Berthon, one mentioned by Mr. Traill Taylor, and one described and illustrated by an instrument by Mr. Dallmeyer himself.

The subject on Thursday, February 13th, is "Landscape," when a paper will be read by Mr. Graham Balfour.

London and Provincial Photographic Association.

At the meeting on the 30th ult., Mr. T. E. Freshwater occupied the chair.

Mr. A. Cowan said that he had continued his experiments with a view to test what part the alkaline salts played in the developer in connection with and without sulphite of soda. Two plates were shown, one developed with a ten per cent. solution of sulphite, and the other with a twenty per cent. solution of sulphite, two grains of pyro being used in each case. The increased strength of sulphite added considerably to the density of the image.

Mr. A. Haddon was still of opinion that the developing power of sulphite was due to its degree of alkalinity. Three solutions he had tested, all indicated the presence of excess of alkali.

Mr. J. B. B. Wellington exhibited a 15 by 12 collodio-bromide plate, showing after development innumerable black spots ; these spots were absent in small plates coated with the same emulsion.

Mr. W. E. Debenham thought the spots might be caused by the plate not having been thoroughly clean.

The Chairman drew attention to a report in one of the journals of the bursting of a gas cylinder. Remarking upon the danger of sending out both oxygen and hydrogen in black bottles, which in many instances was done, he would urge upon all users of the two gases to insist upon having these gases delivered in red and black bottles.

Dundee and East of Scotland Photographic Association.

February 6th.—The first popular lecture this season, under the auspices of the above Association, was given in the Kinnaird Hall on Wednesday by Mr. J. W. McCall. The scenery illustrated was that of Orkney, Shetland, and Greenland ; the pictures had been prepared by Messrs. Valentine and Sons. A large screen was used, some thirty feet square, and special lantern arrangements had to be made.

Starting from Kirkwall, with its celebrated cathedral, the various islands were visited in turn, and the Orkney group was next shown, besides views of Lerwick, Stromness, and Scalloway, the old castles and ruins found on the various islands, and scenes illustrative of the habits and customs of the natives. The series closed with views of the Tay and Forth Bridges; several other large structures were also shown by way of contrast.

Sheffield Photographic Society.

The monthly meeting was held on Tuesday evening, the 4th inst., at the Masonic Hall, Mr. B. J. Taylor in the chair.

A series of 180 slides was passed through the lantern, which was manipulated by Mr. G. Bromley.

On the table were laid the competitive enlargement pictures, prizes for which had been given.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

AT the meeting held on the 30th January, at 3, Lord Street, Mr. PAUL LANGE occupied the chair.

Messrs. J. W. Warburton, M.D., John Price, M.I.C.E., Rev. G. F. Wills, H. Cope West, E. S. Gladstone, B. Cooksou, and J. Watkins were elected members.

Mr. P. LANGE spoke at some considerable length as to the benefit derived from Conventions generally, more particularly when attention was drawn to something really practical. He advocated that a better feeling should be cultivated with kindred Societies, and drew attention to the Chester Conference to be held shortly, of which Mr. F. Evans was the Secretary.

A short discussion on the subject of "The Best Lenses for Detective Work" then followed, in which Messrs. Sayce, Wilkinson, Earp, Lange, Kirby, Williams, Tomkinson, and Swinden took part. It was pretty generally allowed that an ordinary French lens, working at *f* 11 with a rapid shutter, gave good results; especially so when working with a lens covering the next larger sized plate than the one used.

Mr. W. J. ARCHER exhibited a selection of Woodbury lantern slides and a series of views of the Paris Exhibition, including a few panoramic slides, which gave great satisfaction.

The exhibits consisted of snap shots by W. Wilkinson, on glass and film; new lantern slide carrier, by W. J. Chadwick (Manchester); and Mawson and Swan's transparency and photograph frame.

The twenty-sixth report of the above Association sets forth that the President and Council have much pleasure in congratulating the members on the continued prosperity of the Association. In previous reports the attention of the latter had been drawn to the years 1883 and 1884 as phenomenally prosperous ones, showing in the former 32 new members and in the latter 37—an increase of 69, and accounted for by the increased facilities offered to amateurs by the introduction of the gelatine dry plates.

In the years 1888 and 1889, there has been a yet greater increase; in the year 1888 there were 49 new members, and in this year 74, showing an accession of 123, or an increase as compared with 1883 and 1884 of 78 per cent. In 1889 alone the number exceeds that in 1883 and 1884 together. The accession to the roll of membership has been the highest yet attained, and the total number of members 238. There can be little doubt that this increase is in a great measure due to the prominence the Association secured in connection with its exhibition held in the Walker Art Gallery in 1888, and to the securing of club rooms situated in the centre of the city, giving members such convenience, comfort, and advantages of association as cannot be surpassed by any similar photographic society in the Kingdom.

The following is a record of the numbers joining the Association during each year of its existence, viz.:—1863, 17; 1864, 4; 1865, 1; 1866, 0; 1867, 1; 1868, 0; 1869, 3; 1870, 1; 1871, 1; 1872, 3; 1873, 2; 1874, 4; 1875, 2; 1876, 2; 1877, 7; 1878, 7; 1879, 6; 1880, 6; 1881, 8; 1882, 19; 1883, 32; 1884, 37; 1885, 23; 1886, 18; 1887, 19; 1888, 49; 1889, 74.

The number of members at the commencement of the year 1889 was 181, and 17 have left the Association, thus making the net number at the present time 238. The numbers on the books for the last six years are as follows:—In 1884, 138; 1885, 134; 1886, 140; 1887, 144; 1888, 181; 1889, 238. There have been two removals by death, viz.:—W. P. Riley, a member of the Council, and one of the most promising and active members; and C. J. Renfrey, who had but recently joined the Association. The Association has also lost the services of two valued members of the Executive, owing to business appointments removing them from this part of the country, viz.:—H. N. Atkins, Vice-President; and W. A. Watts, M.A., Hon. Secretary. These vacancies have been filled by P. Lange to the former, and W. Hughes to the latter. W. H. Tyerman and C. A. Timmins have been elected to fill the other vacancies. The year 1889 is prominent in the records of the Society on account of the permanent club rooms which have been so happily acquired. The committee appointed to select and furnish suitable premises for the club rooms consisted of the following members:—Messrs. J. H. Day, J. Earp, A. W. Cornish, A. W. Beer, B. J. Sayce, and G. H. Rutter; but before any action was taken Messrs. B. J. Sayce and G. H. Rutter retired from the Committee, and Mr. H. Lupton was elected in their place. The Committee thus formed was subsequently appointed as the "House Committe." Owing to the substantial balance from the Exhibition account of £257 18s., and the ordinary balance on the 24th November, 1888, of £77 8s. 5d., making £335 6s. 5d., the long-desired wish of many members has been attained. Thanks to the House Committee and to Mr. Day, their Secretary, a number of works of art have been secured for the adornment of the room from Messrs. H. P. Robinson, "Carolling," and own etching; F. M. Sutcliffe, "Water Rats;" R. Keene, "Tissington Spires;" A. Pringle, "Dove Dale;" Rev. H. B. Hare, "Thirsty Moments; W. W. Winter, J. P. Gibson, B. Wyles, H. S. Mendelssohn, M. Auty, Rev. H. J. Palmer, and F. Whalley. The rooms have been well furnished, and the comfort and convenience of members have, as far as practicable, been attended to. An enlarging camera has also been provided for the convenience of members, and has been of service to many. The entrance fee on membership has been increased to £1 1s. The Treasurer's account shows a balance remaining to the credit of the Association of £48 13s. 8d. after investing the sum of £194 14s., and writing off £14 5s. 4d. as depreciation on club room furniture, &c. There has been a great increase and improvement in photographic work done by the members this year, and it is encouraging to note that, instead of the higher class of results coming only from a limited few as heretofore, there is now a fair distribution amongst the younger members. Nothing of a very startling character has been submitted to photographic workers generally during the year. Developers are now fairly divided in numbers of their respective adherents—pyro-ammonia and hydrokinone; yet another "Richmond" has appeared in the shape of Dr. Andresen's "Eikonogen," of which we may hear more next year. Celluloid films have apparently displaced "paper"-work to a great extent, and have recently been much improved. Platinotype has been increasingly adopted, the process being simple, results artistic and permanent, and the price of the paper has been greatly reduced. Much attention has been directed to "detective" or hand-camera work, though, as yet, with but limited success; still, the difficulties attendant upon this interesting branch of photography have been met with praiseworthy determination, and many ingenious devices and improvements have been affected, notably the camera invented by two of our members—Messrs. Swinden and Earp—which obtained the only medal given for apparatus by the Photographic Society of Great Britain at the recent Exhibition at Pall Mall, keeping up the traditions and *prestige* of this Society in the advancement of photographic art. Early in the year we received from the Boston (U.S.) Camera Club a series of lantern slides, in trust, for exchange with other societies, entitled "Illustrated Boston," and which has been *en tour* during the year. The series was carefully prepared, and reflects the highest credit on the Boston Camera Club for the manner in which the slides were completed as a representative set. The idea was one worthy of following, and the Council has requested the members of this Association to make up a Liverpool set as a "return" series for the Boston Club, and also a representative set for reciprocal exchange with other societies in our own country, especially as so many societies have already adopted the plan as a great incentive to individual work, and an encouragement to the respective societies in a new branch of activity. The meetings have maintained their interest throughout the year. Papers have been read and demonstrations given by Messrs. W. Tomkinson, on "An Easter Trip to the South of France and Northern Italy"; F. A. Bartlett, M.A., on "A Month in Normandy and Brittany"; J. Earp, on "Ten Days in Holland and Belgium with a Hand Camera"; S. J. H. Dearle, on "English River Scenery"; P. Lange, the representative series of lantern slides sent by the Birmingham Society; W. A. Watts, M.A., the "Illustrated Boston" slides sent by the Boston (U.S.) Camera Club; F. T. Paul,

F.R.C.S., a demonstration on "Micro-Photography"; Vero C. Driffield, paper on the "Actinograph"; G. A. Kenyon, M.D., on "Film Photography"; P. Lange, demonstration on "Enlarging"; H. Wilkinson, paper on "The Intelligent Use of the Detective Camera;" G. E. Thompson, on "Rambles along the Riviera, from Marseilles to Genoa;" J. S. Brown, "From Cairo to the Cataract;" Messrs. Sinclair, Tomkinson, and Tunstall, on "Normandy and Brittany;" while discussions have taken place upon "Cloud Negatives," "Warm Tones by Development in Lantern Slides," "Eikonogen as a Developer," and also upon the various demonstrations, papers, and novelties submitted to the meetings. Much interesting work has been shown and other exhibits brought forward by Messrs. W. Rogers, E. Roberts, S. J. H. Dearle, P. Lange, J. Comber, H. Wilkinson, A. W. Beer, W. Tomkinson, T. S. Mayne, C. A. Timmins, E. M. Tunstall, J. L. Mackrell, J. A. Forrest, H. Holt, R. Crowe, B. J. Sayce, W. C. Bustard, A. F. Stainstreet, and others. The social element has also received attention. Four smoking concerts have been held, and largely attended.

The annual competition for Prints, Enlargements, and for Lantern Slides has received increased attention from the members this year, and some excellent work has been submitted.

The thanks of the Association are due to the following judges, viz.:—*For Prints and Enlargements*—G. Watmough Webster, F.C.S., John Finnie, and E. Rimbault Dibdin. *For Lantern Slides*—G. E. Thompson, Paul Lange, W. D. Mead, and E. Landseer Grundy.

The judges' award is as follows:—

		Sets No.	Name.
Set of six prints, half-plate and under...	*Silver Medal*	11	T. B. SUTTON.
	Bronze Medal		W. TOMKINSON.
Set of six prints, over half-plate ...	*Silver Medal*	4	J. L. MACKRELL.
	Bronze Medal		D. CUNNINGHAM.
Set of two enlargements	*Silver Medal*	4	F. K. GLAZEBROOK.
	Bronze Medal		J. L. MACKRELL.
Set of six lantern slides	*Silver Medal*	23	A. J. CLEAVER.
	Bronze Medal		T. B. SUTTON.

The excursions arranged for out-door photography this year have been numerous, and the following table of particulars of attendance and results will no doubt be interesting:—

Date.		Place.	Attendance.	Exposures.
April	22	Ludlow and District ...	*	—
May	4	Rossett	15	56
	18	Instantaneous—River	7	60

	11	Excursions ...	168	913
Last year ...	3	,, ...	49	362
Increase ...	8	,, ...	119	551

Arrangements were made for sixteen excursions, but five (*) had to be abandoned; the attendance at the eleven excursions was 168, and the number of exposures made was 913. As compared with last year, there is an increase in the number of those present of 119, and in the exposures 551.

The following are the officers of the Association for 1890:—*President*, Mr. Paul Lange; *Vice-presidents*, Messrs. Wm. Tomkinson, W. D. Mead; *Treasurer*, Mr. Joseph Earp, c/o Edward Thin, 3, Rumford Place; *Council*, Messrs. W. H. Tyerman, D. Lewis, C. A. Timmins, G. H. Rutter (to serve one year); R. Crowe, E. Roberts, B. J. Sayce, J. H. Sinclair (to serve two years); A. W. Beer, J. H. Day, E. M. Tunstall, J. L. Mackrell (to serve three years); *Librarian*, Mr. J. McDonald Bell; *Auditor*, Mr. A. Bradbury; *Hon. Secretary*, Walter Hughes, 3, Lord Street, Liverpool.

DERBY PHOTOGRAPHIC SOCIETY.

ON Wednesday night the members of the Derby Photographic Society held their annual conversazione at the St. James's Hall. The work of some of the members of the Society was exhibited in the room. Among the exhibits, many of which consisted of well-known local scenes, prints were shown by Messrs. Winter, Keene, Thomas Scotton, A. B. Hamilton, C. J. Chadwick, C. Bourdin, W. Hart, and others. In addition a competition had been organised by the Society, three prizes being offered for the best work by amateurs, for which the following seven entered: Messrs. F. Benrose, C. Bourdin, C. J. Chadwick, Cope, A. B. Hamilton, T. A. Scotton, jun., and G. Walker. The judges (Messrs. Simmonds and Arthur Cox) had some difficulty in making their awards. Eventually, Mr. T. A. Scotton, jun., took the first prize with a photograph of a country lane near Birmingham. Mr. Bourdin was awarded the second prize; the scene of his photograph was "Derby from Exeter Bridge," and the third prize fell to Mr. C. J. Chadwick, whose picture was a scene at "King's Mills." The judges also highly commended the work of Mr. A. B. Hamilton, who from a lady's photograph had taken the head as a statue.

In opening the proceedings, Mr. HERBERT STRUTT, J.P., delivered a brief address, and said that in an assembly like that, he should be the last person to introduce any controvertial matter or technicality, because he was fully aware of the fact that he was speaking to gentlemen who knew more about art than he did himself, and he should only display his ignorance. He thought no one present needed to be told that during the past ten years the number of amateur photographers had greatly increased, the reasons having been the great reduction which had taken place in the cost of the outfit and the simplification of the process. The result was that the number of amateur photographers was about 500 per cent. larger than it was ten years ago. He looked upon the art as one of the most fascinating that could be taken up, not only because it led one to the most interesting places, but when they had taken the photographs they could enjoy the sight of them for the rest of their lives. He had spoken of the increase of amateur photographers, and he might say that their Society, which was established in 1884, had now about sixty-five members.

During the evening Mr. F. G. PIERPOINT, of Leicester, gave an exhibition of lantern slides, executed by the members of the Society, and Mons. Julien Lachapelle a shadowgraph. In addition, Mrs. Sim, Mrs. Hamilton, Capt. Sim, and Mr. Drury took part in a musical programme.

PHOTOGRAPHIC SOCIETY OF PHILADELPHIA.

A MEETING of the Society was held January 1st, President FREDERICK GRAFF in the chair.

The secretary read a communication inviting entries to the exhibition of the Worcestershire Camera Club at Kidderminster, to be held from March 1st to 15th. A prospectus accompanied the communication.

The annual report of the treasurer was presented, showing a cash balance on hand of 820.68 dollars.

The annual report of the Executive Committee was read, giving a resumé of the work of the Society for the past year. A number of valuable additions to the library had been made, and a considerable sum expended for binding of journals.

Reference was made to various papers read before the Society, to the Third Annual Joint Exhibition held under the auspices of the Society during the month of April, and to the Fall Competitive Exhibition, now in progress, from which the Honour pictures for 1889 would be selected.

The Committee on Lantern Slides reported as follows: At the Conversational Meeting, held December 18th, the interchange slides shown were those of the Syracuse Camera Club. This organization was admitted to the American Lantern Slide Interchange only this year, and their first contribution was

creditable to the members of the Club, and a pleasure to the members of this Society who saw them. There were seventy-six slides in all, most of them on gelatine dry plates, and represented a wide stage of subjects, including some fine studies in Europe.

Dr. Charles L. Mitchell showed fifty slides, on gelatine plates developed by eikonogen. The views were chiefly marine studies, made with a Hawkeye Detective Camera, and the cloud effects in most of the views were excellent.

The election for officers and committee for 1890 resulted as follows:—*President*—Frederic Graff; *Vice-Presidents*—John G. Bullock, Joseph H. Burroughs; *Secretary*—Robert S. Redfield; *Treasurer*—Samuel M. Fox; *Executive Committee*—Ellerslie Wallace, M.D., Charles L. Mitchell, M.D., Edmund Stirling.

A paper prepared by Dr. Charles L. Mitchell and Mr. John G. Bullock on the "Dangers of Flash-Light Compounds," was read by Mr. Bullock (see p. 109).

Bath Photographic Society.

January 29th.—Meeting at 10, Quiet Street, Mr. W. Pumphrey in the chair. Messrs. H. J. Lewis, H. G. P. Wells, D. Swain, and J. S. Gibbs were elected ordinary members. Messrs. Ernest Pitman and J. Day were appointed auditors.

A circular letter was read from Dr. P. H. Emerson, offering a copy of his work, "East Anglian Life," to the Society. This generous proposal was accepted with thanks.

Messrs. Dugdale and Davis then, by means of the oxy-etho light, showed a series of views representing places visited by the Society during the summer excursion.

Dr. Dutton passed round developed prints on celluloid, opal, and cardboard. He remarked that the percentage of failures with celluloid was high.

The annual meeting will be held on February 26th.

Manchester Amateur Photographic Society.

The fifth annual report was presented at the annual general meeting held at the Manchester Athenæum, Princess Street, on Tuesday, January 28th, from which we give the following:—

Eighty-six new members have joined since the fourth anuual meeting, and during the year there have been no fewer than 353 members on the books. The present actual numerical strength stands at 293 members.

The Treasurer's account shows a balance in hand of £44 8s. 10d., as against £41 3s. 9d. last year.

An addition of 17 volumes has been made to the library during the year, making a total of 171 volumes. The number of books issued to the members was upwards of 250.

Since the issue of the last report there have been added to the apparatus belonging to the Society a fine lime-light enlarging lantern, at a cost of £13 (exclusive of the condensers, which were presented by a member), a lime-light lantern, costing £20 8s., and a screen. In addition to the lanterns, the Society has a slide cabinet containing upwards of 300 slides contributed by members, which slides have been in much request during the year.

The Camera Club.—The *Camera Club Journal* says about the probable new premises of the Club:—"Provided that the details now under arrangement can be settled to our satisfaction, these premises will be erected to comprise five floors and a spacious basement, the entrance to the building belonging solely to the Club. The divisions into rooms will probably be as follows:—Eight or nine separate small dark rooms, work-room and storage, a waiting-room and porter's lobby, large meeting-room, still-room and offices, library, billiard-room, workshop fitted with lathe, &c., committee and secretaries' rooms, grill-room, kitchen, resident porter's rooms, studio and enlarging room, and lead flats."

Received.—From Messrs. Perken, Son, and Rayment, a simple and inexpensive magnesium-ribbon lamp—an improvement on one figured and favourably noticed in these columns about a twelvemonth since.

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

Ligroine Lamp.—A correspondent in Vienna has been good enough to seek out the maker of this incandescent lamp, which costs 22 gulden (about £1 18s.) all complete, with benzoline boiler, gas burner, and a spare Welsbach gauze. Our friend saw it in action. The power is said to be 100 candle-light, and it works very efficiently, bearing out Dr. Eder's report of it. The maker is Herr C. Fabricius, II Erzherzog Karl Platz, No. 16, Vienna. Benzoline vapour mixed with air is burnt at a jet surmounted with a Welsbach incandescent gauze, giving a brilliant white light. See Year-Book, page 170.

Pr. O. S.—The best hand camera. If you are intent upon using glass plates, the camera mentioned is as good as any, but the most portable form is now the new Kodak No. 2, worked with a roller of flexible celluloid. This gives circular pictures of 3½ inches diameter, very suitable for lantern transparencies, but of course not answering your requirement of taking negatives 3½ by 5 inches.

Noriam.—Plate-glass for studio roof. Under the special circumstances of your case, being already in possession of a large square of plate-glass, it might be well to make it do duty as part of the roof of your studio. The lower slope, and not the top light, is certainly the best place to put it, for in this position it may rest on a faced iron horizontal ledge fixed directly on the iron support as sketched. With regard to the probability of its changing colour, examine carefully the edges with a white card behind to see whether, in the protected parts under the rabbet, where it was originally screened from sunlight exposure, there is the slightest indication of a paler tint than in the rest of the glass, and be guided accordingly.

M. W.—Your letter was duly received and acted upon a fortnight ago. You will know the result next week in ordinary course.

W. T. D.—The back numbers of the *Photographic Times* (1889) are not just now accessible at the Patent Office Library; they have been sent away to be bound. There is no English patent in the name of F. Winterhoff. You probably saw a notice in this column last week, asking for information as to present address.

Residues.—You are using vastly too much chrome alum in your fixing bath, and every fresh addition of potassium sulphide merely precipitates the oxide of chromium along with the sulphur. But the silver is thrown down first, and this with a moderate quantity. When you smell sulphuretted hydrogen in the liquor you have added enough, or you can tell by the colour of the precipitate. The zinc method of reduction is slow and unsatisfactory.

W. H. L.—Gelatino-Chloride Printing-Out Process. Dr. Barker's formula:—

Nelson's No. 1 gelatine	175 grains
Coignet's gelatine	175 ,,
Sal ammoniac	36 ,,
Rochelle salts	100 ,,
Nitrate of silver	150 ,,
Alcohol	1 ounce
Water	10 ounces

Soak the gelatine in part of the cold water, then heat to 100° Fahr. with all ingredients added, and maintain at this temperature for ten or fifteen minutes after everything is dissolved. See also page 201 of the Year-Book, for Ashman and Offord's formula for a Citro-Chloride paper.

Flux.—In addition to the details given last week, we may refer you to "The Reducer's Manual and Gold and Silver Worker's Guide," by Victor G. Bloede, published in New York (J. H. Ladd), and to be had of Messrs. Trübner and Co. The little book is full of practical details which cannot fail to be of service to you.

Other correspondents in our next.

PENZANCE HARBOUR

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1641.—*February* 14, 1890.

CONTENTS.

FOCUSSING APPLIANCES.

PLENTY of room exists for improvements in focussing appliances for photographic cameras, and a recent invention in connection therewith made by Mr. Frank Bishop, of the firm of Messrs Marion and Co., may be explained by the aid of the accompanying diagrams. It consists of an ordinary focussing glass and tube, and to this larger tube a smaller one is soldered, as in Fig. 1. The smaller tube ends in a small india-rubber cup, which, when wetted, will hold on by the pressure of the atmosphere to the polished side of the glass focussing screen, and can readily be pushed about with an easy, sliding motion, to any part of the surface; in short, it is on the principle of the "sucker" used by schoolboys. The object of the invention is to allow the photographer the free use of both his hands while focussing, instead of employing one of them to retain the focussing glass in position, and this purpose it achieves admirably. Fig. 2 represents the focussing glass holding on, limpet-like, to the screen, as it does when in use. It adheres with considerable tenacity.

Fig. 1.

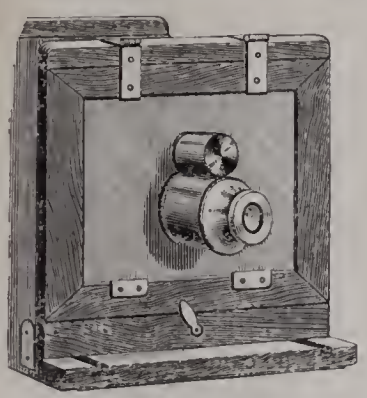

Fig. 2.

The method recommended in another column by Mr. Varley of using ground glass to ascertain the exact amount of subject upon the plate, and afterwards a plain piece of glass with scratches upon it to get a critical image, is often employed in photo-micrographic work; but it is doubtful whether it will ever come into general use with ordinary cameras, especially those for outdoor purposes; in the latter case it would form an item adding somewhat to the weight of the instrument, and be a step in the direction of complexity rather than of simplification. Probably what may be called a "piebald" screen would answer better, that is to say, a screen of finely ground glass, with perfectly transparent spots a quarter or a third of an inch in diameter scattered over its surface. The ground glass would give the general view, and the spots would favour the easy focussing of a critical image.

A good focussing screen made on the principle of those now in common use would consist of much finer ground glass than such as is ordinarily employed, and more approaching in appearance unground glass. With two lenses on Ramsden's principle mounted in one tube, a focussing glass is formed transmitting much more light to the eye than those at present in use, and when employed to view the image upon exceptionally fine ground glass there is a pleasure and ease in focussing to which the majority of photographers are entirely unaccustomed; when once they have tasted the luxury they will never return to the present appliances. Now that the magnesium light is coming into more general use, and that the operators have usually to focus beforehand by gaslight or lamplight, the desirability of being able to get a brilliantly illuminated critical image when focussing, is all the more palpable.

THE "PHOTOGRAPHIC NEWS" SUPPLEMENT.

TO-DAY we issue as a Supplement a photo-mechanical reproduction, on a reduced scale, of the photograph of Penzance Harbour, by Col. W. Noverre, which was so much admired at the last Photographic Exhibition. The original was upon very rough drawing paper, and was of a terra-cotta red colour.

ATHANASIUS KIRCHER, THE INVENTOR OF THE MAGIC LANTERN.—No. I.

BY JAMES MEW.

SOME years ago* an occasion was taken to notice in the columns of this paper a communication made to the London and Provincial Photographic Association by Mr. W. H. Harrison, containing many interesting and historical notes on the optical or magic lantern. In this communication we learnt that the magic lantern was invented by Athanasius Kircher in the year 1646. A few lines, which many of the present readers of the PHOTOGRAPHIC NEWS have never seen, and many others perhaps forgotten, may be here copied out of that interesting and ably conceived communication. "There are," says Mr. W. H. Harrison, "speculations that the magic lantern may have been known before Kircher's time. Some have ascribed its invention to Roger Bacon, who, in his 'Discovery of the Miracles of Art, Nature, and Magic,' written about the year 1260, displays knowledge of the uses of lenses. Others have speculated that it may have been known to Egyptian hierophants, because they understood the properties of concave mirrors. Cellini, who died about 1570, describes spectres which had been seen in ascending smoke, and it has been said that these must have been produced by an optical lantern. All this is but speculation. The one thing which can be clearly seen by us when peering into the mists of antiquity is that Kircher gave the first clear description of an optical lantern, and was personally proud of its invention." But whether Kircher be the inventor of the magic lantern or not, supposing even it could be demonstratively proved that this machine—which, in the English Patent Office, is not entered under the heading of Optics, but, curiously enough, by a strange system of governmental classification, under that of Toys—was the invention of another, and not Kircher, Kircher would still be of the greatest interest to photographers from his remarkable work, written in Latin at Rome, in the middle of the seventeenth century, entitled "The Great Art of Light and Shade." This large folio volume, digested into ten books, contains so many matters of interest to photographic artists that we propose to reproduce a portion of it in these pages. We will preface this reproduction with a short biography of the author.

"In the year 1602, on the second day of May, on the third hour after midnight," says Kircher in the story of his own life, entitled by him 'The Life of the very reverend Father Athanasius Kircher, of the Society of Jesus, a man most celebrated throughout all the world,' on the festal day of Saint Athanasius, was I by my parents, John Kircher and Anna Garsekin, catholic persons and most devoted to divine worship and pious works, brought forth into this common air of calamity in the town of Geyssen, distant some three hours' journey from Fulda." He speaks of his father as a high-souled person who, refusing all gifts from the governing Prince, constantly asserted that one ounce of liberty, the wise man's true delight, was of more value than kingly honours of many thousand pounds.

Athanasius was the youngest of nine children. His name was derived from the great veneration in which his father held that saint on account of his constancy and imperturbable fortitude in the Arian persecution. In his tenth year the young Kircher learnt music, Latin, and geography, and afterwards was sent to the Jesuit College at Fulda, where he also acquired Greek and Hebrew.

Kircher speaks at some length of the weekly purgation of his conscience by confession, and of the Divine aid by which he was encouraged to fight against all the enticements of puerile play, and all the idle occupations which are wont, in ill-conditioned bosoms, to constitute childhood's chiefest charm. The Divine clemency preserved him, he tells us, from manifold dangers. On one occasion—it was on a bathing excursion, chosen with some apparent heedlessness in the vicinity of a water mill—Kircher was sucked under the wheel by the current, but emerged uninjured on the other side, to the astonishment of himself and of his companions. Another miracle happened in his favour on the day of Pentecost, on which a procession took place to consecrate certain fields by sacerdotal aid from satanic storms. This solemn lustration was succeeded by a horse race. Kircher, being in the first rank of the spectators, was pressed by a sudden impulse of those behind him into the middle of the racecourse just as the horses were about to pass. "I lay," complains the unhappy Kircher, "having commended myself to Supernal protection, with a contracted body and prone till all the horses had passed over me, after which I arose safe and sound." On being asked how he had managed to escape, he replied that there was no diminution in the power of Him who delivered Jonah from the ingurgitating whale, Tobias from the devouring fish, and Daniel from the ravening lions. On a third occasion Kircher was lost in a wood at night, and was so terribly frightened in consequence that he determined to renounce this wicked world and enter a religious order. He chose that of the Jesuits, and was admitted a novice at Paderborn on the 2nd October, 1618. Here he studied logic, physics, mathematics, and philology.

The greater part of Kircher's autobiography is made up of most disastrous chances, of moving accidents by flood and field, from all of which he, like the Moor, escaped scot free. His descriptions of his dangers, from which he considers himself liberated by Divine intervention, are sometimes highly picturesque. He gives, for instance, a very graphic account of how he avoided on one occasion his enemies by a flight in the winter time. The ways were deep with snow, which covered his knees; dire hunger assailed his stomach, a cold wind froze his extremities. His sole food was a loaf of barley bread mixed with a great quantity of bran which, not without difficulty, had been extorted from a surly peasant; bread of the very worst condition, and yet to him in his famished state, delicious beyond all compare. It is a long story, but it ends well. He escapes his foes after persistent prayer, though his knees are trembling, the rest of his body—Kircher writes "my whole body," but this must be an error arising from some mental confusion induced by a reminiscence of his agony—rigid, and his face a livid blue. One more of these disastrous chances will probably suffice the reader's curiosity. It is told at some length by Kircher, who insists on every circumstance of his peril with naive minuteness. We can find room here only for an abstract or a digest of this particular danger, a danger so formidable that he cannot call it to mind without much horror. It happened in a garden of the Jesuits' College at Avignon, to which he had retired in 1635 after the celebrated thirty years' war which Gustavus Adolphus of Sweden had carried on in Germany, where Kircher was professor of philosophy and oriental languages at the College of Wirtzburg, in Franconia.

In the garden of the Jesuits' College at Avignon was a large water wheel, placed between two high walls, and

* "Historical Notes on the Optical Lantern," by W. H. Harrison; PHOTOGRAPHIC NEWS, Dec. 23, 1887, p. 803.

driven round by horse power. The wheel stood in a narrow pit of deep water, and, raising the fluid in buckets, cast it into a stone basin, from which it was distributed by channels through the whole garden. The ill-starred Kircher, while standing near this water machine involved in thought, was suddenly knocked down by the pole to which the horse was attached, and became, by some untoward destiny, inextricably involved with the machinery. "The wheel continually moving, I was," says Kircher, "nowhere able to fix my foot, nor was it allowed me to escape sideways, on account of the close proximity of the walls which, within a little, touched the wheel. Being in this extreme necessity of peril I implored the assistance of my companion: but he, being occupied in a remote part of the garden, gave no heed to my clamour, what time I was revolving with the wheel, and was expecting death with every moment." Then, says this victim of accidents, *solita fiducia ad Deiparam confugi*, whereupon the wheel incontinently stood still, and Kircher, who by this time was up to his neck in the water, managed to clamber out of his difficulty and find a way to escape.

With the good Jesuits at Avignon he passed two years, occupied entirely with the study of antiquities. It was during his sojourn here that he became acquainted with the learned Peiresc, who advised him to apply himself to the explication of Egyptian hieroglyphics. Elected to a Professorship of Mathematics at Vienna, he was about to return to Germany when he received an order to journey to the Vatican. He was charged by the Pope in 1637 to visit Malta. He went afterwards to Sicily and Naples, and ultimately taught mathematics for eight years in a college at Rome. Here he had a dispute with Father Maignan on the subject of the invention of an optical instrument. Kircher, on seeing it, said, "*Quod stupes, an non hoc est figura mei libri?*" What do you wonder at? Is not this the figure of my book? Whereupon one who was present, comprehending that Kircher was for taking to himself all the credit of the invention, replied, "On the contrary, it is the book of your figure (*Imo, hic est liber tuæ figuræ.*") This account is given by Bayle, who adds that the matter would have rested there had it not been that the honour of two nations French and German was supposed to be involved. After all, each mathematician may have invented the machine independently.

Kircher died at Rome on 28th November, 1680. He was a man of immense erudition, but ill-digested and uncritical, endowed with the wildest imagination, a most retentive memory, and an untiring patience. He composed twenty-two folio, eleven quarto, and three octavo volumes. It is not to be supposed that from such a mass of literature error could be excluded. One of his books, "*Musurgia Universalis*," published in 1650 in two heavy folios, treats of the principles of music. The celebrated Dr. Burney, in his criticism of this composition, speaks of it as a large work which might give occasion to one yet larger, if all the errors contained therein were duly annotated and corrected. Not only was Kircher on some occasions inaccurate—as who, indeed, is not?—but he has also been charged with too careless credulity. How far this charge is borne out by what the reader has already perused, is for him to determine; but in a story commonly adduced to support it we can find nothing to Kircher's discredit.

The Jesuit was more than ordinarily addicted to the study of hieroglyphical characters. Mystery is pleasing to most of us; for Kircher it had an especial charm. Some gentlemen—as the term was then, perhaps is now, generally understood—proposed to divert themselves at the scholar's expense. With this excellent view they caused to be cut by a common stone-cutter some fantastic, unmeaning marks and figures upon a rude block of stone, and had it buried in a spot which Kircher had been commissioned to excavate and explore. The learned antiquarian stumbled on this stone, regarded it in the light of a singular curiosity, and, enraptured with his discovery, set himself at once to work to ascertain its meaning. After several days' assiduous study, he lighted upon an elucidation satisfactory to himself, and—here the jest came in. As to whether any of the gentlemen apologised to the student for having made him their laughing stock, we consult history in vain. Perhaps the whole account, of which there is another version, is apocryphal. In the other tale we learn that one André Muller did some scribblings on a parchment, and forwarded them to Kircher as antique records; that the unsuspecting *savant* replied that they were true hieroglyphics, and sent Muller the translation.

This prefatory article cannot be concluded in justice to Kircher without a short notice of his manifold works. Casting aside some religious compositions, these may be divided into historical, antiquarian, linguistic, hieroglyphic, mathematical, and physical. Of all these the last are chiefly our concern. One of the first and rarest of his works, which, by the way, are nearly all written in Latin, was called "Magnetic Art, or Experiments on the Operations of the Magnet," published at Wirtzburg, 1631, in quarto. In an extension of this same subject he published in 1641, also in quarto, a book entitled the "Magnet," in the third part of which is a description of the Tarantula, with two portraits of him, one exhibiting his belly, the other his back, and a legend underneath declaring in a Latin hexameter that music is the only potion against the poison of his bite. Above is a geographical sketch of the places where the beast is mostly to be met with, and again above that on this full-page plate is the musical composition in which Kircher confides as a certain cure.

"The Subteranean World, in which is shown the Majesty and Riches of Nature," was published in two folio volumes at Amsterdam, in 1668. Kircher, being anxious to discover the interior of Vesuvius to see, in fact, if there was anything in it, let down a man hired for a price into the principal crater, and held him suspended there until he had fully satisfied his curiosity. In this book will be found many bizarre and apocryphal accounts of giants, dragons, devils, and men all living underground, with the secret of palingenesis, or the way to resuscitate a plant from its ashes. But Kircher's greatest work for the photographer is his "Great Art of Light and Shade," already mentioned, published at Rome in 1645. Of this book, from which it is proposed to extract much which will be interesting, there has already appeared a short notice in the PHOTOGRAPHIC NEWS (December 23rd, 1887), where we read that in Kircher's preface to a portion of the book devoted to optical instruments and peculiar kinds of cameras, he says that the secrets contained therein are by no means satanic work, but the result of study and contemplation. He adds that he has to tell of some of the rarest marvels in nature, such as will excite admiration in the minds of those who behold them, that nobody has done anything of the kind before, and that he, Kircher, made his first

experiments before any one else knew anything about the matter. There is evidently here a little side-wind directed against his worthy colleague above mentioned, Father Maignan. Other people (Father Maignan?) sometimes promised rare wonderful and unheard of things which afterwards proved all wrong, but what he (Father Kircher) had to tell would prove all right. It is at least clear that the worthy priest stood upon excellent terms with himself, and was not devoid of that self-confidence which has been said by an excellent authority to be essentially requisite to all great undertakings.

(*To be continued*).

PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

FRENCH PHOTOGRAPHIC SOCIETY—INTERNATIONAL PHOTOGRAPHIC LABORATORIES—ORTHOCHROMATISM APPLIED TO THE REPRODUCTION OF PICTURES—POSITIVE PAPER WITH CHLORIDE OF IRIDIUM—NEW ENGRAVING PROCESS—PROOFS FROM ORTHOCHROMATIC COLLODION—THEORY OF CONTRETYPES—LANTERN IMAGES.

THE district photographic club of the south-east of France at Lyons has written to the French Photographic Society to announce that its photographic laboratory is at the service of members of the Paris Society on presentation of card. A similar notice comes from the Italian Photographic Society in Florence. This movement in a direction so useful to amateur photographers appears to be spreading. It is to be desired that in every part of the civilised world there were international laboratories of this kind, at the service of members, duly accredited, of all the photographic societies.

Mr. Edwards has just presented to the French Photographic Society some fresh specimens in support of the results that he obtains upon his orthochromatic plates in the reproduction of pictures. He sends an interesting note on this subject, and the specimens presented are generally speaking good. We are not the less convinced, however, that orthochromatism does not suppress the effects of reflection, for in that case it would be necessary to suppose that what the eye sees, and to the degree to which it sees it, is not rendered on the orthochromatic plate. Let us commence by saying that both here and in the Society, we discuss the matter from the purely technical point of view only. We do not know Mr. Edwards; we have no interest in being disagreeable to him, still less to speak ill of him, and when we said that the presentation was not candid (*sincère*), we merely made allusion to the proofs placed in our hands without questioning the good faith of the author of those proofs, without having the slightest intention to injure him. What interest could we have in doing so? The word *sincère* in the present case signifies real, true (*vrai*). We can make plain by an example furnished to us by Mr. Edwards himself, what we understand by the word. The example is as follows:—Mr. Edwards displayed various photographs on ordinary and isochromatic plates; amongst these photographs were two representing a vase of jonquils (a beautiful yellow flower). On the ordinary plate these flowers came out as rich black, almost *velvet black;* in the isochromatic plate the same flowers were a beautiful *white velvet* in appearance.

Well, this is not *real;* if the intention has been to force the effect, to exaggerate the contrast, the fact shows that the desired quality of scientific inter-comparability is wanting. The ordinary plate, of whatever make, will yield in the hands of any photographer a reproduction of these flowers that shall be *less black*. It suffices to expose a little longer, in order that in place of a degree of blackness answering to 100, we have, for example, a middle tone of grey of the degree 50. Now it seems to us that the ordinary plate is bad, defective in consequence of insufficient exposure; it might have been less black by half; then it ought so to have been in order that a technical comparison fulfilling the desired conditions of scientific candour might be made. As for the photograph on the isochromatic plate, it is *too white*. The plate should represent yellow more with its true value—that is to say of a light grey—evidently more closely reproducing the effect produced upon the eye by the tonality of yellow. As an orthochromatic result it is therefore defective; we should give to this too-white proof the designation 0 (Zero), answering to complete absence of black. There is thus between the two proofs exhibited a range of from 0 to 100, but if each had been made with the exact value that it might have yielded, the ordinary plate might be represented by 50 (*half as dark as it appeared*), and the isochromatic plate by 15 (*the shade of grey about equalling the apparent tonality of the yellow jonquil*), and the relation of one to the other would then not have exceeded that of 15 to 50. The effect of contrast has thus been exaggerated by 65, since it is 100 in the one case, and 35 in the other. We have set out, thus, exactly our impressions, and that is the explanation of the expresssion *absence de sincèrité*, regarding only certain results that were exhibited, and going no farther. We wish to say shortly that, in order that results of this character should be comparable with each other, it is necessary to show the best that can be done with the ordinary plate as well as with the isochromatic plate, in which case the contrast would have been less, and the result not less favourable to the employment of isochromatic plates.

In so far as concerns the reproduction of pictures, that which we criticised represents the Doge Loredano, by Jean Belin; here, again, we have not called in question the faith of Mr. Edwards in our criticism, but we have the conviction that with a longer exposure the photograph upon the ordinary plate would have been better, less harsh, less violent; with less exposure the photograph upon the isochromatic plate would have shown more pronounced relief; it would then have been less soft, less harmonious, but more true. Thus, to our thinking, the contrast has been forced in this case as in that of the flowers before mentioned. The ordinary plate is not so good as it might have been, the isochromatic one also; we have not, therefore, been shown the best possible result in the two cases; that is the origin of our impression that the true conditions of inter-comparability have not been obtained, but that is all we desire to say, using the right of scientific criticism which absolutely belongs to us.

M. Berthiot presented some beautiful prints obtained on paper containing chloride of iridium. This product promises stability in the prints, but as yet the value of the process is scarcely settled.

M. Chas. Guillaume Petit has perfected a process of typographic engraving which insures with skill the absolute purity of the whites. This is the process:—The photograph is printed on a copper plate, covered with

bitumen, and developed with essential oil, which leaves the copper bare in the absolute lights. It is washed, dried, and finally covered with powdered resin. It is then heated until a grain is perfectly formed. This dressing of resin on the insoluble bitumen has the property of rendering the bitumen soluble wherever the grain is formed. By plunging the plate again into the turpentine bath, the dissolved resin leaves a deep perforation in the bitumen. The plate is then re-coated with a solution of bichromatised gelatine; it is then exposed under the same negative by the aid of registration stops previously arranged, and is developed with perchloride of iron. In the pure whites there is no grain, and we have a plate where there is no need to have recourse to a tool in order to obtain the whites. Prints were shown in support of this process, which is very interesting, and may lead to other applications. M. Petit says that the dressing of resin has the effect of de-oxidising the bitumen rendered insoluble by light. We ought to know, in the first place, whether this insolubility proceeds from oxidation. Messrs. Chevreul and Kaiser have demonstrated that the effect caused by light is produced without the presence of oxygen, but with this reserve concerning a detail only affecting the theoretical question, we recognise the truly practical and very interesting communication of M. Petit.

M. Vallot, whose patriotism—like ours—will doubtless be attacked, presents proofs obtained with the isochromatic collodion emulsion of Dr. Albert, of Munich. As to the isochromatic properties of this emulsion M. Vallot says textually "above all, without the employment of a yellow screen before the lens, the effect is much more pronounced than with the best gelatino-bromide plates prepared either with eosine or with azaline." M. Vallot insists upon this point, which is of very great importance in his opinion, as in the reproduction of pictures the operator has a facility for varying at his will the effects of isochromatism by adding to the emulsion, as the case may require, divers colouring matters, such as cyanine, erythrosine, and chlorophyl.

M. Bordet explains how a contretype is formed when using the process with a bichromated gelatino-bromide plate, indicated by Mr. Bolas in the NEWS in 1880, and afterwards by Capt. Biny in 1882, and studied afresh by M. Balagny in 1889. According to him the theory is as follows: Bichromate in presence of light renders the penetration of solutions difficult in the insolated portions, from which fact arises the phenomenon of reversal of the image. He has verified his statements by dispensing with bromide of silver, and has obtained just the same a contretype by plunging the film of insolated bichromated gelatine into a colouring bath. From the fact of a more or less profound imbibition, according to the degree of the action of light, he obtains all the values of the negative, and the contretypes are equal to those obtained in the same way on gelatino-bromide plates. M. Vallot has also studied this question, but he has arrived, he tells us, at a different conclusion regarding the theoretical explanation.

M. Molteni presented transparencies of various tones obtained upon Ilford gelatino-chloride plates, and pointed out the different modes of development. M. Audra has done the same for the Perron plates. Shall we be accused of defamation if we timidly suggest that, in spite of all the improvements brought to bear on sensitive films of gelatine for transpareneies, we have not yet found them to equal what has been obtained on albumen or collodion?

DR. OTTO JUST.*

OUR club has to mourn the loss of an active member in Dr. Otto Just, the owner of an ocular institution in Zittau, Saxony, who died suddenly on the 5th of January last. The deceased was born in Zittau on the 7th of September, 1836, and was educated in the Gymnasium there, and afterwards at the University of Leipzig, after which he studied diseases relating to the eye under Professor Arlt in Vienna, and Professor Graefe in Berlin. In 1861 he established himself at Zittau as a surgeon and specialist for eye diseases, and a year later founded on a very small scale an institute for the cure of eye diseases. This undertaking succeeded so well that in 1869-70 he built a large house in which the Institute remained until his death. The skilful surgeon enjoyed a high place in the profession, and his reputation extended far from his own abode. Since 1886 Dr. Just occupied himself much with photography, and he joined the Club of Amateur Photography in 1887. At the Exhibition of Amateur Photographers in Vienna in the autumn of 1888, he showed a beautiful collection of landscapes, groups, instantaneous pictures, and reproductions. Dr. Just wrote articles for the *Photographische Rundschau*, having for their subject his varied experiments with Eastman's negative paper. In an early number we propose to issue one of his works as a supplement.

Although not personally acquainted with Dr. Just, we lament not the less his sudden death, which has deprived photography of so earnest an adherent.

THE SOLUBILITY OF GLASS BOTTLES.

DR. THRESH said at the British Pharmaceutical Conference, some years ago he was investigating the action of rain in certain districts on vegetation. It was supposed that some lime kilns, which had been recently erected, materially affected vegetation, and he had collected the rainfall at many different points. When he collected the rain on litmus and other papers he almost invariably found that it had an acid reaction; but, strange to say, when collected in bottles, it was either neutra or distinctly alkaline. On investigating the cause of this, he discovered that in all the bottles he employed—he tried all kinds and found the results the same—some decomposition took place in a very short time, and the free acid disappeared. His impression was that it was a decomposition of silicate of soda or of lime, in which the acid combined with the base, and the silica was thrown down. That this was the case was the more probable, because in evaporating samples of rain water he found that when collected in platinum dishes the solid residue per gallon was 1 to 4 grains less than when collected in glass, and this residue was chiefly silica. He also noticed, in making further experiments, that in titrating an acid solution, if the acid were run in until a faint tint was produced with litmus, and then the liquid were boiled for a few minutes in a glass vessel, the colour would disappear. Upon adding acid, the colour would again be obtained, which would again disappear on boiling, and so on; and he had seen students in the examination room go on repeating that process for an hour, thinking they were increasing the accuracy of the result, evidently not having observed that this naturally occurred when these solutions were boiled in glass flasks. Another thing still more interesting was this: if in one of these bottles—and they varied considerably, though they were all acted upon—a mixture practically neutral and containing tincture of cardamoms, were placed and kept in it for some time, it would vary considerably in colour in the course of, say, a month, and it was quite possible that the complaints sometimes made as to the colour of such a mixture were due to this cause.

* Translated for the PHOTOGRAPHIC NEWS from the *Photographische Rundschau*, organ of the Amateur Photographic Club in Vienna.

THE ROYAL INSTITUTION.

VI.

DR. THOMAS YOUNG'S DISCOVERIES AND PHOTOGRAPHS.

YOUNG'S researches on light were ably and briefly summarised on the 22nd of January, 1886, at the last Friday evening lecture which Professor Tyndall delivered at the Royal Institution, and whose utterances on the subject are here quoted :—

The physical meaning of all the terms applied to light was soon fixed. *Intensity* depended upon the amplitudes of the waves. *Colour* depended on the *lengths* of the waves. Two series of waves coalesced and helped each other when one was any number of complete undulations, or, in other words, any *even* number of half-undulations, behind the other. Two series of waves extinguished each other when the one series was any *odd* number of semi-undulations behind the other. But inasmuch as white light is made up of innumerable waves of different lengths, such waves cannot all interfere at the same time. Some interfere totally, and destroy each other; some partially; while some add themselves together and enhance the effect. Thus, by interference, a portion only of the white light is withdrawn, and the remaining portion is, as a general rule, coloured. Indeed the most glowing and brilliant effects of colouration are thus produced. Young applied the theory successfully to explain the colours of striated surfaces which, in the hands of Mr. Rutherfurd and others, have been made to produce such splendid effects. The iridescences on the polished surfaces of mother-of-pearl are due to the striæ produced by the edges of the shell-layers, which are of infinitesimal thickness; the fine lines drawn by Coventry, Wollaston, and Barton upon glass also showed these colours. Barton afterwards succeeded in transferring the lines to steel and brass. Most of you are acquainted with the iridescence of Barton's buttons. A descendant of Mr. Barton has, I believe, succeeded in reproducing the instrument wherewith his grandfather produced his brilliant effects.

But the greatest triumph of Young in this field was the explanation of the beautiful phenomenon known as Newton's rings. The colours of thin plates were profusely illustrated by the experiments of Hooke and Boyle, but Newton longed for more than illustrations. He desired quantitative measurement. The colour of the film was known to depend upon its thickness. Can this thickness be measured? Here the unparalleled penetration of Newton came into play. He took a lens consisting of a slice of a sphere of a diameter so large that the curved surface of the lens approximated to a plane surface. Upon this slightly convex surface he placed a plate of glass whose surface was accurately plane. Squeezing them together, and allowing light to fall upon them, he observed those beautiful iris-circles with which his name will be for ever identified. The iris-colours were obtained when he employed white light. When monochromatic light was used he had simply successive circles of light and darkness. Here then, from the central point where the two glasses touched each other, Newton obtained a film of air which gradually increased in thickness as he retreated from the point of contact. Whence this wonderful recurrence of light and darkness? The very constitution of light itself must be involved in the answer. His desire was now to ascertain the thickness of the film of air corresponding to the respective rings. Knowing the curvature of his lens, this was a matter of easy calculation. He measured the diameter of the fifth ring of the series. This might be accurately done with a pair of fine compasses, for the diameter was over the fifth of an inch in length. But it was the interval between the glasses corresponding to this distance that Newton required to know, and this he found by calculation to be 1-37,000th of an inch. This, be it remembered, is the distance corresponding to the fifth ring. The interval corresponding to the first ring would be only a fifth of this, or, in other words, about 1-180,000th of an inch. Such are the magnitudes with which we have to deal before the question "What is Light?" can be scientifically answered.

Newton's explanation of the rings, which he was the first to discover, though artificial in the highest degree, is marked by his profound sagacity. He was hampered by the notion of the "corporeity" of light. He could not get over the objection raised by himself as to the existence of shadows in a fluid medium. He held, therefore, that light was due to the darting forth of minute particles in straight lines; and he threw out the idea that colour might be due to the difference of bigness in the particles. He endowed these particles with what he called fits of easy transmission and reflection. The dark rings in his immortal experiment were produced where the light-particles were in their transmissive "fit." They went through both surfaces of the film of air, and were not thrown back to the eye. The bright rings occurred where the light-particles were in their reflective fit, and where, on reaching the second surface of the film, they were thrown back to the eye. The cardinal point here is, that Newton regarded the recurrence of light and darkness as due to an action confined to the second surface of the film. And here it was that Young came into irreconcilable collision with him, proving to demonstration that the dark rings occurred where the portions of light reflected from both sides of the film extinguished each other by interference, while the bright rings occurred where the light reflected from the two surfaces coalesced to enhance the intensity.

Young next applied the wave theory to account for the diffraction or inflection of light, that is to say, the effects produced by its bending round the edges of bodies. When a cone of rays issuing from a very minute point impinges on an opaque body so as to embrace it wholly, the shadow of the body, if received upon a screen, exhibits fringes of colour. They follow so closely the contour of the opaque body, that Sir John Herschel compared them to the lines along the sea-coast in a map. If a very thin slip of card, or a hair, be placed within such a cone, it is noticed that besides the fringes outside the shadow, bands of colour occur within it: the central or brighest band being always white when white light is employed. It is a singular and somewhat startling fact that, by the interposition of an opaque body, say a small circle of tinfoil, the point on which we should expect the centre of the shadow to fall is, by the joint action of diffraction and interference, illuminated in precisely the same degree as it is when the opaque circle is withdrawn.* In reference to the interior fringes, Young made the observation, which is of primary importance, that, if you intercept the light passing by one of the edges of the strip of card, or of the hair, the fringes disappear. It requires the inflection of the waves round both edges of the object, and their consequent interference, to produce the fringes.

Young's attempt to explain the phenomena of diffraction was a distinct advance on the extremely artificial hypothesis of Newton. Still, his attempt was not so successful as his explanation of the colours of striated surfaces and of thin, thick, and mixed plates. Here the young officer of engineers to whom I have already referred, Fresnel, entered the field. He presented in 1815, to the French Institute, a memoir on diffraction, which marks an epoch in the history of the wave theory. It is usual when such a paper is presented to refer it to a "Commission," who consider it, and report upon its merits. The commissionaires in this instance were Arago and Prony.

Arago had read the memoirs of Young in the "Philosophical Transactions," but had not understood their full significance. The study of Fresnel's memoir caused the full truth to flash upon him that his young countryman had been anticipated thirteen years previously by Dr. Young. Fresnel had re-discovered the principle of interference independently, and had applied it, with profound insight and unrivalled experimental skill, to the phenomena of diffraction. It was no light thing to Fresnel to find himself, as regards the principle of interference, suddenly shorn of his glory. He, however, bore the shock with resignation. He might have readily made claims which would have found favour with his countrymen and with the world at large; but he did nothing of the kind. The history of science, indeed, furnishes no brighter example of honourable fairness

* A similar diffraction has been proved by Lord Rayleigh to occur in the case of sound.—J. T.

than that exhibited throughout his too short life by the illustrious young Frenchman. Once assured that he had been anticipated —whatever might have been the extent of his own labours, however independently he might have arrived at his results, he unreservedly withdrew all claim to the discovery. There is, I repeat, no fairer example of scientific honour than that manifested by Augustin Fresnel.

Fresnel was a powerful mathematician, and well versed in the best mathematical methods of his day. With enormous labour he calculated the positions where the phenomena of interference must display themselves in a definite way. He was, moreover, a most refined experimentalist, and, having made his calculations, he devised instrumental means of the most exquisite delicacy with a view of verifying his results. In this way he swept the field of diffraction practically clear of difficulty, solving its problems where even Young had failed.

Truly these were minds possessing gifts not purchasable with money, and round about the central labours of both of them, minor achievements of genius are to be found, which would be a fortune to less opulent men. I hardly know a finer example of Young's penetration than his account of the spurious or supernumary bows, observed within the true primary rainbow. These interior bows are produced by interference. It is not difficult, by artificial means, to form these bows in great number and beauty. This is a subject on which, as you are aware, I worked a couple of years ago myself. And often, when looking at these bows, the words of Young seemed to me like the words of prophesy. The bows were the physical transcript of what Young stated must occur : a transcript, moreover, which, when compared with his words, was far more complete and impressive than any ever exhibited by the rainbow in nature. Many of you are acquainted with the beautiful rings of colour observed when a point of light is looked at through the seeds of lycopodium shaken over a piece of glass, or shaken in the air so as to form a cloud whose particles are all of the same size. The iridescence of clouds that I have once or twice seen in great splendour in the Isle of Wight, but more frequently in the Alps, is due to this equality in the size of the cloud-particles. Now the smaller the particles, the wider are the coloured rings, and Young devised an instrument called the *Eriometer*, which enabled him, from the measurement of the rings, to infer the size of the particles. Again, Ritter had discovered the ultra-violet rays of the spectrum, while Wollaston had noticed the darkening effect produced by these rays when permitted to fall on paper or leather which had been dipped in a solution of muriate of silver. Employing these invisible rays to produce invisible Newton's rings, Young projected an image of the rings upon the chemically prepared paper. He thus obtained a distinct photographic image of the rings. This was one of the earliest experiments wherein a true photographic picture was successfully obtained. Young had little notion at the time of the vast expansions which the art of photography was subsequently to undergo.

But Young was not permitted to pursue his great researches in peace. The *Edinburgh Review* had at that time among its chief contributors a young man of vast energy of brain and vast power of sarcasm, without the commensurate sense of responsibility which might have checked and guided his powers. His intellect was not for a moment to be measured with that of Young ; but as a writer appealing to a large class of the public, he was, at that time, an athlete without a rival. He afterwards became Lord Chancellor of England. Young, it may be admitted, had given him some annoyance, but his retaliation, if such it were, was out of all proportion to Young's offence. Besides, whatever his personal feelings were, it was not Young that he assailed so much as those sublime natural truths of which Young at the time was the foremost exponent. Through the undulatory theory he attacked Young without scruple or remorse. He sneered at his position in the Royal Institution, and tried hard to have his papers excluded from the *Philosophical Transactions*. "Has the Royal Society," he says, "degraded its publications into bulletins of new and fashionable theories for the ladies of the Royal Institution? Let the Professor continue to amuse his audience with an endless variety of such harmless trifles, but in the name of science let them not find admittance into that venerable repository which contains the works of Newton and Boyle, Cavendish and Maskelyne, and Herschel." The profound, complicated, and novel researches on which Young was then engaged, rendered an occasional change of view necesssary. How does the reviewer interpret this praiseworthy loyalty to truth? "It is difficult," he says, "to deal with an author filled with a medium of so fickle and vibratory a nature. Were we to take the trouble of refuting him he might tell us, '*my opinion is changed, and I have abandoned that hypothesis. But here is another for you.*' We demand if the world of science which Newton once illuminated is to be as changeable in its modes as the world of fashion, which is directed by the nod of a silly woman or a pampered fop? . . . . We have a right to demand that the hypothesis shall be so consistent with itself as not to require perpetual mending and patching ; that the child we stoop to play with shall be tolerably healthy, and not of the puny and sickly nature of Dr. Young's productions, which have scarcely *stamina* to subsist until the fruitful parent has furnished us with a new litter, to make way for which he knocks on the head, or more barbarously exposes, the first." He taunts Young with claiming the inheritance of Newton's queries, "vainly imagining that he fulfils this destination by ringing changes on these hypotheses, arguing from them, as if they were experiments or demonstrations, twisting them into a partial coincidence with the clumsy imaginations of his own brain, and pompously parading what Newton left as hints, in a series of propositions, with all the affectation of system."

To Brougham's coarse invective Young replied in a masterly and exhaustive letter. A single copy, and one only, was sold by its publisher. There were at that time in the ranks of science no minds competent to understand controversy. The poison worked without an antidote, and for thirteen years Young and his researches on light had no place in public thought. His discoveries remained absolutely unnoticed until their re-discovery by Fresnel lifted the pall which for so many years had been thrown over this splendid genius.

SCHIRM'S NEW FLASH-LIGHT GALLERY.

BY DR. H. W. VOGEL.

What is the latest novelty in German photography? Answer: The lightning gallery of Professor Schirm in Berlin. The event hinted at by us repeatedly of the establishment of a Blitz gallery dispensing entirely with daylight has at last become a fact, and immense progress in photography has been made thereby, which cannot be estimated highly enough, particularly during the present dark days of winter and the holiday season. The Instantaneous Blitz Gallery has been open since December 1st, under the modest title of "Gallery for Artistic Portraits," Potsdam Str. 20. This Blitz light is employed not only for taking negatives, but also for the production of prints. This is a still greater progress, the negatives being of not much advantage if the cloudy winter days make printing an impossibility.

Our advice to apply the Blitz light, if not rejected, at least met with indifferent consideration, and thousands of reasons were brought against it. We have here an artist, one of the best in his profession, and at the same time a clever amateur of photography, and he accomplishes what professionals would not risk to touch, and in such a masterly manner, that every one who has seen his establishment must be at once convinced.

It was no easy matter for Mr. C. C. Schirm to train his operators for this entirely new mode of photography. He has succeeded because he is not easily disconcerted.

Schirm's gallery is one of the usual elegant dwellings on the first floor, with a small hall and ante-chamber serving

as a reception room, two rooms which are arranged as Blitz galleries, and a large passage-room with one window, into which daylight penetrates only from one corner, and which bears the name of "Berlin room," as an authorised Berlin peculiarity.

This ordinarily partly-dark Berlin room forms the large Blitz gallery for groups. Each of these rooms has, so to speak, a firmament of Blitz lamps.

Schirm's lightning apparatus is known. He works, as Piffard has done before him, by blowing magnesium powder through the flame with an apparatus; but while Piffard applies large quantities—more than 1 gram—he proves that a minimum quantity, 0·03 gram (½ grain) is sufficient for one sitting, and that more is rather injurious than useful. This apparatus is excellent for single pictures, but not sufficient for larger views in grand style. Here it is oftentimes necessary to apply 7, 8, and even 15 to 20 lamps, and to ignite these simultaneously, the latter being of great importance. It is also important not to let the lamps be too near to the subject.

In Schirm's gallery they move therefore on rails, about four meters from the floor and near to the ceiling. Each lamp consists of a Bunsen flame, through which the magnesium is blown, and an illuminating flame, which serves for studying the light effect of the lamp. Some of the lamps are ignited in front of the subject, others from the side. The arrangement is such that the ceiling contains a system of rails, which might remind one of the game called "Mill." An exterior square of rails is placed round the four walls, and in the small room an additional inner square of about half the size. In the Berlin room, intended for groups, is a third and still smaller one. Upon these rails the lamps can be moved at will. Each lamp carries gas tubing and a tube for blowing, which are connected with the main gas pipe and also with the bellows.

This rather complicated system of tubing swinging from the ceiling leaves a peculiar, still not disturbing, impression at first sight. In the small room I counted fourteen on the exterior square, eight on the inner one. In the large room there were sixteen lamps outside. Each lamp (illuminating burner as well as Bunsen burner) had a cock with a long lever, which from the floor could be opened and closed with a pole-hook. Above each lamp burns continually a small igniting flame, from which the gas will ignite by opening the cock. The Bunsen burner is in connection with a small magnesium powder reservoir, which, on being closed, after ignition of the powder, will drop a new, small quantity of 1½ centigram of magnesium into the blow-pipe for the next view. A larger quantity of magnesium has not been found effective: if more light is required, more lamps should be used.

At a single sitting we saw nine lamps in activity—four from the side, four in front, and one from the other side almost behind the sitter. Most of the negatives are taken on old, extra blue sensitive plates, the magnesium light containing mostly blue rays. A mechanical electrical arrangement is used for the exposure, which, after the subject has been posed, opens first the flap on the objective, and immediately afterwards sets the blowing apparatus to work, which blows the magnesium powder through the flame, after which it closes again the objective flap, all by electrical movement.

The whole system is so neat and well executed that we cannot sufficiently praise the inventor.

The blow-light itself is not instantaneous, and lasts about one-half second, but the time of the objective shutter is only about one-tenth second, so that the exposure can be considered as instantaneous. It is remarkable that all brands of dry plates have not proved equally good and effective. The sensitive Beernaert plates cannot be used at all. Voigtlander's Euryscope, Series III, second diaphragm, was used as an objective. It remains a fact that a well-exposed negative was obtained. It may have had a pretty strong top light character, according to the judgment of some; but that pictures can be obtained of faultless illumination is proved by Delden's magnesium Blitz pictures, *Photographische Mittheilungen*, 1889, May 2. It is also evident that in such a room one is enabled to utilize every place, under the window, the piano, the stove, near the door or in any corner, for posing the subject, so that more change in the artistic arrangement is possible. The decoration of the whole room should of course be selected and gradnated photographically, and if this has not been done, it is an error which can easily be remedied.

The Blitz printing process is also interesting. This is executed on bromide paper. To prove that paper copies could be obtained at once, Professor Schirm pressed a piece of paper upon a gelatine negative, quite wet, and washed only for ten minutes, placed this upon a table arranged with a measure (rule) opposite a vertical ground glass at a distance of about 120 cm., and ignited behind it, with his military Blitz lamp—which is commonly used for signalling,—a flash of 1½ centigrams of magnesium powder. This was sufficient to obtain, with eikonogen development, a well-exposed print. It is peculiar how the character of the pictures and their tone changed by placing the negative nearer to the light or further off. Those near-by appeared browner and softer.

Ordinarily the prints are made after the negative is thoroughly dry and has been retouched, and a dozen cartes-de-visite can easily be printed with one flash. The tone of the prints I saw was perhaps a little too cold, but warmer tones can easily be obtained by a change in the lighting and development. Dr. Just's book, "Guide for Positive Developing Processes," gives the desired information. By the powerful action of the Blitz light it is shown that two flashes were sufficient to obtain a very intense positive from a drawing on bromide paper. Prints from these flash negatives can, of course, also be made by any of the other processes, so that in this respect no objection can be made to them.

Mr. Van Delden is fitting up another Blitz gallery in Breslau, but Mr. Schirm deserves the merit of having been the first to introduce this new kind of Blitz gallery. This is certainly a new step forward in photography—emancipation from daylight and emancipation from time, and I am convinced that it will have considerable influence on the progress of our beautiful art.—*Anthony's Bulletin.*

"THEY have been having *tableaux vivants* at Osborne," says a daily contemporary, "and the Royal photographer of the Isle of Wight has been busy. A photographer of Ryde has been nearly a dozen times to the Court, and the other day Princess Beatrice, on her way back from visiting the scene of the Needles wreck, called at his establishment and left her likeness in the costume of Mary Queen of Scots."

FOR a lantern slide, a *special negative* should be taken, or, in other words, if a lantern slide of a view or object is desired, it should be taken and manipulated all through with reference thereto. That it should be sharp, clear, and brilliant, is a *sine qua non*. But it is not enough that this alone should be obtained, for there is an enemy lurking in your every surrounding, against which you must be on constant guard, and that is DUST.—*Mosaics.*

SOME FURTHER APPLICATION OF THE RAMSDEN EYEPIECE TO PHOTOGRAPHY.

BY F. H. VARLEY, M.I.E.E., F.R.A.S.

THERE is nothing like having a hobby, and riding that hobby; it is a cheerful exercise, and does no one except the rider any harm, unless the hobby be ridden down to the death.

The Ramsden eyepiece as a hobby I do not think has been made to run the heedless course. We find it employed in the double capacity of a microscope and an eyepiece in surveying levels, theodolites, transit instruments, and micrometers for telescopes; also as a microscope for reading off the fine divisions of the vernier and the divided circle. The eyepiece micrometer of telescopes, the eyepiece of the surveying level, the theodolite, and the transit instrument are all positive eyepieces—that is to say, that the image is formed in front of the field lens. The reason for using the positive eyepiece is obvious. These instruments require the cross hairs, or spider lines, to be in distinct focus whilst viewing the correctly focussed image produced by the object glass; or, in other words, the image formed by the object glass falls exactly upon the same plane as that occupied by the spider lines. Thus, if we make the adjustment of the Ramsden eyepiece to be in correct focus with these spider lines, and then adjust the object glass to correctly focus the image, both will be in critical or precise focus. Now if we make the adjustment of the Ramsden eyepiece as described in my communication of the 31st ult., to be coincident with the image focussed on the ground-glass screen, but employing a plane of clear glass of equal thickness crossed at right angles with parallel rulings inserted in the camera at the same position as the ground screen, a transparent critical focussing plane is secured. The use of this transparent plane shows at once how very much detail is really lost by dispersion from the ground surface. The image formed by the camera lens, instead of appearing with a woolly indistinctness, comes out much sharper, brighter, and clearer. This facilitates focussing, as it dismisses all fear and doubt from the mind as to whether the best possible focus has been obtained. When using the focussing apparatus, already described in my former communication, at an angle to the ruled glass plane, there is a small amount of error due to refraction of the incident ray falling at an angle to the glass surfaces. Practically, however, this may be disregarded, so long as the rulings on the glass are in distinct focus at the centre of the field of the eyepiece. I should therefore recommend, first, focussing with the ground-glass screen in the usual way. For the general effect apply the focussing apparatus to that part of the picture which it is desired to be critically focussed, and obtain the correct adjustment; remove the ground screen, and insert the clear glass with rulings, and verify the focussing.

Those who have not tried the difference of effect produced by the interference and diffusion created by the numerous prismatic points of the ground glass surface, will be astonished at the clearness of the detail and brilliancy of the image obtained by means of the Ramsden eyepiece.

There is one more use to which this eyepiece can be applied with advantage, and that is as an illuminator for the microscope in place of the achromatic condenser, especially as it can be employed for micro-photography, and is less costly.

The eyepiece I have employed for this purpose is constructed with a field lens, $\frac{3}{4}$-inch focus, eye-lens $\frac{3}{8}$-inch, both plano-convex, placed about $\frac{1}{2}$ths of an inch apart, with their convex side turned toward each other. In front of the field lens I place a diaphragm with an aperture of $\frac{3}{32}$-inch diameter. The distance of this diaphragm from the field lens is so adjusted that if the eyepiece is held at a distance of two or three inches from the eye, upon looking through, the margin of the hole is seen sharply defined; it is ready then to be placed in the secondary stage of the microscope. I prefer to turn the microscope so that the body is in a horizontal position, and place it in a direct line with the source of light, then focus the object, after which I adjust, by means of the secondary stage, the illuminator, so that the margin of the diaphragm is distinctly focussed; next I place a condensing lens between the light and the diaphragm, and so adjust the distances of both that the image of the light is focussed upon the diaphragm. The image should be just large enough to uniformly cover the aperture and the fringe of the light caught upon the margin. In this way an uniform and perfect disc of light is obtained, and but little difference between this mode of illumination and that from an achromatic condenser is discernible.

I do not remember having seen the Ramsden eyepiece so applied as a condenser for the microscope except when I adopted it myself as a convenient expedient upon occasions when an achromatic condenser has not been available. By its means I have obtained, with a one-third of an inch objective and a high-power eye-piece, the markings of Navicula, Formosa, and Podura scales perfectly resolved. The reason for employing it as a condenser is identical with that of focussing the image on the ground-glass screen—viz., to obtain a critical image of the flame—or surface of the incandescent lime when the oxyhydrogen light is employed—coincident with the object focussed. I believe it will be found to be of considerable utility when photographing by artificial light. I may here state that when a condensing lens is employed for throwing the image of the light upon the diaphragm, it is very desirable, and for photographing I believe it is absolutely necessary that this condensing lens should be achromatic. The two objectives of an opera glass whose combined foci is about two or three inches, answer this purpose admirably. If they are not available, place the light as near to the diaphragm as possible, but do not employ a monochromatic lens. The Ramsden eyepiece and an achromatic lens for producing the luminous image on the diaphragm give the most perfect combination, as well as greater brilliancy of illumination.

If the microscope has the achromatic illuminator fitted to it, always use it directed to the light. To obtain the critical image, if this image is too small to cover the whole of the field of view, a condensing lens has to be employed; it is very important that this lens be achromatic.

So that, after all, the Ramsden eye-piece is practically as perfect as the more elaborate and costly achromatic illuminators generally employed: I am referring to the use of artificial light. The most perfect, of course, though very seldom attainable in this country, is to direct the achromatic illuminator to a well-lighted cloud. In this case also the Ramsden eyepiece can be applied, if the image of the cloud is focussed, or the diaphragm by means of an achromatic lens.

A PARTNERSHIP has been arranged, we are informed, between Mr. M. Auty, of Tynemouth, and Mr. Richard E. Ruddock, late of Messrs. W. and D. Downey's Studio, London. The style of the firm will be Auty and Ruddock.

Notes.

An astronomical photographic curiosity was exhibited at the last meeting of the Royal Society in the way of a photograph, by Mr. Isaac Roberts, of the Orion nebulæ, on which two exposures of two hours and two and a half hours respectively, at an interval of five days, had been juxtaposed. While the pairs of discs for most stars were sensibly equal, the pairs for at least ten faint stars showed great differences in intensity. Mr. Roberts considers that this indicates the variability of these stars in a few days. But, as the *Observatory* points out, confirmation of this view is eminently desirable. A similar pair of exposures should show the same ten stars as variable, if we are to exclude the possibility of accidental appearances. Indeed, this principle of duplicate exposures might be carried much further. Despite delicacy of manipulation in the preparation and development of negatives, films may behave with eccentricity, and minute imperfections may be taken for stars, and *vice versa*. This system of duplication would, however, entail enormous expense, and at the present moment is impossible.

Pinhole negatives are attracting much attention just now, and the study is gradually taking form in regard to the principles of working. Captain R. Colson has given to the *French Photographic Society* some curious calculations *apropos* of the relationship which exists between the size and clearness of the picture and the dimensions of the pinhole that takes the place of the lens, and those who are curious on the subject will find his figures in the Transactions of the Society. With regard to the time of exposure, Captain Colson is of opinion that it is impossible to give exact figures, as the circumstances differ. His own experience on a particular brand of plates furnishes, however, the following data:—For distant objects, four seconds; for objects in sunlight, at a distance of ten to a hundred metres, fifteen seconds, and for portraits well lighted, twenty seconds.

A graceful allusion to the late Father Perry is made in the *Observatory* by Mr. H. Turner. In regard to the special photographic work of the expedition, Mr. Turner says the sudden illness of the chief member of the expedition made it advisable not to attempt development of the photographs so obtained. These were brought by Mr. Rooney to England, and have recently been developed. Those actually taken by Father Perry show the very great care he must have taken to focus his instrument, and the results generally are successful.

The exhibition to be held in March, promoted by the Royal Meteorological Society, promises to be exceedingly interesting from a photographic point of view. Meteorological science, we understand, will be illustrated by the largest and most complete collection of instruments and photographs which can be got together. So many uses have been found of late years for photography in connection with meteorology, from sunshine recorders to M. Janssen's photographs of mists, and the recent pictures of lightning, that the exhibition promises to be altogether unique.

An appreciative biographical sketch of the President of the Photographic Society appears in the *Popular Science Monthly* (New York), accompanied by a very excellent portrait. Mr. Glaisher's labours in connection with astronomical and meteorological work are well known, and of these labours the writer of the sketch gives a very complete epitome. It is sufficient to say that Mr. Glaisher is the author of more than one hundred books and papers relating to astronomy, meteorology, and the theory of numbers, to indicate his untiring industry. Although entering upon his eighty-first year, he retains all his old vigour and energy, as was evident at the dinner of the Society on Monday.

The Japanese are enthusiastic over photography. The Minister of public instruction in Japan has announced that at the next term, photography will be taught in most superior schools, notably at the Archeological Institute, at the Forester's Institute, and in the Military Academies. *La Nature* enquires when it will be that the same course of instruction is organised in the special large schools of France, and in those of art and drawing, and the same question might be asked in England were it not that amateurs are so numerous and so diligent as to almost render unnecessary any stimulus from the legislature.

The ter-centenary of the invention of the compound microscope, which is to be celebrated this year at Antwerp, reminds us of the respectable age to which this instrument has attained. Of late years, microscopical appliances have been vastly improved, and the application of photography has given to microscopical study fresh interest and fresh power. Photographic attachments will make a large show at the exhibition proposed to be held, and among the subjects to be discussed at the inevitable conference will be photo-micrography.

The annual report of the Harvard College Astronomical Observatory just issued gives much interesting information as to the valuable work performed under the direction of Professor Pickering. The handsome gift of 50,000 dollars by Miss Bruce for the construction of a photographic telescope of novel form is specially alluded to, and it is foreshadowed that, when completed, the instrument will effect a total change in the work of the observatory. For instance, in 1885 it was proposed to photograph the entire sky with the eight-inch telescope, enlarging the plates three times, but the generous aid of Miss Bruce will permit this result to be attained in the original photographs without enlargement—an enormous gain both in time and economy. A contract has been made with Messrs. Alvan Clark and Sons for a telescope having an aperture of 24 inches, and a focal length of 11 feet.

THE LATE DR. E. HORNIG.

Hon. President of the Photographic Society of Vienna.

From a report of the speech of Professor Fritz Luckhardt, delivered at the January meeting of the Photographic Society of Vienna, in the *Photographische Correspondenz*, we abstract the following account of the life and labours of the late Dr. Emil Hornig.

We have lost, says Prof. Luckhardt, in Dr. Hornig one of our best friends—one whose heart was full of warmth towards the Association and its members. Hornig was one of those men who, with the appearance of a somewhat rough exterior, possessed a kernel of noble quality. Those who knew him well, recognised him as one of the best of men. He was born in the year 1828, the son of the Royal Counsellor Josef Hornig, who, at that time, was professor of Roman law at the University of Vienna. He was educated from his fourteenth year at the Academic Gymnasium, and after studying philosophy and, for some time, jurisprudence, he applied himself with the greatest diligence to the study of chemistry and physics at the Polytechnic Institute. He was one of the most industrious students at the laboratory of the Institute, where he interested himself in all matters concerned with applied chemistry, and diligently occupied himself with analysis—both qualitative and quantitative.

In the year 1851 he was appointed provisionally instructor in the high school, and some years afterwards prepared himself for obtaining the grade of professor. As a teacher he understood, as few do, how to combine necessary firmness with kindly forbearance. He was at the same time the instructor and friend of his numerous students, as is evidenced by many examples communicated to me by those who, as pupils, drew their inspiration from him—the councillor Dr. W. Exner amongst others. Shortly after attaining his professorship, he was appointed corresponding member of the Imperial Geological Institute, and the College of Doctors of the Philosophical Faculty elected him as Dean. He acted for some time as counsellor of the administration of the Lower Austria Industrial Guilds, and edited its weekly journal. Dr. Hornig instructed himself in all the domains entered upon in connection with this work, and was on that account a many-sided man. When his excellency Baron Schwarz-Senborn was intrusted with the guidance of the Universal Exhibition of 1873, Hornig was one of the first whom he called to his side to assist in the undertaking. For his successful activity in this matter he received the title of royal councillor, and was decorated with the Swedish order of the Northern Star.

The experiences thereby gained caused him to be selected in connection with the Philadelphia Exhibition of 1876, after which he was decorated with the order of Francis Joseph, and in 1878 he was appointed as Royal and Imperial Commissioner for the Paris Exhibition. I had the opportunity in Paris to learn the pre-eminently superior, though little known side of our friend's character. I have seen how he struggled on behalf of those who felt that they had been overlooked or not fairly appreciated, and especially how he always stood up for his own countrymen. France recognised his merits by conferring on him the title of the Legion of Honour, whilst his Majesty the Emperor distinguished him with the Order of the Iron Crown, a distinction which awakened much jealousy and envy in some quarters. He now applied his whole energies to the advancement of our Association, the Photographic Union, to which he had belonged from its foundation. He was now chosen for the chief office in our Society, and under his thoughtful care discord vanished and the Association grew and prospered. He took over the *Correspondenz* from the then editor, Herr L. Schranck, and advanced the undertaking by attracting notable writers in technical matters and at considerable pecuniary sacrifice. He devoted his time from early till late to the work of the Association, and, as far as possible, concentrated in his own person the labours connected with it. A new era was thereby inaugurated in the life of the Society.

In his own family he was the best of sons; it was touching to see the tenderness of his attachment to his mother. The worthy matron died the preceding year at the age of ninety years. It is a happy circumstance that Hornig, in his illness, knew nothing of the pain of this loss; he could not have endured it. Four years since Hornig suffered from a paralytic seizure from which he never recovered. His faculties became more and more dimmed, until at last his tongue could no longer move, and he was unable to pronounce a word. I shall never forget how, when I last visited him a few months since, his eyes seemed to lighten, and he appeared to recognise me, and to endeavour to say something, but in vain.

Hornig was an acute observer, such as is seldom met with; on this account he was often applied to as an expert. He was president of the Association of Gas Industries; especially he was a many-sided man, and it was never in vain to knock at his door when advice or aid was wanted. It was he whom the council of the Voightländer Institute employed to give the impulse to scientific enquiry into the action of chromium salts upon gelatine, albumen, and such like substances. The selection fell upon a young man whose talents Hornig had recognised, and who he expected would be able to trace out the kernel of the question. The prize was won by Dr. Eder.

It was Hornig's constant idea to create an institute for photographic research, and he worked at it incessantly until that object was reached; the idea was even enlarged, and a school erected for instruction in combination with the institute for research.

Hornig's literary ability was shown amongst other things in technical chemical works, of which may be noted a treatise on glycerine, one on cheesemaking, and one on mineral analysis. He also contributed many treatises in the technical journals, and was on that account made corresponding member of the Austrian Museum of Art and Industry, and honorary member of many societies.

From the year 1871, with but little interruption until 1885, Dr. Hornig, without any payment, edited a photographic annual which he presented to the members of the society. This included a note-book for photographers and amateurs, with exposure tables and negative register.

In 1880, Gerot, in Vienna, published Hornig's "Handbook of Technical Chemistry for High Schools and Technical Institutes of Instruction." In 1882 Hornig published under the title "Photographica" sheets illustrating photographic processes in four series.

Dr. E. Hornig was elected President of the Association in 1871, and presided for the last time in February, 1885. In the following May he was appointed Honorary President, and at the same time was awarded the gold medal of the Society.

In the beginning of the year 1870 he commenced a course of lectures upon photographic chemistry at the Polytechnic Institute, which, however, was abandoned in

consequence of the unequal preparatory schooling of the hearers.

It is in our loving remembrance that our journal—the *Photographische Correspondenz*, was presented by him to the Society. As Baron Burg has said, "The loveliest attribute of mankind is gratitude." Our grateful remembrances are given to the memory of Dr. Emil Hornig.

PHOTOGRAPHIC WASTE PRODUCTS.

MR. JOHN YOUNG, of 84, Market Street, Chicago, has issued the following circular to photographers:—

1st. *Paper Clippings, all Untoned or Over-Exposed Prints, Blotters, Filters, &c.*, should be introduced by degrees into an ordinary stove and burned to ashes in the most thorough manner. It is important that the ashes be not withdrawn from the stove until the whole of the carbonaceous portion of the paper is entirely consumed. The paper should be kept free from admixture with tin-type clippings, glass, nails, and other extraneous matter, which is a positive injury to the waste. Before burning see that the draught is completely shut off, otherwise much loss of silver will be occasioned.

2nd. *Print Washings and Old Positive and Negative Baths.*—To save the above waste in the easiest and most economical manner, procure a good sound cask, of dimensions suitable to your needs, loosen the top hoops in order to remove the head, and replace the hoop tightly. Next have a hole bored through the side of the cask about seven or eight inches from the bottom; into this insert a wooden faucet, and the barrel is ready to receive the waste solutions referred to. To precipitate the silver from these, proceed as follows: Make a saturated solution of common salt, and add it to the liquid in the barrel; the precipitate which forms is chloride of silver. An ounce of common sulphuric acid, added occasionally, acts beneficially, keeping the solution in an acid condition. Should the liquid, after standing twenty-four hours, refuse to clear up, a wine-glass full of a saturated solution of common alum or proto-sulphate of iron will bring about the desired result. When the precipitate has subsided, the waste water can be drawn off by the faucet and thrown away.

3rd. *Fixing Solutions from Prints and Dry Plates, and Cyanide Solutions from Tin-Types.*—These should be introduced into a barrel similar in every respect to that referred to in No. 2. Instead of *salt*, however, the savory compound known as *sulphide of potassium* must be dissolved and added so long as it forms a precipitate. The latter is of a very dark colour, and in this case is termed *sulphide of silver*. In these, and indeed all waste solutions, large stoneware crocks may be advantageously substituted for barrels, should the volume of waste not be too large.

4th. *Wet Plate Developer Washings.*—These may be introduced into a large stoneware crock, and allowed to stand untouched for twenty-four hours or so. No re-agent for precipitating the silver need be added, as the proto-sulphate of iron necessarily present accomplishes this in the most thorough manner, more especially if an ounce of common sulphuric acid be added. The latter prevents the formation of a useless deposit of iron along with the silver, and the refining as a natural sequence is rendered less difficult. A few drops of any "light oil" sprinkled on the surface likewise retards oxidation.

5th. *Gelatine Emulsions.*—To recover the bromide and iodide of silver which are present in the above waste, introduce the emulsions into a large stoneware crock to a height of one-third; a quantity of common sulphuric acid, say one or two quarts, must now be added. This in a few hours will result in the degelatinization of the gelatine, the latter losing its setting qualities. A large amount of boiling water must now be added, so as to make the solution as attenuated as possible. The silver will now, by reason of its superior specific gravity, gradually subside, forming a pale yellow deposit at the bottom of the vessel. Allow the crock to stand several days, and then decant off the supernatant liquid, and throw it away. Dry the precipitate spontaneously, or by filtration, through *very fine* bleached muslin, and it will be ready for treatment by the refiner.

6th. *Gold Solutions.*—Old "spent" toning baths sometimes contain a small amount of gold. To recover this proceed as follows:—Pour all these solutions into a stoneware crock; next add an ounce or two of common sulphuric acid, and finally, also, a strong solution of freshly dissolved protosulphate of iron. The precipitate will soon subside, and in time form a brownish-black deposit at the bottom of the vessel. The deposits, also, which invariably form while the toning bath is being neutralized by carbonate of soda or other alkali, should be saved and thrown into the crock.

7th. *Concluding Remarks.*—If absolutely necessary, the wet plate developer waste may be thrown into the barrel containing the print washings, but it is best kept separate.

8th. Should space be limited, the print washings and fixing solutions, &c., may be kept in the same barrel, and sulphide of potassium *only* used to precipitate the silver. We do not recommend this, however, if it can be avoided.

9th. A piece of very fine bleached muslin makes a good filter for all the wastes we have alluded to. An old felt hat or chamois leather skin is also very good, but acts slowly.

10th. In sending wastes, mark each lot with its appropriate designation, and observe that no gold will be sought for in silver residue, unless specially desired. Do not fail to mark on outside of package the name of the firm on whose account the waste is to be refined, and endeavour to allow at least fourteen days to elapse before asking about returns. Very large sacks or boxes of waste may be forwarded by freight; smaller and more valuable parcels by express, and very small lots by parcel post. If sent by freight, invariably forward a bill of lading, or delay will certainly occur.

WATER FOR PHOTOGRAPHIC PURPOSES.—Ordinary tap water is generally to be recommended for washing operations and for preparing solutions. For a stock solution of gold, however, and for nitrate of silver when that is required, distilled water should be employed. In solutions containing oxalates, such as the ferrous oxalate developer, and the solution for developing platinum prints, it is well to avoid the presence of lime salts, as these give a turbidity with oxalates. If distilled water is not at hand in sufficient quantity for these purposes, tap water may be made almost as good by removing the lime from it. This may be done by adding a little potassium oxalate, and allowing the precipitate formed to settle down. The quantity of oxalate to be added will depend upon the quality of the water; and it may be a guide to say that for New River water about thirty grains of potassium oxalate to the gallon would probably be a suitable amount.—CHAPMAN JONES in *Abraham's Photographic Annual.*

A NEW EYE.

BY CAMILLE FLAMMARION.

It cannot be gainsaid that the human eye is an admirable optical instrument. What transparency in this living crystal: what delicious shades of colour in this iris; what depth, and what charm! It is life, it is passion, it is a desire, it is the will, it is light! Close all these eyes: what would remain of creation? And, nevertheless, we have here a new eye—complementing our own and excelling it—still more marvellous. This eye, whose visions I have just admired, measures more than a metre in diameter, and fifteen metres in depth. Its crystalline lens is formed of an immense piece of glass, and its retina of a highly sensitive chemical plate. The eye of a giant, in verity, as the man possessing it should measure in our organic proportions 100 metres in height, and he would not be able to pass under the Eiffel Tower without humbly bending. A gigantic eye, possessing four marked advantages over ours: It sees *quicker*, *farther*, *longer*, and, precious faculty, it fixes, prints, and preserves what it sees.

Quicker: In the millionth of a second it photographs the sun, its spots, its vortices, its flames, its mountains of fire, and gives them to us in the form of an imperishable document. Farther: Directed toward any point of the heavens, in the darkest night it discovers in the abysses of the infinite, stars, worlds, universes, creations which our eye could never see with the aid of the best telescope. Longer: That which we have not been able to see after a few seconds' attention, we shall never see. This eye only has to look long enough: at the end of a half hour it will distinguish what it did not see; at the end of an hour it will see still better, and the longer it remains fixed upon unknown space, the better it will possess it—without fatigue, and always better; and it preserves on the plate, serving as its retina all that it has seen: our eye retains images but a moment.

Let us suppose, for example, that a man is killed at a moment when quietly seated in his arm-chair, and having his eyes open before a brilliantly-lighted window, and that his eyes should be removed and immersed in a solution of alum. These eyes would preserve the image of the window, with its transversal bars and its illuminated openings. But in the normal condition of things, our eyes do not retain images—there would be too many. The giant eye of which we speak retains all that it has seen; we have only to change the retina.

This new eye is the photographic eye. The principal astronomers of the world have just met at the Paris Observatory in order to decide on its immediate application to a new and complete study of the starry heavens. Magnificent specimens of photographs of the moon, the sun, the stars, the nebulæ, and even of the planets, were presented to the congress, and showed what may be expected from the new processes. Some photographs among them show us the lunar mountains and craters, such as they would be seen at a distance of forty leagues.

Yes, this artificial retina sees quicker and better, and by an absolutely different faculty it can penetrate into abysses into which we cannot see, and will never be able to see anything. We have here, perhaps, its most extraordinary feature.

Let us place our eye, for example, to the eye-piece of a telescope whose objective has an opening of thirty centimetres—these are the best instruments now in practical use in observatories. In this telescope of thirty centimetres in diameter and of three and a half metres in length, we discover stars up to the fourteenth magnitude—that is to say, about 44,000,000 of worlds of all kinds. Now, instead of our eye, let us use the photographic retina. Instantly the most brilliant stars will imprint their image on the plate. Five-thousandths of a second suffice for stars of the first magnitude, one-hundredth of a second for stars of the second magnitude, three-hundredths of a second for those of the third, one-tenth of a second for those of the fourth order, two-tenths for those of the fifth order, and five-tenths of a second for stars of the sixth magnitude. Thus, in less than one second, the photographic eye has seen all that we can perceive with the naked eye. But this is yet nothing. The telescopic stars visible in the instrument will also imprint their image on the plate. Those of the seventh magnitude require one and one-third second, those of the eighth magnitude three seconds, those of the ninth magnitude eight seconds, those of the tenth twenty seconds, those of the eleventh magnitude fifty seconds, those of the twelfth require two minutes, those of the thirteenth five minutes, and, finally, those of the fourteenth, thirteen minutes. It follows that, if we have given our plate an exposure of one-quarter of an hour, we will find imprinted on this plate all that portion of the heavens towards which the glass had been directed, and all that that region possesses—all that which with infinite trouble we might have been able to discover, to measure by a series of laborious and very lengthy observations. A sufficient number of instruments pointed so as to embrace the whole of the heavens will fix on an immense chart all that astronomical observations can study, and which could only have been obtained after a lapse of several centuries.

But here is only the commencement of the marvellous. Let us allow the photographic eye to look instead of our own; it will penetrate into the unknown. Stars invisible to us become visible to it. At the end of an exposure of thirty-three minutes, the stars of the fifteenth magnitude will have impressed the chemical retina and formed their image. The same instrument which shows to the human eye stars of the fourteenth magnitude, and which in the entire heavens would register about 44,000,000 of stars, shows to the photographic eye 134,000,000 at the first requisition for obtaining the fifteenth magnitude. It would reach the sixteenth at the second requisition, in an exposure of one hour and twenty minutes, and throw before the astonished gaze of the beholder a luminous dust of *four hundred millions of stars*.

Never before, in all the history of humanity, has man possessed the power of penetrating so profoundly into the depths of the infinite. With the new improvements, photography gives us clearly the image of each star, whatever its distance, and fixes it on a document where it may afterwards be studied at leisure. Who knows, if at some future day, in the photographic views of Venus or of Mars, a new method of analysis will not enable us to discover the inhabitants!—and its power extends as far as the infinite. Here is a star of the fifteenth, sixteenth, seventeenth magnitude, a sun like our own, at such a distance from us that its light requires thousands, perhaps millions, of years to reach us, notwithstanding its prodigious velocity of 300,000 kilometres in a second; and this sun lies at such a depth that its light, so to speak, no longer reaches us. The natural eye of man would never have seen it, the human mind would never have guessed its existence with the instruments of modern optics; and yet this feeble light,

coming from so far, is sufficient to impress a chemical plate, which will indelibly preserve its image. And this star might be of the eighteenth, of the twentieth order, and still smaller, so small that never human eyes, assisted even by telescopes of the highest power, will see it—for there will always be stars beyond our vision; and, nevertheless, with its little ethereal arrow it will reach the chemical plate exposed to await its coming and to receive it. Yes, its light will have travelled for millions of miles. When it started the earth did not exist—the present world with its inhabitants; there was not a thinking being on our planet; the genesis of our world was about being developed; perhaps only in the primordial seas which enveloped the globe before the upheaval of the first continents. The elementary primitive organisms were being formed in the bosom of the waters, slowly preparing the evolution of future ages. This photographic plate sends us back to the past history of the universe.

During the ethereal voyage of this luminous ray, which to-day reaches this plate, the entire history of the world was accomplished, and in this history that of humanity is but a ripple—but a moment. And during this time the history of this distant sun, whose photograph we now see, may also have been accomplished; perhaps it has long been extinguished, perhaps it no longer exists!

This new eye that carries us through the infinite causes us at the same time to ascend the stages of a past eternity.

Eternity! The Infinite! Contemporaneous astronomy plunges us into their depth and overwhelms us. How can we measure them? Flying with the quickness of the lightning, it would require millions of years to reach the regions in which these distant universes shine; but carried thither, we would not really have advanced a single step toward the limits of space—as space is without boundaries, the infinite without measures; and everywhere, in all directions, there are so many worlds, so many consecutive suns, that if we were to give the photographic plate the sufficient exposure, it would be covered with contiguous luminous points, so close as to only show one heaven of dazzling light; as everywhere, to whatever point we may direct the visual ray, there is an infinity of suns back of each other.

And we live on one of these worlds, on one of the most insignificant, at some point of the limitless immensity, receiving the light from one of these innumerable suns, in a limited horizon, a veritable cocoon of the silk-worm, ignorant of all the causes; ephemeral of a moment, imbued with an illusory view of the world, hardly seeing anything insignificant enough to imagine that we know something, even flattering ourselves with a sanctimonious sentiment of pride to be able to dominate nature; proud of an illusion mistaken for reality, we solve all questions. We call ourselves materialists without knowing one word of the essence of matter; spiritualists, without knowing a word of the nature of the spirit; but at the bottom of all thinking beings scepticism resides, because we are incapable of appreciating anything. Our lost little planet is still too vast for our conception, as we have invented local patriotism and the whole organisation of the divers social groups which divide the world between them is founded on the force of arms. Ah! the astronomer would wish that the leaders of the people, the legislators, the politicians, had the faculty to look at a celestial chart and to understand it. This calm contemplation might perhaps be more useful to humanity than all the congresses of sovereigns, and all the speeches of diplomacy. If it were known how small the earth is, perhaps man would cease cutting it to pieces. Peace would reign over the world, social wealth would take the place of the ruinous and shameful military craze, political divisions would be obliterated, and then only would men freely rise to the study of the universe, to the knowledge of nature, and enjoy the pleasures of an intellectual life. But we have not yet reached this point, and the photographic eye will reveal many celestial mysteries before the human eye sees reason and science establish their reign on our revolving ball.—*Paris Figaro.*

A WIFE'S VIEW OF AMATEUR PHOTOGRAPHY.

GENTLEMEN,—A letter from you addressed to my husband has come to hand. You ask him to write you an article for your photographic annual that is to be published next year, and you put in some taffy about his being a well-known amateur, and some stuff about what he writes being of interest, and that sort of thing. My husband is now on a photographic tour, as he calls it, and, of course, I open all his letters. It is not likely that my husband will be back in time to write the article you wish. When he goes off with that confounded camera of his you never know when he will come home. So I am very pleased to give you a woman's view of amateur photography, and if you print it in your annual I think you will not have another article just like it.

My unfortunate husband was stricken with the amateur photographic plague about three years ago. Up to that time I always considered him reasonably sane. I made no objection at the time to his joining the army of photographic cranks, because, you see, I knew nothing of the subject. I have done everything I could since that time, but, although he has quit smoking at my request, he refuses to give up the camera habit. At the time he began this so-called recreation my house, or perhaps I should say our house, was one of the neatest in the neighbourhood. You ought to go through it now. My carpets have been ruined with those abominable chemicals which he uses. I don't pretend to know their names, but I know well the effect they have. Then the bath room is something frightful to behold. He uses that for what he calls his dark-room, and has contrivances for shutting out the light.

I notice that, in one of the books you sent him, Daguerre was the inventor of photography. He may have been the inventor of photography, but I think it was another sulphurous gentleman with the same initial who was the inventor of amateur photography.

My husband was reasonably good tempered until he took up your diabolical art. I one time opened the door of the room in which he was working. It was all dark inside except a fearful red lamp, which threw a ruddy glow on his face, and made him look as if he were going to have an epileptic fit. The moment I opened the door and let some light into the room that man went perfectly crazy. He claimed I had spoiled a dozen of his plates, although I had touched nothing, and I came near suing for a divorce because of his awful remarks. If the evil one was not the inventor of amateur photography then I would like to know who was. Then the pictures he does turn out when he gets them finished are perfectly awful. He has tried at different times to photograph the children, but the poor little dears looked like wooden images in the pictures. I went into the bath-room once with the baby

and put him in the bath tub. There was some water there already, and it looked clear enough, but in it was some horrible solution of silver, that turned most of the baby jet black, and we haven't been able to get out the colour to this day.

Then the cost of the thing is something frightful, although my husband carefully conceals what he spends on it. I came across one of the photographic dealer's bills the other day, and it was enough to make one's hair stand on end. Pyrogallic acid, whatever that is, was fifty cents an ounce.

Just think, if I had to pay that price for sugar! Eight dollars a pound instead of ten cents.

Fifty cents an ounce! And that wasn't the worst of it. Now what do you think chloride of gold costs? For fifteen grains he is charged fifty cents. Now that, as you know well enough, is very near twenty dollars an ounce, and twenty dollars an ounce is over three hundred dollars a pound! I don't know how many pounds of the wretched stuff he uses every week, but if he uses ten pounds of it, and I am sure ten pounds of sugar don't go very far in a house with a large family like ours, you would see that that is 3,000 dols. for that one thing alone, not to mention the dozens of other chemicals he uses, and I am sure I don't know what the price of them is.

I tell you that amateur photography was invented to drive a poor woman crazy who has a husband that is a victim of the villainous practice. No wonder he says he can't afford a new dress for me when I ask him for it. The house is stained with horrible solutions from cellar to garret, and I am always afraid to use any cups or glasses for fear there is some dreadful poison in them. The cat took some milk out of a saucer that had something or other of potassium in it, and it just curled up and died.

I'm always afraid to sweep in any part of the house for fear it will raise a dust that will spoil something that he has tacked up on a board to dry. I wouldn't mind all this so much if he ever took a picture that was worth looking at; but, as I said before, he never does. There, now, print that in your miserable photograph book if you want to. Mrs. John Tripod.

N.B.—If you ever write to my husband again telling him that his articles on photography will be appreciated, I will burn your letter, and you will lose your postage stamp. So just remember that.—Mrs. J. T.—*Detroit Free Press.*

THE NEW PHOTOGRAPHIC DEVELOPERS.

BY PROF. CHARLES F. HIMES.

For bromide paper, according to General Brown, eikonogen is undoubtedly the developer of the future, affording warmer tones than the oxalate, and beautifully clear whites, without acid flushing, with simple rinsing with water before fixing. Whilst the appearance of the picture is slow, especially as a used developer, preferably twenty-four hours old, is preferred, the development is regular and uniform to every detail, without risk of staining; and the same solution can be used for a number of prints. It is said to be unaffected in its action by variation in temperature, and therefore adapted to all climates. It is non-poisonous, does not stain the fingers, will keep over a month mixed, acts so energetically that only half the exposure is required as that with pyrogallol, and development occupies a much shorter time. The solution can be used over and over again without staining until its reducing power is exhausted. It is, on the other hand, especially adapted to development of over-exposures. With all its excellences it is a cheap developer, and will keep indefinitely as a dry powder. Its slight solubility, however, will prevent its use in concentrated stock solutions, as pyrogallol.

The commercial article is accompanied by formula for its use, and the recommendation by some to reduce the strength of these does not seem to be approved by the most successful experimenters with it. The following formula by General Brown, for a normal developer, will serve to indicate the general character of solutions used:—

No. 1.	Sodium sulphite	15 grains
	Eikonogen	7½ ,,
	Water	1 ounce
No. 2.—	Carbonate of potassium	80 grains
	Water	1 ounce

For use, mix three parts of 1, one-half to one part of 2, according to exposure.

Pyrocatechin. — Orthodihydroxybenzol, an isomer of hydroquinone, with the formula $C_6H_4(OH)_2$ is at present a subject of careful investigation as a developing agent for dry plates. The results thus far are quite promising. Its use as a photographic developer was suggested as early as 1859 by Wagner. Eder and Toth announced its developing power in alkaline solution in 1880. Prof. Benoist, of Toulouse, last year published results of considerable experience with it. Dr. Arnold pronounces it fifteen times as energetic as hydroquinone, and enumerates among its chief excellences the excellent tone and good qualities of the negatives produced by it, the absence of fog, loss of sensitiveness to light of the plates after immersion in the developer, so that development may be continued, after immersion, in ordinary gaslight, or even in diffused daylight without injury; great latitude of exposure, as development proceeds slowly, but uniformly; freedom from stain to the hands; simplicity of formulæ for solutions, and possibility, on account of its solubility, of preparing concentrated stock solutions which will keep well if the pyrocatechin is chemically pure, and which can be used by the drop; convenience in carrying the small quantities of ingredients required for development; development without motion; and withal, on account of its high reducing power, the expense, at twenty-five cents per gramme, is not exorbitant, as that quantity will develop 100 to 150 plates 13 by 18 cm. He employs the following stock solutions: *a*, one per cent. solution of pyrocatechin; *b*, twenty per cent. solution of potassium carbonate. Sodium carbonate he does not find to answer as well. For development of a well-exposed plate, 7 by 9 inches, one cc. of *a* and five to ten cc. of *b* are mixed with sixty to eighty cc. of water. Sulphite of soda does not seem necessary or desirable. The mixed developer will not keep, and should be used only once. Carl Srna, employing it with carbonate of soda and sodium sulphite, as in Balagny's formula for hydroquinone, found it more energetic than the latter, whilst others have found it less so. Dr. Eder, in his more recent experiments, was particular to employ it in its purest form, as was Dr. Arnold, and found it a rapid, energetic developer, yielding coffee-brown negatives

of good quality. He employed the following solutions:—

A.—Pyrocatechin	... ...	1 part
Sulphite of soda	... ...	4 parts
Water	... ...	40 ,,
B.—Carbonate of potash	... ...	4 ,,
Water	... ...	40 ,,

mixing for use one volume of *A* with two of *B*. The sulphite of soda is not absolutely necessary, but with it the solution will keep clear much longer.

Paraphenylendiamin—$C_6H_4(HN_2)$ has been found by Dr. Eder to act well as a developer for dry plates, having about the same energy as pyrogallol or hydroquinone. As far as experiments have been conducted, the development with it is regular, and negatives produced are delicate and soft. It was used with potash, without sulphite, which retards the development greatly, but prevents the solution from becoming coloured.—*Franklin Institute Journal.*

THE DINNER OF THE PHOTOGRAPHIC SOCIETY.

LAST Monday night the annual dinner of the Photographic Society took place at the Café Royal, London, under the chairmanship of Mr. JAMES GLAISHER, F.R.S., President. There was a large attendance.

Mr. W. S. BIRD, Treasurer, proposed success, and prosperity, and usefulness to the Photographic Society of Great Britain, coupled with the name of Mr. Glaisher. He spoke of the high influence of its Journal in times past, until affected by the advent of weekly newspapers, and how great improvements had been made in its last two numbers by the Honorary Secretary. The last exhibition of the Society he considered to be, perhaps, the best ever held in this country. Their President was more than fourscore years of age, and gave to his duties in the Society, as to everything else he undertook, his best work.

The PRESIDENT felt honoured by the trust reposed in him; he had tried to be faithful in his work, and to hold the scales of justice evenly. He wished to see the Society placed in a firm permanent position, and hoped that it would be one day known as the Royal Photographic Society; he also expected that before long it would have a good library.

Mr. SEBASTIAN DAVIS stated that there are now about 400 photographic societies in different parts of the world. He spoke highly of Rejlander, and the way in which he had promoted the artistic side of photography, and proposed prosperity to the photographic societies throughout the world, coupled with the name of Mr. George Davison, of the Camera Club.

The PRESIDENT thought that every society in this country should be connected with the Photographic Society; the parent society was proud of its children.

Mr. G. DAVISON said that the photographic societies of the country looked to the Photographic Society to keep photography up to the highest standard from a scientific point of view. It was also desirable that photography should have high standards from a fine-art point of view. He returned thanks on behalf of the photographic societies, and of himself individually.

The PRESIDENT then proposed the toast of the photographic press, coupled with the name of Mr. W. H. Harrison, who had been known to him at the British Association meetings years before his reappearance in photographic circles.

Mr. W. H. HARRISON responded, and in the course of his remarks said that he ventured to suggest that the photographic societies of this country should enter into closer relationship with foreign societies, and not, as was sometimes the case, act as if the latter had no existence.

Dr. CHARTERS WHITE responded to the toast of the ladies, and narrated some mistakes made by girls at Board School examinations. One girl said that some food was flesh-forming, and other food bone-forming; if they ate too much of the latter they would grow too many bones, and would look funny.

Mr. W. S. BIRD spoke of the admirable photographic work done by Mrs. Cameron and other ladies.

Songs, recitations, and music were given by Miss Friese Greene, and Messrs. Wilson, Brain, Braham, Lowe, Protheroe, and Cowan (senr. and junr.).

Mr. Glaisher had to leave somewhat early, after which Mr. Bird and Mr. W. England presided in turn.

Correspondence.

GAS CYLINDERS.

SIR,—A good deal of unnecessary alarm has been caused by the lamentable accident which occurred rather more than a week ago at Glasgow through the bursting of a cylinder. There is no occasion either for alarm or surprise when the facts of the case are known. If we hear of a man who deliberately throws a lighted match into a barrel of gunpowder, we are neither alarmed nor surprised at the results. This is exactly what has occurred at Glasgow; the unfortunate man who lost his life charged hydrogen into a black cylinder—in direct contravention of the Company's rules—and afterwards, forgetting that he had done so, put oxygen into the same vessel; the result was an explosion, which took place at the first slight concussion which the cylinder received. A piece of the cylinder which was picked up four yards from where the accident occurred was quite hot, showing conclusively that ignition had taken place, and there could have been no spontaneous ignition if the two gases had not been present.

Every precaution is taken by the Companies to prevent the possibility of O and H getting mixed; under no circumstances will they fill hydrogen or coal gas into black cylinders, or oxygen into a red one; neither will they put the one gas into a cylinder which they even suspect has ever contained the other.

With a view, however, of making it absolutely impossible for two gases to be put into the same cylinder, it has been decided by this Company, and also by the Scotch and Irish Oxygen Co., and the Manchester Oxygen Co., to fit all hydrogen cylinders with a left-hand thread, so that they cannot be filled at the oxygen pump, and, in the same way, it will be impossible to fill oxygen cylinders at the hydrogen pump. All consumers are earnestly requested to send their hydrogen cylinders either to the Companies, or to the agents through whom they obtain their supplies of gas, to have the alteration made, and the smallest possible charge will be made for taking off the present valves and fitting on new ones. After a certain limit of time, of which notice will be given, no hydrogen or coal gas cylinders not provided with the new thread will be filled.

In some quarters the fear has been expressed that the accident at Glasgow occurred through over-pressure. Any such apprehension may be immediately dismissed from the mind; explosion from such a cause is impossible. The cylinders are tested to double the pressure at which they are ever filled, and it is impossible to exceed the standard filling pressure of one hundred and twenty atmospheres. They are also re-tested periodically. For years past the Government have been using high-pressure cylinders for ballooning purposes similar to those in use at present; they had them in the Egyptian and Boer campaigns, and they have frequently been rolled from the top of a hill to the bottom, bounding from point to point, and in no single instance has an accident occurred, or a cylinder burst.

In conclusion, I would remind you of the fact that since oxygen and hydrogen have been supplied in high-pressure cylinders—now some three or four years—only two accidents have occurred, and these at the Works; whereas when bags were in vogue, accidents, in many cases fatal, frequently took place. Only last week in America, a lecturer on chemistry and ten or twelve of his pupils were seriously injured by the bursting of a retort in which oxygen was being made by the old-fashioned chlorate of potash process.

T. N. HESTER, *Secretary to Brin's Oxygen Co., Ltd.*

PHOTOGRAPHY AND FIRE INSURANCE.

Sir,—It may interest you to know we have just had our insurance premium reduced 10 per cent. by pointing out to our Insurance Company that no collodion or other such inflammables are stored on the premises. Norman May & Co.

12 & 13, *Church Street, Malvern, and at Cheltenham, Feb. 8th.*

PHOTOGRAVURE.

Sir,—Referring to Dr. Gunther on photogravure, page 99 of the Photographic News this week, can you tell me at what part of the preparation of the *second* stone is the asphalt applied? There is no mention of its application to the second stone, but yet it says at the end of the article, clean it off with turps. If you can give me any information on this point I shall feel obliged, as I intend trying the process to the end. I thoroughly understand a great deal of it already, but cannot see where the asphaltum is applied to the second stone. If successful, it must be a very good process. E. Frewing.

26, *Eden Street, Kingston-on-Thames, Feb. 7th.*

Specifications Published.

18,357.—*December 15th*, 1888. "Changing Camera Slides." Henry Herbert, 119, Hartfield Road, Wimbledon, Electrical and Photographic Instrument Maker.

The object of this invention is to provide means whereby a considerable number of plates, say, for example, a dozen, can be carried, exposed, and changed, in one apparatus, instead of the two plates usually carried in the ordinary dark back.

In carrying this invention into effect, I provide a suitable box or case which may be adapted to slide in the back of the camera, or in a separate frame of its own which may be attachable to the camera in the ordinary way, or may be used separately where required. The sliding box is made of suitable size and shape, and contains the required number of plates, whether exposed or not, and is preferably provided with a closing shutter and a narrow slit or opening at the inner end, through which each plate as it is required for use can pass. This opening may be closed with an automatic shutter, which, upon the removal of the case from its frame or the camera, at once closes the opening and prevents the entrance of light into the case. In the back of the camera or frame I prefer to provide a spring-controlled hinged plate or equivalent device, preferably of wood, which is pressed back into a suitable recess or receptable upon the insertion of the sliding case, and upon the withdrawal of the case springs forward.

In using this apparatus, the sliding case is first charged in the usual manner with the sensitised plates, and is then inserted into the frame or camera, the automatic shutter withdrawing from the aperture in the end of the case as it enters. The case having been pressed home, and it being desired to place the plate in position for exposure, the case is withdrawn, the bottom plate passing through the slit in the casing and remaining in the camera or frame as the case is withdrawn. The spring back is locked by a suitable detent, but when the sliding case is withdrawn sufficiently far from the frame or camera, the detent is automatically released, and the spring back then moves the plate forward to its proper position for exposure, where it is held securely by the sliding case, which is now returned into the frame or camera. After exposure, the sliding shutter is withdrawn, and the plate falls back into the sliding case with the other plates; the shutter is then closed again. To expose the next plate the sliding case is withdrawn as before, leaving the next plate in the frame; this is brought forward as already described, and the sliding case is again returned, and, after exposure, the second plate is replaced in the case by the withdrawal of the sliding shutter as before, and so on until all the plates have been exposed, when the sliding case may be removed and a new one already charged substituted, or the sliding case can be relieved of the exposed plates in the dark room, re-charged with fresh plates, and replaced as before.

In the frame or camera, at the opposite end to that by which the sliding case enters, I prefer to have a spring controlled, rising bottom, carrying two suitable guides so arranged that, when the plate is pushed forward by the hinged back, it must of necessity come into the right position for exposure. When the sliding case is inserted, it pushes back the rising bottom.

1,261.—*Jan. 23rd*, 1889. "Photographic Lenses." Hugh Blackwood, Sidney Cottage, Beckenham, Kent, Gentleman.

In order to take portraits or views by photography in a proper and effective manner, the essential points to be attained are, the option of rapidity, width of angle, combined with flatness of field, clearness of definition, and depth of focus (or field), with a comparatively large stop (or wide orifice).

It has, however, hitherto proved exceedingly difficult to satisfactorily attain all these points in one lens. An improvement has been effected on one point, with a more or less contrary effect upon another point.

Even the lenses of Dallmeyer, Ross, Voigtlander, and other well-known makers, which have been produced with the object of obviating these defects, have not entirely done so, but the improvement is so great that these lenses are much sought after, notwithstanding the great cost of the same; and at this very heavy expense (with added weight when travelling) different lenses have to be used, and have hitherto had to be purchased separately from these makers, for the various subjects to be photographed; thus, for instantaneous and general outdoor work, a comparatively narrow angle lens is used, whilst for indoor work and confined situations a wide angle lens is required, and for indoor portraits a portrait lens.

Now the object of my invention is to entirely overcome the difficulties above mentioned, by simple means, at a small cost.

In carrying out my invention, I employ an extra lens, which I place just in front of the rear lens, or it may be inserted in the stop itself, different sizes and strengths being thus optional.

This extra lens, by preference, consists of a bi-convex and a bi-concave, which may be cemented together, or arranged with a small air space between. I prefer the latter arrangement, as I can thereby substitute for one or both a stronger or weaker glass according to the effect it is desired to produce, as by the addition of stronger bi-convex lenses, the focal length may be shortened down to such an extent that the sensitised plate may almost touch the lens.

The glasses which I employ for my extra lens are ordinary eye glasses that can be purchased for a small sum almost anywhere.

The strength of glass which I find most suitable varies from No. 5 to No. 16 (French Nos.), according to the class of lens to be used; thus, for a whole plate rapid rectilinear, or half-plate Lancaster meniscus lens, Nos. 7 or 8 are most suitable, while, for a portrait lens, the strength may vary from Nos. 5 to 16, according to results required. By the addition of my

extra lens, a narrow angle Ross, or other maker's narrow angle lens is converted into a wide angle; whilst a Dallmeyer, or other maker's wide angle lens, may be converted into a narrower angle of any required degree by substitution of a stronger bi-concave. Also, if objects at a great distance are to be photographed—say from the top of a hill—flatness of field and depth of focus—with a large stop or orifice, enabling instantaneous effects—will be attained. A Voigtlander or other portrait lens becomes, by addition of my lens, applicable for all known purposes, as the good qualities previously sacrificed, to get the greatest possible rapidity, are regained. Similarly, any ordinary lens, with addition of my lens, becomes increasedly efficient for purposes of enlargement.

I also find that, whilst with the lenses of Dallmeyer, Ross, Lancaster, and other well-known makers, my adaptation produces greatly improved results, it with some French and other lenses acts as a detective, in case such glasses are badly paired, or the lenses be of poor marginal definition, though at the same time it practically removes this defect, as it permits of the lens being stopped down to overcome the defect, but with a larger stop than could be otherwise used.

I have found that with many meniscus lenses, by the mere addition of one bi-convex glass of No. 8 strength, I obtain rapidity (shortened focal length) width of angle, clear definition, and flatness of field, but in most cases I prefer to use the compound lens.

Similarly, with an addition of one No. 1 or 2 short-sight eye-glass inserted in the stop, an ordinary ¼-plate portrait lens will cover a ¾ or 7″ by 5″ plate at the same focal length (viz., 6½″) as before with a large (⅝″) stop, yet with flatness of field and depth of focus, or a Dallmeyer 2C. Baby lens will cover from a ¼ to a 12″ by 10″ plate, with a larger orifice than at present, and attaining increased rapidity and brilliant effect.

In all cases a diaphragm will be placed between the extra lens and the rear lens in the combination.

1,334.—*21th January*, 1889. "Lens Diaphragms." JOHN STUART, The Hollies, Clapham Common, Surrey, Optician, and GEORGE HARROP, 30, Russell Road, Holloway, London, Engineer.

This invention relates to the stops or diaphragms known as the "Iris," and has for its objects to enable the diaphragm or stop and its holding and operating rings to be contained entirely within a lens tube or mounting of the usual size, and also to provide means whereby the operator can (without necessitating reference to a scale), with great facility and certainty, adjust the diaphragm or stop definitely to any set size of aperture, without danger of its accidentally becoming altered. To effect this, the ring to which one end of the component members, leaves, or strips are centred is made of a size to fit in the lens tube or mounting, and the ring to which the other ends of the said members, leaves, or strips are centred is provided with slots extending from the inner circumference to near the outer circumference, where the said ring is strengthened by a supplementary ring or annulus, preferably at right angles thereto. A stem attached to this slotted ring, or the supplementary ring, projects through a slot in the tube or mounting for enabling the operator to adjust the aperture.

In a suitable part—for instance, in a ring secured within the casing which contains the diaphragm—notches or recesses are made, with which engages a spring or catch secured to any suitable part—for instance, to the ring which is slotted as aforesaid. The free end of the spring catch that enters the recesses or divisions in the ring allows the ring to be rotated; but as it comes opposite the notches or recesses, the operator is aware that the diaphragm or stop then presents a certain known and definite aperture, in accordance with the recess or notch with which the catch is engaged.

The tube or mounting of the lens may be provided with divisions marked so that the position of the stem corresponding with any given aperture may be ascertained by reference to the scale or projections; recesses or the like may be used instead of the scale, or in addition thereto, so that by running the finger over them, they may be readily counted, and the aperture thus ascertained in a dark place.

The inventors claim:—

1st. In diaphragms or stops of the kind described, the actuating ring having a strengthening rim or ring and radial slots therein, opening from the inner circumference of the ring or thereabouts, with which slots engage pins on the leaves, members, or strips of the diaphragm or stop.

2nd. In diaphragms or stops of the kind described, the combination with an indicator or scale of a spring engaging with a notched ring for indicating the degree of aperture, and retaining the leaves, members, or strips of the diaphragm or stop in their adjusted position.

3rd. The arrangement and combination of parts constituting a lens tube or mounting, provided with a diaphragm or stop of the kind shown in the drawings accompanying the specification.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE annual general meeting of this Society was held on Tuesday evening last, the President, Mr. JAMES GLAISHER, F.R.S., in the chair.

The report of the Council was taken as read, and Mr. J. STILLER proposed its adoption; Mr. SCAMELL seconded this motion.

Mr. A. MACKIE made some strictures upon portions of the report, and was followed by Mr. W. BEDFORD, who, while not altogether approving of Mr. Mackie's remarks, thought there was more that might have been done. The question of affiliation with other societies had not been advanced, neither had that of establishing a photographic museum.

Mr. S. G. B. WOLLASTON considered that the papers that had been presented to the Society were, on the whole, of too scientific and abstruse a character.

Mr. G. DAVISON held the contrary view, and thought that the dignity of the Society was best upheld by papers of an abstruse and scientific character. As to affiliation with other societies, directly they went into details to see how it would work, they got into difficulties. If the affiliated societies made any payment, their members would expect to enjoy as a right all the privileges that belonged to the present members, who each paid his subscription.

After a few other observations, the report of the Council was adopted *nem. con.*

The HON. TREASURER then read his report, in which it was stated that the capital of the Society had been increased by carrying forward a sum of £139. The profits on the exhibition had been £161. The cost of the Society's Journal for the number printed was about 7s. a page, and the last number was a very full one. There had been a considerable alteration in the character of the Journal, and it was a matter for consideration whether steps should be taken to secure a continuance of similar abstracts of the various photographic subjects. Several members spoke in terms of high praise of the recent change in the character of the Journal, and hopes were expressed that it might be continued, or even further extended.

The adoption of the Treasurer's report was proposed by Mr. Montefiore, and seconded by Mr. Mackie, and was carried *nem con.*

The PRESIDENT then handed the progress medal to the son of Capt. Abney, who was unable to be present and receive the award in person.

Mr. WOLLASTON and Mr. MACKIE thought that under the new rules, the Council had not the power to award medals, and a motion to this effect was put to the meeting, without, however, finding more than two supporters, whilst fifteen voted against it.

Mr. WARNERKE proposed a resolution, which was carried by twenty against three, to the effect that the phrase "Management of the Society" occurring in the rules, included everything that assists in the advancement of photography and the branches of art connected therewith.

The election of officers was then declared as follows:—*President*—Mr. James Glaisher, F.R.S., &c.; *Vice-Presidents*—Capt. Abney, C.B., Messrs. T. Sebastian Davis, H. P. Robinson, and John Spiller; *Treasurer*—Mr. W. S. Bird; *Members of Council*—Messrs. G. L. Addenbrooke, W. Bedford, Valentine Blanchard, Lyonel Clark, Francis Cobb, A. Cowan, T. R. Dallmeyer, Major L. Darwin, George Davison, W. E. Debenham, W. England, J. Gale, H. Chapman Jones, Capt. A. M. Mantell, Sir T. Prescott, Sir D. Salomons, J. W. Swan, J. T. Taylor, Leon Warnerke, and H. Trueman Wood.

After the customary votes of thanks, Dr. LINDSAY JOHNSON read a paper, in which he pressed upon the notice of the members of the Society the advantages that would be derived from the formation of a museum, and of an institute for instruction and research. Some months since, he said, there had been announced a sale of some very valuable historical objects of great photographic interest. When he heard of the sale he wrote to the Society to see if they could not see their way to purchasing them for the benefit of the Society. Some friends offered to assist with money, but the scheme fell through, and, if he recollected rightly, many of the things were bought for the museum at Bath. As the Society existed at present, it was liable to be turned out of its place at any time. He proposed several alternative schemes, the chief of which was that the Society should obtain premises of its own, where a permanent museum could be established in connection with an institute for instruction and research in photography. This had been done by the Governments in France and Germany, but it would not do to expect as much from the Government here. He thought, however, that the aid of the Common Council might be asked for with a probability of success if the Photographic Society were provided with a place and a programme calculated to inspire confidence. He thought that a place might be obtained in the vicinity of Shaftesbury Avenue, and that if a design for a building were prepared by a competent architect, a building to cost £20,000 to £30,000, the Court of Common Council might be induced to assist, supposing, that is, that it could be shown to be for the advantage of the metropolis that the scheme, as a whole, should be carried. Other alternatives were to apply for space for a museum at South Kensington, which, however, he considered to be too far off, and to hire a flat in a convenient locality, where part of the programme at least could be carried out.

The consideration of Dr. Lindsay Johnson's paper was deferred till the next ordinary meeting, March 11th.

Mr. Enrico Resta was balloted for and duly elected a member of the Society.

CAMERA CLUB.

ON Thursday, February 6th, a paper contributed by Sir DAVID SALOMONS was read, with Mr. E. R. SHIPTON in the chair. The paper contained formulæ for ascertaining the exact distance of the lantern from screen when a particular amplification with a given lens is desired, and for finding the focal length of lens to employ for a fixed distance and enlargement. An exhibition of lantern slides followed of views in the Netherlands, by Messrs. H. M. Elder, E. G. Spiers, and W. A. Greene. These were succeeded by a set of New Zealand scenes by Mr. Wray Palliser, and the first club loan collection of slides, sixty in number, contributed by various members. Other sets were shown by Messrs. Andreae, Dresser, Harding, Tidey, Payne, and A. Shipton. Nearly 300 slides in all were brought by members for exhibition.

At the commencement of the meeting the Hon. Sec. handed round an instrument sent by Mr. Dresser called the "Lanternscope," an apparatus devised for the effective viewing of lantern slides. The lanternscope exteriorly is a little like the stereoscope, but without the means of securing stereoscopic effect. The transparency is viewed through a magnifying eye-piece, the picture having behind it a piece of ground glass for diffusing the light from the lamp. It strongly resembles the instrument devised by Mr. Bow, C.E.

A photograph of the Eiffel Tower, taken by M. A. Pepper, of Paris, was sent for inspection by Messrs. Hinton and Co.

The paper on Thursday, February 20th, will be one communicated by Mr. W. K. Burton, "On One or Two of the Tenets of the Naturalists." The meeting opens at 8 p.m.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting on the 7th inst., Mr. J. ZAEHNSDORF occupied the chair.

Mr. A. C. Pemberton was elected a member of the Association.

A negative was handed round marked throughout the film in a similar way to one exhibited at a recent meeting; the negative had been varnished.

Mr. A. HADDON believed the defect arose from particles of dust in the varnish, causing the gelatine film to be imperfectly protected. Moisture eventually finding its way through the varnish, caused the gelatine film to swell and so split up the varnish, each particle of dust in this way forming a nucleus of the geometrical markings.

Mr. T. E. FRESHWATER read a letter received from the Scotch and Irish Oxygen Company anent the recent explosion, from which it appears that the bottle, at the time of the accident, was filled with a mixture of oxygen and hydrogen; the cylinder was marked H. A portion of the bottle found proved that it had received a test pressure of 240 atmospheres, dated July 2nd, 1889. The letter further stated that it had been determined in future to adopt entirely different fittings for oxygen and hydrogen bottles, to prevent any mistake in the filling of the cylinder, and make it impossible to put the two gases in one bottle.

Mr. J. S. TEAPE showed a stoppered bottle of eikonogen; the crystals had turned quite black. The bottle had only been opened once. Some eikonogen kept in paper a similar length of time was only slightly discoloured.

Mr. W. E. DEBENHAM had kept a sample in paper for some time. It had scarcely changed colour.

Mr. A. COWAN believed the changing of colour of the eikonogen shown by Mr. Teape was due to its having been put in a damp bottle.

Some crystals were taken out of the bottle and placed in water, when it was found that the black colour was only on their surfaces.

In reference to a question asked at the last meeting for particulars as to the photographic inventions of the late Dr. Joule, mentioned in a letter to the *Daily Standard*, Mr. A. Haddon brought down to the meeting a volume of Dr. Joule's scientific papers, collected by the Physical Society of London, in which no trace could be found of any reference to any photographic discoveries.

Mr. J. B. B. WELLINGTON asked what material was considered the best for a lantern screen, and whether bamboo or pine would be best for the frame.

Mr. T. E. FRESHWATER said bamboo of course was the lightest, but it was difficult to get it quite straight, and it was very unequal in thickness; each ferrule would in consequence have to be marked. These objections did not apply to pine wood, to which he would give preference.

Mr. F. A. BRIDGE said that a medium thick calico was the best material for the screen. It was resolved that at the next lantern meeting in March a slide competition should take place.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

THE fourth general meeting of the session was held on Feb. 6th at 207, Bath Street, Mr. WILLIAM LANG, Jnr., in the chair.

The following new members were elected:—Messrs. Paul Rottenburg, James Richardson, C. J. Anderson, J. T. Darling. Ex-Provost Clark was elected an honorary member.

In the question-box the following questions were found:—(1) "Can anyone give any information about the explosion at Pohnadie? Is there to be any public or scientific report to be made regarding the same?" (2) "What method of varnishing celluloid films is the best?" (3) "Can anyone mention a formula for toning Alpha lantern plates?"

Regarding the first question, after some discussion, it was

thought that the authorities would be sure to investigate the matter. The second question was, to a large extent, unanswerable. It was understood that the Eastman Company were working to produce a suitable varnish.

Professor E. J. MILLS then gave a communication, "Some Practical Notes," in which reference was made to eikonogen, its discovery, chemical constitution, and its rôle as a developer. Several interesting novelties were shown by Dr. Mills, notably a lens mounted in aluminium.

Mr. H. M. SMITH, representing the Eastman Company, exhibited the new Kodak, celluloid film negatives, new glass tray for developing same, and other apparatus.

Specimens of a new glass etching process (Mallodi's patent) were next passed round, and the proceedings closed with a series of photographs illustrative of the various photographic conventions, forwarded by Mr. A. Pringle, and some micrographs by him were shown by means of the Society's lantern.

SHEFFIELD CAMERA CLUB.

AT the meeting of the Club on January 27th, the following were elected officers:—

President—Mr. G. T. W. Newsholme, F.C.S.

Vice-Presidents—Messrs. J. H. Merton, M.D., and J. H. Rawson.

Treasurer—Mr. B. W. Winder, F.C.S., F.R.M.S.

Hon. Secretary—Mr. G. E. Maleham.

Council—Messrs. Wm. Gillig, junr., W. Genkinson, Prof. Arnold, H. Morrell, J. A. Manton, F.R.C.P., M.R.C.S., T. S. Yeomans.

The inaugural meeting of the new session takes place on Feb. 26th.

PHOTOGRAPHIC CLUB.—The subject for discussion on Feb. 19 will be "Lantern Illuminants, including the New Benzoline Limelight."

EAST DULWICH AND PECKHAM PHOTOGRAPHIC SOCIETY.—A lantern entertainment was given by this Society at the Collyer Hall, Peckham, on the 17th inst., when a large number of slides, the work of various members, was shown.

A NEW CHEMICAL SOCIETY, it is said by the *Monthly Magazine*, is likely to be formed before long on the other side of the Atlantic. It is to be called the American Chemical Society, and is to have local sections at Boston, New York, Philadelphia, Washington, Baltimore, and other towns. The new society will, it is anticipated, be an imitation of the English Society of Chemical Industry—that is, a national organisation with local sections.

FLUID MEASURE.—The *Monthly Magazine* describes and illustrates what it terms the "Excelsior" fluid measure, which consists of a well-made tin can or pot of the ordinary shape, with spout and handle, the capacity of which is exactly one imperial quart. Up the side of this vessel are fitted in four glass discs—looking something like the port-holes of a toy merchantman or frigate—duly protected from a chance blow by cross-bars of metal. In this way the level of the interior liquid can be seen, and the quantity graduated into pints, half-pints, and so on.

RECEIVED.—"Abraham's Photographic Annual," though in the main a catalogue of photographic goods, includes some sixty pages of original articles contributed by Messrs. Lyonel Clark, George Davison, A. R. Dresser, E. A. Golledge, W. Jerome Harrison, Chapman Jones, Major J. W. Nott, Andrew Pringle, E. J. Wall, W. Willis, and others; it contains also formulæ, statements of processes, and other useful items well worth the outlay of the few pence charged for this combination of guide-book and trade list.——From Mr. A. R. Wormald, a specimen box of assorted coloured lantern slide masks, which are made in any desired colour, and in gold and silver paper. They are supplied in various shapes assorted, five shapes in each box. With the foregoing is also forwarded a sample sheet of twenty-four colours.

X.—The list of awards at the Royton Exhibition was not received by us.

Answers to Correspondents.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

HISTORICUS.—Early history of photography. Consult the Rev. T. F. Hardwich's "Manual of Photographic Chemistry," or pages 18 to 20 of Chapman Jones's "Science and Practice of Photography;" or, lastly, look up the dates for yourself in the early copies of the NEWS, and the first few volumes of the *Photographic Journal*.

NATURE PRINTING does not come within the province of photography. Henry Bradbury's lecture on the subject was delivered at the Royal Institution in May, 1855. The results were certainly very beautiful, but they have been to some extent superseded by photo-mechanical methods, and we do not hear of the process being in actual use at the present time.

E. P.—The print and sensitized paper both show markings, such as would be caused by fine particles of pyrogallic acid or other reducing agent becoming accidentally dusted over the paper either before or during the silver treatment. See page 84 of the YEAR-BOOK. Another batch, you say, does not show this defect when sensitized on the same (filtered) baths and blotted off on the same pads. It would seem, therefore, to be due to some such impurity in this particular delivery of albumenized paper. Get some witness to overlook your work and certify to these particular defects, if your own affirmation is distrusted.

COLOUR (Exeter).—"The Art of Photographic Painting," by A. H. Bool—a little shilling manual to be had of our publishers—gives all the information required to make a start.

H. C. S.—When ordering the rapid plates of Messrs. Marion and Co., be sure to advise them of your special requirement of extreme rapidity. If these should not succeed, try Messrs. Wratten and Wainwright's instantaneous plates.

PHOTARGUS.—Removal of brown silver spots from gelatine negatives. Immersion in excessively weak cyanide of potassium, after removal of the varnish, will sometimes answer, but it is apt to pull down the intensity of the negative. Remember to wash well afterwards. Valuable negatives are often printed with a film of mica between, but the new Eastman celluloid ought to be tried, as it is cheaper. Goldbeaters' skin would not be sufficiently transparent. It is a well-known fact that gelatine negatives are more liable to stains in the printing than were the old collodion plates when treated with the same varnish. In the latter case, the shellac gets through the film down to the glass, but not so with the gelatine, which stands, moreover, in higher relief, and is especially sensitive to the most minute traces of silver. Some advise a preliminary coating of plain collodion before varnishing.

E. F.—Partly answered by post; the other enquiry is proceeding, and your letter inserted.

IGNORAMUS (Dublin).—Formula for collodio-chloride is given at page 203 of the YEAR-BOOK. Chloride of strontium, being more soluble in spirit, is sometimes preferred to chloride of calcium, and may be used in the same proportion.

S. V. W.—Silver washings.—In cold weather the precipitated chloride does not settle down so quickly. An acid reaction favours its separation, so you should use hydrochloric acid instead of salt at this season, and take care to stir well. Your remark about short returns from silver residues may admit of another explanation, and be accounted for by the fact that less silver nitrate is commonly employed in the ready sensitized papers.

F.R.A.S.—An excellent portrait of the late Father S. J. Perry, F.R.S., appeared in the *Illustrated London News* of 18th ult. It is a Meisenbach block from a photograph by Messrs. Maull and Fox, 187, Piccadilly, from whom an original copy may very probably be obtained.

SPOTS and another letter received,

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1642.—*February* 21, 1890.

CONTENTS.

THE REPORT OF THE INTERNATIONAL PHOTOGRAPHIC CONGRESS.

THE official report of the International Photographic Congress held last year in Paris has been issued this week by the Minister of Commerce, Industry, and the Colonies. It contains a report of the opening speech of Dr. Janssen, the President, also brief reports of each of the sittings of the Congress, and, finally, the conclusions at which the Congress arrived in relation to the various subjects brought under its notice. The report is published by the *Imprimerie Nationale*, of Paris.

Some of the resolutions adopted by the Congress have already been criticised in detail by the photographic press, because of the official abstract of them published last autumn. Among those now given in detail, that relating to the terms used in photography is of much interest, for there is no doubt that the variety of words now sometimes employed to denote one and the same process is objectionable. The Congress proposed to lay down a basis for a rational nomenclature, by means of the following rules :—

1. The expression *photo* shall be employed, to the exclusion of the word *helio*, to indicate processes due to the action of light from any source whatever, and not alone to the action of solar light. The expression *helio* is exclusively reserved to indicate those processes only in which solar light is used.

2. The expressions *positives* and *negatives* are reserved to indicate respectively the images in which the effects of light and shade resemble those of nature, or in which those effects are reversed.

3. In that which concerns *photographs* obtained solely by the chemical action of light, the name of *phototypes* will distinguish those produced directly by the use of the camera. The name *photocopies* will be given to the reproductions of these by a new photographic operation by means of a sensitive surface acted upon by light.

The name *photocalques* (photosketches ?) will be given to reproductions made in the same way from non-photographic original designs.

4. Photomechanical prints, or *phototirages*, which may also be called *photoprints*, will be differentiated by the following appellations :—

To designate these different processes, an insertion will be made between the two radicals which form the word *photography*, and which will indicate the principal characteristics of the particular process.

According to this rule the word *photocollography* will indicate reproductions in various inks by processes in which colloids (gelatine, albumen, bitumen, and so on) are spread upon various supports, and rendered fit for inking by the action of light.

The word *photoplastography* will be employed to indicate processes in which a plastic substance changes its form because of the action of light, and returns to a thickness suitable for a coloured gelatinous ink.

The word *photoglyptography* will be used for processes of engraving in intaglio by photography.

The word *phototypography* will be employed for photographic processes of engraving in relief for use in the type-high letter printing press.

The word *photochromography* will be applied to printing processes for the reproduction of photographic images of several colours.

5. More extended designations of photographic processes or operations may be applied, so far as the French language is concerned, by introducing generic words preceding the necessary indications of the nature of the processes or operations.

For instance, the preposition *à* or *par* (by), according to the case, will precede the words indicating the nature of the sensitive substance employed, or that of the mode of operation ; and the preposition *upon* precede the words indicating the nature of the support of the preparations. The names of inventors, if they have to be used, can be placed at the end. EXAMPLES : — *Photographs*. — 1. Positive phototype ; iodide of silver on a metallic plate (Daguerre's process). 2. Positive photo-type ; collodion on a metallic plate

(Ad. Martin's process). 3. Negative photo-type, collodio-bromide of silver on glass. 4. Positive photo-copy, gelatino-chloride of silver on paper. 5. Positive photo-copy, in mixed colours (Poitevin's process). 6. Negative photo-sketch, ferro-prussiate blue paper (Motileff's process). 7. Positive photo-sketch, gallate of iron. *Photo-prints.*—8. Photo-collography, bichromated gelatine on ground glass. 9. *Photo-plastography*, coloured gelatinous inks (Woodbury's process). 10. Photoglyptography, by bitumen of Judea on steel (Niepce's process). 11. Phototypography, by bitumen of Judea on zinc.

6th.—For the designation of the divers applications of photography to special purposes, are reserved compound words obtained by prefacing the word photography, with radicals indicating by abbreviation the particular applications. EXAMPLES :—Chronophotography; the photographic production of successive images taken at accurately measured intervals of time. Microphotography; the photographing of microscopic objects. Heliophotography; the photographing of the solar surface. Spectrophotography; the photography of the spectra given by luminous sources. Uranophotography; the photography of celestial spaces. Chromophotography; the direct obtaining of the reproduction of colours by photography.

Such is the substance of the decisions of the Congress on this particular question. It will be noticed that the Congress has not vainly attempted to introduce French terms into photographic circles all the world over, but has culled, as customary in the scientific world, from the Greek. The Congress has, in this matter, accomplished some useful work, in attempting to bring chaotic nomenclature into something more resembling law and order. How far the improvements it advocates will—either before or after their revision by other Congresses—be brought into general use is another question. The higher the education of any scientific fraternity, the easier is it to introduce more accurate terms; indeed, chemistry and physics have seen vast improvements in this respect within the memories of many persons now living. The lower the education of any scientific fraternity, the more conservatively does that fraternity hold on to words it has once adopted, however unsuitable those words may be. Photography includes all sorts and conditions of men, so how any attempt to revise its scientific nomenclature will succeed, remains to be seen.

This year an International Congress, an outcome and continuation of that at Paris, will be held in Brussels, in which city also an International Photographic Exhibition will take place at the same time. At the Brussels Congress the late Paris Congress will be represented by a committee it has appointed, consisting of MM. Alex. de Blochouse (Belgium), the Prince de Molfetta (Italy), and Gylden (Sweden), honorary presidents; Dr. Janssen, president; MM. Davanne, Marey, and Wolf, French vice-presidents; MM. de Vylder (Belgium) and Petersen (Denmark), foreign vice-presidents; M. S. Pector, general secretary; M. Leon Vidal and A. Lende, French secretaries; MM. Wada (Japan), and Stanoiewitch (Servia), foreign secretaries; Col. Sebert, and MM. A. Martin, Cornu, de Villechole, Bordet, Perrot de Chaumeux, Warnerke, and Fabre, members. M. Macs, of Antwerp, the President of the Belgian Photographic Association, was present at the Paris Congress, and said that Belgium would be delighted to receive the Congress this year. M. H. Gylden, of Sweden, returned thanks at the Paris Congress for the warm welcome which had been given thereat to foreign visitors, after which the Congress came to an end at five o'clock, August 17th, 1889.

It is a remarkable circumstance that three photographic exhibitions will be held this year on the Continent, within easy distance of London and the larger part of England, by the night service of boats *via* Harwich. In the course of the year Brussels, as already stated, will hold its International Photographic Exhibition; another Photographic Exhibition will take place at Amsterdam, and at Antwerp will be an Exhibition specially devoted to Photomicrography.

FILMS ON GLASS SURFACES.

LAST Saturday, at the Royal Institution, Lord Rayleigh, in the first of a series of lectures on "Electricity and Magnetism," stated that glass has a great power of condensing moisture upon its surface. Some German observers, he added, have of late years discovered that it depends in a great degree upon the condition of the glass itself, and upon the alkali which the glass contains. The alkali causes it to attract moisture from the air around, even when the air is not saturated with aqueous vapour. Glass can be cured of this habit for a time by boiling it for five minutes. Much depends upon the kind of glass; for instance, flint glass behaves better in resisting the formation of these films than do the softer glasses usually employed for chemical apparatus.

In the course of the same lecture, Lord Rayleigh exhibited by means of the optical lantern some slides from negatives, which he had had to take by exposures of excessive rapidity even for what is called "instantaneous" work. He had photographed some falling drops of water so quickly that they appeared quite globular and not elongated in form, and had sharp, well-defined edges. The exposure and illumination were effected by means of a single electrical spark, given by the discharge of a battery of Leyden jars.

PHOTOGRAPHIC CLUB.—Wednesday, February 26th, monthly lantern night—ethoxo *versus* the new benzoline light. March 5th, "Artificial Light as an Auxiliary to Daylight."

THE INSTANTANEOUS PHOTOGRAPH, says the *Washington Post*, bids fair to become a very potent aid to artists who seek to teach their pupils that reproduction is not art; for it is clearly demonstrated by this means that the real is in nowise like the apparent. For example, an instantaneous photograph of a man in the act of running never looks as much like a man in the act of running as the pen-drawing of a true artist does. The reason is that the photograph reproduces the one exact position of the runner at the instant the picture is made, while the artist pictures several positions in one, and makes his man appear to be moving.

PHOTOGRAPHY IN HOLLAND.

Amateurs and Professionals.

In the February number of the current year of *Lux*—an illustrated monthly journal devoted to photographic interest, and published at Amsterdam under the able guidance of its editors, A. D. Loman, jr., and Chr. J. Schuver, for the furtherance of photography and all arts and sciences thereto related—we find an able article by Photophotos on "Amateurs and Professionals."

Were I, says Photophotos, a zoologist instead of a photographer, and supposing I was required to draw a distinction between the two above-named persons, this distinction would probably run as follows:—

Type: *Animalia Vertebrata.*
Class: *Mammalia.*
Order: *Bimana.*
Genus; *Homo.*
Species: *Fotograficus.*
Varietas (1): *Amateur.*
Varietas (2): *Professional.*

The difference between the individuals composing the first variety and those composing the second can, in the opinion of Photophotos, be confirmed by several distinctive marks and characteristics. For example, it will be generally allowed that the amateur is accustomed to make raids when he wishes to capture spoil or booty; the professional, on the other hand, lies, as a spider, in wait for his prey, and has generally a horror of the traitorous means employed by the amateur to accomplish his nefarious purposes. It is, moreover, to be noticed that the amateur is generally sociable—indeed, he might be called gregarious; while the professional, on the contrary, affects isolation, and loves to remain alone. One, however, of the most pronounced characteristics of divergency is undoubtedly the winter sleep or hybernation of the amateur; what time the professional, though feeling the season's difference, and by no means insensible to the rude attacks of Jack Frost and his cold confederates, nevertheless loses not his wonted wakefulness, and accosts with equal alertness, activity, and zeal the probable customer, whether that customer's waistcoat is unbuttoned in sultry August, or his teeth chatter in cold December. But the amateur, falling to sleep, poetically, with the fading rose and the exodus of the swallow, awakens not again for any care of customer till the rose returns, till the flowers again appear on the earth, till the time of the singing of birds is come, and the winter is past, and the rain is over and gone. Cases, indeed, have been known—but they are rare—in which the amateur has been aroused from his wintry sleep by the sunny brilliancy of a magnesium flash-light, when he will, on occasions, feebly partake of a little nourishment in the form of lantern plates of bromide of silver for sciopticon exhibitions.

The relation of these two interesting varieties to each other is mostly of an inimical and sometimes a malignant character, though, in some instances of perfect neutrality on both sides, a sound and lasting friendship may be found to subsist.

It is a sufficiently well known fact that photography, which was formerly practised only by professionals, has, in the course of a comparatively short period, spread itself widely among the most different ranks of society interested in it, partially from a scientific and partially from a business point of view. From the nature of things it must necessarily follow that the branch of photography to which the amateur directs his attention is very different from that which engages the thoughts of the professional. The latter has, we will say, a well appointed studio, and devotes himself exclusively to the study and practice of portrait photography in the widest sense of the word; the former, intimidated by the costly apparatus necessary to procure a really good portrait, and anxious in no small degree to avoid the labour—the normally requisite labour—of retouching, turns his 'prentice hand mainly to such outlying subjects as landscapes, *genre* pictures, instantaneous pictures, detective exposures, and photo-mierogravures.

Although Photophotos is by no means prepared to deny that portrait photography may be, and is, occasionally practised with no inconsiderable success by amateurs, it is, he thinks, as a general rule, advisable for them to busy themselves therewith only in a small degree, or still better, not at all. For this opinion he gives the following reason.

The condition of those who pursue photography as a profession is, no one will perhaps venture to deny, far from satisfactory. It has not been a favourable condition for some little time. Although this may doubtless in a great measure be ascribed to the increased facility in photographic manipulation—a fact which has brought studios and ateliers from the ground like mushrooms or Jonah's gourd—still the amateur photographers, or at least some of them, are mainly accountable for this unsatisfactory condition of their brother professionals.

What is indeed too often the case?

Take a respectable family rejoicing—or the reverse—in a youth, one of its members, with a passion for photography. This youth has managed to secure for himself some area of space, a courtyard—a garden, be it said, for politeness' sake—or even a chamber where, with the assistance of a friend who can retouch, he is able to take the portrait, always made ship-shape by the said friend, of some one or other of his associates; or suppose him visited by a nephew, a niece—a more dangerous visitant—in short, by any relation or acquaintance, but above all, by an aunt with small children, all of whom, with unmistakable signs, declare their desire, their ardent desire, to have their portraits taken by this able amateur. Then comes his moment of peril. He takes a negative, good or bad, as the case may be; they with one accord beg a copy to send home; they obtain it, send it, and no harm ensues. But if the plate pleases, if they long, like the daughters of the horse leech, or the unhappy Oliver, for more, then must the amateur at once put himself in a position of defence, and make use of such artillery of refusal as his experience has collected, or his imagination can suggest. If no better safeguards are procurable, such common forms of denial will serve as failure of time, pressure of business, inability as a mere amateur. Let him profess himself content with his work, but let him also add that if a really good portrait is required, the applicant must at once betake himself, and especially herself, to a professional artist. If the negative is really worth the trouble, the applicant will surely not grudge the payment of a reasonable price for as many copies as may be chosen to an accomplished workman.

But the case is considerably altered if the amateur, for divine charity's sake, or any other motive, is weak enough to bestow a dozen or more copies on the applicant. For the recipient, beguiled by this cheap method of acquisition, and totally blind to the errors and imperfections which swarm in the amateurish gift, conceives at once an antipathy to the professional photographer, who makes worthy

people pay for their portraits through the nose. He forgets that the labourer is worthy of his hire, and that the professional workman must be recompensed for his painfully acquired proficiency of skill, and the consequence is that he either ceases to visit the professional altogether, or visits him only to find fault with his prices, to cheapen a bargain, or to return pictures with which he is displeased.

Some people may think the foregoing description exaggerated, but its truth will be acknowledged by everyone who is practically acquainted with this subject, and is alone, therefore, able to give an opinion of value.

A portion of photography which may be cultivated with success by amateurs is the grouping of companies at festive gatherings, such as picnics, concerts, marriage breakfasts, cricket matches, and other diversions of a like nature. Little or no need is here of such technical knowledge and appliances as are indispensable to the photography of portraits. Besides, and in a measure owing to this, the artist will be far more satisfied with his work, and will, in addition, accumulate for his later years a fund of pleasing recollections which he may draw upon without let or hindrance at his own sweet will.

The *dilettante* must never forget that he pursues photography as a plaything, or, if this term be not sufficiently dignified, as a science or as an art, but not as a means of earning a livelihood; and such as devote themselves to this occupation for amusement should not complain hastily of the expenses or trouble which it necessitates or involves. "He who keeps a monkey," says an old adage, "must be ready and willing to make good any damage which may arise from his malfeasance." He must pay, like the amateur photographer, for the glasses he breaks.

It is only fair to add that some of the essential and most important services to photography have been rendered by amateurs, and from them will doubtless be stretched out in the proximate future many hands of support and assistance to this seductive art. Its varied fields of labour are indeed large enough for all.

It has been in several times and places asserted, with such degree of confidence as the absence of experience and knowledge can alone inspire, that the amateur will in the end destroy the professional, and survive alone as the fittest when the New Zealander acts according to Macaulay's imagination. Hitherto, however, there has been but slight sign of the professional's decadence, and it must also be borne in mind that the amateur is too frequently an amateur not in name only, but in deed. Witness, for instance, him who goes in summer to the Baarnsche Bosch to photograph and—drink Bittertjes. No! we need hardly make ourselves uneasy as yet concerning the future condition of the skilled and capable professional.

The existence of the amateur has in this article been considered as an important factor in the present evil condition of photography as a trade and calling. It is only just to mention also the far more important and deteriorating effect of the exceedingly low prices which are asked for portraits in several small studios. It is indeed unfortunate that the majority of people, who probably find even these prices sufficiently high, are unable to discover the low quality of such low-priced wares, wares which may well be called photographic offscourings and rubbish. It is through the existence of this trash that the intelligent artist suffers, and the grass, so to speak, grows on the threshold of his door. A radical medicine for this evil could be dispensed and made up with successful result if photographers would but unite and establish a definite minimum price for a dozen portraits.

Since the above was written, it has been ascertained that M. van Os has set such a plan in operation. In a late number of the *Fotograaf* some of the principal photographers of Amsterdam, as Woodbury and Page, Max Cosman and Koene, and Buttinghausen; of the Hague, as J. Ch. Mirande; of the Bosch, as Pierre Weynen; and of Nijmegen, as van Wens, have been reported as expressing their adhesion to the formation of a committee with such an object in view.

THE ACTION OF HEAT ON SODIUM CARBONATE.

FRESENIUS and other analytical authorities teach that, when sodium carbonate is moderately ignited and has lost all excess of water, &c., it undergoes scarcely any further loss; but that it loses materially if it is heated—even moderately—to incipient fusion.

Dr. Richard Kiessling has studied this subject more in detail, since the use of sodium carbonate as one of the fundamental chemicals in preparing volumetric solutions would become objectionable if its absolute stability were shown to be fallacious.

In making his experiments, he started from a bicarbonate which had the following composition :—

Sodium carbonate	64·4 per cent.
Water...	11·6 ,,
Excess of CO_2	24·0 ,,

A pure sodium bicarbonate of the formula $NaHCO_2$ has the following composition ;—

Sodium carbonate	63·114 per cent.
Water	10·711 ,,
Extra CO_2	26·175 ,,

Of the former a quantity of 6·170 gm. was subjected, on a watch glass, in a drying oven, to a gradually increasing temperature. At 65° C. there was no loss; at 70° C. the loss was very trifling; at 90° C. it had become quite material, and all of the extra carbonic acid was dissipated by heating to 125° C. The residue weighed 3·982 Gm., or 64·54 per cent. This consisted of sodium carbonate, absolutely free from caustic soda. It was now heated to 200° C., which caused no further loss. On raising the temperature to 400° C., however, a loss of 0·02 gm. (0·33 per cent.) was incurred, and the residue gave a decided reaction of caustic alkali.

On repeating the experiments in a platinum crucible, which permitted the employment of higher temperatures, the above results were confirmed. By increasing the heat to incipient melting, the residue gave a strong reaction of caustic soda.

It follows from these experiments that a perfectly homogeneous and standard sodium carbonate may be obtained by exposing the pure bicarbonate to a temperature of 150° C. until it no longer loses weight.

The author suggests to control the purity of the sodium carbonate by using potassium tetroxalate ($KHC_2O_4.H_2C_2O_4.2H_2O$) as a control-basis for volumetric purposes.—*Zeitsch. f. angew. Chem.*, 1889, 332.

CAMERA CLUB NOTICES FOR MARCH, 1890.—Monday, March 3rd, 8.30 p.m., smoking concert; Thursday, March 6th, 8 p.m., Mr. Andrew Pringle on "The Optical Lantern"; Thursday, March 13th, 8 p.m., lantern evening; Monday, March 17th, 8.30 p.m., lantern in operation (evening for testing slides); Wednesday, March 19th, 8.30 p.m., special smoking concert, and opening of members annual exhibition of photographs; Thursday, March 20th, 2 p.m., opening of conference and exhibition of apparatus at the Society of Arts by the President, Captain W. de W. Abney, C.B., R.E., F.R.S., papers from 2 p.m. to 5.30 p.m.; Friday, March 21st, 10 a.m., exhibition of apparatus in library of Society of Arts; 2 p.m., renewal of conference, papers from 2 p.m. to 5.30 p.m.; 7.30 p.m., annual dinner at Frascati Restaurant, Oxford Street (near Tottenham Court Road); Thursday, March 27th, 8 p.m., Mr. W. Willis on "Platinotype Possibilities"; Thursday, April 3rd, 8 p.m., lantern evening; Monday, April 7th, 8.30 p.m., smoking concert.

ATHANASIUS KIRCHER, THE INVENTOR OF THE MAGIC LANTERN.

II.

BY JAMES MEW.

BEFORE coming to a consideration of Kircher's already mentioned work, the work most important and interesting for the photographer, the "Great Art of Light and Shade," some more of the celebrated Jesuit's compositions merit attention as not only in themselves curious, but as bearing rich testimony to the wide and varied character of Kircher's intellectual study and attainments. No regard will be had of date in the enumeration of these books; concerning their size, it has been already said that they are mostly in ponderous folios. Dipping, then, our hand into this learned lucky bag at a venture, we draw out first what may well be considered a prize, bearing the title of "Polygraphy, or the Artifice of Tongues," a marvellous volume expounding a project of universal writing, and containing instructions for the composition and unravelment of secret ciphers. After this we light upon the "Egyptian Œdipus," a work in three volumes, the fruit of the arduous toil of twenty years, now read by linguists only with a strange sensation of wonder. Two more works, almost equally astonishing in their different respects, follow the "Œdipus;" one the first scientific work on the Coptic language, under the title of "Prodromus Coptus;" the other, "China Illustrated by its Monuments, Sacred and Profane." It has been said that both these books abound in errors. How far this statement is accurate the learned reader can, if he chooses, decide for himself. Next we have the "Specula Melitensis, or Watch Tower of Malta," a work dedicated to the Knights of St. John, and containing a description of rare physico-mathematical instruments. It is worth while noticing in passing that a curious misconception has arisen with regard to this work from a confusion between *specula* and *speculum*, which has led many to suppose that it is a treatise on burning glasses, with which instruments, indeed, Kircher was much concerned during his residence at Malta. The "Ecstatic Heavenly Itinerary" gives an exposition of the planets and fixed stars. The "Noah's Ark," in three books, treats of matter before, during, and after the deluge. Then we have a "Diatribe" on some wonderful crosses which appeared on men's garments and elsewhere, an "Arithmetology" or treatise on the hidden mysteries of numbers, a "Phonurgia," a "Physiologia," a "Mystagogic Sphinx," a "Tower of Babel," a "Subterranean World," and a "Great Art of Knowledge." The titles alone of these works will surprise the reader, though they give but a faint idea of Kircher's intellectual activity. His literary correspondence extends to fourteen volumes. We find in these volumes letters addressed to him from the principal men of his day. Turning then over at haphazard we come upon one from the celebrated Leibnitz, who speaks of Kircher's enduring merit, and, punning on his name Athanasius, prays for him the *immortality* he deserves.

But it is high time to take in hand that book which chiefly interests us.

The first edition of Kircher's "Great Art of Light and Shade" was published at Rome in 1646. The second edition, much more copious than the former, at Amsterdam in 1671. The whole title of the work runs thus:—"Athanasius Kircher's Great Art of Light and Shade, digested in ten books, in which are shown for many uses of mortals the wonderful powers and effects of light and shade in the world of universal nature, by a new and varied exhibition of novel and recondite instances and ensamples." The title page bears the mystic figure of a sun with a Hebrew quotation taken from the Psalms (139, 12), which, being literally translated, signifies, *As its darkness is, so is its light.* The author, after saluting the Philomath, or learning loving reader in his preface, thus addresses him:—"The same thing appears, O reader, to have happened to me as happened to that young man mentioned by Crassus in Cicero's work, *De Claris Oratoribus*. For he, walking one day and meditating idly by the seaside, lit by chance upon a thole, or peg to which the oar was commonly strapped, lying half hid amidst the seaweed and the sand. Taking it up and finding it unbroken, complete, and fit for service, he procured for himself, so that the little instrument might not remain useless, an oar, and having attached the oar to the thole, and being delighted with the contemplation of what he had done, went on to purchase a mast, and after that sailyards, which he set crosswise on his mast in due order. Not content, however with thole and oar, with mast and sailyards, he got sails and ropes, and so, by degrees, continually adding to his incomplete endeavour, at last fitted out a perfect ship, in which he sailed over sea and acquired much riches." Thus, says Kircher, have I also acted. For my little work of ten small pages has grown gradually into a large volume of ten big books. Starting from the thole of a stray remark suggested to me in the course of my precedent study, I have furnished out a ship which has sailed, so far as it is permitted to the frailty of the human mind to guide its course, through the immense ocean of aerial space, and so have I found and exposed as common merchandize to the world treasures of light and shade as yet unknown, in this my work divided into ten parts, as a ship furnished with ten banks of oars; and this division into ten parts has been suggested to me by the analogy of the ten divine rays which the Hebrews call *Sephiroth*, and the Latins *Emanationes*. And just as the wise Jews affirm the world to have been built by the ten rays of the divinity, so have we constructed upon our ten foundations of books our own little world of light and shade.

Kircher's first book is concerned with what he is pleased to call *Sciagnomics* and *Chromatics*. "Having ridden," he says, in a chariot far more sublime than that drawn by two dragons which was presented by Ceres to Triptolemus, through the varied orders and classes of nature, "I was astonished by the admirable marriage of the sidereal and the terrestrial world, in which ceremony Light officiated as a bridesmaid. Having afterwards discovered that there exists nothing in the innermost recesses of the mundane mass save that which has the principles and elements of its composition from light and shade, I succeeded, by varied combinations of these, in building up a new *Photosophy*, which, of its own natural fecundity, produced two daughters, *Sciagnomice* and *Chromatice*, which again produced wondrous births, described at large in my first book."

The second book of the *Ars Magna* treats of *Radiations*, or, as Kircher calls them, *Actinobolisms*. "When," he says, "I perceived that all things are affected by the wide-extended dominion of light, owing to a certain spherical diffusion of its forces, I built up at once the art of actinobolisms of things in nature, which again in their turn produced *Echocamptice*, or the radiation of sound; *Osmetice*, or the radiation of smell; and *Optice*, or the radiation of sight, besides other matters of rare doctrine and curious experiment, which are fully set forth in my second book."

The third book introduces the reader to the doctrine

of *Conic Sections*, and comprehends an apparatus of *Gnomonics*. "When I considered," says the author, "that shade is constant, whereas light affects motion, and that this motion of light is the sole base and foundation of all astronomy, the gnomon became my pen, any assumed plane my paper, shade my ink, and the Sun the artificer's hand, and the several natures of gnomon, plane, and shade, or pen, paper, and ink, are declared in my third book."

The fourth book is wholly concerned with sun-dials or horologes, Italian, Babylonian, and others.

The fifth is divided into *Gnomonic Ouranography* and *Gnomonic Geography*. *Ouranography*, or the description of the heaven, originally the title of a work by Democritus, comprehends the doctrine of the *Primum Mobile*, the description of *Almucantars* and *Azimuths*, and of the zodiacal arc on polar, meridian, vertical, and horizontal planes; with the whole system of fixed stars so described as to show both their risings and their settings.

The sixth book is called by Kircher the *Sciatheric Proteus*. Some of the readers of this paper may stumble at the word *sciatheric*, but this will become clear to them by the consideration that *sciatheras*, or shadow-catcher, is the Greek term for the gnomon of a sun-dial. Another title given to this book by the author, who rejoices in long words, many of which are his own invention, is the *Figured Astrolobiography*. It treats at great length of the mechanical construction of horologes, horoscopes, astroscopes, horolabes, astrolabes, and gnomonic globes.

And now, says Kircher, in his preface to the seventh book, which he calls the *Anacamptic* or *Reflected*, as he calls his eighth the *Anaclastic* or *Refracted Art*, and now we shall behold light instinct with some Promethean skill, delineating with its golden pencil the immense volumes of the heavens in the dark lurking-places of our homes so deftly that we, though shut up in a narrow hovel, may feel ourselves placed in the open fields of air, and wander over the universal ways of the sidereal world, and behold sacramental mysteries hitherto unseen. And this is our *Anacamptic Art* or *Reflected Astronomy*.

And again I observed that where light or shade passes into the recesses of a denser medium, it fallaciously withdraws itself, and affects manners altogether exotic, now stretching itself longitudinally, and now curving itself into I know not what of curvature after the fashion of a hedgehog or land-urchin. On this hint of occasion, I built up my *Anaclastic* art, or *Refracted Astronomy* through which it is given to all to hunt after heaven's unapproached riches with the weaving of an astronomic net beneath the water by an artifice singular, and hitherto unknown. In this book are tables for the compilation of refractions, an anaclastic table of rays incident in wine, oil, &c., after the author's observation. A paragraph on the refractions of the atmosphere is succeeded by a table of the refraction of the stars. We also meet with the construction of vertical and horizontal anaclastic astrolabes; the construction of an astrolabe in a concave hemicycle or hemisphere, showing nothing unless previously filled with fluid, which he calls the horologe, or deal of Ahaz; and the construction of an anacamptic-anaclastic horoscope.

Kircher's ninth book is called "Gnomonic Cosmometry," and is occupied with an investigation by means of light and shade of the position, magnitude, quantity, and altitude of the various mundane bodies, or parts of the world, and their distance from the earth. "Conceiving," says the author, "of light and shade as the most absolute geometer, and that the ingenious doctrine of conic sections came from no other school, and that the first elements and foundations of practical geometry arose from the proportions of shade to the unshaded, I concluded that nothing in this sensible theatre of the world was so remote that an approach to it could not be made by means of light and shade. Going therefore by their direction I attained the tops of the highest mountains and clouds, I climbed up to the tents of heaven, I measured by a new invention (*absit jactantia verbo*, let me be excused the boast), the quantities, distances, and depths of all heavenly bodies. Lastly, from this above mentioned supply of light and shade, as from a cornucopia filled to the brim, having selected some of the rarer and more recondite secrets by a certain hidden application of the active to the passive, I have constructed my "Magic of Light and Shade," by which is gained the threefold result of wonderful *horolabes*, *parastases*, or representations of things unseen, and by the aid of mirrors *paradoxical metamorphoses*, which new and rare matters have been deservedly reserved as the complement of all the books for the tenth and last of them."

It is this book on the "Magic of Light and Shade" which is the most interesting of all to the photographer, treating as it does of the application of their more hidden effects to the various uses of mankind. Of this book the first part is chiefly concerned with marvellous horologes, such as catoptric, heliocaustic, magnetic, sympathic, botanic, zoologic, rotatile, hydraulic, aquatic, and sympathetico-magnetic horologes. The second part treats of *Parastatic Magic*, or prodigious representations of things by means of light and shade. Under this part is included the artificial exhibition of aerial spectres; the wondrous paintings of nature on plants and stones; the exhibition of things by rays refracted in water; the construction of a machine by which images may be made suddenly to appear and disappear; the exhibition of wondrous spectacles by glass prisms; a disquisition of the author as to whether, according to Anaxilaus, Albertus, and Porta, houses full of serpents and other animals can be represented, and the display of fiery spectacles or *pyroparastases*. There are several experiments belonging to this last head, as the production of a fountain of fire, and of a dragon flying in the air, followed by a short discourse on the eagle of Regiomontanus and Architas' dove. Then comes a chapter on *Dioptrics* and the place and effect of lenses. The third part of this book deals with *Catoptric Magic*, or the marvellous representation of things by mirrors, and herein of mirrors, spherico-convex and spherico-concave, cylindrical, conic—as parabolic, hyperbolic, and elliptic—and caustic or burning. Then we find how to construct an artificial machine by which writings can be read at a remote distance, and then finally how to construct a *Thaumaturge* or magic lantern.

We have received from Mr. Martin a specimen of his Autocrat Magnesium Magazine, in shape like a powder flask, intended to contain magnesium powder, and to measure out, by a spring opening slide, a given quantity for the purposes of the flash-light.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION. — The annual meeting of the above Association was held on the 14th inst. The questions of reducing the subscription of professional photographers, and amateurs being allowed to serve on the committee, having been discussed, the report was adopted, as was also the balance sheet. Mr. Spiller was elected treasurer, and votes of thanks were passed to the late treasurer, to Mr. Harland, and to the president.

AN ISORADIAL FOCUSSING EYEPIECE.

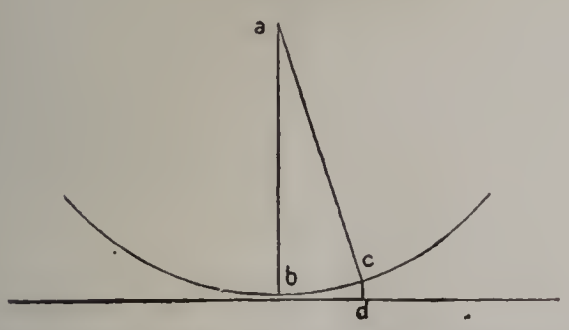
BY W. E. DEBENHAM.

As the subject of eyepieces for use upon the focussing screen of a camera has been recently brought forward in the columns of the PHOTOGRAPHIC NEWS, I send a description of one which, like that of Mr. Varley, described in the PHOTOGRAPHIC NEWS of the 31st ult., has been contrived for the purpose of examining portions of the field other than the centre, but which does not require fresh adjustment of the focus for each change of position.

In the eyepiece described by Mr. Varley the inclination of the instrument is effected by means of a ball-and-socket joint. As the centre of rotation is in the body of the instrument itself, the distance from the ground glass varies with each inclination. If a rather rough ground glass is used, the image will be focussed thereon, and slight differences of distance caused by varying but small angles of inclination may not place the image at a distance greater or less than the accommodation of the eye will make up for. When, however, a very fine surface is employed, it is, as pointed out by Mr. Varley, possible to obtain a sharp image which is not coincident with the ground surface, and, of course, with a focussing screen in which there are clear patches of unground glass, this will be still more easily done. With a smooth or semi-smooth surface, therefore, it becomes necessary to confine the plane of focus of the eyepiece strictly to the surface of the glass coincident with the plate, and to do this with a ball-and-socket arrangement requires continual adjustment of the focus of the eye-piece itself, as will be seen from the following diagram. This refocussing of the eyepiece will be found, if not quite impracticable, a difficult thing to accomplish on a fine surface covered with an image.

Let *a*, fig. 1, represent the centre of rotation. As the

Fig. 1.

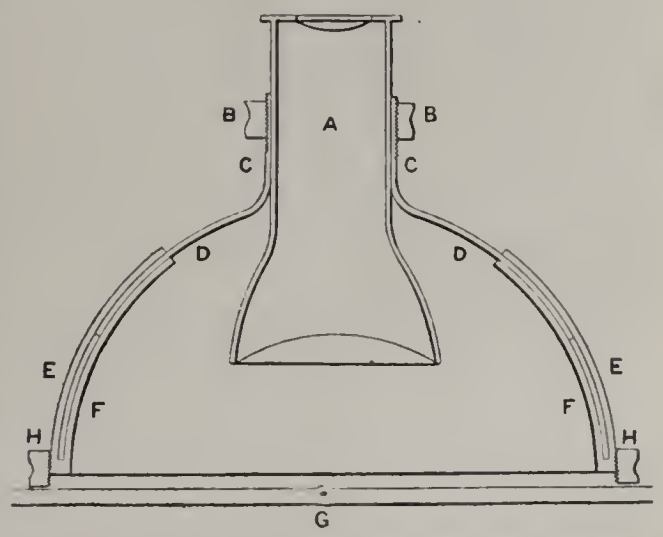


eyepiece is inclined, the focus, instead of remaining upon the plane of the ground glass, follows the arc *b c*, until at the latter point, which is distant only 20° from the vertical line *a b*, it is removed from the flat surface by the length of the versed sine *c d*. Supposing the distance *a b* to be $1\frac{1}{4}$ inch, which is about what would be indicated by Mr. Varley's dimensions, the versed sine for 20° with that length of radius being represented by ·06 × 1·25 of an inch, = ·075, or about the thirteenth of an inch—quite enough to put the image out of focus.

The accompanying sketch, fig. 2, shows a Ramsden eyepiece, A, of the construction in general use. There is the usual tightening nut, B, acting upon the thread on the jacket C. This jacket, however, is enlarged at D into a cup-like form, which slides between the surfaces of other cups, E and F. The latter are united at the bottom, as shown in the drawing. The dot at G indicates the centre of rotation, with which the surfaces of the cups are made concentric. The screw-ring H is for the purpose of distancing the whole system, according to the thickness of the ground glass, so that the centre of rotation may be in the proper plane.

It might be supposed that this centre of rotation should be on the ground surface of the focussing screen. This would be the case if the ground surface were outwards,

Fig. 2.



but as it is, the focus is interfered with, and lengthened by passing through the substance of the glass itself. It is owing to not taking this factor into consideration that photographers sometimes fall into an error when taking a negative through the glass, in order to obtain a non-reversed image, in supposing that, when focussing, an allowance must be made equal to the thickness of the glass upon which the sensitive film is spread, so as to keep the film at the same distance from the lens as that occupied by the focussing screen. If half the thickness of the plate is allowed, it will be nearly enough true for most purposes.

The objection to the use of the eyepiece, as figured, is the size of the cup or bell—about $3\frac{1}{4}$ inches in diameter—necessary. It might be reduced by making the whole thing on a smaller scale, but I am afraid is not likely to find much favour with those tourists who carry small cameras only. The convenience of examining parts other than the centre of the image, by the help of all the light available, should render it very serviceable not only to those who may be engaged in examining and testing lenses, but for many other purposes, such as that of focussing large groups, dark interiors, copies of paintings, and such subjects generally.

HALFPENNY INLAND POSTAGE.—Messrs. Erdmann and Schanz forward us a letter on this subject, from which the following is extracted:—"For the financial year ending 31st March, 1889, the Chancellor of the Exchequer received from the Postmaster-General £3,199,000. This represents $27\frac{1}{2}$ per cent. on the gross revenue, but the actual profit on the sale of stamps which are used for the transmission of letters within the British Islands is much larger. Happily, Mr. Goschen is likely to have a surplus by the 31st March next, and for this reason, among others, the time is particularly opportune for suggesting the introduction of a halfpenny postage for letters weighing less than a half ounce. The postage on letters to nearly all countries is calculated by the half-ounce. Why, therefore, should we be excluded from the benefit of being able to send half-ounce letters to residents within the British Islands at a lower charge than is now levied for an ounce letter?"

THE TEMPERATURE OF PHOTOGRAPHIC MANIPULATIONS.

ABOUT this time every winter season we get our regular line of letters containing questions involving difficulties in photographic working, that are due directly or indirectly to a total disregard of temperature. The old, old questions :—My developer stock bottle contains a number of crystals at the bottom ; will these make any important difference in developing? My toning-bath works slowly, and after going a certain distance the prints refuse to tone ; what shall I do to overcome the difficulty? I have had quite a good deal of trouble lately with my fixing bath ; the same brand of plates that I used several months ago, and out of the same box, take twice or three times as long to fix as formerly, and I use the same formula for bath ; please tell me the cause of the trouble—have the makers of the plates changed their formula of manufacture?

To all these questions, and a score of others, there is but one answer. Don't forget that the difference in temperature between June and January, for this latitude, may be as much as 96°, and that a difference of 25° may occur within twelve hours on any day in January. In summer, the fall of temperature from the heat of daytime to the cool of night has no harmful effect upon photographic processes, but in winter, when the day temperature is only 40° or 50° at best, a drop of 25° means a reduction of temperature below the freezing point of water.

As some of the results of these low temperatures in photographic operations, we may mention the crystallizing out of the salts in the stock solution of developers ; the mottling and blistering of albumen paper ; slow and obstinate toning solutions, together with hard negatives containing too much contrast.

In the case of developing solutions which deposit crystals it is very important that these crystals should be made to go into solution again, or the character and working qualities of the developer will be entirely changed. A change of temperature such as we have indicated above as possible at this time of year, would cause the separation of much of the alkaline ingredients of the developer, and a consequent slowing of its action from this cause alone. In case the developer bottle has become chilled and crystals have deposited, place the bottle in some warm (not hot) water for a short time, and then into water that is quite hot. Do not try to raise the temperature too quickly, or you will surely lose the solution from the fracture of the bottle.

The mottling and blistering of albumen paper can only be overcome by one method of working : always have the silver bath, the toning bath, and the fixing bath as near the same temperature as possible ; and be careful that this temperature is between 60° and 70° Fahr. Slow toning is also due to the use of baths at too low a temperature ; 70° Fahr., or even a little warmer in winter time, will be found to give the best results.

As to the character of the negatives produced in cold weather, they are usually hard from want of activity in the developer. Some writers have suggested that stronger developers should be used in winter ; but it appears to us that the best course to pursue is to keep up the temperature of the developer. Alfred Stieglitz, writing in the *Photographische Rundschau*, says :—"The temperature of the developer in slow development is particularly important ; for rapid development deviations are not so important." If the development is slow (and everybody should follow this method, as only by slow development the finest half tones can be realised) the developer must be kept at a pretty constant temperature 15° C. (60° F.) preferred, which degrees can be easily obtained in winter by addition of warm, and in summer by cold water.

By applying a developer of constant temperature, the time of exposure can be regulated much better. The first appearance of the image, after the plate is in the developer, depends always upon the following three conditions :—Time of exposure, concentration of developer, and temperature of the same.

A developer of about 13° C. (55° F.) acts ordinarily three to five times slower than it would at 15° C. (60 F.), that is, at a so-called normal exposure ; the plate would thereby become hard, while by an increase of temperature of the same developer to 17° C. (65 F.) with the same time of exposure quite a weak negative would be the result.

Cold developer gives hard negatives with correct exposure. For under-exposed plates it is, therefore, best to develop them with warm developer, as already proposed for instantaneous views ; care has to be exercised, of course, or the plate will become foggy.

The assertion that more detail could be obtained from a warm than a cold developer is erroneous ; the developer applied warm accelerates only the development of the shadows—that is, the negative remains soft, and will, therefore, furnish harmonious and handsome prints.

In short, I would recommend to everybody not to disregard the thermometer during the development of the plate.

To the above timely suggestions we would add that it is equally important to be sure that the fixing bath for the negative is not too cold, in order to secure negatives free from stain and that do not turn yellow with time. A cold fixing bath is slow-working, and although it may dissolve out the silver haloid, it may not cause the complete solution of the hyposulphite of silver, and a decomposition of the latter will make the negative turn yellow with age. Therefore, maintain a fair average of temperature (60° to 70° Fahr.) for all photographic manipulations, and very many if not all your difficulties in winter will disappear. —*Anthony's Photographic Bulletin.*

ENTERPRISING PHOTOGRAPHERS.—There are some enterprising photographers in Munich, as a well-known artist discovered the other day. He had seen some photographs which took his fancy greatly, one of the fairy-like palaces built by the crazy King Louis. Nothing would satisfy him but a visit to the spot for the purpose of making some sketches. Accordingly he set out for his destination, arrived at the romantic place where the castle is situated, and toiled up a mountain which he imagined commanded the view of the castle he had seen in the photograph. But when he reached the top of the mountain and looked at the castle, it did not seem the same as it had appeared in the photograph. He was greatly puzzled, for there was the front of the castle taken in the photograph staring him in the face, and no other part save the top of the mountain available for the planting of a camera. Yet the picture was different. He made enquiries, and discovered the reason. The photographer had had himself tied to a rope, and had been lowered a hundred feet or so down the perpendicular side of the huge rock, and so had obtained the view he wanted.—*The Picture and Art Trade.*

CONTINENTAL photographic societies will be busy this year, as no less than three exhibitions will be held, namely, at Brussels, Amsterdam, and at Antwerp.

PHOTOGRAPHY IN SWITZERLAND.

The Swiss *Photographic Review*, bearing the motto *Omnia luce*, published monthly under the direction of Dr. E. Demole, at Geneva, is the chief exponent of several photographic societies, as, for instance, of the Society of Geneva, of Lausanne, of Zurich, and of the Photo. Club of Neuchatel. This Review, which is now in its second year, contains an interesting article on some meetings of the Photographic Society of Zurich from July to December, 1889.

The author of the article, after alluding to a previous description of the transactions of the Society till the month of June last, notices the increased interest in the last six sittings of the bygone year, evidenced by the attendance on every occasion of more than half the members. In these sittings, the chief objects of curiosity and debate were the orthochromatic plates, and the new developers, hydrochinon and eikonogen, and many specimens and experiments of the working of these materials were submitted to the congress.

It will doubtless be of some interest to other amateurs to learn the several results of these varied experiments. By far the greater number of members had tried their hand with orthochromatic plates, and the outcome of their endeavours was so far satisfactory that the author asserts that the use of these will probably become more common, perhaps universal.

The experiments were chiefly concerned with Vogel and Obernetter's eosin silver plates, which certainly possess remarkable orthochromatic properties. It was, however, unhappily agreed upon by all the members who had meddled with these plates that, in a comparatively short time, a strange marginal veil was formed, developing a tendency to become even broader, so that, for instance, on a plate 13 by 18, after a short period, a picture of the dimensions 10 by 15 was with difficulty to be obtained. The author concludes that this defect has been occasioned probably by the use of unsuitable packing paper, and confidently hopes that the manufacturers will in future remedy this evil. The article says, Herr Scheuermeier, of Zurich, has lately manufactured orthochromatic plates of excellent quality, and such as show, even after the lapse of three months, no kind or sort of defect or alteration.

No good yellow screen is procurable in Geneva; those to be met with in the glass factories, made of coloured glass, are all far too thick and uneven; the glass plates covered with yellow collodion, and the yellow gelatine films display too clearly the injury arising from dust and other causes.

As far as regards developers, experiments were made by the great majority of the members with hydrochinon and eikonogen, which, as a rule, were sufficiently successful. It was, however, found that the hydrochinon developer procured from an emporium was not durable, and that the composition, after the flask had been once opened, without being further called into use, within the space of two or three weeks acquired a brown tint, and became utterly useless for the purposes of photography.

Even with the pulverized eikonogen, like results were attained. Many of the members, however, spoke in high terms of eikonogen developers made with good chemicals as quick and clean workers. In opposition to these newly christened agents, the ammonio-pyrogallol developer of the formula of Dr. Barbieri and his fellow-workers was praised as most successful and of the highest value.

In the positive process, aristo paper has now been for about a year principally employed, and this paper, says the author, is highly to be recommended to every amateur, not only on account of its durability, but for the reason of its many other good qualities. For toning, the combined toning and fixing bath is commonly used. But it does not invariably act as might be desired, and we give our readers the following gold bath recommended by Dr. Barbieri with the addition of a few drops of hyposulphite of soda—4 gr. sulphocyanide of ammonium, 200 c.m. water, 10 drops hyposulphite of soda, solvent (1 : 10), 10 c.m., chloride of gold 1·50, and as a solvent 100 c.m. water. The addition of the hyposulphite of soda produces colder tones. This bath is not durable.

Platinum paper cannot as yet claim the right of full citizenship in the photographic burgh. The experiments shown on this material seem not to have been taken with sufficient care; in every case the cautions as to the conservation of this paper appear to have been neglected.

It was resolved early in the spring of 1889 to make an attempt to facilitate the passage through the Custom Houses of photographers with highly sensitive preparations, as, for example, by the formation of dark-rooms at the principal seats of Custom, or by some course of instruction of the minor officers. As, however, no instance of damage or loss accruing from the want of such provisions was brought forward, the Custom House authorities declined to interfere with the matter for the present, but gave an assurance that they would not hesitate, as far as lay in their power, to put a stop to any impropriety of action on the part of their officers which should be brought before their notice.

The International Photographic Congress at Paris has interested itself particularly in this matter, and has resolved, as we are informed, to procure the erection of dark-rooms at the principal Custom Houses. It would, however, be a great help to any effort of this nature, if notice was at once taken by the Swiss Photographic Union of any ill or damage, so that later on, when a society found it advisable or necessary to take further steps in the business, the material evidence might be close at hand.

In the course of the meeting, several exceedingly interesting photographic novelties were displayed: objectives with iris diaphragms, detective cameras, instantaneous shutters, &c. In the November meeting, Dr. Barbieri showed a large collection, chiefly of objects of practical interest which he had collected and gathered together during his summer journey.

Dr. Weyl, of Berlin, has just discovered that the anaërobic bacteria exert a powerful reducing influence. They will reduce indigo blue to indigo white.

Lustrous Surfaces on Glass.—The following method of preparation of lustrous metallic surfaces on glass and glazed ceramic ware is described in the *Journal of the Society of Chemical Industry*. An aqueous solution of silver nitrate is mixed with a paste which when heated in a muffle at a low temperature will not fuse to the glass or porcelain, but can be readily detached from it. Suitable pastes may be made from chalk, earth, lamp-black, sulphur, madder lake, manganese dioxide, and oxide of iron. During the heating in the muffle the silver passes from the paste to the surface of the glass or porcelain, the paste is then carefully removed, and the article heated gently for a few minutes in a reducing atmosphere, preferably in carbonic oxide. An adherent lustrous metallic coating is produced which in transmitted light appears light yellow to dark green white, while the lustre varies in appearance from that of silver to greenish gold. Three parts of paste are used for one part of silver nitrate. Chloride or sulphide of silver may also be used, the former imparting a greenish and the latter a yellow colour.

Notes.

Most photographers have noticed the common resemblance which exists between middle-aged and elderly married couples, but they will scarcely be prepared to hear that this resemblance is also just as marked in the case of youthful husbands and wives. Professor H. Fol, a German *savant*, has been making some experiments on the subject, and out of seventy-eight young couples whom he photographed, he found that twenty-four bore a stronger resemblance to each other than that of brother to sister. In thirty the likeness was marked, and in twenty-four only was there a total absence of resemblance. What bearing this fact, if it be established, has upon the great question, "is marriage a failure?" is difficult to say without further data. If the history of these seventy-eight couples could be closely followed up, and it was found that the twenty-four pairs who were like each other were "happy ever afterwards," as the old story-books used to say, and that the twenty-four unlike had to seek the assistance of the German equivalent of Sir James Hannen, we should arrive at a decidedly valuable conclusion. Unfortunately for the present generation, at least half a century would be required to test the theory fairly. In the meantime it would be decidedly rash to advise two young people to marry simply because their photographs resemble each other.

The universal application of the electric light would be an enormous boon to photographers. Could the light be supplied cheaply, they would be rendered independent of fog and dark days, and in addition be able to work as well in the night as in the daytime. We believe that most of the leading photographers who introduced the electric light, working it from their own engines, have relinquished this method, not only on account of the expense, but by reason of the uncertainty. Those who do use the light take the current from the mains, but this can only be done in exceptional cases. Were the electric light pretty general, a dozen photographers would employ it where only one does so at the present time.

Another important branch of photographic industry would also greatly benefit; we refer to photo-zincography. The electric light here is indispensable, if a business is to be carried on satisfactorily. The enormous increase of illustrated papers, and the exigencies of competition, have brought the time allowed the photo-zincographer for the photography of drawings and the production of blocks within very narrow limits, and unless the electric light were used, business could not be carried on. The electric light can be obtained easily enough in the great printing centre of London, Fleet Street, but there is a serious drawback to successful results in the constant vibration. The use of the electric light in the suburbs would give enormous facilities to photo-zincographers, as here they would be able to work without the risk of doubling or thickening of the lines of a drawing.

The Turkish authorities have a strange horror of photography. A year or so ago all the photographs in the Pera shops of the Sultan's brother were seized, because it was suspected the prince was conspiring against the Commander of the Faithful. Two months after, the death took place in prison of a young Armenian whose only offence was that he photographed the pictures of the old Armenian kings, and now a German photographer has paid the penalty of a rash attempt to take an instantaneous portrait of the Sultan as he was going to the mosque. The gendarmes fell upon the unlucky man, smashed his camera, and carried him off to prison, where he lay three weeks. After that he was bidden to depart from the Turkish coasts, and was not allowed so much as twenty-four hours in which to wind up his business. Amateur photographers who think of going to Turkey had certainly better leave their cameras behind.

Painters will have a fresh grivance against photographers. At one time the painter was an indispensable official at all great ceremonial functions, such as royal marriages, christenings, funerals, and the like, and terrible work it used to be for the unfortuate man, as Mr. W. P. Frith, R.A., in his "Reminiscences," graphically relates. The difficulties of securing a separate portrait of each actor in the scene were enormous, and the wonder is that any artist could be got to undertake the commission. We manage things better now-a-days. When the Princess Louise of Wales was married to the Earl of Fife, the ceremony was photographed by Messrs. Byrne, of Richmond, and this photograph, we read, has now formed the basis of a painting also executed by the same firm. The transaction has a commercial ring about it, and artists may lament the decadence of the times in such matters, but on the whole the new order of things is much more comfortable for everybody concerned.

One peculiarity of photography is that in many cases it acts as a sort of barometer of public taste. An attentive study of the principal photographic print dealers' windows will generally disclose what is the fleeting fancy. Very recently there has been a sort of worship of muscle. All the strong men who have been exhibiting themselves on the music hall stage have had their torsos and biceps photographed, and that these photographs attract is shown by the gaping crowds. The pictures of the strong men certainly have an advantage over the photographs of prize fighters, who are generally posed in the most ungainly and vapid of attitudes, with the muscles inactive and flaccid, and suggesting anything but strength. Perhaps the photographing of Samson's and Sandow's arms will lead to the photographing of some famous pedestrian's legs, or the pectoral and spinal muscles of a contortionist. We do not say that such photographs are desirable, we only suggest what is likely to happen.

PHOTO-LITHOGRAPHY AND THE NEW ALBERT PHOTO-LITHOGRAPHIC TRANSFER PAPER.

BY HERMANN E. GUNTHER.

The following is a detailed description of the photo-lithographic process as it is in practical use in the most eminent printing establishments in Austria and Germany. I have very often had opportunity of seeing how successfully it is worked, and can therefore state that the firm of E. Jaffé and A. Albert, of Vienna, deserves much credit for having introduced the new transfer paper, which is a boon to all photo-lithographic workers.

The bichromate bath consists of :—

Water	1,000 c.c.
Bichromate of potash	50 grammes

To this solution, caustic ammonia is added until the reddish colour of the bath turns to a light yellow colour; an excess of ammonia does no harm. The temperature of the bichromate bath should be about 66° F. It is filtered into a flat dish of sufficient size, and the paper, with the prepared surface up, entirely immersed, and allowed to remain in the bath until it is quite soft. This is of importance, for, if it is not soaked long enough, also if the temperature of the bath is below 66° F., the bichromate solution will not enter sufficiently into the prepared film, and consequently, at the subsequent inking up of the copies, the colour will adhere but badly to the exposed parts, especially to the broader lines and surfaces of the picture.

If sufficiently soaked, the paper is removed, held over the dish so that the fluid flows off only at one of the lower corners, and allowed to drain until the liquid only drops. Then the two corners of the paper, which have been held, are given to a second person, who now holds the sheet over a plate glass a little larger than the paper. This plate-glass must previously be well cleaned, then rubbed in with talc powder, and the surplus of the latter dusted off with a broad, soft brush. On this glass plate the sheet is placed with its lower edge of the prepared surface, and smoothed down by means of a soft cloth. During this operation the person assisting holds fast the corners of the paper until the mounting is finished, and only gives slowly way to the pressure of the smoothing down.

If too much of the talc powder has been dusted off the plate glass, it may happen that the paper, after drying, partly adheres to the glass, and even tears here and there; it is therefore necessary that a certain amount of the talc powder remains on the plate, and better a little too much than too little. Should the paper, after entirely drying, still adhere to some parts of the glass, then the latter has been badly cleaned.

Care should also be taken that in smoothing down the paper no air-bubbles arise between the glass and the paper, since they will appear on the dry paper in the form of matt spots, which will interfere in the case of fine work. As soon as the sheet lies quite flat on the glass, the back of it is well rubbed with a soft cloth, applying thereby a certain degree of pressure to suck up the fluid on the back of the paper, and also to squeeze out the bichromate bath between the paper and the glass, and by this means to accelerate the drying process.

The glass plate, together with the paper on it, is now placed in a darkened, not too warm room, and dried spontaneously; after six to twelve hours it will be dried. This may be ascertained by touching the back of the sheet, and by the paper easily stripping off.

After stripping, the paper shows a beautiful, high gloss; it is now ready for copying, and must, of course, be kept in the dark. The sensitised paper should be used up within twenty-four hours, because if it is kept for a longer time it is more difficult to work. In the stripped state the paper should be kept in a not too dry place, for if it is too dry, or even brittle, no sharp copies are to be obtained with it, since it does not join closely to the negative. Besides, it is important to preserve in the paper a certain degree of flexibility, because it will then be possible to open one half of the printing frame in order to control the progress of the printing process, without fear of obtaining a doubled print. Should it, however, occur that the paper is too brittle, it may be placed between slightly moistened blotting-paper, but care must be taken that the transfer paper does not become too damp.

In printing, it is not necessary to use a photometer, since, as we have mentioned above, it is possible to watch the progress by opening one side of the back of the frame, provided that the paper is sufficiently smooth. The print should have a brown tone, and appear in visible relief from the ground. Over-printing is very injurious, because the lines and points of the image become thereby broader, and the development of the copy becomes difficult. If, however, it is under-printed, the colour does not adhere to the image in development, or, at least, it adheres only to the vigorous parts of the print.

Care should also be taken that the backs in the printing frame are not damp, because this is obnoxious to the sharpness of the print. Sometimes it will happen, especially in the case of copies from densely-drawn originals, and in the case of copper engravings, that certain parts of the negative will print too quickly; parts of this kind are varnished on the back with carmine, as it is usually done in the case of negatives with half-tones.

The inking of the transfer may be carried on in different manners, but in all cases it is essential to lay on a light colour-tone evenly over the whole of the copy. This may be done by means of a sponge or a rag, as well as with a velvet roller; the main point is always the result. The manipulations are as follows:—The smooth face of a lithographic stone is, by means of an ordinary lithographic leather roller, inked up with good transfer ink, and the velvet roller, which perhaps serves the purpose best, carefully charged with a thin coating of the ink; then the copy, which has been placed on an even, smooth surface, is inked up with the velvet roller until it is evenly covered with a middle grey tone. The vigorous parts of the image should still be visible through the colour, otherwise too much ink has been applied. When the transfer is successfully inked up, it is placed in clean, cold water, but care should be taken that no air-bubbles adhere to the copy in the water, and that the back of the paper remains completely covered with the water. After ten to fifteen minutes the transfer is removed, the water allowed to drain, the copy laid once more with its back on the smooth plate, and the water squeezed out from the film side by means of fine tissue paper, which is done best by rolling over it with an old, clean lithographic roller, avoiding, however, carefully the formation of wrinkles, because, otherwise, the film will probably be damaged. The moistened transfer is now once more inked up with the velvet roller charged with colour. If, after some rolling, the image comes out quite distinctly, the paper, at the same time, being clear of the yellow colour produced by the bichromate bath, it is only necessary to wash off with a clean, very fine, and soft sponge

moistened with water the colour which still adheres to the unexposed parts of the impression. If, however, the transfer, after being inked up, appears still yellow, it must be placed, before the application of the sponge, once more in the water, and the inking up with the velvet roller must be repeated.

The ready developed transfers are placed between dry, clean, and perfectly smooth blotting-paper, and by gentle pressure freed from the still adhering water. Then they are fastened by means of drawing pins on a board, and dried spontaneously on a slightly warmed place free from dust.

The dry copy is placed between damp blotting-paper. In the case of grained or stippled impressions, tissue paper must be used instead of the ordinary blotting-paper.

In pulling through the press for the first time, only a slight pressure should be applied, it being increased at each stroke. As usually, the transfer is several times wetted with water. After the last pulling through, the transfer is removed without again being wetted; if there is any difficulty in doing so, the stone may be taken out of the press, and placed for a short time in a cold room, or the transfer may be dried spontaneously. In both cases the removing of the transfer is facilitated.

The "rubbing-in" or intensifying of the image on the stone is done as usual, but in the case of very fine drawings, grained or stippled images, a very slow procedure will be necessary. The sponge which is used in intensifying should contain only a small quantity of the colour.

The etching may be done in the ordinary manner with slightly acid gum-water; in the case of fine drawings, however, it is recommended to apply a "sharp or high-etching" bath, it offering also otherwise some advantages.

For this purpose the transfer is dusted in at first with resin powder, then with talc powder, and the excessive powder carefully removed with a pad of cotton. Then two narrow, long strips of wood, about one-eighth of an inch thick, are placed on the two longitudinal edges of the stone, clear of the impression, and fastened at one end in any convenient way. Then a wooden lath, about three inches wide, 1½ inches thick, and a little longer than the stone is wide, is taken, covered with cloth, and moistened with sulphuric ether; it is then placed on the two wooden strips, at the end that has been fastened to the stone, and slowly pulled over the strips at full length of the stone. It is sufficient to go once over the stone in the manner described in order to melt the resin powder, together with the colour, by means of the ether vapours. Then the stone is etched for about one minute with the gum etching bath, which should be strong enough, so that it slightly scums if poured on the stone. The stone is then ready to be printed from.

With the same paper, transfers can also be made on zinc to produce relief blocks, and, indeed, it is used for this purpose by many large establishments. This process, however, we shall describe on another occasion.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—Technical meeting, Tuesday, February 25th, at 8 p.m., at the Gallery, 5A, Pall Mall East.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday, Feb. 27, Mr. A. Haddon will give a lecturette and practical demonstration of "Glass Blowing as Used in the Chemical and Physical Laboratories." Visitors are invited.

"How shall we move the masses?" cried the Chicago anarchist on Christmas day. Just then an amateur photographer was seen pointing his camera out of a window—and the masses moved.—*Wilson's Photographic Magazine.*

DESTRUCTION OF DRY PLATES BY INSECTS.*

ONCE more an American industry is menaced and in danger of being proscribed in Continental Europe; this time it is the American dry plate that comes under the ban. The current number of the *Photographisches Wochenblatt* sounds the note of warning, and urges all amateur and professional photographers, under the circumstances, to beware of the purchase of any "Amerekanische Troeken-platten" (dry-plates), or keeping any upon their premises. The cause of this agitation is said to be the discovery of an insect which breeds in the emulsion on the dry-plates and films, and is said to prove as destructive to the plates as the potato-bug is to vines of that tuber; and if the pest once gains a foothold in any gallery, every plate and negative will soon be destroyed, and the place become infested as a barn or granary with weevil.

Since the above-mentioned urgent note of warning was issued to all Continental photographers, further particulars have reached us, together with the circumstantial account connected with the alleged discovery of one of the much-dreaded insects.

It appears that the son of Herr Isidore von Dunkelkammer, K. K. Geheim-Commerzien-rath, in Berlin, purchased from a local dealer a box of dry-plates of a celebrated American maker. On opening his purchase in his dark room, he found securely entrenched between the two packages of plates a nondescript bug or insect. The youth, who is an active member of the "Sonntags-Photographischer Jager-Verein," at once surmised that here was one of the much-dreaded insects, against which the note of warning had been sounded in the *Fach-blätter*. He reported the matter to his father, who, as an officer of the Government, felt the weight of the situation which rested upon him; repairing to the dark-room, von Dunkelhammer ordered that the animal be put in a vial and hermetically sealed, and sent to the "K. K. Academic der Naturlichen Wissenschaften." A special meeting was called for the occasion, when the extreme thinness or flatness of the specimen was much commented on, whereby it would be able to force its way between the sheets of glass or film as they were packed in merchantable packages. The vial containing the specimen, as an extra precaution, was enclosed in another bottle, which was also sealed, and was ordered to be made the special subject for the next regular meeting of the faculty a week hence.

When the day arrived Professor Raupe von Cassettenschieber opened the subject by stating that it was his sorrowful duty to inform the Academy that another American pest had appeared at the threshold of Europe, and threatened the ruin of one of the Fatherland's most beautiful professions and amusements, viz., die Kunst der Photographie, but that he had positive assurance that the Government would at once take the most radical steps to prohibit the introduction of any photographic material from America; in fact, that the Imperial Council would place the same interdict on American films and dry plates, as the Imperial Chancellor had placed on the American hog. The learned Professor was seconded in his remarks by Herr K. K. Hof-Photograf Weitwinkel; after which Dr. Aaron Eisenoxolat, inspector der Deutschen-reichs-Trocken-plätten, offered a resolution of thanks to all editors who had given publicity to the new danger which threatened to ruin every photographer within the realm, which was passed unanimously; after which Herr

* *American Journal of Photography.*

Rudolphsohn von Momentverschluss, who was also "Intendant und Geheim-Inspector des Staats-Detective Polizei," stated that by order of the Imperial Chancellor his department would at once take measures to seize all American dry-plates and films wherever found within the Empire, and that the confiscated material would immediately be taken to the Imperial Crematorium at Spandau, and there subjected to a heat of at least 2,400° Fahrenheit, which the Sanitats Behröde had judged to be ample to destroy any molecules or germs which might escape from the packages during the operation.

A further resolution of thanks was passed complimenting Geheim-Commerzien Rath von Dunkelkammer for his courage and diligence in capturing the dreaded insect, and his disposition of the same.

The members then adjourned to the Laboratory of the Academy for the purpose of making a thorough and scientific examination of the captive specimen, so that an exact description could be published for the information of the public in general. Special preparation had been made. Dry-plates of all known makers, domestic and foreign, were placed side by side, so as to allow the insect to pass over them consecutively, to see if any one make offered special attraction to the destroyer. It was concluded not to experiment on the subject with the various poisons, as in case any should prove fatal it would undoubtedly interfere with further investigation.

Not the least results were expected from the microscopic examination; this was to take place by the great bi-ocular-plano-electro-objective. For this occasion the subject was to be illuminated by an electric light generated by a purified current of electricity of at least 3,000 volts, Siemen measurement; this part of the investigation to be under the immediate supervision of the celebrated specialist, Herr Baron Natron-Ritter v. Fixirlösung, and "Reichs-Staats-Geheim-Insecten Anatanom" der Kaiserlichen Academie, who was himself an enthusiastic amateur photographer of no mean pretensions. After the specimen was brought forth, and taken out of its double receptacle, it was carefully laid under the objective of the great microscope. As an extra precaution, the receptacles which had come in contact with the insect were all treated with a 99 per cent. solution of the new disinfectant, "Eiko-Galliol."

After the focus had been properly adjusted, the learned Professor ordered the following description of the specimen to be inscribed on the bulletin:—

Genus.—Epizoa.

Order.—Hemiptera.

Head.—Small, from which project two long antennæ.

Eyes.—Compound, behind which are two transparent flaps covered with bristles, which are the rudiments of wings.

Thorax.—Broad and short.

Abdominal Segment.—Very large, broad, and extremely flat.

Colour.—Reddish brown.

It was further ordered that Herr Grobschmidt, the Librarian and Archivar, should properly classify and enter the subject as "Der Americanische-Gelatin-Brom-Trocken-plätten-zerstreungs-Käffer.

The members now in turn examined the subject under the microscope. Something of a sensation was caused when one Griffelschaber, a schoolmaster, and who was only a member by courtesy, ventured the opinion that possibly the learned President was mistaken in his diagnosis, as in his humble judgment the specimen under examination certainly bore a strong resemblance to the *Cimex lectularius vulg.* The schoolmaster was at once called to order and threatened with expulsion if he did not remember his position.

After the ripple caused by the above interruption had subsided, the specimen Käffer was subjected to a current of electricity of fully 8,500 volts, to insure its destruction, after which it was suspended in a vial of 95 per cent. alcohol, properly sealed and attested, and placed on exhibition in the "Museo der Academic."

When the action of the faculty was brought to the attention of the Imperial Chancellor, he at once entered upon the suggestions and issued the necessary edict, and as a sequence American dry plates will soon be excluded from Europe.

That this manifestly unjust action will be resisted to the bitter end by interested parties in this country, as the matter becomes known, may be taken as a foregone conclusion. It is hard to state what complications may arise if the German government persist in its course in the premises.

The initiative in the matter of retaliation was taken at the last meeting of the "Leopardville Camera and Tripod Club," where a resolution was passed: "Not to use any chemicals or photographic paper imported from Germany until the obnoxious edict reflecting on American dry plates be repealed."

A communication was also sent to the State Department at Washington, with the request that the matter receive immediate attention. In response, the Consul General at Berlin has been telegraphed to, and several messages have passed to and fro on the subject.

Personally, we have no doubt that taking into consideration the fact that the squadron of evolution is now in European waters, the whole matter will be amicably adjusted without delay.

There is some talk of a committee of the Royal Society being appointed to investigate the subject of colour-blindness, and the proper methods of testing the colour-vision of *employés* on railways.

Oxygen in Water.—At a meeting of the Chemical Society a paper was read on "A New Method of Estimating the Oxygen Dissolved in Water," by Mr. J. C. Thresh, M.B. The process is based on the observation that whereas, in absence of oxygen, nitrous acid and hydrogen iodide interact to form iodine, water, and nitric acid; in presence of oxygen the nitric oxide becomes re-oxidised, and, serving as a carrier of the oxygen, an amount of iodine equivalent to the oxygen present is liberated, in addition to that resulting from the initial action of the nitric acid; hence, deducting the amount liberated by the nitrous acid and by the oxygen dissolved in the solutions used from the total amount, the difference will be that corresponding to the oxygen dissolved in the water examined. The solutions used are:—(1) A solution containing ·5 gram sodium nitrate, and 20 grams potassium iodide in 100 c.c.; (2) a solution of 7·75 grams sodium thiosulphate in 1 litre, 1 c.c. of which corresponds to 0·25 milligram of oxygen; (3) a clear solution of starch; and (4) diluted pure sulphuric acid (1 : 3). The apparatus required is a simple one.

Hypo in Negatives.—An American writer says that he finds that a good way to remove hypo from negatives is to lay them face down in a dish or trough with a concave bottom. "If you make but few," he says, "an agate-ware wash basin does first-rate. The hypo falls from the film by its own weight, it being heavier than water, and in five minutes will be cleaner even in still water, than in ten minutes running water with face up."

DR. ANDRESEN'S EIKONOGEN PATENT.

No. 5,207. *Mar. 26th*, 1889.—The following is the complete specification of Dr. Andresen's patent entitled, "Improvements relating to the Development of Photographic Pictures":—

I, Momme Andresen, of 44, Melchiorstrasse, Berlin, in the empire of Germany, chemist, do hereby declare the nature of this invention, and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

My invention relates to the development of photographic pictures by means of diamidonaphthaline $C^{10}H^6\begin{cases}NH^2\\NH^2,\end{cases}$ amidonaphthol $C^{10}H^6\begin{cases}OH\\NH^2\end{cases}$ and dioxynaphthaline $C^{10}H^6\begin{cases}OH\\OH\end{cases}$ as well as their sulpho acids:—

Diamidonaphthaline monosulphonic acid	$C^{10}H^5\begin{cases}NH^2\\NH^2\\SO^2\,OH\end{cases}$
Diamidonaphthaline disulphonic acid	$C^{10}H^4\begin{cases}NH^2\\NH^2\\(SO^2\,OH)^2\end{cases}$
Amidonaphthol monosulphonic acid	$C^{10}H^5\begin{cases}OH\\NH^2\\SO^2\,OH\end{cases}$
Amidonaphthol disulphonic acid	$C^{10}H^4\begin{cases}OH\\NH^2\\(SO^2\,OH)^2\end{cases}$
Dioxynaphthaline monosulphonic acid	$C^{10}H^5\begin{cases}(O\,H^2)_2\\SO^2\,OH\end{cases}$
Dioxynaphthaline disulphonic acid	$C^{10}H^4\begin{cases}OH\\OH\\(SO^2\,OH)^2\end{cases}$

As is well known in photography, it is the practice to treat the sensitive plates (prepared with chloride, bromide, or iodide of silver, or with two or all of the salts) after exposure with a developing solution, in order to bring to view the image produced on the sensitive plate. The developing solution hitherto employed for this purpose has usually consisted of a solution of oxalate of iron, pyrogallic acid, or hydrochinone.

Now, I have found by experiment that the before-mentioned substances, diamidonaphthaline, amidonaphthol, and dioxynaphthaline, as well as their sulpho-acids, are exceptionally suitable for developing photographic pictures produced on the said sensitive plates, and give better results than can be obtained with an alkaline pyrogallol developer, and excel the latter by giving the plates a blue black tint similar to that produced when developing in a bath of oxalate of iron, without in the least colouring the sensitive plate, but enabling the plate to better resist the alkaline action of the bath. I thus obtain the advantages possessed by known developing baths without their disadvantages.

A developing bath prepared with my naphthol-developer in which it is intended to immerse the sensitive plate after having been exposed, for the purpose of producing a visible picture is, for instantaneous photography, advantageously composed of the following ingredients:—

5 grammes of the hereinbefore described napthol developer.

15 grammes of sulphide of soda.

250 grammes of distilled water; and

5 grammes of potash.

The above proportions can, however, be varied, or one or the other of the ingredients can be substituted by others providing the essential part, namely, the before-mentioned naphthol developer is contained in the developing bath.

Instead of potash soda-carbonate, soda lye or potash may be used, in which case it is preferable to replace the before-mentioned 5 grammes of potash by 20 drops of a concentrated or saturated soda or potash lye, and this is especially recommended when diamidonaphthaline or its sulphonic acids are used. In the same proportion the quantity of sulphide of soda can be advantageously increased when alphanaphthol derivatives (such as amidoalphanaphthol) or their sulpho-acids as mentioned above, are used.

The before mentioned five grammes "napthol developer" may be used with any of the above combinations.

As any one of the "naphthol developers" is suitable for the present purpose, I find it is not absolutely necessary to restrict myself to the use of only one of the "naphthol developers" for the bath, so that the quantity of "naphthol developer" to be used refers also to mixtures of the above-named "naphthol developers."

After having immersed the photographic plate in this bath till the picture becomes completely developed, it is then fixed in the usual way.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—

The process herein described of developing photographic pictures on coatings of chloride of silver, bromide of silver, or iodide of silver, or of any two, or of all three of them in combination, such process consisting in treating such coatings in a developing bath containing diamidonaphthaline, amidonaphthol, or dioxynaphthaline, or their sulpho-acids.†

PHOTOGRAPHING CHURCH ARCHITECTURE.*

BY THE REV. T. PERKINS, M.A.

WE often find difficulty in getting general views of churches and cathedrals, on account of adjoining buildings. Still, in many cases of parish churches we are enabled to get the best general view from the south-east. People did not like to be buried on the north side of a church, so that the grave-yards often extend furthest on the south side (the chief entrance generally being the south porch), and this allows us often to get sufficiently far away to the south-east to get in the whole of the church, tower and all, with a lens of moderately long focus. This is a thing to be aimed at, as if we get too close and use a lens of short focus in comparison to the plate, the tower is dwarfed, and the chancel roof rises too high on the picture, and the chancel itself is exaggerated in size from our being so much closer to it than to the tower. A sunny day, shortly after midday, when the eastern side of the tower is in shade, is the best time to choose for a view from the south-east. When we wish to make the tower the chief object, the best position is from the western side, but a little either towards the south or north; the church, however, itself does not generally look well from this position. In the case of cathedrals, the north side is generally to be preferred, the cloisters, the bishop's palace, or the deanery often proving obstacles on the south side. If we take a cathedral from the north-east, we must choose early morning or late evening in summer, as the whole of the building will be in shadow in our picture. The west front of a

* A portion of a paper read before the Camera Club, and published in its Journal.

† In the patent, "sulphide" seems to be a misprint for "sulphite."—ED.

cathedral is often well worth a plate. Generally speaking, the use of a wide-angled lens used to its full extent is to be avoided. It is often better to take a view of a portion only of the building than to endeavour to get the whole in at the risk of exaggerated perspective. In taking an interior, windows are often troublesome, as halation spoils the effect. Films, backed plates, or plates thickly coated on ground glass, should be used, as these decrease halation. A lens with a somewhat curved field is useful, as with it, if we are taking a view from either end, we can get the distant end and the nearer pillars and roof in fair focus together with a comparatively large stop; a lens whose focal length is about equal to the length of the longer side of the plate is generally the best. It is a mistake to endeavour to get too much in. I would strongly deprecate the use of wide-angled lenses for interiors; for general views of exteriors they are sometimes a necessary evil, but for interiors I would scarcely if ever use them. In the first place, the exaggerated perspective due to including too much on the plate is painfully obtrusive in an interior; and in the second place, the falling-off of illumination towards the margins is a serious drawback, as it generally happens that those parts included towards the top of the plate are the worst lighted. As I said just now, a lens with focus equal to the length of the plate, with the front raised so that the lens is opposite to a point about two-thirds up the plate, will be the best; a lens of the portable symmetrical type is the one I always use for this work.

A day when the light is diffused is better than one on which the sun, shining through the windows, throws patches of light on the floor and pillars. There is little fear of giving too long an exposure, as our object should be to get plenty of detail in the shadows. It is well, in fact, to over-expose, and develop slowly with a weak developer until all detail is out, and then to strengthen the developer or trust to subsequent intensification. It is often useful, if time is a consideration, to begin the exposure with stop *f*/32, and after a time to carefully change it to *f*/16 without shaking or moving the camera; the former gives sharpness, the latter shortens the time of exposure. In taking a general view from the nave it is well to get as far back as possible, and to place the camera a little to one side, say to the north, and to turn it somewhat to the south, so as to get the east window somewhat to the left of the centre of the picture. An artist making a drawing of an interior looking to the east would, I believe, construct his outline according to the rules of perspective, imagining himself to be standing outside the building, and drawing it as it would appear if the west wall were removed. The photographer cannot do this. He must be content, I think, if he desires to have a picture with pleasing perspective, to embrace only perhaps the eastern half of the nave, and not to attempt to get in his picture that part of the roof which he can only see by turning his eyes upwards. But not only is it worth while to take a general view of the interior; many charming bits may be got in most of our cathedrals looking up or down the aisles, or diagonally across the transepts, and individual monuments, and chapels, and screens are also often worthy of the exposure of a plate.

THE CRYSTAL PALACE PHOTOGRAPHIC EXHIBITION will be opened on the 11th of March; the last day for receiving intended exhibits will be March 1st.

FOUR DIFFERENT PRINTING PROCESSES SUITABLE FOR COPYING TRACINGS.*

BY J. E. GOOLD.

I WILL briefly describe four different processes by which an exact copy of a drawing on tracing paper can be made.

Colas's Process, which gives a black line on a white ground, is now greatly in use for copying tracings; it prints quickly, and is very simple to work. The exposure ranges from five to ten minutes in the sunlight, and from twenty to forty minutes in the shade. I find the best results are got on a bright day, and printing in the strongest light. I have very often to reduce large drawings made on yellow tracing paper to a small scale to transfer to a stone for lithographic purposes, and use this process to get a more suitable copy to photograph from. To make a print, you put the tracing face downwards in the printing-frame, and place the sensitive paper on the top of it, then a piece of thick felt, and then the backs, and put a good pressure on by means of screws, which are much better than springs, as you are able to get a more even pressure. To ascertain if sufficiently printed, lift up one corner, and if the greenish-yellow tint has disappeared, except where covered by the lines, it should be taken out and immersed, face upwards, in a bath composed of gallic acid, 20 parts; alcohol (methylated), 200 parts; and water, 1,000 parts; and remain for about three minutes; at end of time, the lines will be up strong and black; it should then be thoroughly washed in running water for a quarter of an hour, and surface rubbed with soft sponge; then taken out and hung up to dry. The following will be found a good formula for sensitising the paper:—

Water	300	parts
Gelatine	10	,,
Perchloride of iron	20	,,
Tartaric acid	10	,,
Persulphate of zinc	10	,,

Apply this by means of either a broad, flat camel-hair brush, or a fine sponge, to a hard, well-sized paper, then hang up to dry in a dark room. To over-expose a print means losing the lines, and under-exposure gives a very dirty, neutral tint ground, and very faint lines.

Pellet's Process.—This is the best process I know of for copying tracings, it being much quicker than any other, and giving a brighter result, although there is more trouble in finishing the print, as it requires developing on a saturated solution of yellow prussiate of potash. The print must be allowed to remain for half a minute, then lifted out of the bath and hung up by means of American clips until the lines have developed up to a strong dark blue; then immediately lay face down in a tray of water to stop the action of the developer, and by means of an india-rubber pipe splash water on the back of the print. It must then be placed, and completely covered, in a bath composed of one part hydrochloric acid to ten of water for five minutes; now take out and well wash the surface, and rub with a broad camel-hair brush to remove the loose blue sediment that would otherwise remain; after again rinsing, hang up to dry, and the result will be a beautiful clean white ground with strong blue lines.

Ferro-prussiate Process gives a white line on a blue ground, but is not so suitable for copying tracings—(1) because you cannot very well alter anything on the print, and (2) a mechanical or architectural drawing cannot be tinted as

* A Communication to the Newcastle-on-Tyne and Northern Counties' Photographic Association.

in the other processes previously described, although it is a cheap and rapid method of printing from negatives of drawings, giving a blue line on a white ground, the exposure only taking from five to ten minutes in a good light. The great advantage is, the prints require neither toning nor fixing; all that is needed is to wash in a plentiful supply of clean water until the lines are dark, and the ground perfectly white. Or if a copy from a tracing, the lines should be quite white, and the ground a good dark blue.

Messrs. Halden, of Manchester, supply a paper which gives a similar result to Pellet's, and only requires to be immersed in one bath containing red and yellow prussiate of potash, and then rinsing in clean water. I have not been able to give this paper a fair trial since it was introduced to me, but have made one or two very fair prints.

STEREOSCOPIC PHOTOGRAPHY.

THE following is a portion of a paper delivered a few days ago by Mr. G. D. Macdougald before the Dundee and East of Scotland Photographic Association :—

In what does stereoscopic vision consist? That is a very difficult question to answer. We know the conditions, or some of the conditions, under which we have such vision, and can only say it is the natural state of matters set up in the brain itself by the combination of two distinct impressions. When we look at a stereoscopic photograph we become aware that we are imitating nature, we feel we have a near approach to natural vision. By the well-known device of taking two pictures a little distance apart we take another step forward. In viewing such pictures we become aware of very perfect stereoscopic impression. There is greater solidness and relief.

I can only speak to my own impressions, and I say that a good stereoscopic view gives me very great satisfaction indeed. Mr. Pringle says that stereoscopic impressions are only fit to amuse children or savages a few times. . . . . .

One might be tempted to think that, having two pictures photographed at about the average distance of the eyes apart, hardly any difference would be observable between nature and the delightful representation as seen in the stereoscope, yet there is considerable difference. In looking at nature the eye has to adjust itself in focus for the near and the far-away objects. Every photographer knows that while photographing a near object the back of the camera has to be drawn out farther than in the case of a far-away object. Some have gone the length of maintaining that our knowledge of distance when looking at a view is mainly due to the brains interpreting the continuous stream of telegrams intimating the various focussings of the eye. That, however, will hardly hold good, as in a stereoscopic picture all the focussing is already accomplished. The picture being really flat, the eye has no focussing to do.

Any one possessed of a stereoscopic picture of some place to which he can get access may easily carry out an experiment on this point. Comparing his impressions of nature with the impressions as derived from the stereoscope, one quickly finds that the action of the eyes is decidedly different in each case. In looking at nature the eye has work to do, and feels the distance, so to speak, between each object. No such action takes place in the stereoscope.

But one may explain stereoscopic vision to his heart's content, and, after all, there remains the element of the wonderful in it. We confess to as much of the child or savage as to permit of a feeling of wonder at the possibility of combining two impressions by the mechanism of the brain itself. It appears to me there is something so many-sided about this fact as to indicate its being a fruitful starting-point for many investigations—anatomical, physiological, psychological, and metaphysical. It at least permits of a slight insight into the working of the occult mechanism which lies between the action of the eye and the final translation of the eye's messages to our consciousness.

In conclusion, is stereoscopic work suitable for the amateur? I venture to say it is eminently suitable. While it allows of the exercise of as high art as any other branch of photography, it gives an undoubted helping hand to the worker who does not aim high, who may work under circumstances where high photographic art can hardly be looked for. In shorter language, its range is wider, and it gives hope of more return for labour. The amateur rank and file do not aim at large work. The conveniences necessary for large work are not to be lightly estimated by any one limited in one way or other by space, time, or cash ; and one or other of these things, in the case of three out of four amateurs, comes in to limit his effort.

I shall state the advantages of a stereoscopic outfit from the amateur's point of view :—

(1) Compactness of apparatus. (2) Great certainty of producing a pleasure-giving result under disadvantageous circumstances. (3) Suitability for production of lantern slides directly. (4) Suitability of apparatus for taking single pictures of artistic proportions, and large enough for most amateurs.

ISOCHROMATIC OR ORTHOCHROMATIC.

A WRITER in the *Swiss Photographic Review* objects to the words orthochromatic and isochromatic, as signifying a different thing from the meaning they are intended to convey. "Now, what is to be defined? A process by which we correct the incapacity of the ordinary plate to render exactly the value of colours. According to the dictionaries, isochromatic means of uniform tint; as to the word orthochromatic, it seems to have been invented for the purpose of commercial competition with the first. The two Greek adjectives *isos* and *orthos* are nearly synonymous, and signify both of them "equal, right, true"; the two words in question would, therefore, be translated by: a process giving the exact colour. Now, as the artifice thus qualified does not give colour, it is necessary to have recourse to a cumbersome paraphrase in order to translate the thought of the coiners of these words: a process by which the colours of the objects do not prevent them from being reproduced with their proper luminous value. I would therefore propose the use of a better word—*orthophotic*—that is to say, a process giving the exact rays."

To these remarks the editor of the *Swiss Review* replies as follows :

"We are happy that our correspondent has raised this interesting question. It is true the vocables *iso-* and *orthochromatic* have but an erroneous and conventional signification. The word *orthophotic* seems preferable, but is it very correct? Our eye classifies the seven colours of the spectrum, according to the luminous intensity proper to each ; the photographic plate is impressioned by these same colours, not in the ratio of their luminous intensity, but in accordance with the chemical property which each possesses, more or less, of decomposing the silver salts. The physical action of shining which strikes our eye, and the chemical action of destroying which impressions the plate, do not move in parallel directions. Our eye is *orthochromatic*, the ordinary plate is *orthoactinic*. Does the word *orthophotic* well convey the meaning of the chemical properties of the rays of light which are alone to be considered in photography? This does not seem to be so, and we have here, we think, something wanting, It is not the *luminous* action that the word should recall, it is the *chemical* action. We have just said that the ordinary plate is also *orthoactinic*, as it exactly renders the relative powers of the diverse rays to decompose the bromide of silver. A plate that did not express this relative power, a plate in which the actinism of the rays was palsied, in which the green

and the red would end by attracting the bromide of silver in a certain measure, would possess properties outside of those of the ordinary plate; it would no longer be *orthoactinic*, but rather *paractinic*. Now this is the property of iso- and orthochromatic plates. We ask our correspondent if this word suits him."

Correspondence.

PHOTOGRAPHY IN NATURAL COLOURS ON SILVER PLATES.

SIR,—In your article on "Photography in Natural Colours on Silver Plates," in the YEAR-BOOK, you mention only one name connected with the development of the method which may be termed composite heliochromy, and only to remark that his (Hauron's) method "is occasionally re-invented," &c. Inasmuch as I have done more actual work in this line, and written more upon this branch of the subject than anyone else, you will no doubt allow me to call attention to the fact that my own method is a more radical departure from that proposed by Hauron, than was Hauron's from that proposed by Henry Collen in 1865. This must be admitted if it is true, as I assert it to be, that my method is the first and only one which is based upon, or which is consistent with, or which in any way recognizes the modern theory of colour vision which distinguishes between primary spectrum colours and primary colour sensations. Hauron and Cros would have made photographs by orange, green, and violet light, for projection by orange, green, and violet light, or for pigment prints in exactly complementary colours. A recognition of the theoretical distinction I have mentioned involves the production of a photograph by the joint action of red, orange, yellow, and yellow-green spectrum rays, in definite proportions; for projection by red light, a photograph by the joint action of orange, yellow, yellow-green, green, and green-blue spectrum rays, in definite proportions; for projection by green light, &c.

It seems to me that nobody who knows this can help admitting that there is a radical difference in the methods, as well as in the principles involved, and that this difference is of exceeding importance. FRED. E. IVES.

911, *Filbert Street, Philadelphia, Feb. 7th.*

PHOTOGRAVURE.

SIR,—In reply to Mr. E. Frewing's letter in yours of the 14th inst., I am sorry that a slight error had slipped into my description of Mr. Carl Eckstein's litho-photogravure process. There is, of course, no asphalt at all applied to the second stone, and the passage in my letter, page 99, should therefore run thus:—"As soon as the desired depth of etching is attained, the stone is removed to a trough and thoroughly washed in running water; then *the gelatine film* and *the colour of the stippled image* is washed off with turpentine," &c.

Proceedings of Societies.

CAMERA CLUB.

Thursday, February 13th.—The Rev. A. B. W. WHATTON in the chair.

Previous to the lecture the HON. SEC. read an extract from an alleged old book entitled "Giphantia," published in 1761. This extract, which had been sent up by a member, Mr. A. C. Lyster, gave an account of a vision relating to photographic agency, said to have been experienced in Central Africa. A viscous substance received images which became fixed on removal to a dark chamber.

Mr. GRAHAM BALFOUR read a memoir on "Landscape," in which he dealt with the relative artistic merits of pure landscape and landscape with figures, and stated that he felt inclined to recommend the former; he preferred work done to satisfy the sense of beauty or art for art's sake. When figures are omitted where their presence might seem most desirable, their absence may be compensated by the introduction of well-chosen articles of human use. The effect of a desolate scene is usually enhanced by the absence of the human form, although there are exceptions: a solitary human figure in the vast expanse of the Great Sahara increases the feeling of desolateness, but such an adjunct is best left out in a landscape wherein its presence would be incongruous with the spirit of the scene. Mr. Andrew Pringle maintains that figures in landscape photographs are scarcely ever in the right place, and that it is better to leave them out. The old masters almost invariably introduced figures of men and animals, or suitable substitutes, into landscapes; but in these latter days painters no longer feel that course necessary, the truth being that in the olden time the feeling for beauty in landscape had not been born in the human race, for we live in days of new ideas and new conditions. The great appreciation of the external world, which has grown up within the last hundred years, is due to ideas externalised by modern painters and poets; also to the wonderful discoveries of science. In short, he denied the supremacy of ancient authority on this subject, and believed that we should not worship our ancestors as do the Chinese. Besides, painters have an object, which photographic workers in monochrome have not, of sometimes introducing figures to get a few bright points of positive colour in suitable positions. He thought beauty to be a sufficient quality for any picture to possess.

Mr. HUMPHERY considered the seeking for beauty to be one of the greatest curses of photography at the present day, for the human mind required something grander, something more suggestive than prettiness; it wanted soul, and soul could not be found in mere beauty. As to figures, the introduction of them would utterly spoil certain pictures, such, for instance, as those of the wild waves of the ocean breaking over the rocks; but there were other scenes, such as some of those of a rural nature described by Wordsworth and by Gray, in which the introduction of human and other figures enhanced the effect.

Mr. ASHBURY GREENE agreed with all that Mr. Balfour had said in his paper. Beauty should not be confounded with prettiness, for it includes scenes of grandeur and majesty, and in a beautiful scene he considered figures to be incongruous. It is absurd to use the term "beauty" as including only subjects which are merely pretty.

Mr. GEORGE DAVISON believed that there might be as much beauty in a simple landscape, or a tree, or a bit of a pond, as in grand scenery, and he did not think figures to be essential to pure artistic work. In the past, those who have posed figures in the attempt to represent them in motion, have usually failed, but the resulting un-

naturalness is not seen when a hand-camera with a lens of long focus is used upon a figure in action not specially posed. Fine art cannot be governed by any didactic reason of any description, for then it would become more or less a science.

Mr. E. R. SHIPTON remarked that in the old photographs upon the wall of the room in which the meeting was held, figures had been introduced largely into the landscapes, and those pictures taken in the old collodion days proved that photographers had not advanced as much as they ought to have done. He did not think that Mr. Pringle's attempts to introduce figures into landscapes had been generally successful, judging from the lantern pictures he had recently exhibited. He thought a thorough grounding in art principles to be essential to good artistic work, and did not think that more than one photograph in five hundred was worth calling a picture.

Dr. C. S. PATTERSON said that the objection made that figures are usually placed wrongly in landscapes is no argument against their being put in right positions therein.

The CHAIRMAN would ask, "What is beauty?" If the reply were that it is truth, then they were driven back to the old question, "What is truth?" He was utterly unable to grasp the idea of pure beauty. He could imagine the beauty of ideas; for instance, the idea of the mathematician about the fourth dimension in space, and could become lost in admiration thereat, and he thought that pictures are beautiful only when they start a train of ideas, for beauty cannot be reduced to mere symmetry. Early Greek sculpture began with the idea of pure beauty, or of art for art's sake, but, as it improved, it tried to convey ideas to the mind; in its early stages, Phidias and Praxiteles produced nothing but Venuses and forms due to "art for art's sake," but later on Grecian art tried to convey ideas, by representing wrestlers and other subjects full of action. Any picture, he thought, which had motive in it must include figures.

Mr. WILLIAM ENGLAND was of opinion that it is desirable to introduce figures into landscapes where it can be judiciously done, and that in some cases it is absolutely necessary. He had seen American stereoscopic pictures in which the introduction of the human figure gave an idea of the approximate height of the geysers in the Yellowstone Park. Sometimes the introduction of a figure will help to suitably break up a landscape foreground, and in the instance of a trout stream, the introduction of a man fishing was an improvement.

Mr. BALFOUR, in the course of his reply, said that in the term beauty he included grandeur, and that he considered prettiness to be about the greatest curse which could be called art. When figures were introduced, he strongly advocated the use of the instantaneous shutter. The great experience of Mr. England made his utterances welcome and valuable, but that evening they were rather outside the range of the subjects dealt with in his paper. When figures were introduced to give the scale of the dimensions of a geyser, he should consider the result to be more properly classified with diagrams than with works of art.

The subject on Thursday, Feb. 27th, is "Photography as Applied to Medicine," when a paper will be read by Dr. C. S. Patterson.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting on the 13th inst. Mr. G. W. ATKINS occupied the chair.

With a view to test the question asked at a previous meeting, whether plates coated with collodio-bromide emulsion were subject to reversal of image, Mr. J. B. B. Wellington had during the week tried three plates, exposing for one minute, twenty-five minutes, and one hour respectively—the latter in bright sunshine. Although all showed more or less over-exposure, no trace of any reversal of image was observable.

Mr. W. E. DEBENHAM said the resistance to reversal of image might be due to the vehicle or the molecular condition of the film. It was a question whether a plate coated with gelatine emulsion made as slow as collodio-bromide would not offer the same resistance to reversal.

A question from the box was read, "When developing a plate which is known to be over-exposed, is it better to begin with the usual amount of pyro and bromide and a very small quantity of ammonia, and as the development proceeds to add more ammonia, or to use a solution weak in ammonia and bromide, and to add the pyro by degrees, beginning with only a very small quantity of pyro, and finishing with the usual developer?"

Mr. A. HADDON referred to Captain Abney's remarks, published in the YEAR-BOOK, endorsing the system of obtaining detail first and density afterwards, this method of procedure proving particularly successful in developing negatives of Swiss scenes. By commencing with a minimum quantity of pyro, details of distant snow-covered mountains, as well as the foreground, were obtained in the same negative.

Another question from the box: "Does anyone know of a formula for polish suitable for cameras, that can be put on rather thickly and finished at once?"

Mr. A. C. PEMBERTON said adding ether to French polish caused it to dry very quickly, but the article coated was not so satisfactory in appearance as when the French polish was used without the ether.

The CHAIRMAN said a good black for brass articles was made by dissolving copper turnings in nitric acid. The article, freed entirely from grease, was dipped into this solution, then passed through the flame of a Bunsen burner, and afterwards washed in water.

Mr. J. J. BRIGINSHAW exhibited two prints from negatives of the moon, taken recently with the great Lick teleseope. He believed this teleseope was provided with a second lens for photographic work.

A Member asked the foeus of the objeetive the negative was taken with.

Mr. A. HADDON said from the size of the image in the prints passed round he should say from 50 to 60 feet.

Mr. T. E. FRESHWATER referred to the exeellent negatives, full of detail, obtained of the moon by Mr. Lewis M. Rutherfurd, of New York, in 1863-5, with very rude apparatus.

The remainder of the evening was devoted to the optieal lantern. A varied and interesting selection of slides was projeeted on the screen, contributed by Messrs. G. W. Atkins, A. C. Pemberton, T. E. Freshwater, R. P. Drage, J. Teape, and J. B. B. Wellington.

WEST LONDON PHOTOGRAPHIC SOCIETY.

AN ordinary meeting of the above Society was held at the Addison Hall on the 14th inst., Mr. F. H. Low, M.B., in the chair.

The members were informed that Mr. Wilson intended to present the Club with a selection of photographic works for the library.

Mr. RONALD WHITING read a paper on "Reducing and Intensifying Negatives."

Mr. C. WHITING remarked that negatives which had been dried quickly by immersion in spirit, to drive the water off, are generally much denser than those dried in the ordinary way, and that a negative which was dry in some parts and not in others, on being put into the spirit and dried, was found to be almost twice as dense in the parts which had not been dry on immersion in the spirit. He also mentioned that if a very much under-exposed negative were simply bleached with mercury and then used, it would be found to be decidedly improved, for although the contrasts before were too violent, the bleaching remedied that to a large extent.

Mr. BLACKMORE said that he did not approve intensifying a badly under-exposed negative. It had its proper place, which was certainly not in the printing-frame.

Mr. R. WHITING, in replying to questions, remarked that the different processes of intensification he had described could be used with films, and he did not think there would be found to be any action on the celluloid backing.

The CHAIRMAN requested those members who had won medals at the late exhibition to send them to the secretary, as they were to be engraved with names and date, and he announced that a special general meeting would be held on the 8th of

March to consider matters relating to the Exhibition, except that the subject of the awards must not be touched upon in the sense of questioning any of them. The meeting of the 8th of March is not to interfere with the holding of the next ordinary meeting on the 28th inst.

HACKNEY PHOTOGRAPHIC SOCIETY.

MR. G. H. SLIGHT read a paper on "Retrospective Photography, from Personal Recollection," on Thursday last, going back over forty years. He illustrated his paper by showing some old wet plate negatives, positives, and prints. He liked the old process, and was loath to leave it in favour of the present dry plates.

Dr. GERARD SMITH, who began photography twenty years ago, said he liked it better, and it was admitted by a number of people to be better, seeing some plates were advertised "like the wet plate in results."

The SECRETARY announced that on the 27th an exhibition of "Apparatus" would be held, and invited members to send apparatus by six o'clock on that day. He said all the members would be pleased to hear that Mr. Hubert had secured a silver medal at the Royton Exhibition.

Mr. Dean showed some micro-enlargements.

Mr. Hart showed the photograph he had taken of the members at the preceding meeting. Owing to the camera being a new one, the drawing of the slide had caused it to shift, thus getting it a trifle out of focus.

The SECRETARY said he had been trying pyrocatechin (Dr. Arnold's formula), but could not recommend it, as it was too slow, and had no advantage over any of the developers now in use.

Mr. REYNOLDS wanted to know how to remove films off useless negatives.

Dr. GERARD SMITH advised salt and water.

Mr. Birt Acres was nominated as a member.

NEWCASTLE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

THE annual meeting was held on Tuesday, the 11th inst., in the Mosley Street Café, Newcastle-on-Tyne, Mr. J. P. GIBSON in the chair.

The election of officers was as follows :—*President*—Mr. A. S. Stevenson, J.P.; *Vice-Presidents*—Messrs. J. P. Gibson and H. R. Procter; *Council*—Messrs. M. Auty, James Brown, T. Galloway, J. E. Goold, W. Parry, G. Proud, H. G. Ridgway, J. Hedley Robinson, H. Shand, and L. Williamson; *Hon. Treasurer*—Mr. J. W. Robson; *Hon. Secretary*—Mr. Edgar G. Lee, 11, Beverley Terrace, Cullercoats.

The Treasurer's report showed a balance in hand of £2 13s. 3d.

The following were elected as members of the Association : Miss Annie Philipson, Messrs. W. R. Ferguson, W. W. Fry, A. E. Harris, W. Milburn, and Lyddell Sawyer.

Mr. J. E. GOOLD read a paper on "Four Different Printing Processes suitable for Copying Tracings" (see page 151).

Other printing processes were described by Messrs. M. Auty, Jas. Brown, J. P. Gibson, W. Parry, and J. Pike.

Some very fine photographs by Mr. Robert S. Redfield, Philadelphia, were exhibited by Mr. J. P. Gibson.

Messrs. M. Auty, Jas. Brown, J. P. Gibson, J. E. Goold, and W. Parry exhibited a number of photographs, the work of the past season.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

A MEETING was held in the Mayor's Parlour, Old Town Hall, on Wednesday, Feb. 12th, Mr. J. T. COOK in the chair. One member was elected, and one proposed for ballot at the next meeting.

The exhibition of lantern slides for competition in class A was then proceeded with, Mr. F. Pierpoint manipulating the lantern. Eight members sent in six slides each, which, after being passed through the lantern, were voted for by ballot by the members present, with the result that the first prize silver medal was awarded to Mr. Porrit, and the bronze medal for the second prize to Mr. W. Joliffe.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

ON Feb. 10th the members of the above Club discussed the best light for use in the dark room, and submitted the several samples of glass to a practical test. For this purpose, pieces of Ilford rapid bromide paper were used, and an exposure of ten minutes was given. The following were the results obtained :—That exposed to the light of one thickness of cathedral green, after being in the developer for about one minute, was quite black, while that with two thicknesses was of a dark grey; that exposed to the yellow and ruby was still quite white; in about two and a half minutes longer, that exposed to the yellow began to show a grey, the ruby—the darkest procurable—following one minute later.

Mr. PAUL remarked that at previous meetings when he had recommended cathedral green to be used, he had never advised that it be used alone, but in conjunction with a screen of canary medium, and expressed his belief that if forty thicknesses were used, it would still be easy to fog a plate.

Mr. GOODHEW remarked that the safety, or otherwise, of a particular screen was largely influenced by the make of lamp, for one in which the burner was six or eight inches from the glass would be found much safer than one with the burner only two inches from it; also that one with two screens placed a few inches apart would be found much safer than with the same screens placed close together, although they apparently gave the same light.

The SECRETARY said that in choosing a light to work by we had the choice of two evils: either it was necessary to have a light that was practically if not absolutely *no* light—if it was desired to have one that would have no effect upon the sensitive film, however long exposed—or a light which, while promoting ease of working, would cause fog, if allowed to act for a comparatively short time. And, therefore, it was necessary under these conditions to choose one which hit the middle course; that is, a medium which would not show any trace of fog with the longest *necessary* exposure on the most sensitive plates. Anything which cut off more light than this was not only needless, but was an actual disadvantage, and detrimental to the best results, as nothing was more necessary than a good light to judge the negative by in developing, and for this reason he objected to such screens as had a mottled appearance (as cathedral green), as he opined that it made the judging of fine detail more difficult, and remarked that all knew the nuisance of emulsion on the back of a negative.

The vote of the meeting was taken, when it was found that canary medium and yellow glass were the favourites.

Next Monday, February 24th, Mr. George Davison (of the Camera Club) will give a lecture entitled "A Chat on Pictures by Photography." Visitors are invited to attend.

BRIGHTON PHOTOGRAPHIC SOCIETY.

THE first annual meeting was held on February 11th., the President (Dr. REAN) in the chair.

The SECRETARY read the committee's report, which stated that the Society now numbered sixty members. It also referred to the papers read during the year, which have been of a high class, and evoked considerable discussion. The lantern evenings have also been a feature, and have proved entertaining. During the summer months excursions have taken place to the most picturesque spots in the vicinity; these have been thoroughly appreciated. Two interesting competitions have also taken place, one for the best set of lantern slides being keenly contested.

The officers for the current year were then elected as follows :—*President*—Mr. W. H. Rean; *Vice-President*—Mr. W. Jage; *Treasurer*—Mr. J. P. Slingsby Roberts; *Committee*—Messrs. Bedford, Caush, Hardcastle, Graham, Perren, Mitchell, Tate, Webbing, and Wicks; *Hon. Secretary*—Mr. A. H. C. Corder, 42, Montpelier Road, Brighton.

The prints sent in for competition were on view during the evening. The judges, Messrs. Allen, Fry, Hunter, Graham, and Rean, awarded the bronze medal to Mr. W. Duddell. The silver medal was withheld, as, in the opinion of the judges, there were no exhibits of sufficient merit to justify their awarding it.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

February 6th.—General meeting ; Dr. TULLOCH, President, in the chair.

Mr. G. D. MACDOUGALD read a paper on "Stereoscopic Photography" (see page 152). Mr. Macdougald then gave a description of the lime-light jet used at the Society's lantern exhibition on the 29th ult.

Dr. TULLOCH exhibited an apparatus for magnifying lantern slides he had made from a design published in the current YEAR-BOOK. It consisted of a cardboard box with a plano-convex lens mounted at one end, the other end being made of ground glass. The lantern slide is placed in a groove sufficiently far into the box to throw the ground glass out of focus when the instrument is held up to the light to view the slide.

Beck's new camera, the "Pecrops," was on exhibition. Messrs. Beck had also two of their "Autograph" lenses on view ; one mounted, as usual, in brass, the other in aluminium.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

AT the meeting held on the 13th inst., Mr. W. JEROME HARRISON, F.G.S., occupied the chair.

The Birkenhead Photo. Survey slides were advertised to be shown, but as these were not ready, a very good substitute was given through the kindness of the following photographers and societies, who sent a number of slides for exhibition ; viz., Messrs. C. W. Hastings and H. Sturmey, the Camera Club, and the Leicester, Wolverhampton, and Coventry Societies. Those from the Camera Club were the new set of animal studies, and were sent out with very appropriate readings of particulars. The new club lantern was on view, and, at the close, some pictures were passed through.

It was announced that Prof. Muybridge would give his exhibition at the Birmingham Town Hall during March.

SOCIETY OF AMATEUR PHOTOGRAPHERS OF NEW YORK.

THE regular monthly meeting was held on the evening of Jan. 14th, President C. W. CANFIELD in the chair.

Mr. F. C. BEACH read a paper on "Camera Shutters," and exhibited a number of different models. He thought almost all shutters were operated either by gravity, spring power, or pneumatic power.

Mr. CYRUS PROSCH exhibited a skeleton model of his present triplex shutter, and a model of the first one he invented.

Prof. L. H. LAUDY thought the word "instantaneous" should not be used, as there was not, and could not be, an instantaneous shutter. All required time to operate.

Mr. WM. T. GREGG preferred a shutter operating between the lenses, and exhibited a model of his diamond shutter, called such because of the diamond-shaped diaphragm it made. Very few shutters worked quicker than the $\frac{1}{100}$th part of a second, and the average about the $\frac{1}{50}$th of a second.

Mr. H. M. GRISDALE showed a combination drop and door flap shutter having attached spring hinges, designed to prevent the jar of the doors as they fly open. He also explained a model of a shutter (sector-shaped), in which a simple movement of one lever actuated by a spring operated two blades in opposite directions. He believed in having the apertures in the shutters considerably longer than the actual area of the lens, in order that a large amount of light may enter it.

Mr. F. C. BEACH exhibited a German prayer-book camera made on Mr. J. A. Harrison's principle.

Mr. A. PEEBLES SMITH made a flash-light exposure of the audience early in the evening, developed the negative, dried it, placed it in Dr. Just's automatic exposing and photo-printing machine, sent by the United States Photographic Supply Co., and exposed, by the aid of an incandescent electric lamp, thirty impressions on a continuous band of bromide paper. These were quickly developed with the eikonogen developer in large trays, fixed, cut off, and the prints presented to each member of the audience before the meeting broke up.

EXPERIMENTALIST.—Your letter affects a known person, yet you do not append your own name and address for publication.

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

SPOTS (Buxton).—Small blue marks on silver prints. We have seen several instances of late very like yours, but of more pronounced character. If correct in our surmise, they are really small blisters, or places of loose attachment, where the gold toning solution has got underneath, and so acted in advance, or more powerfully than on the rest of the photograph. By soaking in water we expected to see corresponding blisters rise up, but no such result was apparent even when examined with a magnifier. Avoid the use of a freshly-made toning bath, and keep a look-out for anything in the shape of blisters.

A. M. M.—Inks for india-rubber stamps. No fatty or oily matter should ever be used, for they are apt to corrode the face of the stamp. Spirit solutions applied from a stretched flannel pad are commonly employed, the most suitable colours being extra dahlia for a violet ink, spirit induline for black, or this latter tempered by the addition of a little Atlas blue. All these colours may be procured of Messrs. Brooke, Simpson and Co., Atlas Works, Hackney Wick, E.

F. S. A.—The photograph of the Rosetta Stone, plate 278 in the British Museum series, will be of no use to you, for the inscriptions are not legible on account of the stone being covered with its protecting plate of glass. Apply to Messrs. W. A. Mansell and Co., 271, Oxford Street, W., to know whether they can supply you with any photograph showing the actual inscriptions. Even then you would require an enlarged copy to exhibit the details properly, or they might be sufficiently apparent if a transparency were produced and thrown upon a screen.

R. L.—Testing the speed of shutters. This problem would appear to be solved in a very simple and satisfactory manner by Mr. H. O. Hughes, who describes his apparatus in the YEAR-BOOK, page 109. He uses the swing of a second's pendulum, painted white against a black background, upon which a graduated arc is described, and lets go the mechanism of the shutter when the bob is oscillating regularly. The plate, when developed, will show how far the blurred image extends, and, consequently, the period during which the aperture of the lens remained uncovered. For further details, see the author's published account.

L. P. C.—A pamphlet entitled "Some Recent Advances in Photography," by Frederick E. Ives, reprinted from the *Journal of the Franklin Institute*, May, 1888, can be seen in the Patent Office Library, Southampton Buildings, Chancery Lane.

P. B. A.—The distinction between "professional" and "amateur" is not easily defined. Many so-called "amateurs" have at times sold their negatives, or furnished photo-sketches of passing events, ceremonials, &c., for which they have been paid. Others, again, may have filled temporary engagements, accepting pay, and yet long since discontinued to make any profit by photography. Another large class, of uncertain qualification, may be photo-mechanical printers, opticians, and makers of apparatus, or of various specialities demanded by photographers. The itinerant operator, who practises only during the season, and carries on another trade in the winter months, is, we suppose, a legitimate "professional." But, for an authoritative answer to these points, we must refer you to the newly appointed honorary secretary, whose advent to office at the annual meeting was hailed as a very satisfactory omen for the future prosperity of the Association.

W. M.—1. Where many copies are required, and in all really important cases, it is usual to print from reproduced negatives. 2. Varnish for negatives on Eastman's new rollable celluloid. Mr. W. H. Walker recently stated that his Company were experimenting with several kinds of elastic varnish, and that he hoped very shortly to introduce that which proved the most suitable for general use.

Received copy of the regulations of third annual Photographic Exhibition at the Crystal Palace, to be opened on March 11th.

A. C., T. S., J. C., and PHOTARGUS, in our next.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1613.—*February* 28, 1890.

CONTENTS.

A MACHINE CAMERA TAKING TEN PHOTOGRAPHS A SECOND.

For some months past rumours have been published in various photographic journals in England and America, about the advent of an automatic camera to make a large number of consecutive exposures in a second, by the act of merely turning a handle. This camera has been invented by Mr. Friese Greene and Mr. Mortimer Evans, civil engineer. The object of it is to obtain consecutive pictures of things in motion, which can afterwards be rapidly consecutively projected on a screen, so as to reproduce, say, street scenes, with the horses, human beings, and other living things, moving as in nature. For instance, a cab may be seen passing in one direction, and a dog in the other. Mr. Muybridge, to produce something yielding approximately the same results, used from two to three dozen cameras, and made the exposures by means of a wheel electric commutator; these cameras took the moving objects from either two or three different points of view, so that, practically, he obtained but a dozen or two pictures of a continuous series of motions. The camera now under notice, however, can take a continuous series of three hundred photographs, so as to represent a long stream of street life as it is to-day. What would we not now give for a series of similar pictures representing street life in the days of Queen Elizabeth, with the dress and gait of the citizens of that time, and their antique streets and houses as a background?

In the scientific world such an instrument is likely to be useful. One well-known naturalist—not of the Camera Club, but a real naturalist—has suggested that by means of this camera, the actual motions of the legs of the centipede may be followed; with the eye this is difficult, because the animal has too many legs, and it is difficult for the observer to keep the reckoning, unless he be a Zerah Colburn or other "calculating boy." To the meteorologist it may be useful, when more or less rapidly worked, for showing the formation and dissipation of clouds. Mr. Friese Greene has already, by its means, photographed a spider making its web. This may interest Mr. C. V. Boys, who has also studied the characteristics of the spider, by placing the prong of a vibrating tuning fork, instead of a fly, in the centre of the web; the spider valorously laid hold of it, but observed that he had never seized such a muscular fly before. Next Mr. Boys tried a hot tuning fork, but as a hot fly was outside the experience of the spider, the spider at last took to his heels—supposing him to possess such—and looked on from a distance, with palpitating heart, at his demoniacal visitor. All this, and more, can the new camera photograph; but now it is high time to describe the instrument itself.

Fig. 1 represents the exterior of the machine camera, which is simply a box with a lens attached, and has also a winch handle protruding at the back. Its exterior dimensions are 8 in. by 9in. by 9¼ in. Mr. Mortimer Evans has recently improved upon this, by making a modified form of the instrument for popular rather than scientific use; this smaller camera is little larger than a "kodak," and will take a hundred consecutive pictures by the turning of a handle.

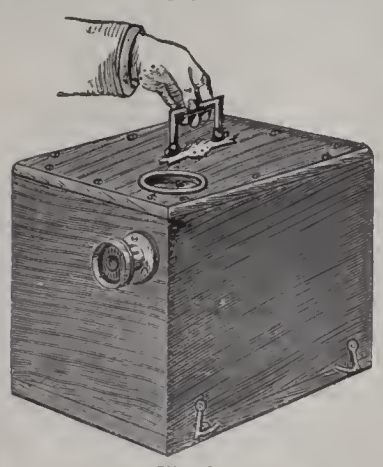

Fig. 1.

Fig. 2, on next page, represents the working parts of the larger instrument as seen from above, and Fig. 3 the working parts of the machine camera as seen from below.

Messrs. Greene and Evans provide a main shaft, which is actuated by a winch turned by hand. To this shaft are attached wheel work and counter shafts,

by which the whole apparatus is driven. The rotation of the shaft pays out the prepared film, and places it in position to receive the photographic impression, in which it is automatically exposed to the action of light. The light is then cut off, and the exposed film, which was motionless at the instant of exposure, is passed on, and wound on a receiving roller on the lower part of the machine. The pictures continue to be taken so long as the main shaft is rotated, and so long as any film remains to be paid out. The inventors wind a long roll on one of the spindles or countershafts, and this spindle is so arranged that as it rotates it pays out the film as fast as necessary. To

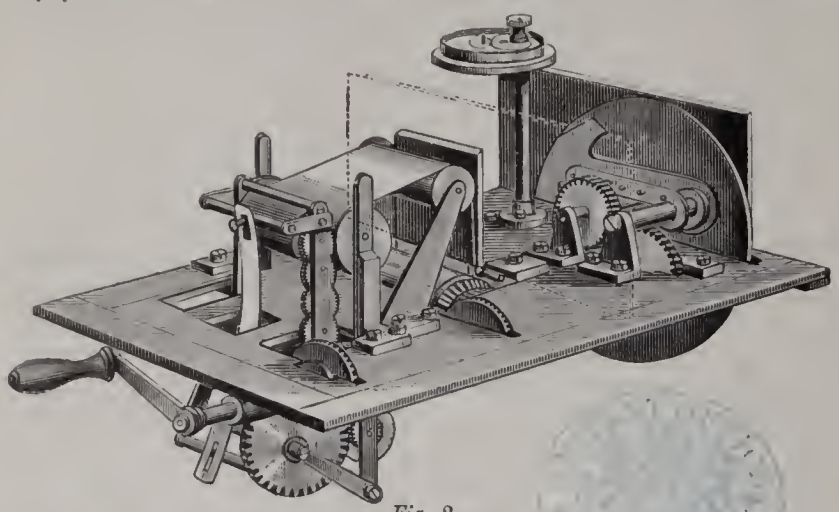

Fig. 2.

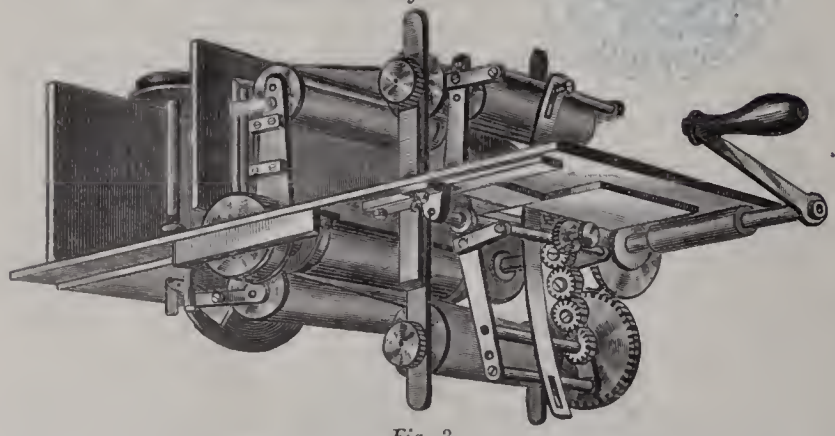

Fig. 3.

another spindle the free end of the film is attached, and by suitable arrangement the second countershaft is caused to rotate in a reversed direction, and to wind up the film.

Between the two rollers is arranged an exposure screen conveying the sensitive film to the rolling-up shaft, and when on this exposure screen, the film is subjected to the action of the uncovered lens.

As both the paying-out and rolling-up rollers have a continuous motion communicated to them by the driven shaft, and as it is desirous that the film, during its exposure to the light, should be at rest, an arrangement to effect this is provided as follows, and this is the cleverest part of the invention:—Immediately beyond the exposure screen, and between it and the up-winding roller, is an intermittently-acting drum of such diameter or circumference as that each turn thereof will take up and roll forward the exact amount of film required for each picture; in passing this film forward, the drum also draws into the exposure position a fresh length of film ready to be exposed. To effect this intermittent motion, the aforesaid drum has a single, long escapement tooth, which, when the drum is not in motion, rests on the cylindrical surface of a slotted pinion, which gears into, and is driven by, the main shaft with a continuous motion. The slot in this pinion is so arranged that once only during each revolution of the pinion does it allow the escape tooth to pass, and when this occurs, the drum, under the action of a driving spring, with which it is provided, makes one full turn, when the escapement tooth, coming round again, rests on the cylindrical portion of the slotted pinion as before. The spindle on which the drum revolves also gears into, and is driven with a uniform motion from, the main shaft, and to this shaft is attached the one end of a coiled spring, the other end of which is fixed to the inner circumference of the drum itself. As the spindle revolves, this spring winds up, and, on the release of the escape tooth and drum, the spring unwinds, carrying both the drum and escape tooth with it. Then the film is passed forward between the winding and unwinding rollers at this point only, with the necessary intermittent motion. The constant uniform motion of the paying out spindle as it unwinds, causes a certain uniform length of the film to pass forward towards the exposure screen, when it collects into a kind of loop in readiness for use. It cannot, however, pass into the position of actual exposure until that portion of the film occupying such position has been withdrawn. As soon, however, as the detent tooth attached to the drum escapes through the slot in the pinion, the drum makes a single revolution, and in so doing both removes the exposed film from the screen, and, at the same time, draws a loop of fresh film which has been gathering, into the exposed position, and, at the same time, passes forward the already exposed film into the form of another loop in readiness to be wound up on the winding roller. The latter is provided with a similar uniform continuous motion, from the main shaft in the paying out roller, and proceeds gradually to wind up the loop, so that the loop is wholly taken up by the time the escape tooth again rotates, when a fresh loop of film is passed forward.

The shutter for exposing the film to the action of light is made in two portions, each provided with an aperture or slot, which in one position only allows the light from the lens to pass, and it is only by this simultaneous action of these two shutters—that is, when

the apertures in each coincide at a given moment—that any action of light on the film can take place. One portion of this shutter is caused to revolve with a uniform motion as it is driven from the main shaft; the other portion is worked by a rocker, or slide, actuated by a cam; to this latter portion of the shutter is attached a spring, with a tension screw to regulate its speed of action. In this way the duration of exposure is rendered entirely independent of the speed of the driving shaft, because by the turning of this screw a somewhat longer or shorter exposure within limits can be ensured, whatever the number of exposures per minute may be. The moment the aperture in the revolving shutter comes into position with the lens, the cam lets the sliding shutter go, and by means of its attached spring the aperture in the sliding shutter also crosses, and the exposure is effected. The action of this shutter is so arranged that each exposure occurs simultaneously with the "at rest" position of the drum, escape tooth, and the film on the exposed screen.

Mr. Friese Greene thinks this machine camera to be likely to be useful for military purposes. For instance, several of them might be employed, driven by any suitable motive power, to automatically photograph the leading features of a battle. Some years ago he exhibited to the Photographic Society a little optical lantern which cast four pictures in succession upon the screen, and, before the one was quite removed, the next was superimposed; thus he showed the change of a countenance from grave to gay, and the very motions of the skin of the face could be seen, without the presence of any of the unpleasant "jerkiness" incidental to a series of pictures automatically projected by apparatus made on the old-fashioned principle. In Mr. Greene's lantern demonstration, colour gradually came into the moving face and into the dress, because he had washed different parts of the portrait on the slide with various "sympathetic inks," as they are called, consisting of suitable solutions of cobaltic and other salts. The heat of the lantern caused the colours to come out. Mr. Greene stated to the meeting that the lantern had been invented by an acquaintance of his in the west of England. By an improvement upon that lantern, now in course of manufacture, Mr. Greene hopes to be able to reproduce upon the screen, by means of photographs taken with his machine camera, street scenes full of life and motion; also to represent a man making a speech, with all the changes in his countenance, and, at the same time, to give the speech itself in the actual tones of the man's voice by means of a loud-speaking phonograph.

A CAMERA is, it is said, among the presents with which Miss Amy Fowler has left New York for Molokai; she has also received gifts of 2,200 dollars, a type-writer, piano, and music.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.—The executive have, we are informed, decided on holding in 1891 another large photographic exhibition. At their club rooms the exhibition of Mr. H. P. Robinson's pictures will close to-day. Over 1,200 visitors, it is said, have attended. The work of Mr. Harry Tolley will be the next feature at the Liverpool rooms.

THE ROYAL INSTITUTION.

VII.

DR. THOMAS YOUNG'S DISCOVERIES AND PHOTOGRAPHS.

ON the 24th of November, 1803, Young delivered the Bakerian lecture of the Royal Society, and in the memoir published in *The Philosophical Transactions* of 1804, he records how he photographed Newton's rings, so that he had his share in some of the photographic work which Wedgwood originated at the Royal Institution. The following are his own words on the subject, copied from the original printed memoir, for in this series of articles we are careful to deal only, wherever possible, with the oldest records extant, and not to quote at second-hand from books of later date; thus the chance of error is reduced to a minimum. He says:—

"The existence of solar rays accompanying light, more refrangible than the violet rays, was first ascertained by Mr. RITTER: but Dr. WOLLASTON made the same experiments a very short time afterwards, without having been informed of what had been done on the Continent. These rays appear to extend beyond the violet rays of the prismatic spectrum, through a space nearly equal to that which is occupied by the violet. In order to complete the comparison of their properties with those of visible light, I was desirous of examining the effect of their reflection from a thin plate of air, capable of producing the well-known rings of colours. For this purpose, I formed an image of the rings, by means of the solar microscope, with the apparatus which I have described in the Journals of the Royal Institution, and I threw this image on paper dipped in a solution of nitrate of silver, placed at the distance of about nine inches from the microscope. In the course of an hour, portions of three dark rings were very distinctly visible, much smaller than the brightest rings of the coloured image, and coinciding very nearly in their dimensions, with the rings of violet light that appeared upon the interposition of violet glass. I thought the dark rings were a little smaller than the violet rings, but the difference was not sufficiently great to be accurately ascertained; it might be as much as $\frac{1}{30}$ or $\frac{1}{40}$ of the diameters, but not greater. It is the less surprising that the difference should be so small, as the dimensions of the coloured rings do not by any means vary at the violet end of the spectrum, so rapidly as at the red end. For performing this experiment with very great accuracy, a heliostato would be necessary, since the motion of the sun causes a slight change in the place of the image; and leather, impregnated with the muriate of silver, would indicate the effect with greater delicacy. The experiment, however, in its present state, is sufficient to complete the analogy of the invisible with the visible rays, and to show that they are equally liable to the general law which is the principal subject of this Paper. If we had thermometers sufficiently delicate, it is probable that we might acquire, by similar means, information still more interesting, with respect to the rays of invisible heat discovered by Dr. HERSCHEL; but at present there is

great reason to doubt of the practicability of such an experiment."

In the first volume of *The Journals of the Royal Institution*, London, 1802, pp. 241-45, is Young's description of his arrangement for photographing Newton's rings by means of the solar microscope. Newton had observed that the colours are more vivid when a plate of a rarer medium is interposed between two denser mediums. Young thought the apparent difference to be due to the quantity of diffused light present, and, to remove this foreign light, he employed one glass in the form of a prism, and coated the lower surface of the other with black sealing-wax. The light reflected by the oblique surface of the first was thus thrown in another direction, and the reflection of the inferior surface of the second was so reduced that it could be disregarded. In fact, this device of Young's is the same in principle as that sold by opticians at the present day to produce Newton's rings.

The most perfectly plane glass Young could obtain was that used in Hadley's quadrants, one side of which he had ground, so that the plate became a thin wedge; the surface of the lens employed was a portion of a sphere of from five to ten feet radius. The glasses were thick, as they had to sustain considerable pressure, which was applied by means of three screws. For adjusting the glasses to the microscope, he fixed them in a cylinder, so that they could be easily turned "so as to reflect the light coming from the speculum into the direction of the axis of the microscope: it is obvious that in this case they must be somewhat inclined to the light, so that the focus of the whole image will never be equally perfect; and, instead of being circular like the rings themselves, their images on the screen will be oval."

In one of his experiments he placed a prism a few feet from the microscope, and cut off most of the image of the rings by means of a diaphragm with a central slit in it, whereby he was enabled on the screen to analyse the light of the different rings. Young said, as other Royal Institution lecturers have often said after him, that "the colours of thin plates, as seen by transmission, are also easily exhibited in the solar microscope; but since it is utterly impossible to exclude the very great proportion of the light which is not concerned in their formation, they never appear so brilliant as the colours seen by reflection."

Photography and Electioneering.—A daily paper says that, at a political meeting on Saturday last, the crowd gathered together "had more than verbal eloquence to speak to them, for, by the aid of a series of limelight pictures, the chief features of Balfourism in Ireland were illustrated. Mr. Harmer, of the Home Rule Union, gave graphic little descriptions of the scenes and incidents represented, and the whole lecture was a highly useful object lesson to the large number of electors present. The magic lantern ought to be requisitioned for the rest of the campaign. Judging by its stirring effect on Saturday it would prove a very powerful ally to the speeches of the coming week and more. Those who see it will remember that, though orators may be accused of exaggeration, a photograph does not lie."

AN OLD PHOTOGRAPH BOOK.

Only an old photograph book, found in the dusty lumber closet of an old country cottage, when the death of the farmer tenant has suddenly introduced strange faces into the old home, and necessitated an examination of the property of which the deceased in legal language stood possessed. The deceased stands no longer; he lies now in the village churchyard, possessing nothing, but among sundry articles which erst belonged to him, is found, with his name carefully and laboriously written in a vignette, on the title page, an old photograph book. Let us look at it before it is cast aside as rubbish. For who can tell with what solicitude this book was once preserved? May it not contain the portraits of his parents, his wife in the days when she was his sweetheart, the young woman he kept company with, the one woman in all the world for him; her portrait and the portrait of her children? Of Homer's heroes we know nothing but the name, either of Trojans or well-greaved Greeks, of Antilochus or Ablerus, of Leitus or Phylacus, of Enrypylus or Melanthius, of Polypœtes or Astyalus, of Teucer or the divine Aretaon. The sixth book of the Iliad gives the names of these combatants and of many others—the names and nothing more, save the distinction between the conqueror and the conquered, the slayer and the slain. It is all one in some of our most important Biblical genealogies; we know that Matthew records that Eliakim begat Azor, and Azor begat Sadoc, and Sadoc begat Achim, and Achim begat Eliud; but how little do we know of Elind, or of Achim, or of their progenitors?

Our old photograph book can do more for us than the great Epic poet or the Evangelist. Therein, as in a Nigaristan, or silent Valhalla, we see in their habits, as they lived, the family and the friends, humble folk, the common delf of human kind, which, so many years ago, made merry or mourned with them on summer afternoons and in the winter fire-light in the old and now deserted cottage home.

Photography, like the grave, has, in one respect, made the poor and the rich equal. Formerly, it was only the wealthy who could hand down conventional presentments of themselves to their descendants. The labours of Gainsborough and Reynolds, and of many succeeding portrait painters and miniaturists, demanded a hire far beyond the capacity of the poor little purses of the poor. Nor has the present, in this respect only, an advantage over the past. Phœbus is an artist who cannot flatter.

But all this is by way of preface to our book—our old book of photographs. It is of the common almost cubical shape, with the embossed leather covers, and the metal clasps long ago oxidised into a rusty green.

A pleasing feature in this old photograph book, which is observable also in other books of the same nature, is the subordination of the private to the public, of love to loyalty, of the ties of kindred to the exigencies of caste. The first portrait we meet is that of Her Most Gracious Majesty. She looks, however, neither happy nor glorious; the carte, like most of those in the book, is considerably faded, and suggests a suspicion of a reproduction from a positive, a branch of dishonest piracy. Next after Her Majesty follows in stereotyped and toast-like succession the photograph of the Prince and Princess of Wales. This was evidently taken just after their marriage, when they were both young and fresh in this grey world. The picture of their life's spring is presented to us by *Ghémar*

Frères, Photographes du Roi, Bruxelles. The Prince has a slim appearance, with an abundance of curly locks. The Princess wears her hair in a net, and is encased in a crinoline which occupies fully one half of the carte. She leans on the Prince in what is doubtless intended to represent an affectionate attitude, with her hands lightly touching his omoplates, but the impression produced on the non-artistic eye is that she is taking his measure for a coat, and observing with interest the narrowness of his shoulders. After these portraits, succeed in due order portraits we may suppose of the rustic family, and portraits of their friends. But all of them suffer from the same disability. Whether from rural nervousness, or a determination to follow the prevailing fashion, they are, without exception, unable to stand alone. One lady, to save herself apparently from falling, clasps spasmodically, and with both hands, as a drowning man is proverbially supposed to clutch at a straw, the back of an antique, elaborately carved chair, such a chair as we might hope to meet in an old baronial hall, but would certainly never expect to find in a country cottage. Another lady of more mature age, and therefore, perhaps, of a more sedate and pious turn of mind, rests one hand on a portion of what appears to be a sepulchral monument, or the construction of a tomb, lacking, indeed, nothing but the usual "Here lies," to complete the resemblance. Several gentlemen who have evidently doffed the rustic blouse and assumed their suit of Sunday black for the occasion, place a weather-beaten hand, accustomed to drive the plough, on a portion—usually supported by one leg—of a chiffonier or bureau, which exhibits such exquisite wood carving as reminds us of the work of Grinling Gibbons, to be seen at Chatsworth and St. Paul's. Ladies and gentlemen alike, who, even with the assistance above mentioned, are yet wholly unable to maintain that erect position which is supposed to be the privilege of humanity, are represented seated, usually with a table on which a vase of flowers is commonly placed by their side. If the sitter be a gentleman, the table not infrequently supports his hat, which he is, apparently—like the nervous member of a club, who will not make use of the hat-stand in that case made and provided—extremely anxious should not for a moment be out of his sight. The old photographic chair is rarely of the ordinary pattern; it is either of the ancient, high-backed, intricately turned style, or of that style which is termed rustic, and supposed to be suitable to a country landscape. The sitter is evidently uncomfortable in it, but his discomfort we may hope is mitigated by the elegance of his surroundings. In the background on one side of him is a marble column; on the other, a curtain of deftly-worked tapestry. Through a window appears a view of gardens, such as might have belonged to the chatean of a French marquis. What can a man desire more?

All these portraits of rustic men and maidens have precedence over such distinguished statesmen and humanitarians as Lord Derby and Mrs. Fry, who follow mixed up with such unlikely companions in real life as Agnes Willoughby and Tom Sayers. This confusion of persons in our old photograph book reminds us of that democratic disregard of rank, that supreme negligence of order of any kind, which prevails in our National Portrait Gallery (free) of the present day—the stationer's shop window—where gaping crowds are delighted at one view with such discordant elements of the social fabric as Nellie Farren and Lord Napier, Sandow and Damiens, the Duc d'Orleans and Lilley Langtry, Mr. Chamberlain and Miss Letty Lind, and the Bishop of Manchester and Miss Mabel Love. Our old photograph book concludes with such accidental varieties—comets in this system, padding in this magazine—as a fat baby, with "ketchy-wetchy," or some other infantile language, probably alone intelligible to the mother and the monthly nurse, printed beneath it; one or two landscapes of moor and fell; a display of architecture (most likely the village high street); two dwarfs, male and female, propped up by two chairs, the former holding a hat which, from its undue prominence, is big enough to cover much more than his head; and on the last two pages, two Welshwomen, each with her conical and hideous head gear, each with her coloured apron, and each with her particular umbrella.

More than a quarter of a century ago, Schubert, a painter of Berlin, laid down some rules for posture in taking portraits. Of these, more than one rule survives still. For example, the rule which, embodied in the form of a direction, was once almost invariably heard by the person who wished a portrait taken as soon as the camera was suitably adjusted. "Let," we may suppose the photographer saying to the originals of the portraits in our old photograph book, "let your position be easy and unconstrained"—and here was the rub, or the beginning thereof. They tried, doubtless, their best to throw themselves into a careless *degagé* attitude, but their efforts were not crowned with success. "Oh, dear me!" we can imagine the artist saying, "this will never do; your feet are too forward; your hands are not sufficiently drawn back. This hand," he takes it with all due delicacy, "should rest on the side table thus, clasping this book thus;" he suits his action to his word, introducing the hand to the well-worn volume, and steps back the ligitimate number of paces to watch the effect. "No," he says with a puzzled expression, having arranged the matter, as he conceives, satisfactorily; "no, this won't do! The thumb should be shown in the foreground, and the fingers should be bent more inwards; yes, and you must show more of the back of your hand." They conscientiously endeavoured—this rustic company—to follow out, so far as they understood them, these varied directions, not without some danger of a sprained muscle, owing to such unusual contortions, and achieved finally, after effort, what they hoped was a successful result. But they were doomed to disappointment. "No," says the photographer, "no," adding with a vexed air, "Didn't I begin by suggesting to you that your position should be easy and unconstrained? and," as one of the martyr band glances at the professional behind his apparatus, "pray don't look at the camera" (or, as he probably called it, the apparatus); "it will tend to impart to your face an expression in the highest degree dolorous and dissatisfied." The martyr thinks at once how well such a photograph would express his feelings, but is unwilling to follow the example of Oliver Cromwell, who charged young Lely to paint him as he was, with all his pimples, warts, protuberances, and other deformities, and, failing this, threatened not to pay him for his picture a single farthing, and so directs his wearied glance to the door, perhaps thinking in this evil moment of suddenly making his escape. "That is quite right," murmurs the photographer; "the position of the eyes is excellent, and now please call up a 'pleasant' look."

Alas! this "pleasant" look and this "easy and un-

constrained" position—seemingly so simple, practically so difficult. A few only, a very few, of these old portraits have successfully managed both. The pleasant look has lapsed far too often into a fatuous simper, or, in cases where we may suppose the sitter's patience has been supremely tried, into a stern scowl of Spartan endurance, or even a truculent expression of internecine hatred; the easy and unconstrained position has become so strange and forced an attitude that it communicates a feeling of discomfort even to the casual spectator, and makes him wish that the hands especially had been hidden in the sitter's pockets, or anywhere out of the picture, instead of being ruthlessly brought to the front by that favourite old photographic expedient of a book, a table, or a high-backed chair.

Literary Notice.

SUN ARTISTS, No. II. (*Kegan Paul, Trench, and Co., London.*)

THE second number of this excellent quarterly periodical—just published, although dated January—contains some good photo-mechanical reproductions of four of Mr. H. P. Robinson's photographs, namely, "Carolling," "A Merry Tale," "Dawn and Sunset," and "When the Day's Work is Done." It also contains an article by Mr. Andrew Pringle upon Mr. H. P. Robinson and his works. Mr. Pringle says: "Mr. Robinson was born in 1830 at the pretty little town of Ludlow, in Shropshire. Art seems to have claimed him for her own at a very early period of his life, for he 'cannot remember the time when he was not drawing.'" He also says: "The greatest service that Mr. Robinson has rendered to photography has been, in our opinion, his bringing under our notice, in an orderly and categorical way, many of the principles which guide artists in their work. It is hopeless to argue that art has no rules."

Last week a newspaper adversely criticised the prints issued in this number of *Sun Artists*, and expressed the opinion that Mr. Robinson would not like them. He has, however, written a letter expressing his thorough approval of them.

Mr. W. Arthur Boord is the honorary editor of *Sun Artists*, and the periodical is a credit both to him and the printers and publishers.

THE PHOTOGRAPHIC SOCIETY.—*The Manchester Courier* of February 13th published the following paragraph about the recent dinner of the Photographic Society, written by its London correspondent, who was among the guests:—"The Photographic Society of Great Britain has celebrated its annual dinner at the Café Royal, Regent Street, under the chairmanship of its President, Mr. James Glaisher, F.R.S., and was remarkable for the varied races and conditions of men, and of the regions of the earth which it represented. Persons from nearly every quarter of the globe met together on the common ground of devotion to the science and art of photography. On the chairman's right hand, for instance, sat Mr. Chang, of the Chinese Embassy, a member of nearly all the photographic societies in London, and whose speciality is the production of pictures by magnesium flash-light. On Mr. Chang's right hand, again, sat Mr. Leon Warnerke, a Russian artist, founder of the Photographic Societies of Moscow and St. Petersburg, in which latter capital he inaugurated the first photographic exhibition. This was visited by the Emperor and his family, and won for its promoter the Order of St. Stanislas."

AN INSTITUTE OF PHOTOGRAPHY.*

BY G. LINDSAY JOHNSON, M.A., M.B., B.SC., F.R.C.S.

SOME months ago a notable sale of photographic relics in connection with Daguerre, Talbot, and other fathers of photography, was announced to take place. When I heard of it, I wrote a letter to the Society urging them to do what they could to collect sufficient money to purchase the collection for the Society. Many of the members sent cheques, but notwithstanding, the scheme fell through, and the collection was distributed, a portion going to the Museum at Bath. Now, as we are told to-night that the Society is likely to be turned out from its present home, the future will have to be discussed.

As far as I can see at present the position is this:—A museum and collection of photographic materials and views is a scheme which has been received with more or less approval by the Society. To attain this object three ways appear open: either to get a permanent building, or at least a suite of rooms of our own to arrange them in, or we must place ourselves in the hands of the Directors of the South Kensington Museum, or the Imperial Institute. This latter scheme would certainly be financially the easiest, as I am (unofficially) informed the Government would probably be disposed to grant a suite of rooms to the Society in return for equivalent benefits on our side. On the other hand, Kensington is too far from the majority of the members to be altogether desirable. The Institute would not be finished for eighteen months or more. A more central place near Charing Cross would doubtless meet the views of the majority; but the scheme that would comprise a building in the City must fall through unless we can gain the support of the City magnates. Before February I hope to have sufficiently sounded several influential City men to be able to form an idea how far they would lend their aid.

The third and last way would be to endeavour to come to some arrangement with an Institute like the School of Mines or Society of Arts; but here again the question arises (apart from the feasibility of the scheme, which is also open to question) whether the sacrifice of individuality is not too high a price to pay for the benefits to be gained. It is clear the Government will only help us just as far as it can see an *immediate* advantage or return for so doing. It is also clear that anything in the nature of a permanent collection can only be obtained when we have already a place of our own to arrange it in.

Now, a building suitable for the purpose would cost far more money than the resources of the Society can hope to reach, even if we abandon the scheme I proposed to you of having an institution where the higher branches of art photography can be taught and practised, as well as original researches conducted.

How are we to get these necessary funds, for I consider, at a rough guess, that at least £10,000 or £15,000 would be required for the mere building, apart from the ground value? It seems to me the only practical way will be to try to convince the leading men in the City that the Institute and Society will be of permanent value to the City of London. Considering the fact that almost every branch of art and science is enriched by the aid of photography, and that newspapers, books, and literature gene-

* A paper read before the Photographic Society, and entitled by its author, "A Scheme for the Formation and Establishment of a Central Institute of Photography in Connection with the Photographic Society of Great Britain."

rally, not to speak of calico printing and pottery, is becoming daily more and more dependent on it, it may be possible to receive much of the support we want from this source. Much has been done in other directions to encourage us. There is the proposed Battersea Polytechnic, under the management of Mr. Spicer and his colleagues. Here the public has supplied more than £150,000 demanded by the Charity Commissioners as a condition of their providing a like sum. The Goldsmiths' Company are providing a magnificent building at their own expense. There are besides the People's Palace, the Birkbeck Institution, the Regent Street Polytechnic, and the Guilds' Institute in Finsbury. This shows that the public are not averse to giving their support to such objects.

I, for one, would like to see the Society raised from the position of a mere debating club, relieved by an annual soirée and exhibition, to a permanent institution like the Society of Arts, where not only could the trophies of our art be exhibited to an admiring public, but where daily instruction in every department of photography, including the mechanical processes, could be given under suitable instructors, and where, moreover, as in the Royal Institution, a complete laboratory could be at the disposal of members who were desirous of pursuing original research.

I am aware that such a scheme borders on the visionary, but something is surely needed to supply the wants of a properly organised Photographic Technical Institute. Both France and Germany have had them for some years. We, as usual, are behindhand. I admit that in neither country is the institute a part of a photographic society, and I see no reason why it should not be connected with it.

If people, in reply, say we have no need for it, or such a scheme is without precedent, I could at once point to the "Apothecaries' Hall," to the building of the Pharmaceutical Society, to the School of Mines, or, to give a better example, the Royal College of Surgeons, which, on a large scale, comprises everything that I ask for—classes, lectures, practical instruction, reading room, laboratory, museum, and meetings. As in a Law Court when suing a company for damages, it is perhaps better to ask for too much than too little, and although the scheme may evaporate down to a smaller nucleus by asking for too much, I do not think we shall get too little. If the scheme is too premature to be appreciated by the general public at present—although I think you will agree with me it is more practical than, say, the Channel Tunnel—we may be assured of one thing, that photography is progressing by such leaps and bounds that a scheme which appears preposterous now will, in a few years, become a necessity, and by our taking the chief rôle on the stage we may hope to claim the privilege of leading the way.

I can only hope the Council will be induced to take the matter up, and not to give up working until we have succeeded in establishing an institution which shall be a model to other countries. With regard to this matter, I have been at some trouble to try to feel the pulse of the public. I have seen several members of the County Council, the Common Council, and I have also interviewed several prominent men in the City of London, and with scarcely an exception I have had a most favourable and encouraging ear lent to me, and have received promises from several that, if they saw that others would fall in with the idea, they themselves would be only too willing to help. If we find it impossible to accomplish the above scheme, I do not think it altogether impossible to procure a flat in some accessible part of the city which should comprise at least one large room which could be used for exhibition purposes, soirées, and the like, and the results of our art could be shown, and two smaller rooms, one of which could be used as a library and tea room, a committee room, and a cloak room. A double room attached would naturally be a great convenience.

I may add that there are some suitable buildings and flats to be seen about Shaftesbury Avenue, which the Committee might deem it worth their while to enquire into. There is no doubt, in my opinion, that a permanent building would greatly raise the character of the Society in the eyes of the public, and, in consequence, raise its income.

From Royalty downwards the public have always a great weakness for photographs and photogravures, and even if the support of the City Guilds so fell to the ground, I cannot help thinking that an energetic appeal to the public coming from the Council and members of the Photographic Society, and backed up by the Press, who are depending more and more every day upon photography to illustrate their sheets, would answer, for we have only to compare the number of illustrations obtained by means of photography in the daily papers, with the occasional illustrations which now and then, as a kind of phenomenon, appeared in journals as a wonderful exhibition.

Illustrations are becoming a *sine quâ non* if a book nowadays is to sell at all; the knowledge of that fact cannot fail to have influence with the public. But if the public are sufficiently interested to prefer inferior papers only illustrated with miserable daubs, who can doubt that a permanent gallery adorned with the choicest works of art drawn from all parts of the civilised world, will not fail to cause a continual attraction to the public?

This is not the time to enter into details. My object is to see whether it would not be possible for us to pass some resolution in furtherance of the purpose in view. I might say I have been making enquiries with regard to the Imperial Institute in South Kensington, and have spoken to Sir Henry Roscoe and several other prominent gentlemen in connection with the Institute, and I have been assured by them that it is not improbable, if the council were to meet certain members of the Government, assistance might be received in connection with South Kensington. A member of the Common Council, who is very enthusiastic on the idea of a central institute in London, told me that he thought if we got a sketch plan of the building, such as would be suitable, and brought it to the Common Council, together with an estimate of the cost, that it would be favourably considered, and possibly the money might be forthcoming. Another gentleman suggested that we might have a building or a portion of a building in London, where we might have a sort of gallery of photographs and photographic materials drawn from all sources, and to which we might invite photographers to send works which had gained prizes, for exhibition on the walls. There is also a possibility that we might get a loan exhibition from the works at South Kensington placed upon the walls. Thus, while we have the exhibition here, we might have the technical part going on at South Kensington. But whatever decision is come to, it must be arrived at speedily, because our lease has run out, and we shall be without a place of meeting at all. Therefore, I would ask whether it would not be wise to raise a little enthusiasm in the public mind, and get some money together so as to procure a room which we might call our own, and where we could do

what we like. We find that various technical institutes are growing up like mushrooms in and around London; and we ought to do our best to bring forward some practical scheme which would benefit the Society and photography generally.

A PRINTING MACHINE OF THE FUTURE.

TO-DAY we give the first precise public description of a machine camera, rumours about which have interested photographers on both sides of the Atlantic for some months. Our idea is, that the chief value of the machine, or of a modification thereof, may hereafter be found to be in a direction not contemplated by the inventors—at least, they have said nothing to us on the point—namely, in the printing of positives for book illustration, and as another step beyond that taken by Mr. Urie, in the direction of printing newspapers by photography. Years ago, by a kind of prophetic instinct, one of the greatest inventors of daily newspaper printing machines, opined that perhaps photography would hereafter be the successful competitor in such work.

The machine of Messrs. Greene and Evans, depicted in another column, will take from five to ten or even more impressions in a second, according to the rapidity with which the handle is turned, and Mr. Greene says that one can be made to give a large additional number of exposures if necessary. In positive printing through a negative, the amount of light can be made to vastly exceed that present in the photographing of street views, so the limit to speed, especially with improved machines as yet unborn, is at present beyond calculation.

One can imagine the possibility of a practically endless band of paper being covered with some sensitive preparation as it unrolls, then passing on to the exposure platform, and afterwards into developing and fixing baths.

At the present speed, exposing a negative on a travelling band three thousand times in five minutes would not be bad work.

PLATINUM AND PALLADIUM TONING.*

BY FRANK P. PERKINS, F.I.C.

I HAVE observed that it is sufficient to add to a slightly acidulated solution of platinic chloride a fragment of sodium sulphite, and then brush the liquid over a well-washed silver print produced on plain salted paper, for the silver to be almost immediately displaced by platinum. This is a simple method of "toning" for such as have not the ready-formed platinous salt at hand.

I have also noticed that a slightly acidulated solution of palladious chloride may be used in the same way, and with similar results.

LANTERN CLUB.—A meeting of those interested in the formation of a lantern society was held at St. James's Hall, Upper Regent Saloon, on Thursday the 20th, when it was decided to form such a society, and it was resolved that it should be known as "The Lantern Society." The Hon. Slingsby Bethell, of Chelsea Lodge, Chelsea Embankment, was elected Provisional Chairman, and Mr. T. H. Holding, 46, Chesilton Road, Munster Park, S.W., as Secretary *pro. tem.*, together with a committee—to frame rules—consisting of Messrs. E. R. Shipton, A. Mackie, G. R. Croswell, Lieut. C. E. Gladstone, R.N., Mr. A. R. Shophee, together with the chairman and secretary.

* This brief article from *The Chemical News* contains information likely to be of considerable use in photography, as we know from past experiments.—ED.

THE HINGES OF DARK-SLIDE SHUTTERS.*

BY CHAPMAN JONES, F.I.C., F.C.S.

THE deleterious effect of the hinges of the shutters of dark slides has often been observed, the results varying considerably, and showing sometimes as fogging on development, and sometimes as a loss of sensitiveness. But I have not known until lately of a large increase of sensitiveness produced in this way. The dark slide in this instance was bought second-hand; it had leather hinges to its shutters, the effect of which was rapid enough to give a well-marked fog across plates that remained in the slide for a few days. It was sent to Messrs. Watson and Sons to be cured of the defect, and they replaced the leather by the material they have specially made for this purpose. After a few weeks, during which the back appeared to behave in a thoroughly satisfactory manner, it was left with plates in it for about four months, and on a dark December afternoon they were used for making an enlargement, and, as afterwards proved, considerably under-exposed. One plate was developed with pyro and sodium carbonate, and the other with eikonogen, and in both cases that part of the plate that had been opposite the hinge appeared as if it had received two or three times as much exposure as the rest of the plate, but with no tendency to fog, even on forcing the development. The plates were about two years old when exposed.

On mentioning the matter to Messrs. Watson and Sons, they were good enough to give me all the information they had. They say, that having found leather not always reliable for the hinges of dark slides, they "came to the conclusion that some kinds of leather were dressed with ammonia, and that when this was the case the chemical was never thoroughly got out of it, and, therefore, when the leather was used, it fogged the plate in the portion that came immediately underneath it." They continue, "We then gave up using leather altogether, and substituted for it a species of jean, which we have specially made for us, exceedingly thick and strong, and since we have used this we have had a total absence of complaints. When we altered your slide we merely took away the old hinges and replaced them by our new material."

As I happened to have a plate that had been in a back of Watson's make with hinges as described for about two years, the plate itself about three years old, I tested it by exposure and development, and found no sign of any irregularity.

It is not impossible that the increase of sensitiveness now shown is apparent only, and due to a loss of sensitiveness of the plate except where the hinges are; but judging from the exposures given, the result on another plate exposed at the same time, and the behaviour of the back before the hinges were changed, I do not think this is probable.

WHITE DRAPERY.—The weak or diluted developer, with less pyro, is the only one I have ever been successful with in white drapery. Try the slow developer once, and I feel sure you will never use any other. It does not pay to be in a hurry in developing; leave it until evening, when there is no danger of being disturbed, then go slow.—*W. B. Glines.*

A PHOTOGRAPHIC SOCIETY FOR EXETER.—A meeting to inaugurate the above will be held at the New London Hotel, Exeter, on Thursday, at 8 o'clock. Any information respecting the proposed Society may be obtained of Rev. John Sparshott, Fairfield House, Alphington Road; or Mr. Ernest F. C. Damant, 32, Longbrook Street.

* A paper read before the Photographic Society.

DETECTIVE CAMERAS.

BY C. BRANGWIN BARNES.

DURING the last two years there has been a continual advertisement of so-called hand and detective cameras. Each camera maker and dealer in photographic requisites has been competing with the others as to which should bring out the best. They have appeared in all shapes and sizes, from the book camera, taking plates about 1½ inches square, to the larger box or parcel camera, taking quarter and half plates. Amongst the varying shapes may be mentioned the brown paper parcel, the leather portmanteau, and the camera which is concealed under the waistcoat or in a hat.

That there must be a considerable demand for these articles goes without saying, but I fancy that the buyer usually belongs to the amateur ranks. Most things that are made and sold have a use, and perhaps the detective camera has one; but I must confess that, so far as I have seen, I have been unable to discover it. The great difficulty seems to me to be that of obtaining a sharp negative. If the camera is held in the hand it is very rarely that an exposure can be made without moving the instrument, and with the buttonhole apparatus the very motion of the chest caused by breathing is sufficient to give a blurred image, to say nothing of the necessary pull at the cord that releases the shutter. I am myself the happy possessor of one of the latter description, but it came to me in the shape of a prize in a literary competition, for I certainly should never have bought one. A cheap detective camera of the buttonhole class has recently been introduced, and in the advertisement recording its various and manifold merits the following passage occurs:—"Can be used on the promenade, in *law courts, churches, and railway carriages, also in breach of promise and divorce cases*—in fact, at *all awkward moments* when least expected. The artful maiden, the wily detective, the wronged wife, will now be collecting evidence. The bad boy will levy blackmail upon his sisters by illustrating family squabbles instead of angelic sweetness, *and happiness will be within the reach of all.*"

Now every photographer of any experience must be aware that this is mostly "high falutin," as "law courts and churches" are not usually such abodes of light as to render the production of a shutter negative a possibility, although the advertisement goes on to inform us that "every negative is a perfect gem," and I must confess to being somewhat cynical as to the universal happiness which is to be effected by the means of the detective camera when used for the purpose of levying blackmail by the bad boy of the family. We are further informed that the camera "works the same in fog or rain," that "no movement is too quick for it—the racehorse at greatest speed, the flight of birds, or the lightning flash itself."

The Paul Pry character of the detective camera is, in my opinion, one of its greatest drawbacks, although we are well aware that we must take a grain—nay, a whole drachm—of salt with most of the wondrous tales that are told as to what has been done. In the hands of a true gentleman or lady the camera would not be out of place, but I certainly object to it in the possession of the "artful maiden" or the "bad boy." Seriously speaking, I fancy that the hand camera can be made of far more utility if stood down for exposure. A parcel would attract no more attention if placed on a window-sill, or any convenient resting place, for a moment or so, than it would in the hand, and it would certainly give the operator a much better chance of obtaining a fair result. The main advantage of the detective camera lies in the fact of its having a fixed focus, as it enables one to transfer to the photographic plate many things that he would never get the chance of doing if he had to set up an ordinary camera and go through the operations of focussing and exchanging the focussing screen for the dark slide. This renders it especially suitable for animal photography, and during the coming summer I hope to obtain some pictures of deer and cattle by its means.

For indoor work, the small lens puts one at a disadvantage, unless a time exposure can be given, and that of course does away with the secrecy of the business. On the whole, I do not think that the introduction is an unmixed advantage. The sporting papers have lately been printing much about photographing the finishes of races, but the time which would have to necessarily be wasted in developing operations would undoubtedly prevent the camera ever taking the place of the judge's eye in deciding which horse was the winner, added to which it would be very unpleasant for the judge to give a verdict in favour of one horse, and the plate, when developed, to reverse it. The usual run of detective cameras would be far too small for this class of work, as the negatives would have to be enlarged, especially in the case of a very close finish. One paper goes so far as to state that, in its opinion, there never was a genuine *dead-heat* run yet, and that if a photograph had been taken of, say, the Derby finish between Harvester and St. Gatien, the owner of one of the pair would have taken all the stakes instead of half. If some enterprising experimentalist can discover a method of taking a photograph which can be shown immediately, a nice little fortune awaits him on the race course; but until that desirable consummation is arrived at, I am afraid Judge Robinson will not be deprived of his berth by the detective or any other camera.

WARMING SOLUTIONS. – Some professionals as well as amateurs are troubled at this time of the year to obtain sufficient density in their negatives, and it is owing to the coldness of the solutions, plates and pans, which they may not think of as the cause. By warming them this difficulty is overcome. A dark room and all its contents should be constantly kept at an even and warm temperature. Mr. S. Wing says that he remembers a season of unusual success in getting fine results, in a room where a chimney passed up directly through his darkroom, and his silver bath was placed close to this chimney, which was uniformly warm all through the cold weather. Better work he never performed, and he gives the chimney due credit for its valuable assistance.—*Boston Photographic Review.*

EDMOND V. BOISSONAS.—*Anthony's Photographic Bulletin* records the death of this photographer on January 25th, of typhoid fever, after a short illness, and at the early age of twenty-seven and a-half years. Mr. Cramer, with whom the deceased had been associated since last spring, says of him: "He was a young man of remarkable talent, rare abilities, and a highly honourable character—a worthy son of his father, who gave the name Boissonas a world-spread reputation amongst photographers. His sudden death will be one more great bereavement to his family, and particularly to his aged mother, the father having died one year ago." "His greatest achievements," says the *Bulletin*, "were in the line of orthochromatic photography; and we have in our possession a fine series of pictures illustrating this interesting branch of our art, that we shall treasure now more highly since he who gave them will never more be able to give us such evidences of his genius and skill."

Notes.

The latest use of photography in medical science is seen in a new medical publication. The author of a paper on the peptones made some experiments as to the power of various pepsins in digesting albumen, and, desirous of showing his readers the results, he had the flasks in which the experiments were made photographed, and the photographs reproduced for publication. The pictures show the exact relation and proportion of the various residues, and lay the experiments before the mind in a very vivid way. The idea is a capital one, and is capable of much expansion.

The *Queen* observes that there is no reason why a lady should not establish a photographic studio in the ordinary way of business. At present ladies are more frequently employed as touchers up than as operators. For touching up, fifteen to twenty-five shillings per week is an average payment, says our contemporary, and for specially good work thirty to sixty weekly may be earned. These prices are probably correct, though we doubt if the cases of ladies earning as much as three pounds a week are sufficiently numerous to encourage any one to take up this vocation in the expectation of obtaining this sum. The *Queen* recommends any lady desiring to join the photographic profession to enter one of the large photographic firms as a pupil or an apprentice, as it would be quite worth while to pay a high premium to obtain the requisite training, and it would be wiser to pay £100 for entrance into a first rate firm than £30 to a less successful one. The *Queen* has rather high notions; we know plenty of first rate photographers who would be glad to initiate any lady into the mysteries of photography from the beginning to the end for a much less sum than £100.

The most original application of luminous paint is that described and illustrated in the *Scientific American*. The illustration represents an escutcheon for keyholes, designed to be especially convenient on closets and chests in dark places. The escutcheon is formed with glass, and has a concave or recessed back, to which is applied a coat of phosphorescent paint, and this paint is covered with a coat of cheaper or ordinary paint. The escutcheon may be carried by an ornamental metal or other plate secured to the door or other surface in the ordinary way, the shape of the escutcheon protecting the phosphorescent paint. One obvious use of the luminous keyhole the inventor discreetly omits to mention. It would occur to everybody. A luminous keyhole on a street door would certainly be an enormous boon to members of festive clubs, Freemasons' lodges, and the like. The only drawback is that the luminous keyhole would too publicly advertise the propensities of the householder. Of course all invidious reflections would be done away with if every house had a luminous keyhole, but this is too much to hope for.

Photography is the source of a very comfortable income to those privileged persons who, by long usage, acquire a sort of vested interest in "show places." From St. Lawrence in the Isle of Wight, the smallest church in England, to York Minster, every ancient building of importance furnishes work for the photographer. Photographs, indeed, enjoy a relation to sacred edifices accorded to nothing else, as there are few vergers who have not a bundle of photographs of the cathedral to which they are attached about them, and these they do not mind selling within the building itself. We see no particular harm in this, but the vergers would probably be horrified if they were asked to sell anything else. The lowest depth of this kind of thing seems to have been reached in Scotland, where the Burns' Mausoleum has been let to a grave-digger as a shop for the sale of curiosities. The tenant pays a small rent, and disposes of photographs and books over the poet's ashes. This does not look much like reverence.

A capital use has been found for the series of photographs which the firm of Braun and Co. took of the principal pictures in the National Gallery some two or three years ago. Last week Dr. J. G. Fitch delivered a lecture at the Working Men's College on the National Gallery, and provided himself with a series of the photographs just named, which were placed on a stand in view of the audience in the order mentioned by the lecturer, and when required to illustrate his remarks. A further development of this plan of art instruction might be made by exhibiting lantern slides of the pictures. Though Braun's photographs are of a fairly large size, they could not have been seen to advantage by any of the audience save those seated on the front benches. An image on the screen is of course visible all over the room.

Advertisers are always sighing for new worlds to conquer. Perhaps the tallest notion yet put forward is that of constructing an optical lantern of sufficient capacity to throw an image on the clouds. The inventor proposes to use photographic lantern slides of such objects as "You dirty boy!" of Pears' soap fame, and similar subjects. No doubt the project would be a splendid one from an advertising point of view, but we have strong doubts as to its feasibility. Nor does the projector of the plan help us; he fails to tell the world whether he has constructed the necessary apparatus. When this is accomplished, discussion will be possible.

At a meeting of the Chemical Society, a point interesting to photographers was raised by Mr. W. Thorpe, who remarked that people were very apt to think that uncoloured glass was permanent, yet probably most of the members had seen specimens which had begun their existence colourless, yet had before long acquired an appreciable colour. This is a common experience in photographic studios, but is one which is apt to be overlooked.

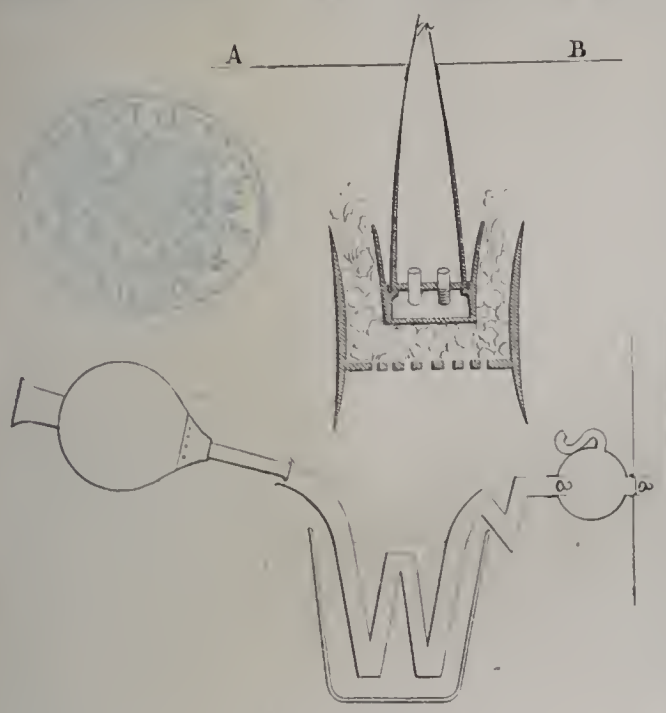
THOMAS WEDGWOOD'S EXPERIMENTS ON LIGHT.

In the series of Royal Institution articles in these pages, one of Thomas Wedgwood's memoirs on "Light," read before the Royal Society, was introduced. The second and last is appended hereto, to assist in the completion of our summary of the life and works of the first English photographer.

XIII.—*Continuation of a Paper on the Production of Light and Heat from different Bodies.**

Experiment 1.

In order to discover what effect the light of the burning fuel has upon incombustible bodies, I fixed into the end of a tube of earthenware† two equal cylinders of silver, with polished surfaces, half-an-inch in length, and a quarter of an inch in diameter (see figure 1‡); one of the cylinders was painted



Figs. 1 *and* 2.

over, except the tube, with a thin coat of incombustible black colour, to make it *absorb* the incident light; the other, intended to *reflect*, was left with its polished surface. Applying my eye to the opposite extremity of the tube (which it fitted exactly, so that no extraneous light could enter), and directing it towards the two polished ends of the cylinders, I held the tube within a red hot crucible, surrounded by burning coaks, and continually turned it round, that both cylinders might be equally exposed to the light and heat. The result was, that the end of the blackened cylinder began to shine a considerable time before that of the polished one, and remained constantly somewhat brighter: on removing the tube from the crucible, still looking within it, I was surprised to see the appearance reversed, the polished cylinder continuing to shine for some time after the blackened one had ceased. Cylinders of gold and of iron treated in the same manner gave the same general result; but the differences between the polished and the blackened ones were not so remarkable in these as in the silver.‡

I repeated this experiment many times and found, by observations with a stop-watch, that the blackened silver cylinder began to shine, at a medium, in two-thirds of the time which the polished one required; and that after its removal from the crucible, it continued to shine only two-thirds of the time that the other did. For this latter observation I was obliged to make a little variation in the apparatus; the tube itself becoming frequently so hot as to make the cylinders continue longer red than they otherwise would have done. I therefore took them out of the tube, to suspend them by a fine wire, and then, heating them in the ignited crucible as equally as possible (for they cannot be made to exhibit to the eye the same precise tinge of redness), I removed them immediately into a dark place.

From this experiment it would seem that a great part of the light emitted by the cylinders was absorbed from the red hot crucible, as the blackened one, which absorbs most rays, not only became first red, but likewise shone brightest. The following experiment, however, affords a different conclusion.

Experiment 2.

An earthenware pipe of a zig-zag form (fig. 2) was placed in a crucible, which was filled up with sand, the two open ends of the pipe being left uncovered; one of them was of a proper form for receiving the nozzle of a pair of bellows, the other bent into angles of the form of the letter Z. On this last was fastened a globular vessel A, with a lateral bent pipe to let out air, but exclude all external light, and with a neck in which was inserted a circular plate of glass. The crucible with the sand and the part of the pipe contained in it was then heated to redness. Having my eye fixed in the neck of the vessel A, and observing it perfectly dark within, I directed an assistant to blow with the bellows. The stream of air sent through the red-hot tube not being at all luminous, I fixed a small strip of gold into the orifice of the tube at B, which, after two or three blasts, became faintly red; thus proving that the air, though not luminous, was equal in temperature to what is usually called red heat. I then heated the crucible to a brighter redness; the stream of air blown through the brighter red hot tube still came out perfectly dark, but the strip of gold exposed to it shone both *sooner* and *brighter* than before.

Hence, it appears, that the greater brightness of the blackened cylinder, in the first experiment, was owing to its being of higher temperature, and that it would have been equally bright had it been raised to the same temperature by any other means than the absorption of *light*, the metal being here brought to a faint and to a bright ignition without the access of any visible light.

But perhaps another consequence may be drawn from this experiment. As the gold may be made to emit *light* for any length of time by being supplied with *heat* from the *dark* air of the temperature of red heat, neither the gold nor the air suffering any chemical change whatever, is not the *light emitted* identical with the *heat received?* This identity appears to be confirmed by the following observation:—That if the solar rays be made to converge upon one end of a blackened cylinder of metal, the other parts will become red hot, and emit light; or, if the rays be converged upon the tube blackened, and air passed through it, the gold placed in the dark current will yield a constant light.

The simultaneous *absorption* and *emission* of light in a red hot body is a subject of very difficult and abstruse investigation, as it involves the nature of the constituent parts of matter, and of their relative actions and arrangements. I shall not attempt any hypothesis for explaining the various phenomena, as I have not been able to form one at all satisfactory to myself; but shall proceed to state a few miscellaneous experiments and observations which, though apparently unconnected, may yet be of some assistance to the speculation of some abler theorist.

Experiment 3.

A quart of oil was poured into a bright tin vessel, which had a Fahrenheit's thermometer fixed in its neck. The mercury standing at 45°, the vessel was plunged into boiling water, and the time which elapsed before the mercury rose to 180° was exactly noted. I then blackened the exterior surface of the tin vessel, and, repeating the experiment, found the thermometer to require exactly the same time as before to rise to the same degree.

* By Mr. Thomas Wedgwood. Communicated by Sir Joseph Banks, Bart., P.R.S. Read May 10th, 1792.

† When earthenware is mentioned in this paper, the cream-coloured or queen's ware is meant.

‡ The line A B, in fig. 1, represents the position of the screen for shading the face.—Ed.

From the foregoing experiment it appears that *black* matter has no particular attraction to light in a *quiescent* state—that is, when combined as heat with other matter.

Experiment 4.

Three equal cylinders of glazed earthenware were fixed in the end of a tube (like the two silver ones in fig. 1); one of them blackened, another gilt, all but the ends within the tube, and the third with its glassy surface. These, treated in the same manner as the silver cylinders in the first experiment, all became *red* at the *same time*.

Without taking them out of the tube, I removed the whole from the fire, and, still keeping my eye upon their ends, observed them all to disappear together.

To account for the simultaneous ignition of these three cylinders, it must be considered that earthenware, being a very slow conductor of heat, the surfaces of all of them are probably heated to redness some time before any such appearance takes place in the ends between the tube. Now it is not unlikely that the black matter, the gold, and the glaze, when red hot, may reflect light equally; and, in that case there should be no perceptible difference in the time of the ignition of the ends within the tube, except the little advantage gained by the blackened one before its black coat becomes red hot, which is partly counter-balanced by the powdery matter, of which the coat consists, obstructing the transmission of heat. The surfaces of the silver cylinders (Experiment 1) on the contrary, do not become red any sensible time before the ends within the tube, the metal conducting the heat rapidly through its whole mass.

An earthenware cylinder, fastened in the end of an earthenware tube along with a gold one, and plunged into melted glass, is much longer in heating than the gold one. This is easily explained upon a well-known principle, namely, that in two bodies of unequal temperature, the colder body conducts the heat from the hotter at a rate proportionate to their difference of temperature. Now the surface of the earthenware cylinder, as the heat is conducted very slowly from it by the interior mass, soon becomes very nearly of the temperature of the hot glass contiguous to it. The surface of the gold cylinder, on the contrary, having its heat conducted from it much faster by the interior mass, is of consequence disposed to receive the heat with greater rapidity.

Experiment 5.

Equal pieces of gold, silver, copper, and iron, blackened all over, and suspended by a wire in a red hot crucible, became red in the order in which they are here set down; and when made equally red, and removed into the dark, they disappear in the same order. When just brought out of the fire they all looked equally red; but when they had cooled a little the iron was much the brightest.

An earthen cylinder tried with the metals disappeared much sooner than any of them, the interior part not communicating its heat quick enough to keep the surface of the temperature of red heat; accordingly, when broken, though the surface gave no light, the mass was luminous internally.

From a parity of reasoning, a gilt earthenware cylinder, suspended in a red hot crucible along with a gold one, would probably become red on the surface before the gold one.

Experiment 6.

A tube of unglazed earthenware, open at top, and having one half of its bottom blackened on the outside, was placed in a red hot crucible, and the eye directed as before to the inside: the part which was externally blackened became always red before the other.

The experiment was repeated with a metalline tube, but no difference could here be perceived between the blackened and unblackened half of the bottom. The reason is obvious from the foregoing observations.

Experiment 7.

To ascertain whether metals and earthy bodies *begin* to shine at the same temperature, I gilded, in lines running across a thin piece of earthenware of the specific gravity of about 2,000, and luted it to the end of a tube, the gilt side being inwards; then directing my eye into the tube, I held it within a crucible, which was gradually made red hot; but I could not after many trials perceive that either the gold or the earthenware began to shine first.

As it appears from this experiment that gold and earthenware begin to shine at the same temperature, and as no two bodies can well be more different in all their sensible properties, may it not be inferred that almost all bodies begin to shine at the same temperature?

Experiment 8.

Observing that colourless transparent glass had a paler hue when red hot than most other bodies, I conceived that it might not be luminous at so low a temperature. I therefore took a circular piece of glass, about $\frac{1}{40}$th of an inch thick, and, having gilt one side of it, exposed the ungilt side to a stream of air passed through a red hot tube, but did not perceive that the gold shone at all before the glass. This experiment, however, is not decisive; glass being so slow a conductor of heat that its exterior surface might have been heated some time before the interior, and thus have deceived the eye. I could not meet with any glass sufficiently thin for this purpose, nor think of any other possible mode of trial.

Experiment 9.

Having often remarked that the surfaces of red hot metals had an appearance different from what they present by reflected light when cold, I had an idea that this peculiar appearance might be derived from a transmission of the light through the superficial parts of the ignited body. To ascertain whether they acquired any degree of transparency by heat, I fixed a circular plate of fine gold, about $\frac{1}{50}$th of an inch thick, on the end of a tube, which was perfectly closed by it; then, having heated it to redness, and, looking down into the tube, I pressed the outer surface of the gold against single grains of gunpowder. The red light of the gold looked whiter on every flash. To be satisfied that no light found admission through the sides of the tube (which were of thick earthenware), I covered the exterior surface of the gold plate with a thick coat of clay luting, and again making it red hot, fired gunpowder with it as before, but no increase of light was perceptible from the flash, which proves that the sides of the tube were impervious to the light. When this gold was cold, I struck a few grains of gunpowder on its surface, and, looking within the tube, fired them by pressing them against a hot iron, but the light of the explosion was not then sensible.

Plates of silver and of iron gave the same results.

Experiment 10.

A lump of the most luminous marble and an equal lump of the same marble blackened over were placed together upon a mass of iron heated just under redness; the former gave out much light, the latter none. Upon a second exposure, the lump not blackened gave a faint light; the blackened one, as before, none at all. Then wiping off the black, and placing them together upon the heater, I found the one which had been blackened to emit as little light as the other; thus the phosphorescent property was nearly destroyed without any visible light leaving the body.

Experiment 11.

If a piece of glass, or glazed or unglazed earthenware, with any enamel, painting, gilding, or writing upon it, be made red hot, the coloured parts appear considerably more red than the others, and continue longer visible. Iron wire within a red hot glass tube looks much more red than the glass. Black matter upon a large polished mass of fine gold did not remain any longer red than the gold.

Experiment 12.

A bit of iron wire becomes visibly red hot when immersed in melted glass. Air, therefore, is not necessary to the shining of ignited bodies.

Experiment 13.

A piece of red hot metal continues to shine for some time after its removal from the fire, which proves that constant accessions of light or heat are not necessary to the shining of ignited bodies. If the piece be strongly blown upon, it instantly ceases to shine, for the cold air continually applied unites with

the light as fast as it leaves the body, and which otherwise would have passed to the eye.

I shall now close this paper with two or three miscellaneous observations.

Red hot bodies, though ignited by *white* light, give out only the *red* rays. Perhaps the other more *refrangible* rays, from their greater attraction to matter, may be circulating as heat, whilst the red ones, having a less attraction, yield sooner to that force which propels the light of red hot bodies. If the intensity of the incident white light be much increased, so as to raise the body to a white heat, the more refrangible rays then come out with the others, constituting together a white light.

The flash of a grain of gunpowder is a pure *white* light; but if the explosion be made within a thin, unglazed earthenware tube, closed at both ends, all the light that pervades the sides of the tube is red; the other rays must, therefore, remain united with the matter of the tube, whilst the less attractive red ones are transmitted. Thus, also, on looking at the sun through the thin bottom of an earthenware tea-cup, only the red rays are transmitted, so that the others must be retained by the matter of the cup.

It would, perhaps, be worth trying whether a body can be made *red* hot by concentrated rays of other colours.

The light produced from bodies by attrition consists of a double light: that which their powder would give out on the heater under redness, and that which particles in their surfaces give out by being made red hot. The sudden heating of a body to redness by a single blow or rub is a remarkable phenomenon, and deserves to be investigated. One effect produced upon a body by attrition is a compression or condensation of the parts on its surface; and it appears from general observation that a condensation of the parts occasions a diminution of its capacity for heat. Iron may be made red hot by repeated blows of a hammer, and I have found that if red hot iron be forcibly struck by a heavy hammer, with a sharp edge to concentrate the action, the part so struck emits a white light for a sensible time, and is probably raised to a white heat; also that my father's thermometer clay has its capacity for heat diminished one-third by being burnt to 120° of his scale, and thus reduced to about one half of its bulk; and as it loses in weight little more than two grains on a pound, the diminution of capacity can only be attributed to condensation. Many other analogous instances might be adduced if necessary; but these will, perhaps, be deemed sufficient to render it probable that the sudden ignition of the particles by attrition proceeds from the compression and consequent diminution of the capacity for heat.

I am not certain that the increase of brightness in the gold plate (Experiment 9) must be attributed to its transparency; it may arise from the gold being suddenly raised to a white heat by the light of the explosion; or the force of the explosion may condense its parts, and diminish its capacity for heat or light. There is, however, a strong analogical argument for the transparency of the gold; every body whatever, when extremely thin, is pervious to light in such quantity as to be perceptible to our eyesight; thus gold, perhaps the most opaque of all bodies, platina excepted, when beaten into leaf gold is so pervious to the green rays that, if held close to the eye, all objects are seen through it with considerable distinctness, appearing of a deepish green hue. Now the particles of matter in the gold plate being much separated from one another, if not more regularly arranged by the heat, and the intensity of the light in the explosion of the gunpowder being so great, it is not improbable that some few rays may be transmitted through the gold.

After some reflection upon the curious result of Experiment 1, I am inclined to think that the blackened cylinder does not begin to shine at so low a temperature as the polished one; and, consequently, that the *commencement* of ignition is not, in all cases, a certain indication of a particular temperature. For, when the two cylinders were removed from the ignited crucible (see fig. 1), the blackened one looked of a brighter red than the polished, and yet, in the course of cooling, disappeared in about two-thirds of the time that the polished one continued to shine, without any apparent reason for its cooling at a faster rate. Should it not, therefore, seem that it requires a greater heat to make it shine?

I am well aware that these appearances may be differently explained; and, to determine this point, I would propose the following experiment: Put larger cylinders into the tube; and, having made them red hot, drop them separately, each at the instant of its disappearing, into cups of weighed water of the temperature of between 211° and 212° of Fahrenheit; then, as any addition of heat will expand the water into steam, the loss of weight of each vessel will give an exact measure of the heat of the cylinders at the time of immersion.

A NEW LITHOGRAPHIC TRANSFER INK.

BY DR. J. M. EDER.

As every one knows, the process of lithography depends on the formation upon the stone of two films or surfaces, with different properties, one of which, secured by fatty chalk or crayon, is of a greasy surface, repels water, and takes fatty inks; the other, secured by etching, is acid and open-textured, absorbs water, and so repels grease.

Good prints depend on the degree of success in securing these different surfaces; the more greasy the one, the more acid the other, the better the lithograph. Up to the present, only two substances have been used to give the greasy surface—soap and fat, brought with wax or shellac to the right consistency for use as paint, crayon, or transfer ink. They fulfil two objects—first, to establish the greasy surfaces; second, to protect those parts of the stone from the subsequent etching action of the acid.

Lithographic ink and crayon have already been brought practically to perfection; but the preparation of a good transfer ink still offers a wide field for experiment; and the transfer inks, often very costly, in the market are still susceptible of improvement. It is still more desirable to find a good transfer ink for working on metal. All are liable to weaken, partly dissolve in the acid, or leave the stone under certain circumstances.

Working from a thorough knowledge of the defects of the existing inks, I have found in gum elemi the most favourable characteristics and consistence of all the substances experimented on; and after several years' use and testing, I believe I have found in it a satisfactory product; which, with the addition of soap and other somewhat fatty substances, such as suet and varnish, on one side takes the ink excellently and transfers well, and on the other is utterly unaffected by the etching acid.

Gum elemi is, according to Valenta, a mixture of acid and neutral gums containing the elemic acid first described by Buri. My own researches prove that this acid acts just like soap and similar fatty substances as a species of cement; hence is evident the possibility of the preparation of a transfer ink upon a basis of gum elemi in place of soap.

The printing qualities of the ink, prepared by me after a well-tested formula, I find in no wise inferior to any of the commercial transfer inks in the market, whose composition is a secret. It is a so-called stiff ink, as every transfer ink must be; but, nevertheless, it may be easily spread in a cold room or on cold stones, holds well, does not smear, and gives most satisfactory prints.

This is my recipe:—

Asphalt	20 grammes
Colophony	100 ,,
Oil of turpentine	40 ,,

Dissolve by warming, and add—

Yellow wax	20 grammes
Suet	140 ,,
Gum elemi	230 ,,
Marseilles soap	30 ,,
Linseed oil varnish (medium strength)	60-80 ,,
Finest soot	80-100 ,,

Another method substitutes ready-prepared transfer colour for soap, leaving out that, and using instead 40 grammes of transfer colour and 200 grammes Venetian turpentine. These are well cooked and rubbed together. The transfer ink works equally well on stone or zinc.

The successful commingling of the ingredients is a manipulation in itself, and requires considerable practice. All must be free from water, and care should be taken not to burn them or set them on fire. The latter part of the heating should be done with the vessel uncovered.—*Photo. Correspondenz.*

Amended Specification.

8,722. MCKELLEN, "Exposing Photographic Paper," 1885.

Specifications Published.

2,295.—*8th February*, 1889. "Optical Illusions." CHARLES EMILE REYNAUD, No. 58, Rue Rodier, Paris, Optician.

The object of this invention is to produce the illusion of continuous or indefinitely prolonged motion of the subjects in apparatus of the "praxinoscope" class patented by the inventor in the year 1877, under No. 4,244, in which, as in the "Zootrope" and other analagous combinations, the illusion of motion has hitherto been necessarily limited to a repetition of the same sequence of positions at each rotation of the instrument.

The present improvements may be applied to apparatus carrying either opaque or transpareut pictures, the former illuminated by reflected light for direct view, and the latter by transmitted light for projection on a screen.

After describing the mechanical details of his invention, M. Reynaud says:—

The "illusion of motion" is produced as in the original praxinoscope and other like instruments, but with this essential difference, that the successive phases of action of the figures, instead of being limited to those comprised in a single revolutiou, may be varied and prolonged to a practically indefinite extent, dependent only on the length of the flexible band, thus permitting, for instance, the reproduction of a continuous theatre scene, comprisiug an almost iufinito variety of actors in their successive positions on the stage.

3,347.—*25th February*, 1889. "Books for Exhibiting Photographs." HENRY WILLIAM TAUNT, 9 and 10, Broad Street, Oxford, Photographer.

My invention consists of an improved method of constructing show books for photographs by which the photograph with its supporting leaf can at once be delivered to the purchaser.

My plan is to make one or more perforations in the leaf so that it can be at once detached, such perforations being free, or protected by an additional backing of thin paper or other material so as to guard it from accidental removal.

4,047.—*7th March*, 1889. "Apparatus for Changing Plates or Films." ENRICO FERRERO, Riva Inglemere Road, Forest Hill, Merchant.

The inventor claims:—

1st. A combined dark-slide and changing-box provided with a flexible bag having a hole or holes for permitting the insertion of the hand or the thumb and one or more fingers, whilst excluding light.

2nd. A changing-box provided with a flexible bag having a hole or holes for permitting the insertion of the hand or the thumb and one or more fingers, whilst excluding light, and with a lid or cover which can be opened and closed within the said bag.

3rd. The pressure-board provided with means whereby it will be drawn back in the operation of opening the lid or cover of the changing-box, and will, when the said lid or cover is closed, press the film or plate against the edges of the exposure-aperture in the dark-slide.

4th. The combination, with the dark-slide, of the changing-box, the pressure-board, and a suitable spring or springs for forcing the said pressure-board and the plates or films against the back of the dark-slide.

5th. The changing-box having the spring lid or cover and the jointed or toggle arms for preventing accidental closing of the said lid or cover.

6th. The improved apparatus constructed substantially as described with reference to the drawings accompanying the specification.

4,131.—*March 9th*, 1889. "Detective or other Cameras." FRANK MIALL, Photographic Apparatus Maker, 13, Shelgate Road, Northcote Road, Battersea Rise, Surrey.

My improvement in detective or other cameras consists of the use of two grooved boxes superposed on each other, with parallel racks on the sides or ends of each box, the said racks to be actuated by a pinion at right angles to and between them, having on its end either a square (to be used with a key) or a milled head, on turning which the one box containing the unexposed plates or films (each in a suitable carrier) advances as the other recedes, and drops a plate or film from the upper box into the lower one, through a fixed slot, thus always ensuring each plate or film to be exposed in a fixed plane to the lens. The said grooved boxes to slide in or on suitable grooves or runners formed in or on an outer case or box, in the front of which said box, and oscillating at will, is a segment of a circle (of metal or other suitable material) either in a vertical or horizontal position, and forming the exposing shutter, the said segment having an opening for the light to pass through the lens to the sensitive plate or film; the outer ends of the said segment to be opaque, so that before and after exposure the lens will be covered. On the centre of the segment from which the radius is struck is fixed a pinion, which engages in an oscillatiug rack, which can be actuated from any part of the camera either by hand or pneumatic influence.

The camera takes the form of a box of such varied shape as may be found most convenient, and can be covered with paper or other material to suit the individual tastes of the users, and either carried by a strap, or handle, or the like.

The inventor claims:—

1. The use of two grooved boxes superposed on each other, and actuated by racks and pinion substantially as described, so that the boxes move simultaneously in opposite directions.

2. The use of a segment of a circle having an opening in the centre, and with opaque ends actuated substantially as described, and forming an exposing shutter.

3,790.—*March 4th*, 1889. "Photographic Cameras." HENRY JOHN GRAY, 225, Piccadilly, London, Truss Maker.

My invention relates to photographic cameras, and has for its object to provide an improved camera which is especially adapted for use by detectives, and which is more compact than cameras of the same kind as heretofore constructed.

According to my said invention, the box of the camera is divided by a partition into two compartments, one of which forms the camera proper, while the other serves for the reception of plates, papers, or other media for carrying sensitised surfaces. The said plates or the like are arranged to lie horizontally one upon another in a stack, and are successively transferred from the bottom of the stack into position for the exposure, and thence to the top of the stack.

The transfer is effected by means of two pivotted lever carriers, and a slide or plunger. The said slide or plunger serves to push the lowermost plate of the stack on to the first lever carrier, which latter then delivers the plate on to the second lever carrier into position for the exposure. After the exposure, the second lever carrier is operated to return the plate to the top of the stack.

The slide or plunger is provided with an auxiliary plunger which serves to push the plate entirely on to the first lever carrier.

The lever carriers are provided with spring clips for holding the plates thereon.

In order to prevent the films of the plates or the like from being rubbed, the said plates or the like are carried in frames or holders.

4,264.—*11th March*, 1889. "Tissue Transfer Paper." THOMAS PHŒNIX, Liverpool Road, Newcastle-under-Lyme, Paper Maker, and GEORGE KIRK (administrator of the personal estate and effects of Mary Ann Lamb, Widow, Paper Manufacturer, deceased), of Uttoxeter, Gentleman.

The inventors claim :—

1. The preparation of tissue paper for printing transfers thereon by sizing the tissue paper by causing it to pass into contact with the upper part of a sizing roller, the lower part of which dips into a trough containing size, and then to pass between the surface of the sizing roller and that of a soft pressure roller.

2. The preparation of tissue paper for printing transfers thereon by sizing the same by causing the paper to pass into contact with a sizing roller, and to be carried down thereby through a trough containing size, into which the lower part of the cylinder dips, and then to pass between the surface of the sizing roller and that of a soft pressure roller.

3. The preparation of printed transfers for transferring designs on to pottery ware by causing tissue paper to pass in contact with a roller, and whilst on the roller to receive size, and then to travel on continuously between an engraved printing roll and a soft impression roll.

4. The preparation of tissue paper for printing transfers thereon by arranging the roll of tissue paper to bear upon the surface of a revolving roller, and so to be driven, and as the paper unwinds causing size to be applied to it, and causing the sized paper to be carried on the sizing roller between the surface of the said roller and a soft pressure roller.

5. A machine for the preparation of printed transfers for transferring designs on to pottery ware consisting of a roll from which the tissue paper is unwound ; a sizing roller ; a soft pressure and impression roller ; and an engraved printing roller ; the whole revolving at the same surface speed, and the paper passing in contact with these rollers successively.

4,261.—*11th March*, 1889. "Photographic Lens Shutter." THOMAS RUDOLPH DALLMEYER, 25, Newman Street, Oxford Street, London, Optician, and FRANCIS BEAUCHAMP, Hope Cottage, Whalebone Lane, Chadwell Heath, Essex, Engineer.

This invention relates to improvements in photographic lens shutters of the kind described in the specification of a patent granted to us, dated the 12th day of October, A.D. 1887, No. 13,844.

In the invention described in the specification of the aforesaid patent, the shutters are opened more or less gradually, and, as soon as opened, they begin to close again more or less gradually, so that the quantity of light reaching the photographic film gradually increases as the shutters open, and gradually decreases as the shutters close, the closing commencing immediately after the maximum opening has been obtained, the result being that the plate receives the maximum quantity of light for an instant only. The object of one part of our invention is to cause the shutters to open as instantaneously as possible, to remain wide open for a definite length of time, and then to close as instantaneously as possible, whereby the plate receives the maximum quantity of light during a longer portion of the time occupied in the opening and closing of the shutters than in the arrangements described in the aforesaid specification.

In order to effect this object, we move the shutters to and from each other by means of two levers somewhat in the manner described in the aforesaid specification, but preferably so arranged that each lever is operated independently of the other, instead of one lever being operated by the other, as in that case. We operate the said levers by means of a crank pin rotated by means of a coiled spring. This crank pin engages in a curved slot in each of the shorter arms of the levers, the said slots being so shaped that the crank pin acting upon them for a very small portion of its revolution suffices to move the two levers far enough to open the shutters to their fullest extent ; when that is effected the crank pin passes along portions of the slots in the levers which are concentric with the path of the crank pin for another and larger part of its revolution, whereby the levers are not acted on by the crank pin, and the shutters are consequently held wide open while the crank pin is traversing these concentric parts of the slots. The crank then reaches and acts upon parts of the slots which are not concentric with its path, and move the levers so as to close the shutters during another very small portion of its revolution. The axis of the crank or crank plate carrying the crank pin, which is actuated by a coiled spring as before explained, carries a disc furnished with three stops. Two of these stops come in the line of a catch or pawl on a releasing lever. When the axis is turned, winding up the coiled spring until the catch or pawl drops behind the first of these stops, the shutters are wide open, and are held so by the said catch and first stop, so that the necessary focussing can be effected. When the axis is turned further, so that the catch or pawl drops behind the second of the stops, the shutters are closed again and are held so by the said catch and second stop until the catch is withdrawn from behind the said stop, when the coiled spring acts, turning the crank pin and causing the practically instantaneous opening of the shutters, their retention wide open for a definite time, and then their practically instantaneous closing as before explained. The third stop on the aforesaid disc has a twofold function : firstly, when the shutters are in the closed position it comes against a suitable stop, so as to prevent rotation of the crank pin beyond a certain point, whereby the said crank pin is prevented from pressing unduly on the slots in the levers ; and secondly, it forms a means in conjunction with an adjustable stop on the releasing lever, or with a stop on a separate lever, whereby the shutters can be held open any required length of time when a long exposure is desired.

Another part of our invention consists of improved means of guiding the two shutters in their horizontal movements to and from each other. Instead of the shutters sliding in grooves made in the upper and lower parts of the lens mount, we arrange them to slide at their upper or lower ends on a guide rod or spindle placed at the upper or lower part of the lens mount, and we leave them free at their other ends, the points of connection of the actuating levers with the sliding shutters being preferably placed near the aforesaid guide, rod, or spindle. By these means the possibility of the shutters jamming in their guides is avoided.

17,998.—*November 12th*, 1889. "Cameras and Dark Slides." THOMAS (Archdeacon) COLLEY, 18, Landsdowne Circus, Leamington, Warwickshire, Archdeacon of Pietermaritzburg in Natal.

The inventor claims :—

1. A plate-holder or dark slide for photographic cameras,

the lid of which plate-holder is so weighted that it shall, when placed at the proper angle, fall open of its own weight.

2. A swing-frame for the said plate-holder, which, when placed in the camera made or adapted for its use, shall so rotate upon its axis that the lid of the plate-holder which it carries may be opened and closed at pleasure.

3. An indicator outside the camera that shall show the position and govern the action of the swing-frame and plate-holder inside the camera when the camera is closed, and everything is ready for immediate and unobserved use.

4,649.—*March 16th*, 1889. "Shutters for Photographic Cameras." THOMAS WRIGHT GREENALL, The Grammar School, Hartlebury, near Kiddermiuster, Clerk in Holy Orders, and FRANK BISHOP, of the Firm of Marion and Co., of 22 and 23, Soho Square, in the County of Middlesex, Dealers in Photographic Materials.

This invention relates to an improved so-called "Instantaneous" shutter for photographic lenses. The shutter is of that kind which opens and closes upon a diametrical line, by the motion in opposite directions from the centre to the sides of a pair of plates or wings pivoted upon a common centre, and overlapping when closed.

The invention relates essentially to the mechanism whereby the plates or wings are operated, and the object of the invention is to simplify this mechauism and reduce the cost of manufacture. The plates or wings are operated by a pin moving in a curved angular or bi-angular slot in each of them, the slots lying in a direction such that the two extremities of each slot are in a line about radial to the centre of motion of the plate or wing, and the slots being oppositely bent or curved so that motion of the pin from one end to the other of the two slots will cause simultaneous motion of the two plates or wings in opposite directious, the motion of the pin through the first half of the slots causing an outward separating or opening motion of the plates, and the motion of the pin through the second half of the slots causing an inward or closing motion of the plates. This actuatiug pin is carried or actuated by a lever pivoted to the frame, and acted on by a spring provided with means of varying its tension for the purpose of regulatiug the velocity of motion of the plates according to the length of exposure required, a spring trigger being also provided having notches or shoulders adapted to engage with the lever, and hold the plates either in the closed or open position as required, said trigger being released either directly by hand or by pneumatic agency, as well understood. The pin through which the plates are actuated projects through a slot in the frame, and serves as the medium through which the shutter may be brought to the open position for focussing for a prolonged exposure, or "set" for a short or "instantaneous" exposure.

19,770.—*December 9th*, 1889. "Photographic Carriers or Sheaths." FRANK MIALL, 13, Shelgate Road, Battersea Rise, Surrey, Manufacturer of Photographic Apparatus.

The inventor claims:—

1. In the constructiou of carriers or sheaths for the holding of sensitive photographic plates or films, the use of retaining catches or clips.

2. The use of retaining catches or clips in connection with carriers or sheaths for holding sensitive photographic plates or films.

PHOTOGRAPHIC CLUB.—The subject for consideration on March 5th will be "Artificial Light as an Auxiliary to Daylight," followed by a selection of lantern slides of Norway, by Mr. J. B. B. Wellington. March 12th, "Sterescopic Photography."

A SIMPLE VIEW METER.—For time exposures carry a light, compact tripod. Ascertain by calculation or experiment the number of inches that at arm's length from the eye will include, with the lens used, the view upon the plate. A small rule, or its equivalent, held with extended arm at right angles to the line of vision, will then always give instant information, required before every exposure.—*A. W. Dimock.*

Correspondence.

STEREOSCOPIC VISION.

SIR,—Mr. G. Macdougald, in his communication to the Dundee and East of Scotland Photographic Association, has, while trying to combat some statements alleged to have been made by me, so completely overlooked my real position in the matter, and has made so many statements, the absurdity of which he might have seen had he consulted the most elementary class-books, that I might well pass his remarks unheeded. Still, it may be well to point out some matters, not of opiuion at all, but perfectly well known to every beginner in optical science, and perfectly clearly laid down by every writer who, within many years, has treated the subject of stereoscopic vision.

In the first place, I suppose I must once more point out that the origin of the discussiou was a remark by "F. M. S." iu *Photography*, May 9, 1889, touching stereoscopic photography *in its relation to art*. I have never denied the scientific uses of the stereoscope; on the contrary, I did them full justice. My poiut all along has been that stereoscopicity is no attribute, much less au essential, of art. But to turn to Mr. Macdougald's optical utteraucos.

He begins with the old story of stereoscopic vision by squinting. That is right enough for those who can do it, probably not one in 1,000 without being educated up to it. Mr. Macdougald's alternative method is to "look at the right picture with the right eye, and the left in like manner with the left." He admits that personally he cannot do it; well, so far as goes stereoscopicity, in which his soul delights, his inability is no loss, for there is no stereoscopic vision in such a case. (Text-books *passim.*)

"It is surely more natural to look at a double pictorial representation than at a single." (Macdougald.) "When a body of moderate size, ascertained by touch to be solid, is viewed with both eyes, the images of it formed by the two eyes are necessarily different. . . Nevertheless, they coalesce into a common image which gives the impression of solidity." (Huxley, *Elementary Physiology.*) "We have two eyes, most of us, but we do uot, under normal conditions of diet, *see double.*" (Pringle.)

Mr. Macdougald writes that it appears that "Mr. Pringle labours under the impression that binocular vision—that is, vision giving the appearance of solidity—requires that each eye looks at the object from a different standpoint." I confess I am under that impression, but find uo "labour" in comprehending the truth, nor in agreeing with every text-book on the subject that I can find. Without the seuse of touch, and without two eyes, we cannot have the impression of solidity, nor of relative distances. I should like Mr. Macdougald to explain how two eyes can look at an object simultaneously from the *same* standpoint. "One may mount two prints from the same negative," says Mr. Macdougald, "and such priuts will give the appearauce of solidity when viewed either by the unaided eye in the manner above mentioned, or through the stereoscope." Here is news indeed: but if there were the slightest foundation for such an assertion, who so foolish as to carry a stereo-camera and make stereo-negatives when single ones will do? If Mr. Macdougald will consult "Hardwich and Taylor," or indeed any class-book on optics, he may derive some benefit.

On the binocular miscroscope, as proof of his theory, Mr. Macdougald surpasses himself. "The binocular microscope," he says, makes it "at once apparent that the appearauce of solidity or stereoscopic impression does not rest on the fact of each eye having a picture for itself." Well, I always thought it did exactly rest on that fact. If Mr. Macdougald ever used a binocular microscope, it is very strange that he did not notice that not only does each eye see the image projected by *one-half* of the objective, but by means of a prism the image projected by the right half of the objective is projected to the left eye, while the right eye views the image projected by the left portion of the objective; and further, when the instrument is so arranged that the right eye looks through the

right half of the objective, and *vice versâ*, the image is not seen stereoscopically, but pseudoscopically. (Another death-blow to the second alternative method of seeing stereoscopically with the unaided eye mentioned above.) The binocular microscope, in fact, furnishes a complete refutation of nearly every sentence on stereoscopic vision in Mr. Macdougald's paper with which he regaled the Dundee Society. (See "Carpenter," and any other text-book on the microscope.)

Mr. Macdougald says I "dislike the small hole trick." This is proof that he has not carefully read what I wrote. I expressed neither liking nor dislike of it. He refers the impression of solidity obtained by the "small hole trick" to suppression of surface on the picture. I do not believe in this theory of his at all; I attribute the illusion to brain action chiefly. But till the elements are mastered there is not much use discussing more difficult matters. Mr. Macdougald says, "In what, then, does stereoscopic vision consist? That is a very difficult question to answer." Possibly, but it is answered for us, even if we are incompetent to work it out for ourselves, in every treatise on elementary optics with any pretension to completeness.

I omit notice of the bantering tone of Mr. Macdougald's paper. No doubt it may have amused such of his hearers as were unaware of the extraordinary weakness of his arguments, and his entire misapprehension of stereoscopic optics.

I also reserve further comment on the fact that in my original article (*Photography*, June 13, 1889,) I dealt with stereoscopicity as related to art. I said, and I say, solidity is not art, nor is art illusion. ANDREW PRINGLE.

AMATEURS AND PROFESSIONALS.

SIR,—There is one consideration that has escaped the notice of "Photophotos" in his critical review of Amateurs and Professionals in Holland (see page 139 of last week's NEWS). The definitions are good and humorous, and the shallow fear that the amateur is likely to supplant the professional is fairly stated and disposed of. Another aspect of the case has, however, been entirely overlooked—namely, the fact that the widespread practice of photography by numerous amateurs tends to elevate the status of the professional, and inspire a higher appreciation for the generally superior character of his work. His claims thus become more widely recognised, and those who seek for experience, especially in portraiture, must needs avail themselves of special talent, training, and appliances. To borrow a simile:—The regular forces of the British army were never so popular or so well appreciated until the volunteers sprang into existence, and then came a laudable feeling of rivalry in shooting and drilling, which has since proved most beneficial both to the regular and auxiliary services. Old methods and weapons were criticised, and the army gained more by friendly competition and healthy rivalry than was possible formerly without such occasional stimulus and review. In fact, the volunteers have popularised and vastly improved the efficiency of the regular army. There is no question about this; and so it may be with the mutual relations of the amateur and professional photographer; the latter gains much by securing a wider appreciation of his highest aims by an educated public, and reaps the benefit of more extended patronage.

If the army of professionals is occasionally recruited from the ranks of trained amateurs, so much the better for all concerned; real progress cannot be in any way imperilled, but, on the contrary, assisted, and a wider *clientèle* created.

Respecting definitions: There is an old adage, "Once a captain, always a captain." Does this stand true of the professional photographer? I know a man who, a quarter of a century ago, took pay for several years as an instructor and photographer in the Government service, but now he only uses his camera as an amateur. To which class does he belong? Again, your Dutch correspondent says, "One, however, of the most pronounced characteristics of divergency is undoubtedly the winter sleep or hybernation of the amateur." But if this be true, what shall be said of the large class of quasi-professionals, like those having studios at suburban or watering places, who regularly "hybernate," or practise photography only during the season, and follow some other occupation during the winter?

Is there any "hard and fast rule" applicable to such cases? I for one would like to know what answer to give to these and similar enquiries. JOHN SPILLER.

HACKNEY PHOTOGRAPHIC SOCIETY.

SIR,—Below is our programme for March, 1890, at Morley Hall, Hackney, Room No. 4:—Thursday, 13th, "A Talk on Photographic Optics," by Mr. J. Traill Taylor. Thursday, 27th, "Photography." Prize lantern slides.

W. FENTON JONES, *Hon. Sec.*
12, *King Edward Road, Hackney, N.E.*

PHOTOGRAPHIC SURVEY OF WARWICKSHIRE.

SIR,—So many applications have been received for copies of my pamphlet on "Methods of conducting a local photographic Survey of Warwickshire" (methods which are equally applicable to other districts) that I have had it reprinted, and copies can be obtained post free, sixpence each, from Mr. A. J. Leeson, 20, Cannon Street, Birmingham (Hon. Secretary, Birmingham Photographic Society), or from

W. JEROME HARRISON,
Science Laboratory, Board School, Icknield Street, Birmingham.

P.S.—The price named just about pays for printing and postage, but any profit will go to the Society's funds.

FOCUSSING APPLIANCES.

SIR,—In reference to the above—*vide* the leader in your impression of February 14th—for about the twentieth time I recommend my brother amateurs to adopt for a focussing screen the plan I have had in use for some years, viz., a circle or strip of plain glass in the centre of the screen. I made mine, and have made a few for friends since, by cleaning and varnishing an old negative plate, when cool rubbing it with the ball of the thumb, to get a *very fine* tooth, much finer than any ground glass, then removing a small circle or strip of the varnish in the centre of the plate. This gives a bright picture quite up to the edges of the plate; and in the centre on the plain glass, with a focussing glass, absolute microscopic sharpness. Lastly, if you should have the misfortune when away on a tour to break your screen it is easily replaced. A quarter of an hour will make it. W. T. F. M. INGALL.
Greenhithe, Kent.

PATENTS AND PHOTOGRAPHIC PROGRESS.

SIR,—There is no doubt that the protection afforded by the patent to the outcome of the labour and ingenuity of the actual inventor is an advantage to scientific progress, inasmuch as it acts as a spur and incentive to experimental research; on the other hand, there is no greater bar to advance and improvements in any direction of progress than the practice of claiming a monopoly of manufacture on the ground of novelty where no such novelty exists. It would be well if claims for invention were more carefully scrutinised than appears to be the case, although every facility has been lately given by the photographic journals which record the applications made in their department. It may be said that the public have a means of redress in cases of invalidity of patents by opposing or disregarding the claims which are made. This may be true in theory, but practically it is well known that the irrecoverable expenses, and annoyance, and loss of time involved, even in cases of successful issue, deter many from taking that step. There may be some of your readers, interested like myself in the special subject of actinometry, to whom the following references to some passages in a work by a well-known writer may, perhaps, be of benefit.

Capt. Abney, in the 1884 edition of his "Instructions in Photography," gives a figure and description of the "Woodbury Photometer," the principle of which is the determination of the actinic power of light by the exposure of a strip of sensitised paper, coiled in a small box, in the form of a compass. The actinic light is measured by the darkening of the exposed paper in comparison with a standard tint or tints

provided for that purpose. The writer goes on to say, "I believe it would be an improvement to *use bromised paper for the actinometer*," and in a former part of the work a formula is given for the use of *nitrites* with the bromised silver solution, the well-known salts by which the bromised paper is made to darken in the light without development.

Since the publication of this edition of the "Instructions" two applications have been made for patents for actinometers, which may now be compared with the above extracts.

I need not point out that the matter has a wider significance than the invalidity or validity of these patents. It is a public, not a personal question, and on the solution of it depends our conclusion as to whether the results of research and experiment given to us by public writers in works of general reference are for the full and free use of the public, or only for the benefit of individual monopoly. EXPERIMENTALIST.

THEODOR PRUMM.—The German Photographic papers announce the death, on the 11th inst., of this well-known and skilful portrait photographer, at the age of forty-nine.

ALBEMARLE AMATEUR PHOTOGRAPHIC SOCIETY.—Mr. Walter Pilkington, of St. Margaret's, Newlands Park, Sydenham, asks us to record the formation of this Society, established for the "social discussion of the technicality of photography."

CAMERA CLUB CONFERENCE, 1890.—The Conference, as already announced, will take place at the Society of Arts on Thursday and Friday, March 20th and 21st, under the presidency of Captain Abney. Amongst the papers to be read and discussed will be the following:—"The Art of Drawing and Photography," by Mr. A. M. Rossi; "Photography by the Light of the Electric Spark," by Lord Rayleigh; "The Latent Image," by Mr. C. H. Bothamley; "Limitations in the Treatment of Subjects by Focus," by Mr. T. R. Dallmeyer; "Collotype and Photo-Etching," with practical illustrations, by Mr. W. T. Wilkinson; and other papers by the President, Mr. Lyonel Clark, and others. It is further proposed to bring forward, in as complete a manner as possible, the subject of photographic exhibitions and their regulations. The exhibition of apparatus will be as usual in the library of the Society of Arts. All photographers or others interested in the subjects under discussion are invited to be present.

THE PHOTOGRAPHIC CONVENTION.—The 1890 meeting of the Photographic Convention will take place at Chester, from the 23rd June to the 28th inclusive. The proceedings will open on the evening of June 23rd with a conversazione, at which the President's address will be delivered, and there will be a lantern exhibition. Excursions have been arranged for each day during the week. The evenings will be devoted to the reading of papers and discussions. An exhibition will be held of novelties in apparatus, and no charge will be made for space. The Convention dinner will take place on the evening of the 27th June. Arrangements are being made for excursions to the following places:—Moreton Old Hall, Conway, Bettwys-y-Coed, Carnarvon, Harwarden, Llongollen, and other places. Also a trip on the Mersey to witness the regatta of the Mersey Yacht Club. Cheap railway tickets to these places will be issued by the railway companies upon production of membership tickets.

PHOTOGRAPHIC NOVELTIES.—From Mr. Robert Talbot, of Berlin, we receive the first number of *Photographische Neuheiten*, or "Photographic Novelties," the object of which is stated to be to furnish the amateur and professional photographer, the photographic printer, the zinc and copper etcher, and the photo-lithographer—all those, in fact, who are directly or indirectly interested in photographic experiment or research—with the latest news in the photographic world, in the quickest, clearest, and most concise fashion. It is proposed by the editorial staff to give a comprehensive description of all the photographic novelties which may be transmitted to them, both from Germany and elsewhere, with their prices attached, and illustrations in such cases as make them desirable or convenient. The editorial staff, through its intimate association with the well-known firm of Romain Talbot, claims to be in a position to give the very earliest notice of all novelties of interest or importance.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

AT the technical meeting of this Society, held on the 25th inst., the chair was occupied by Mr. W. E. DEBENHAM.

A letter from the Secretary of the Royal Geographical Society was read, in which it was stated that the photographs of Caucasian scenery, taken by Signor Sella, would be on view until the end of the month.

A shutter that had been sent by the manufacturer was shown and handed round. The arrangement for resetting after each exposure was effected by the pressure of the pneumatic ball that actuated the release, so that it was always ready for use without resetting. If wanted as a time shutter, there was an arrangement by which two pressures of the ball were used, one for opening and one for closing. A dark-room lamp was also shown; it was for use with benzoline, and resembled a brass candlestick in appearance. There was a ruby chimney surrounding the flame.

The CHAIRMAN remarked that manufacturers of these things were rather conservative in keeping to red instead of using deep yellow.

A letter was read accompanying some photographs sent by a photographer in the provinces, who asked for an explanation of some peculiar markings that covered about half the plate. The photographs had been taken in a hall at night, and one of them showed a row of gas jets. It was noticed that the markings were parallel, and proceeded from the direction in which the gas jets appeared, and the opinion was expressed that the marks were in reality photographs of the gas jets spread across the plate by a movement of the camera, probably caused by opening or closing the dark slide.

Mr. H. CHAPMAN JONES showed a lens and camera, which he called the memorandum camera, for taking photographic notes of any subjects of which it might be required to obtain a reproduction. As it was desired that it should be available under all practicable conditions of light, the lens was of the rapidity taken as unity in the Photographic Society's standard, $f/4$. It was fitted with Swift's iris diaphragm, which was so arranged that there was literally no projection from the tube. The size of plate used was half of the quarter-plate, or $3\frac{1}{4}$ by $2\frac{1}{8}$ inches. The lens for the purpose was of about $3\frac{1}{2}$ in. focus. It was graduated so as to be fixed for objects at certain distances from two feet upwards. At the two feet distance it was practicable to get quite a readable negative from a page of a book, which might be easily done by setting up the book on an ordinary table at the distance mentioned, and adjusting the diaphragm to the smallest opening. The shutter was of the roller kind, and had a long opening in proportion to the diameter of the lens, being more than three times as long as the diameter. The rollers were made one inch thick, so that violent speed of rotation was not necessary in order to obtain a quick exposure. He had found a difficulty in obtaining a material strong enough to bear the strain of the strong spring necessary, but had overcome the difficulty by using black tape at the ends of the rollers, and attaching the blind itself to those tapes. The blinds and tapes passed completely round the rollers at both ends, so as to distribute the pull, and render them less liable to be torn off. Mr. Samuels's arrangement of plates was adopted, although of course a roller slide could be used if desired. The camera, with twelve plates complete, weighed thirty-five ounces. He used a view meter and finder, which was furnished with a square ground glass, on which lines were ruled, which indicated both positions, vertical and horizontal, in which the plate could be used, so that a choice might be made from actual inspection of the two positions. With the shutter working with its full opening, it was fitted for ordinary instantaneous work, but if desired, by narrowing and opening, and placing it next to the plate, a rapidity exceeding that mentioned by Anschutz for photographing such objects as bullets in motion could be obtained. The camera being narrow, could be employed as a secret camera more easily than most others, but he did not personally desire to use it as a secret camera. In order to show that

one need scarcely ever fail to secure a photographic record, whatever the light or time of day. He had taken some street scenes on the 21st of December, at various hours of the day. The day itself was a dull one. These photographs were exhibited, as well as one of a printed page which, under a Ramsden eye-piece, could be easily read. For developing he used a dish of eikonogen, and had another dish at hand containing a weak solution of bromide, into which any plates were removed that gave signs of over-exposure. After a stay in this solution they were, if necessary, returned to the eikonogen bath to gain density.

The CHAIRMAN noted that a lens of f 4 aperture was used, although, doubtless, it would generally be stopped down to $f/8$ or less. When this stopping had to be done, it was, according to his experience, better to use a lens originally not of so rapid a character, as the field might be, and was, made flatter than was practicable with the more rapid lens. Was that in accordance with Mr. Chapman Jones's experience?

Mr. CHAPMAN JONES replied that, in so far as flatness of field is concerned, that was so, but as occasions did arise for using the utmost available rapidity, he had decided to have a lens which would give that when required. The curvature of field with this lens was equal to $\frac{1}{10}$th of an inch at the margin of the plate of the size indicated.

Mr. W. BEDFORD noted particularly the smooth, spiral movement of the lens tube for focussing.

Mr. W. ENGLAND would use the roller shutter next to the plate.

Mr. CHAPMAN JONES said that that was the worst position for the shutter, although, for specific purposes, like that of photographing a bullet, it might be necessary.

Mr. COWAN exhibited three bromide paper photographs of cabinet size to show the effect of a very small quantity of bromide in an eikonogen developing solution. The first had received a certain exposure, and been placed in four ounces of a fresh solution of eikonogen to develop. It came up grey and flat, and the next print therefore received only half the exposure. This came out bright and powerful, but a third print that had received the same exposure as the first one came out best of all. The only difference between this print and the first one was that it was the third to be developed, and the eikonogen had, therefore, accumulated a small quantity of bromide given out in the development of the first two.

Mr. ATKINSON showed a print thirty-two years old, printed upon salted paper, and not mounted. It appeared to be quite free from fading.

The CHAIRMAN said that unmounted prints notoriously had a longer average life than mounted ones. The print shown looked, too, as if it had been toned with sel d'or. Was that so?

Mr. ATKINSON replied that it had been toned in that way.

The CHAIRMAN continued that that process conduced very much to permanency. It was to be regretted that it had not been found practicable to use it generally for albumen prints. Many unmounted, and some mounted, albumen prints certainly existed which had been printed for many years without showing any signs of fading, but the sel d'or bath deposited so much gold on the print that there was considerably more probability of permanency in prints so produced.

CAMERA CLUB.

ON Thursday, February 20th, a paper communicated by Mr. W. K. Burton, on "One or Two of the Tenets of the Naturalistics," was read by Mr. A. Priugle; Mr. W. A. GREENE occupied the chair.

Mr. BURTON, iu his paper, took the view that any want of sharpness in the principal objects or planes, and any falling off away from the centre of interest in the different planes, could not be defended upou optical principles, but that, on the other hand, these principles would appear to demand that planes other than the plane of chief interest should be less perfectly defined. He further dealt with the subject of imaginatiou in the pictorial arts, and the possibility of introducing it in photographic work.

The discussion was opened by Mr. DAVISON, who observed that the variation in focus of different planes admitted and argued by Mr. Burton was one of the chief contentions of those called "Naturalistics." He thought it was more a matter of the mental attitude whether representations should be sharp or not. A definite detailed examination of nature was the scientific, not the artistic attitude. He thought imagination could not be expected to supply the truth of representation, in which lay the thrilling charm experienced by an artistic perception of a beautiful scene in nature.

On Thursday, March 6th, Mr. A. Pringle will treat of the subject "The Optical Lantern." Meeting at 8 p.m.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting on the 20th Mr. A. HADDON occupied the chair.

Mr. J. B. B. WELLINGTON showed two bottles of eikonogen recently received from the manufacturers. In one of the bottles the crystals had become quite dark; there was no trace of any discolouration of the crystals in the other bottle. Both bottles had been received at the same time.

The CHAIRMAN had exposed a mixture of powdered eikonogen and sulphite to the air, and had also enclosed some of the powder in a sealed tube, raising the temperature to boiling heat for half an hour; but little change of colour was noticeable in the samples passed round. He had also taken—

Eikonogen	1 part
Carb. soda	2 parts
Sulphite	4 ,,

A portion of this was kept in paper, and the remainder placed in a sealed tube. In both cases considerable discolouration had taken place. The Chairman said, from his experiments, he was of opinion that the sample of sulphite used by Mr. Cowan, when he succeeded in developing plates with pyro and sulphite, and also eikouogen and sulphite alone, contained a large excess of carbonate.

A questiou was asked whether any member had used anglol.

Mr. J. B. B. WELLINGTON said he had found it a rather slow developer. The results were very similar to those by eikonogen development.

Mr. A. COWAN exhibited a series of bromide prints developed with various developers—ferrous oxalate, eikonogen and carbonate of lithium, with aud without bromide, pyro and carbonate of lithium, pyro and eikonogen mixed, eikonogen, both with weak and strong alkalies, hydrokinone of different strengths, and eikonogen with caustic alkali. Two of the prints were selected, which were generally acknowledged by the members present to be excellent both in detail and quality of image. The prints had been developed by use of the following formulæ respectively:—

Eikonogen	4 grains
Sulphite	32 ,,
Carbonate of lithium	2 ,,
Hydrokinone	2 grains
Sulphite	8 ,,
Carbonate of potassium	10 ,,

Mr. Cowan said his chief object was to find a good developer that did not require to be followed by the acid bath. Hydrokinone gave extreme density, consequently it would be found a good developer for prints from thin negatives.

Mr. P. P. DRAGE showed a negative with some peculiar transparent markings on it. The negative had been developed with washing soda and dry pyro; it took a long time to come out.

Several members gave it as their opinion that the markings were due to air-bubbles.

PHOTOGRAPHIC SOCIETY OF JAPAN.

A MEETING was held at the Chamber of Commerce Rooms, Tokyo, on December 12th, when the following were elected members of the Society:—Mr. Tamamura, Dr. G. Wagener, and Messrs. Katzuzo Takenouchi, E. H. R. Manley, and J. B. Coulson.

Objection had been taken to a certain proposed member on account of his having copied without permission, and sold, the pictures of a member of the Society. An explanation which was satisfactory both to the objecting member and to the Society was given, but the following resolution, proposed by Mr. E. R. Holmes, and seconded by Mr. Pallister, was unanimously passed :—"That this Society discountenances, by all means in its power, the practice of copying the photographs of other artists for sale, and that, if the practice be continued, the Society will take into consideration the desirability of making a bye-law whereby such practice shall *ipso facto* exclude from membership of the Society."

Mr. K. OGAWA exhibited the colossal camera with which he had made photographs direct, measuring 38 by 30 inches, for the forthcoming exhibition, and an enormous tripod intended to be used with it in photographing interiors. The top of the tripod reached the roof of the hall. A monster printing frame for making the pictures on paper measuring 4ft. 6in. by 3ft. 6in. was also shown.

Mr. KONISHI showed the "Kodak," the smallest of the numerous hand cameras now so popular, and Mr. Kajima some very beautiful opalotypes done on opal glass that had been coated with emulsion in Japan.

Mr. W. K. BURTON read a paper on "Eikonogen," the new developer. The results of his experiments had certainly been to make him conclude that the developer had good qualities, but he considered the claims made by the makers to be quite extravagant. On the whole, Mr. Burton doubted if it would oust our old friend pyrogallic acid.

After the ordinary meeting was concluded a special meeting was held, and Messrs. J Johnston and F. Walkinshaw were elected members of Committee. Mr. A. J. Hare was elected Foreign Treasurer.

ABNEY CAMERA CLUB.

AT the meeting on the 21st inst, Mr. A. J. ADKINS gave a demonstration on "Carbon Printing," showing the processes of single and double transfer.

A series of club competitions was arranged for ; the first was for gelatine lantern plates, to be held on March 28th.

On March 7th there will be an exhibition and discussion on "Detective Cameras."

GENRE PICTURES.—Mr. J. Hubert, of Hackney, who has been studying art principles for some time past, has shown us a series of three photographs illustrating incidents described in Longfellow's poem "The Happiest Land," in which four "hale and hearty fellows" by "an alehouse on the Rhine," argue as to the locality of the happy country :—

> And then the landlord's daughter
> Up to heaven raised her hand,
> And said, "Ye may no more contend—
> There lies the happiest land."

At the Royton exhibition these three pictures formed the only entry in the special genre class, but the judges, after due consideration, decided that the pictures were so good that they awarded Mr. Hubert the silver medal, despite the absence of competition.

RECEIVED.—*Fallowfield's Photographic Remembrancer* for quarter ending March. It contains four illustrations of snap shots with the "Facile" hand camera, for the use of which very explicit directions are given. It contains also useful and interesting photographic tit-bits, interspersed among the advertisements of which the paper mainly consists.——*The Art Weekly*, "an independent art newspaper," which, we learn, was to have been called "The Art World," but that the latter title belonged to others. Its object is claimed to be sufficiently set forth upon its title-page.——From *The Photographic Times*, of New York, per the Eastman Dry Plate and Film Company, a calendar for the year 1890, neatly framed, and containing moveable parts,

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

ARTIST (Bangor.)—*Obscuring top lights without blinds.* Papier mineral might do, or tissue paper pasted on ; but if you want a paint for this purpose we should advise you to try the whitest quality of Aspinall's enamel, which dries quickly, and is not affected by light. White lead is not permanent, and zinc white is so slow in drying. Or, try a warm, thin gelatine mixed with zinc white brushed on the glass.

J. C. (Edinburgh.)—*Definition of an "Amateur Photographer."* See reply to P. B. A., last week. A dealer in photographic chemicals and apparatus, who uses his camera habitually for his own pleasure, and makes no profit by the sale of his photographs, is, we think, a *bonâ fide* amateur.

T. S.—Wishes to communicate with IGNORAMUS (post mark Dublin), who sent us an enquiry about collodio-chloride a fortnight ago. By forwarding his name and address to our office, or to Canonbury, he will oblige our Carlisle correspondent.

PHOTARGUS.—*Stained collodion for orthochromatic screens.* Our correspondent finds it difficult to strip tinted collodion films successfully. We would suggest the use of Eastman's rollable celluloid as a foundation, or a plate of mica, if he is not prepared to adopt Captain Abney's plan of applying the stained collodion direct to the back lens. Gelatine skins are not sufficiently tranparent. Or, would a coating of india-rubber in benzol stiffen the collodion up to the point of stripping ?

SAMSON.—*Blue tones in silver prints.* Your complaint that the acetate toning bath works so slowly in giving you the required result may be answered by advising you to use a stronger and *freshly mixed* carbonate or acetate bath ; but you must bear in mind that speed is not always desirable when you look for uniformity of action, and push the toning process to extremities. Prints of this kind will, of course, require more gold than the chocolate shades.

W. MORGAN.—1. *Removal of varnish from old negatives.* There is nothing better than prolonged immersion in two or three changes of methylated spirit, which, in cold weather, may be slightly warmed. Mr. W. T. Wilkinson's manual of photo-lithography and half-tone processes is just now being reprinted. Apply to Messrs. England Bros., 25, Charles Street, Notting Hill, W.

W. W. J. N.—*Robert Hunt's early photographs.* These were shown at the Photographic Exhibition of 1888, and again fully described at page 193 of the YEAR-BOOK. The ferric salt used was ammonio-tartrate (or citrate) of iron, applied as a single wash ; this becomes partially reduced to ferrous salt by exposure to light in the printing frame, and the picture is developed by subsequent treatment with a gold or silver salt, and fixed with hypo. The image being unquestionably composed of reduced silver (or gold) should, if properly washed, be permanent, as our specimens appear to be, and they bear the date of 1852.

ARTISTIC.—It is not clear from your note whether or not you have *read* Mr. H. P. Robinson's article on "Winter Photography for the Artist." You will find that he recommends the use of isochromatic plates for general purposes, and these to be of fairly large size, so as to get foreground details without the necessity of subsequent enlarging. We agree in your estimate of the reproduction of Mr. J. Gale's "Homewards," which is simply superb. For snow pictures, "as a rule choose sunlight," says the author.

E. O. C. (Boston, U.S.A.)—We thank you for the formula of collodion suitable for black-and-white reproductions, and also for your generous offer in the matter of collotype.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1644.—*March* 7, 1890.

CONTENTS.

AN UNSOLVED PROBLEM IN THE HISTORY OF PHOTOGRAPHY.

In historical matter which has been published in these pages during the last four months, it has been made clear that the first publication of Wedgwood's discoveries in photography was made at the Royal Institution in 1802, but the question remains how long before that time Thomas Wedgwood had found out his process. The claim has been advanced that his discoveries were made at least as early as 1799, because a sentence in a letter from James Watt, written in that year, seems possibly to bear reference thereto. In this relation the following paragraph appears in Miss Meteyard's *Group of Englishmen*, London, 1871, page 150:—

"When James Watt visited Etruria in 1799, on business relative to a hand-mill he and Boulton were supplying to the firm, the subject of Thomas Wedgwood's extraordinary discovery seems to have been discussed; and a few days later Watt received a letter (probably a promised one) from Josiah Wedgwood, in which were given the details necessary to experiment. To this Watt replied: 'Dear Sir, I thank you for your directions for the silver pictures, on which, when at home, I shall try some experiments. I was thinking of your mill after I left you, and fear the motion of the spindle is too slow, &c.' *James Watt to Josiah Wedgwood, docketed Hand Mill*, 1799. *Wedgwood MS.S.*'"

Additional examination, however, shows that before that time Thomas Wedgwood was using nitrate of silver at Etruria; at least, such was the case if we assume the accuracy of Miss Meteyard's statements and dates. The silver salt is said by her to have been used in relation to the ornamentation of pottery, and if sometimes applied as sketches for burning-in, Watt might possibly apply to them the term "pictures." Miss Meteyard's statement, given in her *Life of Josiah Wedgwood*, vol. 2, London, 1866, page 585, is:—"To solve some problems connected with light he used silver differently prepared, and his observations thereon led to the invention of what was termed 'silvered ware,' namely, a pattern of dead and burnished silver upon a black earthenware body. We first hear of this ware in February, 1791. *Thomas Wedgwood to Byerley, February*, 1791, *Mayer MS.S.*"

The question therefore is—Did Watt's remark refer to designs for pottery, or to the earliest English photographs?

A few days ago we received a private letter from Mr. Hensleigh Wedgwood on this and other subjects, and, with his permission, now give its contents, as follows:—

"Many thanks for the last NEWS, which completely settles the question. It is clear that Thomas Wedgwood never got beyond the unfixed figure on silver salts in a camera. After 1802 he was in such a wretched state of health as to be quite incapable of research of any kind. If in the nineties he had been capable of producing a true Daguerreotype, it is certain that he would have brought forward that process before the Royal Society, and not the fugitive photographs of 1802. I have no doubt that the silver pictures mentioned by Watt in his letter to my father were the photographs in question. Miss Meteyard's assertions are worth nothing. She could give me no authority for attributing the photographs in her book to Thomas Wedgwood. As a proof of her carelessness and inaccuracy, I may cite her assertion that Thomas Wedgwood bought an estate at *Castle* Flory and lived there for a year. The truth was that the brothers had it in contemplation to purchase an estate at *Combe* Flory, but the plan was never carried into execution, nor did they ever live there at all. No silver pictures were ever made upon earthenware at all."

Possibly some light may be thrown upon the main point at issue by an examination of the documents on which Miss Meteyard founded her statements, to see that she has made no mistakes in dates or facts. Was James Watt engaged in any experiments relating to ceramic art about 1799?

A well-known and popular writer has an article in

the last *Photographic Quarterly*, the title of which pushes Wedgwood's discoveries in photography back to the year 1790, but no evidence is given in support thereof; indeed, the author says in the article, "photography was not discovered during the eighteenth century." The title of his memoir is, "Wedgwood and Davy: What they did for Photography a Hundred Years Ago."

They did nothing for photography a hundred years ago, and Dr. Eder has unearthed evidence that photography was discovered during the eighteenth century, as published recently in these pages.

PHOTOGRAPHY IN BELGIUM.

The *Bulletin* of the *Association Belge de Photographie*, just received, is full of interesting matter, and has for its frontispiece an exquisite specimen of heliogravure by J. Löwy, of Vienna, and some good photo-mechanical prints by M. J. Maes.

At a meeting of the Brussels Section of the Belgium Association, at which Mr. O. Campo occupied the chair, Mr. Van Eechout suggested that the Section should fit up a laboratory for the use of members, and should apply to the city authorities for permission to hold its meetings in the Industrial School, and Mr. W. Janssens undertook to take preliminary steps for the attainment of the object. M. Gèruzet brought under the notice of the meeting his method of taking photographs by means of an explosive magnesium compound consisting of:—

Magnesium powder...	4 parts
Chlorate of potash	6 ,,
Sulphide of antimony	1 part

To obtain diffusion of the light, he, by pneumatic means and the use of spirit flames, fired two small charges of this powder for each exposure, and it was found that there was an appreciable interval between the ignition of the two mixtures; nevertheless, he obtained a good group photograph of the members present. M. Gèruzet would probably find it better to fire the charges by electricity. A dangerous compound, such as that described, should not be kept ready mixed. A few grains only of the powders should be mixed just before use, otherwise a deadly accident may take place at some unexpected moment.

At a meeting of the Ghent Section of the Belgian Association, M. Coupé recommended for the development of lantern slides that the plate should be immersed in a mixture of three parts of a 10 per cent. solution of oxalate of potash with one part of a 10 per cent. solution of bromide of potassium, before the application of the usual iron developer; he said that by this method the high-lights of the image come out absolutely transparent. At this meeting Mr. De Keyzer distributed some platinum prints of a picture which had been much admired at the Exhibition of the Section; it was a view of the banks of the Zwalm, in Flanders.

At the meeting of the Antwerp Section, M. Maes, President of the Belgian Photographic Association, occupied the chair, and he read a report about the work done by this comparatively new Section since its foundation. Three years ago it began with thirteen members; their number has since increased to seventy-two. M. Raymond Storms remarked truly, that much of the prosperity of the Section was due to the devotedness of M. Maes. The President then proposed that the Section should occasionally have demonstrations of ancient photographic processes, practically unknown to most workers who first took up photography in the dry plate era. M. Lunden said that a good way to obtain a matt surface with aristotype paper is to rub a sheet of glass with a solution of green soap (*savon vert*), then gently wash it under a rose tap to get rid of the excess of soap, then apply the print to the glass by means of an india-rubber roller. When dry the print will have a fine matt surface. Mr. Hansen drew attention to a letter from the Minister of Finance, dated November 9th last, saying that positives on glass can enter Belgium duty free, when they are declared as objects of art and collection.

The Ghent Photographic Exhibition, to which allusion has previously been made, was held in the grand salon of the Cercle Artistique. The salon itself, says the *Bulletin*, was coquettishly decorated with dried flowers prepared by M. Schmitz. Mr. Edgar de Keyser was among the exhibitors. M. D'Hoy, a veteran Belgian photographer, exhibited specimens of photo-mechanical printing processes, dating from the time of Fox Talbot down to the present day. Mr. A. Sacrè-Smits exhibited large carbon prints of flowers, reminding the *Bulletin* reviewer, Mr. O. Campo, of a similar type of photographs on view at the Brussels Exhibition in 1883, and exhibited there by an English amateur, "Mr. Stevens, of London."

THE BELGIAN INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

"Because of circumstances beyond its control," the Committee of the Belgian Photographic Association has decided to postpone until 1891 the International Exhibition which it intended to hold in Brussels in August, 1890. The cause of the postponement is said to be the tardiness of the replies of the Belgian Government officials to letters about suitable buildings for the proposed Exhibition.

Mexican Fireflies.—A gentleman travelling from California to Vera Cruz came across millions of fireflies near Jalapa, one of the most beautiful cities in Mexico. He says that the road from this point was lined with a dense chaparral, which was brilliantly illuminated with myriads of fireflies. These are a bug about the size of an ordinary roach, and emit a light almost equal to that of a small wax taper. It is not the occasional sparkle of the little firefly of our country, but a continual blaze, proceeding from the eyes, as well as from two points beneath the wings. Several of these insects, placed in a glass jar, will give sufficient light by which to read the smallest print, and when one rises in the air to any considerable height, it resembles a beautiful meteor slowly crossing the heavens. Numbers of them flying through the air in different directions on a dark night present a very pretty appearance, well calculated to excite the wonder, if not the superstitious fears, of a person unacquainted with the cause of so strange a phenomenon.—*American Druggist.*

SOME RELATIONS BETWEEN FINE ART AND PHOTOGRAPHY.*

BY PHILIP H. NEWMAN.

I SAY "some" advisedly, because I could not, in anything like the time at our disposal, make even a catalogue satisfactorily of all the relations these two subjects bear to one another; so rapid of late years has been the growth and progress of the science which, for good or ill, must affect in some degree every branch of the fine arts in the future. There are doubtless those here who would like, and possibly expect, me to describe and enlarge upon the multiform processes of photogravure, whereby elaborate reproductions of works of fine art have been made in such quantities, and of such quality, as to rival, if not to quite revolutionise, most of the engraving processes. Drawing on wood, for example, seems going the road of lost arts, while chromo-lithography trembles at the advance science is making in the direction of chromo-photography. But however much I may regret I may be disappointing some of my audience in barely noting these important changes, I conceive that my business this evening is with something of greater importance still, namely, with the bearing photography has had, and may be expected to have, not only on the fine art of to-day itself, but upon public taste and criticism, and how that sense of appreciation has been and will be affected in us, without which fine art can have no existence at all, and by which appreciation it has lived and had its being in every period, and thriven under conditions of such exact ratio that its remains constitute for us an intellectual reflex of the ages.

Making due allowance for much exaggeration and the enthusiasm natural to new-born hopes but only partially realised, no one, I suppose, more than myself will acknowledge the many benefits and advantages photography has conferred on the artist, in permanently registering with the rapidity of a flash those effects in nature that are as evanescent in mountain, sea, or cloud; the crisp-cast shadow of the sun-lit snow, the thundering breaker on the storm-lashed beach, or wandering wavelets of a silent strand; the lightning-laden cumulus, the tempest's rack, the myriad-leaved copse, and the bewildering detail of hedgerow and flowering dale: all are brought home to us in light and line, half-tone and shade, in an exactitude no pencil could imitate, and no lifetime be long enough to master. Yet, in acknowledging all this and much more, I am not blinded to the fact that photography is not an unmixed blessing, and that it has exercised, and will exercise, an influence not altogether for good, unless our eyes are opened in time, and a great effort is made to minimise the evil. Should any photographer be here who fears from the foregoing that I am intending to follow any other artist's lead, and run a tilt against the camera, let him be assured I have no such quixotic intention, as I recognise both its stability and its use too well.

But there are photographers and photographers; photographers that are artists, and photographers who never will be artists. Now-a-days, everybody is a photographer, from duchesses downwards, and this increases the danger, because it is in the nature of things that, though photographers be many, artists will always be few. I will go further than this, and say at once there are some people no more to be trusted with a camera than they are to be trusted with a six-shooter; indeed, far less, for he who misused the six-shooter and killed someone, would probably be sorry for it, but those who misuse cameras, and blaze away, pot-shotting—so to speak—anything and everything that turns up, are hardened sinners, and usually very boastful of their enormities. For this reason I look—perhaps with suspicion—upon some recent inventions in photographic apparatus, as offering, by their extreme simplicity, premiums to this sort of people to commit something worse than homicide, for they kill their mother Nature, and glory in the crime. Then there is another class—a class that ought to know, and perhaps does know, better; indeed, its members can often appreciate a work of art when they see one; who, while they are quite able to take a good photograph, will not use their brains when finding a subject, will not bear in mind that detail will never compensate for faulty composition. These people take a view when, if they had simply moved their tripod-stand twenty yards perhaps to right or to left, they might have taken a picture. Here, then, I think is one of the relations of fine art to photography that we may, I hope, profitably talk about to-night, for you know there are those in these highly artistic and æsthetic times who look upon every photograph as a picture. One hears them say: "It must be a picture, you know; it is nature itself, and the detail comes out sharp all over." So like a picture! But absurd as this is, the feeling that prompts this kind of criticism is far wider spread amongst us than we are inclined to allow, and besides affecting photography, from which it has sprung, it has affected fine art in a very marked manner; for while a very great advance must be noted in our drawing and painting, and in the public appreciation of drawing and painting of late years, yet the exhibition of the intellectual qualities of composition and breadth is rarer among us, and not so keenly sought for as it should be by an art loving people; and I have no hesitation whatever in saying that the insidious influence of bad photography has much to answer for in this respect.

There is good cause, then, for us to use our utmost endeavour to guard against the growth of an evil that is likely to bear so seriously upon the art of the future; and where there are so many photographers, the greater reason for the multiplication of critics, and the furtherance of the study of art based on the just contemplation of that of past ages—a study now within the reach of everyone; a study that everyone with any pretension to culture and refinement ought and might make their own. Now I know perfectly well that I shall be met on the very threshold of this argument by the answer, "Oh, don't you think that we have far too many studies already?" Alas! every schoolboy knows that; but with the view of each becoming an admirable Crichton, we do, as a rule, too much of everything, and too little of any one thing to succeed. A bit of Latin, a bit of Greek, a bit of painting, a bit of fiddling, a bit of banjoing, a bit of photography—bits of everything by turns, and nothing long. This is an age of "bits," as regards culture—little "bits," *l'age de morceaux*. One of our most prosperous periodicals is, you know, called *Tit-Bits*. I have no digression to apologise for, as the curse of pretty trifling often follows the photographer into the field, where perforce he goes in for bits—lovely bits forsooth though they be, and full of detail, don't-cher-know. Let me warn him, however, if he indulges much in this sort of thing artistically, he is a lost creature, for he will neglect, and gradually ignore, the higher claims of something greater—the subtle charm of distance midst the rounded hills, the solemn stillness of

* Read February 27th, before the Society for the Encouragement of Fine Art.

the darkening woods, the noble sentiment of landscape, the mystery of light and space. In his hunger for detail his camera so readily gratifies, he is in danger, I repeat, of overlooking the main elements of a grand picture. Pity, indeed, if in this search after ever so enchanting "bits," he and his following become blinded to higher intellectual claims. Surely it were idolatry to worship a goddess at every corner, and forget a uniting and overruling divinity.

From this it will be gathered that I am not of those who think it is in "the very nature of photography to degrade natural appearances"; indeed, it should be known to the merest tyro in the art that where this is the case, the photographer has but himself to blame for having taken his picture with a wrong lens, altering the perspective of the scene, widening his foreground to the sacrifice of his distance. Of course your one-lens man is constantly doing this, and it would seem as though he were often one-eyed, as he does not himself see the distortion. It is, however, when he comes to photograph animals, or the human figure, that these considerations first dawn upon him seriously, especially when he finds a photograph of a horse, for instance, with a head and neck of monstrous dimensions, but with the legs and hind-quarters of a pony. Then, of course, it is admitted that something is wrong somewhere. Only the other day I saw exhibited in the Strand a photograph of this description, certainly not quite so exaggerated, but still defective in proportion, while in all other respects it was really a beautiful work; but it is precisely this beauty that misleads our taste, for, as Pope says:—

> "Vice is a monster of such frightful mien,
> That to be hated needs but to be seen;
> Yet seen too oft, familiar with her face,
> We first endure, then pity, then embrace."

That there are difficulties to overcome to obtain a good photograph goes without saying, and those who cannot, or will not, draw, but rely on the camera as their means of expression in fine art, must be prepared to meet with some disappointment. The camera is a great mannerist in art, and it needs not only very great technical skill, but adaptive artistic capacity of no mean order, to become *facile princeps* with it, and to rise above mannerism; hence the reason why, though photographers are many, really fine photographic pictures are so few.

It has been said that "photography is an operation of chemistry more or less directed by taste." Quite so; this is no disparagement, however, for art of all kinds is brought about by operations, either chemical or mechanical, more or less directed by taste, and it must be admitted that where some of these operations are more difficult of control than others, it simply makes them, when successful, redound the more to the credit of the operator. But we are not now talking so much about the operations as of the taste that directs them. And again, we are face to face with the relation between fine art and photography, for if you set out to take a photograph, unless as a mere topographical memorandum, it is presumably with the idea of obtaining what, for want of a more accurate definition, we term a picture. But to get a picture presupposes a large amount of the artistic faculty, either inborn, or developed by wide education and knowledge of art. The mere use of the camera will not give you what you want, any more than the use, however mechanically excellent, of the pencil. Nature is not art; it must be seen with artistic eyes, or presented by artistic means. Children and naked savages have an advantage over us here: they make nature artistic, because they invest it with their superabundant imagination, untrammelled by the conventions of the artificial and the commonplace. They are the true impressionists, and make a clean sweep of all that detail that we so much require to help our halting fancy. Suppose, for a moment, it were possible to bring back a Viking cruiser, some early hardy Norseman, and give him half an hour's run on the underground railway; if he survived, we know precisely what he would do when he got back to his crags and peaks or native swamp: he would take a deep, deep draught of something; he would free his mind from all considerations of block systems, Westinghouse brakes, and times of trains; he would string his harp as it had ne'er been strung before, and he would sing, until his eyes were bleared and his beard like a waterfall, a saga that, both in artistic truth and poetic intensity, would ring the world through till the crack of doom. Now I do not believe there are many season-ticket holders who could do that. No; as civilization advances, imagination recedes, in many minds "great conjuration," and very "mighty magic" is needed to call up in them the ghost of an idea outside the actual facts of a scene, commonplace or otherwise. This conjuration it is the function and privilege of the artist to supply; he may do it by pen or pencil, chisel or graver, or with the camera to a certain extent, if he choose, but he never can do it at all unless he possess the abracadabra of his art, call it genius, divine afflatus, what you will: merely focussing a view and developing a plate will never succeed in charming a beholder with the result, unless something of this sort has guided the photographer, and been present with him throughout all the operations—that something that you may get a smattering of, at least, in the National Gallery, but which is never learnt in the dark room.

Coleridge has called painting "something between a thought and a thing." I think it would not be amiss if photographers, professional or amateur, would always remember this definition when they focus a view or subject. In these days of perfect appliances, dry plates, and ready-made developers, they are, as a rule, pretty well sure of the "thing" they focus; but how about the thought?

Ladies and gentlemen, the photographers are not all to blame, be they amateurs or professionals. We members of the Society for the Encouragement of the Fine Arts—have we not sinned also? Have we not looked too much for the thing, and gloated over it in our picture exhibitions? Of course we have. Our art training throughout the country is one persistent effort to get the thing, at any rate, and not to trouble much about the thought, leaving it very much to chance, and to come, perhaps, of its own accord. But it does not come. Year after year goes by; the *thing* increases and multiplies, but the *thought*, even when it presents itself at all, is snubbed and passed over for the most part almost as an impertinence.

No, this is not an imaginative, but a localizing age. A writer, in a recent number of the *Athenæum*, instances and comments on this very ably. He says: "Lord Tennyson informed a recent visitor to Farringford that Locksley Hall is no particular hall, and the Moated Grange is no particular grange. But the localizing craze is already busy upon them. So profoundly undramatic is the temper of our times, that a poet is not considered capable of imagining any dramatic action." Had a "Midsummer's

Night's Dream" been written by a contemporary poet, the public would have demanded, and the literary and artistic providers would have provided, a photograph from life of Titania, and an accurate water-colour drawing 'of the bank whereon the wild thyme blows.'"

Let us, then, try and encourage both the "thought and the thing"—the idea and its realization—in future, and, above all, never encourage the *thing* without an adequate proportion of *thought*: we shall then do a great deal to stop reckless pot-shotting in photography. The dry-plate makers will suffer a little, indeed, as they will sell a few thousand dozen less plates each year; but not only will there be a much nearer alliance between Fine Art and photography than there has ever been, but Fine Art itself will be benefitted in every branch, as we shall have the ineffable satisfaction of seeing all picture exhibitions reduced to reasonable proportions, and even sculpture in England may reveal another Galatea. The thing will be inspired with a thought.

In saying thus much on the intellectual side of the question, let me not be considered to ignore what has already been accomplished by photographers and amateurs who have really been artists. An exhibition of the works of the late Mr. O. G. Rejlander, shown in the rooms of the Camera Club, sufficiently indicates, among many failures, many successes in an earnest endeavour and hope to make the camera subserve a very high art ideal indeed; and when we consider that these works were taken under the disadvantages and with the extra labour of the wet or collodion process, we must allow them the greater acknowledgment and praise. At the same time, we cannot help wondering the more, that this higher art ideal has been, so to speak, lost sight of in figure composition, excepting by a few well known names, and this, too, in an age of manipulative simplicity that Rejlander could hardly have dreamt of. All praise, then, to them and he if, ever persevering, they seem to have borne in mind, with Browning, "A man's reach should exceed his grasp, or what's a Heaven for?"

It must always be borne in mind, however, in a materialistic age, that the spread of artistic capacity can never be expected to keep pace with scientific progress, and this has, doubtless, been an obstacle to the higher successes in photographic art; for while there are all manner of aids to scientific research, and the accumulation of scientific fact has contributed to the continuous and progressive excellence in the production of what we have termed the "thing," the thoughtful part of the subject, as we have seen, is a matter of individual effort, and of course of a much slower and laborious cultivation, dependent on a multitude of contributive and, at first sight perhaps, irrelevant studies, besides the divine afflatus, or genius, as it rarely occurs; and where it does not occur, the personal trouble and observation necessary are all the more laborious, before arriving at the most mediocre capacity for compiling or creating the elements that shall stir that something in a spectator which assures him he is in the presence of a work of art.

Now let us see where we are arrived. Firstly, I have endeavoured to show that photography has exercised, and is exercising, for good or ill, an influence on fine art, and that this influence has not been altogether for good in the past, more especially as having occasioned an attention to detail to the prejudice of unity and breadth. Secondly, I express a confident belief that an increasing love of fragmentary studies by photography and painting is tending to narrow the scope of art generally. Thirdly, I insist that, in regard to Coleridge's definition of painting as being "something between a thought and a thing," the *thought* in this country is too often a minus quantity. Moreover, although we have seen that very earnest endeavours have been made from time to time to achieve a very high art ideal indeed with the camera, yet much carelessness and want of training, external to technique, have brought it into artistic disrepute, and made it very productive, in an artistic sense, of bad work. For this reason it behoves us to be more eclectic, not only for the sake of the future of photography, but for the sake of art itself, and it would be well were the photographic societies to offer more prizes for really artistic work, and obtain, where necessary, acknowledged artistic assistance in making the awards.

I have admitted already that the camera has a place among art methods as a means of expression, if photographers choose to make it so. This has been often disputed, and not without great show of reason, and it must be allowed that, while as a means of illustration it is boundless in scope and detail, as a means of expression it is very limited indeed, and can never, in that sense, hold an equal place with brush, pencil, chisel, or graver, implements which, in the nature of things, mostly being moved directly by the artist's hand, in nervous continuity with his brain, express his thoughts more directly. Thus an etching, equal in breadth and light and shade generally with a photograph of the same subject, though the photograph shows an unquestionably greater veracity in detail, the etching will always command our greater interest as being far and away the greater work of art. Another important disadvantage in photography is the inalterability (in general) of the model, susceptible always of modification in other artistic modes of expression.

To show the great appreciation I have for what photography has already done as an assistant to art, I cannot do better now than afford you a few more glimpses of some of my own studies, and those of gentlemen who have kindly lent me some of theirs for the same purpose, not, however, pretending for a moment that they (at least mine) at all adequately illustrate the possibilities the camera may have.

VOCATION OF AN AMATEUR PHOTOGRAPHER.

BY H. POCKLINGTON, F.R.M.S.

The paper defined an amateur photographer as one who practised photography from his love of it. A man did not cease to be an amateur because he chanced to sell a few prints now and then, or become one through photographing for exhibition purposes with the single hope of coming prizes.

The vocation to which an amateur photographer was called consisted:—1st, in following up the line of the history of the relation between amateurs and photography by doing what he could to improve our knowledge of the principles underlying photographic practice, perfecting the technique, and devising new methods; and 2nd, in doing practical work, such as photographing old buildings, historic remains, incidents of daily life, which though of no great interest now, would be excessively valuable to posterity, and especially in photographing carefully year by year those phases of our national life, such as peasant life, which were slowly passing away. In brief, the paper said that the true vocation of an amateur photographer lay in helpfulness.

* Abstract of a paper read at the Yorkshire College, Leeds.

PHOTOGRAPHING THE FORTH BRIDGE.

Last Tuesday the Forth Bridge was opened by the Prince of Wales, and just at the time that this great structure has been completed, the following account of the photographing thereof, written by the editor of *The Journal of the Photographic Society of India*, and published in the Journal, will be of additional interest: —

When at home the other day, I remember being profoundly impressed with the truth of this moral whilst attempting to take within the limits of a 7 by 5 plate some photographs indicative of the colossal proportions of the Forth Bridge.

The resident engineer, Mr. Cooper, had kindly allowed me to photograph the bridge from any part I chose; and no sooner had I landed on one of its enormous piers than my difficulties began. There was no getting far enough away from any part of it. Looking up through the thicket of cross bracings and girders branching out from the gigantic booms, I could see the busy workmen far above me clinging about them like bees. To the naked eye the immensity and grandeur of the noble structure was all present; but when I attempted to focus anything which required much tilting of the camera upwards, the picture on the ground glass became like the stereoscopic puzzle I have been describing, exaggerated and unmeaning. So, wisely refraining from the impossible, I took all I could see from eye level which afforded the chance of a view.

A westerly gale was sweeping the rain clouds down the Firth and screaming through the great bridge on the morning of my visit, rendering it impossible for good photography. But it was my only chance of securing pictures, so, having taken some from the pier level, I was spirited aloft, bag and baggage, in a cage hung from a wire rope, and swiftly deposited on the landing stage at rail level 150 feet high. Here I was conducted by an obliging official to the extreme bed of the cantilever, where the workmen were engaged in adding girder to beam and beam to girder, every day lessening the gulf intervening between the cantilevers. Amidst the hissing of steam cranes, the clanking of the rivetters, the cries of the workmen, and the roaring of the wind, I set up my camera in a sheltered nook to leeward of a huge boom, and, having focussed across the chasm, waited impatiently for a lift in the clouds.

"How would it be," shouted my guide through the temporary fog horn he made of his hands, "were one of the workmen to get out there in the foreground?" pointing to the very outermost cross girder, under which 150ft. below could be seen the muddy water rushing like a mill stream. "A magnificent idea," roared I incredulously in return—"if his life is insured!" Before I could expostulate, he addressed one of the workmen near—"I say, *Wullie*, just slip along that girder a bit, and let the gentleman take your portrait." *Wullie*, who was bolting together a piece of the ironwork, laid down his tools with an "Aye, aye sir," quietly walked out on one of the overhanging beams. Reaching the extreme end, this amateur Blondin then deliberately buttoned up his pea-jacket, and, cramming his peaked cap well down on his head, got astride of the girder, propelling himself with hands and legs right out to the centre. *Wullie* was now exposed to the full force of the wind and rain; but turning his bearded face towards us with a good-humoured smile, he signified his sense of being photographed by stiffening himself into an attitude of muscular rigidity too dreadful to see. However, there was neither time nor opportunity to get him to look less like the girder on which he sat, so, holding up a warning hand, I gave him twenty seconds' exposure, and he was soon back, working away with his tools again. But in my endeavour to pierce the murky atmosphere, this bearded son of Anak is, I regret to say, a mere smudge.

After several attempts at photographing the long vistas of the bridge at rail level I was personally conducted by my obliging companion to the extreme top of the cantilever. To get there we entered a lift similar to the one below, and, on the signal being given, up we went at a great pace, swaying through the keen wind and penetrating rain. I would have given much to have had a good hand camera and a clear day, for the opportunities for pictures on that upward journey, now that the bridge is completed, are gone for ever. On reaching the top, a fresh surprise awaited me. I had been cogitating as to how I could possibly take pictures in such a howling wind, and was astonished to find that I stepped out of the cage into a comparative calm. Here we were with the clouds within arm's length, so to speak. I could hear the wind blowing, and see the rain swishing about. We were in it all, and yet sheltered from it! This phenomenon was presently explained by my companion going to the windward side of the staging, and holding his handkerchief over the rail. There it snapped and wriggled about in a strong upward wind current induced by the obstruction which the structure offered to the blast. This, rushing upwards, formed an invisible arch of shelter over us before speeding on its way. Under this strange refuge and in spite of the rain, I managed to secure some fairly good negatives of the bridge and surrounding country, precious not only for the reminiscences they recall, but also because no photograph, now the bridge is finished, can ever be taken again from its summit.

The painting of this enormous mass of steel is a work the magnitude of which may be faintly estimated from the fact that there are some forty-eight acres of surface to go over with the brush; and parlous besides, seeing the paint has to be applied after the removal of the fixed stagings. Hence the painters have to be raised and lowered on movable stagings hung wherever required. From the summit where I stood, looking down through the forest of framework, I could see the painters no bigger than ants working far below. Here I had pointed out to me the scene of one of the many thrilling incidents attendant on the construction of the Forth Bridge, which I consider appropriate to relate in these pages, seeing the hero of it was a professional photographer, and the story is quite true.

Five painters were painting down one of the colossal booms which radiate from the base of the cantilevers. The stage they were on was suspended near the very top, when, without warning, it suddenly gave way. Three of the poor fellows, long before they reached the bottom, were literally smashed to pieces against the interlacing framework which lay in their way. The other two providentially caught at some of the cross bracings immediately underneath them. There, suspended by their hands, they clung with all the energy of despair. The resident engineer, Mr. Cooper, saw the accident from another part of the bridge, and rushed with others to the rescue. Now, to get at the poor fellows, some of the heavy planking of the overhead staging had to be ripped off. This was done as quickly as a hundred nervous hands could tear it away, and presently, down far underneath, could be seen one

of the men. The other was out of sight, and, to get at him, still another piece of heavy staging had to be cut away. Meanwhile, hasty preparations were made to rescue the one in view; but he, looking up at them, cried out, "Leave me, and save the other man. He is done; I can hold out a bit longer." Thus re-assured, they ran, and lowered down a man with a rope, to which the exhausted painter, on the point of letting go his hold, was securely fastened and hauled up into safety. They then returned and rescued in like manner the brave fellow who had so gallantly risked his life for his comrade. The hero of this adventure was a poor photographer's assistant, called Toddy, who, being out of work, had to accept this perilous painter's work to keep him from starving.

Perhaps the most touching part of the tale was its sequel. Toddy, after this miraculous escape, went to Edinburgh, where he found work in a photographer's studio; but, it having transpired that he had been working on the Forth Bridge, his employer actually turned him into the streets, on the plea that he dared not entertain the services of an artist who had been known to work as a common labourer on the Forth Bridge! Mr. Benjamin Baker, the eminent engineer and designer of the Forth Bridge, has told this story in one of his lectures, and a subscription was being raised for the brave Toddy when I left for India.

PHOTOGRAPHY IN AN AGE OF MOVEMENT.*

BY FRIESE GREENE.

Our age is not only an age of movement, but of movements. None of us who aspire to the keeping pace with the times can afford to be indifferent to photography—it is something which sharpens our intellects, and brings things to our notice whith we are always passing, but never would have noticed but for the knowledge of photography. Besides, there are heaps of things we could never notice—because we never see them—without the aid of photography; so we will call photography an extra bit of sight and an extra bit of intellect, which no doubt it is. And it is not easy to foretell the future of photography offhand, nor yet any other way, so we will keep to the present uneasiness (which is a sure sign of advancement), and dwell upon one or two subjects which are shaping its future.

Now the first is, the interest taken in it by all classes—high, low, rich, and poor; the second is its thrusting its prying eye into everything within the world and, I may say, outside of it too, for it affords the means of depicting the magnitudes and the places of stars which must otherwise have been quite unknown to us. There are still other more marvellous applications which the camera I am about to bring before you this evening, or at least something akin to the camera. It will be able to investigate all the movements of the spider making its web, or a cloud as it forms, and thousands of other things too numerous to mention, because you can take 600 pictures a minute, on one continuous roll of film, by merely turning a handle. When I first saw a roll of paper go through at the rate of ten a second, and stop an instant when each exposure was made, I felt like a child over new toys, though I was as sanguine as possible, notwithstanding that there was a slight feeling within me of doubt if it would really go on doing it. I think my enthusiasm was more than usual over such things. Mr. Mortimer Evans has improved and improved upon it so much that I am positive the results will have a tendency to bring forward a new kind of photography; in fact, it will make an epoch which will be immensely interesting, for the movements of the centipede, the vibrations of the heart, will have to submit to its power of rapid delineation.

Now the next subject I shall connect with this paper, or at least the movement or movements of photography, is the ladies, for they are pushing themselves forward in a marked manner. The interest they take in photography, the patience with which they work, and the amount of pains bestowed by them in the different departments, is something alarming, and we men must look to our laurels when we bring the words comparison and competition into notice, for all advancement is brought within the scope of those two words—two words, I should say, that are shaping a future in photography. The ordinary view held by the majority of people as to the intellectual power of women as compared with men is not very encouraging to the fair sex (still, this is comparatively a bygone notion), whose smaller brain is held to be positive evidence of smaller mind, or of no mind at all. This idea is still cherished by some, though in the face of everything tending to show the opposite it has taken a long time to convince others that women are truly capable of rising to any position above that of slavery, socially and physically. In my opinion it will not be long before we shall be convinced of the fact that women, when given the same intellectual advantages and education as men, will prove intellectually equal. I know it is difficult to realise in the increasing battle for existence that men can be confronted by rivals. An argument may be brought forward that these smaller, delicate beings, with whiter hands and long hair, are physically and therefore mentally incapable of taking an equal place with men in the intellectual world. Well, what they may be I do not know, but I do know this, as regards their intellect in connection with the fascinating art of photography, we shall find a hot competition, and one in which, if we do not help them to win a place, they will win a place for themselves. If you watch closely you can see women's intellect brought into use day by day in connection with photography.

Women, having had greater educational advantages in the last few years, have proved themselves able to appreciate and to bring their refined and cultivated intellect to bear upon the art of photography, and we only want another Mrs. Cameron to set the ball rolling. She was one who was earnest in her work in photography, as her results show. I wish I had some here to-night to bring before you. She was one evidently who knew that true knowledge can but make the learner more humble and more willing to learn. A weakness may hinder, but we must all bear in mind it does not crush mental effort. So let me impress upon you, the members of the Bath Photographic Society, to encourage ladies to join the Society, and, whatever you do, do not ignore their work. Look at it two or three times, compare your ideas with theirs, and you will find you will have soon other ideas cropping up.

Now, a few concluding words to this Society. Can you not begin a museum of photographic relics? and within this museum can you not start a weekly class for young ladies and gentlemen to learn photography, and let some of the members teach them?

* A communication to the Bath Photographic Society.

REACTIONS OF VARIOUS DEVELOPERS.—By L. van Neck.

	Hydroquinone. Dr. Byck's Yellowish crystals.	Pyrogallol. White sublimate.	Pyrocatechin. Greyish.	Hydroquinone. White needles.	Eikonogen. Yellowish crystals.	Resorcine sublimed.	Hydroxylamine hydrochlorate. White crystals.
Taste ...	Sweet; slightly bitter.	Slightly bitter.	Bitter.	Sweet; slightly bitter.	Saline.	Sweet.	Acid.
Solution ...	Colourless.	Colourless, becoming brown.	Colourless, becoming greenish.	Colourless, becoming slightly brownish.	Colourless, turning rapidly dark brown.	Colourless.	Colourless.
Reaction ...	Neutral.	Acid.	Acid.	Neutral.	Neutral.	Neutral.	Very acid.
Action of Heat.	Fusible and volatile.	Fusible and volatile.	Fusible and volatile at 240° C.	Fusible and volatile.	Fixed residue, carbonises and becomes incandescent, leaving a white saline residue.	Fusible and volatile.	Fusible and volatile.
Solution of Ferrous Sulphate.	Nil.	Blue coloration.	Nil, turns green after long standing.	Nil.	Violet colouration.	Nil.	Nil.
Solution of Ferric Chloride.	Nil.	Dark brown colouration, becoming violet with excess of sodium carbonate.	Emerald green, becoming violet with a little sodium carbonate, and red with excess of same salt.	Nil.	Yellowish green, becoming rapidly yellowish brown, and then dirty-brown with sodium carbonate.	Violet blue.	Nil, decolourises the ferric chloride.
Tincture of Iodine.	Decolourises the tincture.	Red-brown colouration.	Nil.	Decolourisation.	Reddish-brown colouration.	Instantaneous decolourisation.	Decolourisation.
Solution of Plumbic Acetate.	Nil.	White precipitate.	White precipitate.	Nil.	White precipitate, turning black.	Nil.	At first nothing; then a precipitate forms.
Solution of Potassium Carbonate.	Yellowish colouration, turning brown in the air.	Yellow, turning blackish brown.	Yellow, becoming brown.	Yellow, turning brown rapidly.	Yellow, turning brown very rapidly on shaking.	Nil.	Nil.
Solution of Silver Nitrate.	After a time a grey precipitate; solution colourless.	Slow reduction to metal; solution brown.	Very slow reduction; solution yellowish.	Slow reduction.	Instantaneous reduction.	Nil.	White precipitate.
Dilute Hydrochloric Acid.	Nil.	Nil.	Violet colouration.	Nil.	Rose coloration in diluted solution, becoming greenish on addition of ammonia.	Nil.	Nil.

These reactions take place in a solution containing ½ per cent. of the developing agent.—*Bulletin Belge.*

TONING WITH METALS OF THE PLATINUM GROUP.

The attempts heretofore made to tone silver prints with platinum have not yielded satisfactory results. In solutions of platinic chloride, the silver image rapidly becomes pale and disappears, for the silver is converted into chloride, and is not replaced by platinum, that metal being simply reduced to platinous chloride. But if a solution of platinous chloride be employed, and, contrary to the requirements of a gold toning bath, this bath be rendered acid with mineral or vegetable acid, the silver prints immersed in it quickly acquire a black tone, passing through intermediate shades of an agreeable purple. Two atoms of silver are then replaced by one of platinum.

Palladium, iridium, and osmium, under the same conditions as the platinum, furnish characteristic tones, and the general method of preparation of the baths appears to be based on the principle that toning by metals of the platinum group must be conducted in acid baths, and the metal must be in the lowest form of combination.

Platinum Toning.—The soluble and very stable chloroplatinites make excellent toning baths. Any of the alkaline chloroplatinites can be employed, the following formula serving as a type :—

Potassium chloroplatinite	1
Sulphuric acid	5
Water	1,000

The sulphuric acid may be replaced by hydrochloric acid, but since the latter renders the chloroplatinites more stable, its quantity should not be greater than 3 in 1,000, or, by organic acids, excepting such as formic, tartaric, or oxalic, which exert a reducing action on the platinum salt, especially under the influence of light.

The toning bath may be prepared directly from platinic chloride by boiling it in the light with an appropriate reducing agent in the exact quantity required to reduce the salt to the platinous condition.

An excellent toning bath may be thus prepared by boiling in a glass flask a mixture of two grams platinic chloride in solution, with one gram sodium neutral tartrate, until the yellow liquid assumes a dull grey colour, then making up the solution to one litre, and adding the proper quantity of acid.

Ruthenium and Osmium.—I have not succeeded in obtaining with ruthenium and osmium other tones than yellow, differing but little from the untoned prints.

Palladium.—A solution containing one gram sodium chloride, two grams palladious chloride, and 200 grams acetic acid to the litre of water, rapidly blackens silver tones, but the paper takes a yellow tint, which, even after bleaching by five per cent. ammonia water, reappears more or less rapidly after fixing, and destroys the value of the prints.

Iridium.—The iridium tone resembles that of gold. The bath may be prepared by dissolving one or two grams of iridium and platinum double chloride in one litre of water, and acidifying as with platinum. Silver prints tone slowly in this bath, but the whites remain pure and hard; some soft, violet tones are obtained.

Osmium.—This metal gives tones quite characteristic. The bath may be made by dissolving one or two grams of ammonia chlorosmite and twenty grams acetic acid in a litre of water. Prints immersed in this bath take first a sienna brown tint; this colour soon becomes modified, first, in the half tones of the image, and changes to a more or less intense sky blue, which affects the whole print. If, instead of allowing the prints to become blue, they are withdrawn from the bath as soon as the blue begins to appear in the whites, a very curious result is obtained after the fixing. Besides the whites of the photograph, two tones are present—a light brown in the deep shadows, and a blue in the half-tones. With mineral acids, the final tone obtained by the use of osmium is not blue, but violet, and this tint appears even in the whites of the print.—*Comptes Rendus.*

A NEW PHOTO-LITHOGRAPHIC TRANSFER PAPER.

This new transfer paper has been used with good results in the Vienna Royal Institute of Photography and Reproduction. A colour is used on it, prepared by Mr. Adalbert Franz, which is put up in foil tubes, like oil colours. The paper carries, as usual, a thin coating of gelatine. The colour is thin and very fatty. Mr. Franz gives the following directions for its preparation :—The sensitising solution is made up of 50 gm. (in winter 60) of bichromate of potash, dissolved in 1,000 gm. of water. After this is completely dissolved, add aqua ammonia until the solution is a bright yellow. The paper is soaked in this solution in a dark room until it is thoroughly impregnated and soft, and then hung up in the same room to dry.

For fine drawings and autotypes, the paper should be squeegeed on to a thoroughly cleaned glass plate; a sheet of waxed tracing cloth or rubber should be laid between the wet paper and the squeegee to avoid rubbing away the former. The exposure should be ample. After exposing, the sheet is fastened on a board with thumb-tacks, and the colour applied as directed below. It should be spread all over the print, very thinly and equally. After about three minutes' immersion in the water the highest reliefs begin to appear, and washing is then continued until all the detail is out, the print finally being laid upon a glass plate and rubbed with a soft sponge or a tuft of cotton-wool until completely developed. Care should be taken that everything is very clean, in order to avoid spotting the whites of the print.

For transfer to zinc the paper must be soaked in a two per cent. solution of alum and washed again. If the colour leaves the print in washing, exposure has been too short. A property of this paper is to be noted—the formation of a hard film on the gelatine in case any of the solutions are too warm, which repels the colour. The sheet may be anchored at the corners by little bits of lead, to prevent its rolling up during development. The colour is squeezed out of its tube in a semi-fluid condition, and is dissolved in a solution, kept ready, of equal parts of benzine and turpentine. Then, with a broad brush or a very soft sponge, it is evenly spread over the print in a thin and equal coating. It should only be used well thinned down with the oils.

Before transferring, the print is laid between sheets of wet blotting-paper until it is soft enough. It should be run through the press under considerable pressure. The colour, it is said, transfers well to zinc, as well as upon stone.—*Photo. Correspondenz.*

Views Wanted.—Mr. R. E. Mack, 24, St. Bride Street, E.C., writes :—"I am wanting some good views of beautiful scenes and landscapes. Could any of your readers recommend one or two really good photographers of these subjects?"

Notes.

A city contemporary is rather behind the times. In referring to some old houses near Crutched Friars, it suggests that these are subjects which the "Society for Photographing Relics of Old London" should interest itself in. This Society has now been extinct some two or three years, as has been regretted more than once in these columns. As for the series of photographs, the result of some years working, we understand, they—or a selection of the most interesting—will shortly be issued to the public in the form of reproductions. The size will be much reduced, and the idea is to form a kind of gift book of an ornamental and tasteful character. Mr. Monks, the secretary of the defunct society, will, we believe, edit the series. With appropriate letterpress well done, the volume should prove very attractive.

Photography, we suppose, has been productive of more verbal quips and cranks than any science one could mention. A pun by Dr. Oliver Wendell Holmes is the latest instance. He used to be an amateur photographer, and whenever he presented a picture to a friend, he wrote on the back of it "Taken by O. W. Holmes and *Sun*." Perhaps the neatest example of word play is that furnished by the late William Brough, who, when shown a photograph of a friend taken by a photographer named Death, exclaimed, "Ah, taken from life, of course!"

Mr. Vicat Cole is painting the Thames from the point of view which fifty years ago or so used to be considered the only one; at least it always figured in the illustrated topographical books of London of the period when steel engravings were most in vogue. We refer to the view as seen from the Observatory Hill, in Greenwich Park. It is rather curious that of late years this singularly picturesque view of London, with St. Paul's as the conspicuously central object, should have been so neglected by photographers. Possibly the reason is that with the enormous steam boat traffic, and the multiplication of factories on the river side, the atmosphere is never free from smoke. This view of London without St. Paul's would be worthless, and it is probable that the times in a year when St. Paul's is visible from the Observatory Hill could be counted on one's fingers. Mr. Cole's experience is, we understand, of this nature. He is anxious to secure an afternoon effect, but though he has visited the place many times, on only two occasions, and then for a very brief space, has he seen the cathedral.

Photography in France still keeps up its character as a political barometer. Those who regarded the escapade of the Duc d'Orleans as the outcome of a boyish impulse must have been somewhat undeceived when they saw the shower of portraits—mostly photographs—with which Paris has been deluged. The inference is that the so-called escapade was the result of a Royalist organization, as these portraits must have taken a long time preparing, and the sudden avalanche can only have had for its object a political demonstration. To anyone ignorant of party tactics the appearance of these photographs might seem an indication of public feeling, but of course it means nothing of the kind.

We have not the slightest objection to supplying our non-photographic contemporaries with information, but we are inclined to raise a protest when our paragraphs are appropriated in wholesale fashion and made to pass as original. In the *Artist*, a sixpenny monthly magazine, for February is a special column headed "Photographic Notes," consisting entirely of unacknowledged paragraphs clipped *nolens volens* from our issue of January 17th.

Jan Van Beers is as lucky over his law suits as he is over his paintings, some of which have made remarkable hits. He was once accused of producing his well-known picture, "La Sirene," by painting over a photographic basis. He brought an action against his slanderer, and won his case. Since then certain art workmen, once in his employ, accused him of signing paintings made by him and others, and selling them as his own. He went to law, but was defeated, one result being that Sedelmeyer, the American art dealer, who exploited Munkacsy's "Christ before Pilate," in the United States, repudiated the contract he had made with Van Beers to allow him the use of his gallery in Paris for an exhibition of his pictures. The artist, however, carried his case to a superior court, and there the judgment of the court below was reversed. On being cleared of the charge of manufacturing spurious "Van Beers," he immediately commenced an action against Sedelmeyer, and has just won the day, the art dealer being compelled to pay damages and costs.

Probably these legal proceedings have prevented the holding in London the usual exhibition of Van Beers' artistic eccentricities and horrors, which had come to be quite a metropolitan institution. Of course it is annoying to be charged with forging one's own productions, but the system of employing others to do the minor details, the characteristic touches being reserved for the master, is by no means an uncommon one. Vandyck, as a writer in the *Times* proved the other day, was really a wholesale manufacturer of portraits. Indeed, in no other plan than by a subdivision of labour could he have executed the enormous number of commissions which flowed in upon him. How much of his own work and how much that of his assistants is to be discovered in his various paintings, only experts can decide; but it may be taken, as a rule, that the arrangement of the figures, the lighting of the hands and face were his, the drapery being left to others. In this respect the system is analogous to that pursued by the busy photographer, who interests himself only in the posing and lighting, his assistant performing the other operations.

PHOTOGRAPHY IN GERMANY.

BY DR. H. W. VOGEL.

Water Lichtdruck Process—Magnesium Flash-Light—Police and Jury—New Magnesium Flash-Light—The Grammophone and Photography—Restoring Yellow Albumen Prints—Yellow Fog on Dry Plates.

In my letter, published December 28th, page 743, I mentioned Husnik's water Lichtdruck process. This process is a curious one. The Lichtdruck process is based upon the principle that a gelatine chromated film becomes insoluble in water by the action of light, but obtains the capability of absorbing fatty ink. If, therefore, a chrome gelatine film is copied under a negative, the parts through which the light can penetrate will absorb fatty ink, whereas the parts on which the light has not acted will not absorb ink. They remain, however, pervious to water, *e.g.*, for water-colours.

If, therefore, a copy has been made under a positive, and the film is rolled with water-colour, this will adhere to the parts which were not acted on by light. This is the principle of the water Lichtdruck process. This has not yet been applied practically as far as I know.

In my last letter I wrote to you about the new magnesium blitz studio. Such a one has now been fitted up at the head quarters of our police to take the portraits of criminals instantaneously. They are taken to this studio, which has the appearance of an ordinary room, and asked to take a seat. Before they are aware of it the proper focus is taken, the magnesium flashes, and their pictures are ready to adorn the album for criminals.

A still more extensive application of photography in the judiciary department is intended to be made.

The many murder cases which have occurred lately point to the necessity of photographing the locality where the murder took place. These photographic pictures are to give not only a true description of the locality, but to reproduce the original position of the corpse, &c., as far as obtainable. They should be made in sufficient numbers to serve at the preliminary investigation as well as during the jury trial, and be handy to judge, jury, experts, and defence. This arrangement would furnish the most correct proof, as such representations would facilitate very much the comprehension of the records and the testimony of witnesses, while otherwise incorrect ideas as to position and locality might often be formed. The photographic pictures seem to be of particular advantage to the jury, who, with their aid, are much better enabled to follow the proceedings. It might, therefore, be recommended to take views of external wounds which are discovered on the corpse for the better understanding of medical experts. If photography is introduced for the purpose above-mentioned, it would have to be applied the same as in railroad accidents and conflagrations. Wherever such a photograph could be handed to the jury, it would simplify the proceedings considerably, as a good many questions might be avoided thereby. The photographic picture would also be of particular advantage in complicated lawsuits.

That the magnesium light is here of importance for views of dark interiors need hardly be questioned. The latest now is the simplifying of the magnesium lamps, so that any common oil lamp can be easily arranged to serve as a magnesium flash-light. This has been accomplished by the "Fulgur" apparatus of Dr. Leonhard. This new flash arrangement is such that it can be attached to any lamp with a chimney, and that here the magnesium is not blown by a cooling forced air-pressure into the lamp in the direction of the escaping gas from the lamp, but, on the contrary, in an opposite direction, and is thrown in by a mechanical appliance. The magnesium is completely burned up with an intense flame; no unburned magnesium powder can fill the air. Black spots on silvered paper are oftentimes caused by the magnesium powder. The arrangement consists of a kind of sling, fastened by means of a spring and pneumatic release, and can be attached to the upper end of any oil lamp or gas burner chimney. If several flashes are to be produced at the same time—in groups, for instance—the several lamps containing the arrangement are connected with tubing and bulb; thus all the lights of a large chandelier can be set off with a single pressure for an instantaneous flash.

The apparatus may remain on the lamp for hours before and after use without the slightest injury. As the burnt magnesium will only adhere to the inside of the chimney as an easily removable dust, one is enabled to take photographs at any time of the day or night in the most luxuriously fitted up salons without the least disturbance to the occupants.

The flashes produced in oil lamps are not so powerful as those from gas burners. Still, two oil lamps are sufficient to produce a single portrait just as good in every respect as one taken by daylight, and they can hardly be distinguished from each other.

It may be mentioned here expressly that it is of no advantage to use too large a quantity of the powder. A few centigrams are sufficient.

To photograph by magnesium light, not too large a room with light walls is the most suitable, saving considerable light in such a place. Portraits of one or two persons can be well exposed with two or three oil lamps or one or two gas lamps, even with a not very rapid objective. Both lamps should be placed on the light side, about $\frac{1}{2}$ m. above the height of the eyes, at a distance of $1\frac{1}{2}$ m. for bust pictures, and for two-thirds or full figures a little further off, so that objective, object, and lamp form an angle of about 45 degrees. The shadow side is lit up by a white screen, to be placed at more or less distance from the object. In this way all light effects can be obtained easily; for instance, by placing the lamp near by, an illumination of plastic effect can be had. An attentive operator can easily regulate the effect of his illumination by the previous picture.

For groups, four or more lamps should be employed, according to the size and condition of the room and the number of persons. They are divided in about the following proportion:—With four lamps—three on the light side, and one on the shadow side, all about $\frac{1}{2}$ m. above the eyes, the distance to be in proportion of how much of the object is to be taken. If the lamps are so placed that no direct light will fall into the objective, then the holder and objective may be opened without the slightest danger of fogging the plate, and, bulb in hand, the suitable moment may be waited for, when the picture is taken. I have observed, oftentimes, how a jovial party was taken at night with this "fulgur" apparatus, using the same lamp that served to light the room. The mirror hanging on the chimney protects the objective from directly penetrating light.

Everybody knows Edison's phonograph. This has now a competitor in the grammophone of Jacob Berliner, which admits the application of photography.

The grammophone reproduces the sound—the human voice as well as music—faithfully, but not always without a disturbing noise. The grammophone is particularly successful in the reproduction of pieces of music of several instruments, which are rendered with an almost faultless expression. In Berliner's grammophone the wax cylinder of the Edison phonograph is replaced by a zinc plate, covered with some protecting coating, into which a point, fastened by a membrane, draws undulating lines corresponding with the vibrations of the membrane, which is set in motion by the undulating sound.

These metal plates are then treated with acids like etchings, and one obtains therewith an imperishable plate, which can be multiplied at pleasure by the galvano-plastic process; yes, it is even possible to make enlarged photographic copies from the original plate, from which new and larger plates of correspondingly stronger sound can be produced. The sound-funnel arrangement of the grammophone, by which the tunes can be so increased that a greater number of people can hear it at the same time, has been more successful than the arrangement with which Edison tried to attain the same effect.

At the last meeting of our Society several questions were asked, which might also be of interest to foreign readers. They are the following:—Is there an effective intensifier for yellow albumen prints, and what is the treatment?

According to Davanne, the picture is removed from the cardboard by soaking in water; it is then plunged into a neutral gold bath with 0·2 to 0·5 chloride of gold and potassium to 100 parts of water, left therein until it has assumed the desired tone, washed in a partly dark room, and is fixed again. We have not obtained very satisfactory results with this method.

How is a heavy yellow fog on the erythrosin bath plate to be removed or to be avoided.

Yellow fog on erythrosin, or erythrosin silver bath plates, has never happened to us. If the pyro developer should be the cause of the yellow fog, it can be removed easily by bathing the plate in aqueous sulphurous acid. A solution of sulphite of soda (10 per cent.), to which is added muriatic acid, or diluted sulphuric acid, until it smells strongly of sulphurous oxide, acts just as well. Another kind of yellow fog, which, if looked at sideways, shows a metallic gloss, forms easily if the developer has been contaminated with fixing soda. The latter dissolves small quantities of bromide of silver, which, being reduced by the developer to metallic silver, settles in the gelatine film. This fog can sometimes be removed from the moist plate by careful rubbing with the fingers, or a cotton tuft. Both kinds of fog appear just as much on ordinary as on colour sensitive plates.—*Anthony's Photographic Bulletin.*

Royal Institution of Great Britain.—The following are among the arrangements for the lectures after Easter:—Louis Fagan, Esq., Assistant Keeper of Prints and Drawings, British Museum—Three lectures on "The Art of Engraving": 1. Line Engraving; 2. Wood Engraving; 3. Mezzotint Engraving; on Tuesdays, May 6, 13, 20. C. V. Boys, Esq., A.R.S.M., F.R.S., M.R.I., Assistant Professor of Physics, Normal School of Science, South Kensington—Three lectures on "The Heat of the Moon and Stars" (the Tyndall lectures); on Thursdays, April 17, 24, May 1. Professor Dewar, M.A., F.R.S., M.R.I., Fullerian Professor of Chemistry, R.I., Jacksonian Professor of Natural Experimental Philosophy, Cambridge—Six lectures on "Flame and Explosives"; on Thursdays, May 8, 15, 22, 29, June 5, 12. Captain W. de W. Abney, R.E., C.B., F.R.S., M.R.I.—Three lectures on "Colour and its Chemical Action"; on Saturdays, April 19, 26, May 3.

PROF. PIAZZI SMYTH ON FIGURES IN PHOTOGRAPHS.

Some time ago we selected some American views, and especially some of natural clouds caught in the White Mountain region, and sent them to our esteemed friend, Prof. C. Piazzi Smyth, the learned astronomer and Egyptologist. His return remarks upon some of them have so interested us that we are impelled to share them with our readers. The learned critic says:—

"And the top one of the parcel (no name) struck me at first speechless in admiration of the clouds, with all the silvery brightness and effective shading they should have in a hand and head painted picture, yet accompanied by trees in the foreground, bright and variously tinted, instead of masses of midnight darkness. Those trees I still admire for those qualities of brightness and illumination, and wonder whether Prof. Vogel's 'orthochromatic' plates could do anything of the kind better, or even so good; but, alas! for the beautiful clouds, and the tops of the hills too, now that I see what I regard as symptoms of their being a printing-in from a second negative of clouds, and clouds alone; taken, too, probably at another place and time.

"Another view, where there is a large, diagonal burst of light coming down from the upper right-hand corner, and forming a central light amongst the clouds, and where the earth part of the view is almost entirely composed of distant aëriform and air-tinted hills, valleys, and plains, and where the dark-green foreground has been, most judiciously, almost entirely cut away, gives a better pictorial representation of earth and sky meeting in a most harmonious embrace of beautiful infinities.

"But what shall I say of the last of the set? A lake and mountain scene, of a larger kind than our Scottish lochs; more like Swiss lakes, but spoilt by that steam yacht lying broadside along parallel to the silvery distance on the water, without any of the beautiful curves which the perspectives of other directions would have given, and all the seven gentlemen on board caring nothing about the grandeur of the scenery, but keeping watch on the photographer to see that he pictures their beautiful physiognomies, little thinking all the time that nobody cares for them when they are indulging in idleness and cultivating vanity!

"This is a maltreatment of the very powers of photography itself, to make it depict what, as a fine art, it must eschew: as bad as the accusation against a Persian king, that he had made the fire, which he worshipped, consume some nasty, stinking stuff—he put it in his way, and the fire-god could not help himself, but was obliged to eat it up.

"It is an unhappy feature, too, in all unartistical minds, whether of the world at large or photographers in particular, which I had hoped the birth of extra-sensitive dry plates, and Kodak, detective, and other instantaneous portable cameras would have been the means of correcting, by furnishing innumerable subjects of figures in action, in their own duties in life, taken unawares to *themselves*.

"I am glad you will soon use the late Mr. Pront's studies to show your readers how figures may be introduced into views, both large and small, so as to add to their interest, instead of causing any real artist to objurgate their unhappy intrusion."—*Wilson's Photographic Magazine.*

At the anniversary meeting of the Institute of Chemistry of Great Britain and Ireland, on the 1st inst., Dr. James Bell was re-elected president.

MORE EXPERIMENTS WITH EIKONOGEN.

BY P. C. DUCHOCHOIS.

Continuing my experiments with eikonogen, I was led to use a more energetic compound to counteract the tendency of this developer to yield flat negatives. It is as follows:—

a. Sodium sulphite, cryst....	20 grains ...	4 grammes
Eikonogen	25 ,, ...	5 grammes*
Water	1 ounce ...	100 cub. cent.
Potassium bromide, 1 : 10	2 drops ...	6 drops

Dissolved by the aid of heat.

b. Sodium sulphite, cryst....	60 grains ...	12 grammes
Potassium carbonate, pure	30 ,, ...	6 ,,
Water	1 ounce ...	100 cub. cent.

These solutions keep well. For use, equal volumes.

In this formula the percentage of sulphite is much larger than that previously given. The reason is that I found the gelatine film liable to be stained yellow by long development. Even a fog, greenish by reflection, pink by transpareney, occurred in one of the experiments made by Dr. Charles Ehrmann. This fog, or better, this dye, was peculiar, being intenser in the great shadows and clear parts of the plate, and melting to yellow in the lights.

Now, as to the capacity of eikonogen. With a view lens 11¼ inches equivalent focus, stop *f*/60, exposure less than one-half of one second, good negatives were obtained on Carbutt's B plates, sensitometer 16, with the above developer. This exposure may be considered as rapid as those by the drop-shutter, when using more rapid plates and the usual *f*/22·617 or *f*/32 stop, according to the subject. The image in these experiments appeared rapidly, requiring from five to six minutes to obtain sufficient intensity.

Carbutt's plates "Keystone special," sensitometer 25, exposed simultaneously with the B, sensitometer 16, developed slowly with potassium pyrogallate, giving, however, good negatives, although they were evidently somewhat under-exposed.

I made only a few instantaneous views, so-called, the persistence of bad weather and the poor quality of light in this season not being favourable. The pictures I obtained —mostly street views—developed much more rapidly with eikonogen than with pyrogallol, and were the best, but none of them were very good. I must say that the days I made them the light was yellowish and variable.

I did not find much difference in the results when treating the plates before development with the preliminary or accelerating bath. I do not deny its usefulness, however, for I did not make special tests for it. I must confess I do not understand its action, mercuric chloride being converted into sulphide by sodium thiosulphate. Perhaps it may be explained by an action similar to that occurring in the curious experiments made years ago by Mr. Carey Lea, which consisted of developing an image in mercury by substituting the nitrate of this metal to that of silver in an acidified pyrogallol developer.

The preliminary bath is compounded thus:—

Sodium thiosulphate (hyposulphite)	5 grains ...	0·2 grammes
Water... ...	25 ounces ...	100 cub. cent.
Bi-chloride of mercury, 1 : 100	30 minims ...	1·2 cub. cent.

* This is the maximum that can be dissolved with the sulphite. By increasing the percentage of the latter, eikonogen, being much less soluble, is precipitated.

The plate is immersed in this for a minute, and then developed without washing.

The following experiments in portraiture were done with the kind collaboration of Dr. Charles Ehrmann:—

Simultaneous exposures were made on Cramer's plate, sensitometer 30, with a Gundlach's rectigraphic lens, 6½ by 8½, stop *f*/15·7, and developed side by side, some with eikonogen, and others with pyrogallol. All the plates yielded good negatives, those developed with pyrogallol being more brilliant than the eikonogen developed plates, which we thought were over-exposed. Therefore, other plates were exposed with stop *f*/22, giving exactly the same time, 2½ seconds, expecting that they would be under-exposed. To our surprise the image came out regularly with eikonogen, while the plates treated with pyrogallol developed slowly, being under-exposed and, consequently, deficient in the shadows.

Theoretically, the increase of exposure between *f*/15·7 and *f*/22 is about twice as long; but we know that in practice it is not so, being much less. One second more exposure would likely have been sufficient to bring out a good portrait with pyrogallol when taking the usual care.

The developers employed in these experiments were compounded by Dr. Ehrmann. They are as follows:—

Ready-made Eikonogen Developer.

Sodium sulphite, cryst....	4 ounces ...	11·3 grammes
Eikonogen	1 ounce ...	2·8 ,,
Potassium carbonate ...	1 ,, ...	2·8 ,,
Water	34 ounces ...	100 cub. cent.

Dissolved by heat.

During the development a few drops of a solution of potassium bromide were added.

Pyrogallol Developer.

a. Sodium sulphite, cryst. ...	4 ounces ...	11·3 grammes
Pyrogallol	1 ounce ...	2·8 ,,
Water	34 ounces ...	100 cub. cent.
b. Sodium carbonate, cryst....	8 ounces ...	22·6 grammes
Potassium carbonate, pure	4 ,, ...	11·3 ,,
Water	34 ,, ...	100 cub. cent.

For use, two drams of *a* and one dram of *b* in one ounce of water, or 24 cub. cent. of *a* and 12 of *b* in 100 cub. cent. of water.

The above results bring me to this question: What is a normal exposure? Under the conditions Dr. Ehrmann and I were working, 2½ seconds with stop *f*/22 was a correct or normal exposure for Cramer's plate, sens. 30, by developing with eikonogen, but a short exposure by developing with pyrogallol. Hence a normal exposure can be defined thus: The minimum of exposure which will yield a perfect image on a given plate developed with a certain developer. But that teaches us nothing about comparative exposures so long as there is not a standard compound for each of the reducing agents employed, and the plate manufacturers do not use the same sensitometer, one graduated something like the United States stops.

The image in all the experiments came out more rapidly with eikonogen than with pyrogallol, but intensity was with the latter more easily obtained.

For over-exposures the development is restrained, as usual, with potassium bromide, using less alkali. Hydroxylamine is said to be an effective restrainer. How can a reducing agent exert a restraining action? It may be so; I did not try it. In cases of short exposures I found it sufficient to use a warm solution—75° F., 19° C. Impressions by drop shutter exposures—stop *f*/22, time $_{2}^{1}{}_{5}''$ —were developed thus by somewhat diluting the developer

with hot water. No frilling occurs with good plates. This manner of operating I found necessary to force out the details, for, as said before, the days I could spare for experimenting were not propitious for rapid exposures, the light being poor. The negatives were weak, and had to be intensified.

The number of plates that can be developed in the same solution depends, of course, upon the subject photographed and the time of exposure, the contrasts increasing gradually with each plate from the accession of more alkaline bromide and the oxidation of eikonogen, which latter diminishes reducing power. The solution, in the meantime, discolours to a greenish tint by reflection, and a yellowish brown by transparency. By adding a small quantity of sodium bisulphite, it clears up to a brownish yellow in a day or two—more rapidly by heating—and deposits a brown substance, which is the dye staining the gelatine film.

The old solution can be used again for the development of over-exposed plates, and to begin that of those normally exposed. For short and even normal exposures, I advise a new solution for each plate, in order to work in the same conditions, which is important to obtain good uniform results; indeed, I never could understand that economy of using the same solution strengthened over and over again, recommended by some authors. That *soi-disant* economy certainly does not compensate the risk of spoiling a negative, or that of obtaining an imperfect one.

As to the compared merit of pyrogallol, hydroquinone, and eikonogen, I will repeat what I have said: each one has properties of its own which the photographer must know how to apply. For myself I do not care whether in time exposures I expose one second more or one second less. What I aim at is to obtain a good negative by being able to control the development at will. Now eikonogen works quite rapidly, brings out the details easily, but in my experience is not so well under control as pyrogallol. For this reason I prefer the latter for time exposures, eikonogen for instantaneous photography, and hydroquinone for diapositives, on account of the colour of reduction.—*The Photographic Times.*

A Cement.—A new cement for securing iron into stone is described in some of the foreign papers. The cement is made by melting resin and stirring in brick-dust, which must be finely ground and sifted, until a sort of putty is formed, which, however, runs easily while hot. In using, the iron is set into the hole in the stone prepared to receive it, and the melted putty poured in until the space is filled; then, if desired, bits of brick previously warmed may be pushed into the mass, and a little of the cement thus saved. As soon as the whole is cool the iron will be firmly held to the stone, and the cement is quite durable and uninjured by the weather; unlike lead and sulphur, it has no injurious effect on the iron.

Cutting Photographic Paper.—Can the following machine be utilised for cutting sheets of photographic paper?—Mr W. Hanlon, of Cohassett, Mass., has obtained a patent, dated November 26th, 1889, for a beheading block and axe. There are five claims; the fifth runs thus:—"5. In an executioner's head-block, the combination, with the body of the block, of a neck-rest composed of parallel uprights and opposing flexible strips secured at their upper ends and bridging the space between them, of a headsman's axe the blade of which is bifurcated and flexibly covered, substantially as described, whereby when brought down upon the neck-rest the forks of said blade will strike upon the posts thereof, and the flexible covering bridge the space between the said posts, and have a yielding contact with the object to be beheaded, substantially as described."

MR. RUSKIN ON "BEAUTY."

Mr. Ruskin's rule for the judgment of beauty is this:—"Any material object which can give us pleasure in the simple contemplation of its outward qualities, without any direct and definite exertion of the intellect, I call in some way, or in some degree, beautiful. Why we receive pleasure from some forms and colours, and not from others, is no more to be asked or answered than why we like sugar, and dislike wormwood. The utmost subtility of investigation will only lead us to ultimate instincts and principles of human nature, for which no farther reason can be given than the simple will of the Deity that we should be so created. We may, indeed, perceive, as far as we are acquainted with His nature, that we have been so constructed as, when in a healthy and cultivated state of mind, to derive pleasure from whatever things are illustrative of that nature; but we do not receive pleasure from them *because* they are illustrative of it, nor from any perception that they are illustrative of it, but instinctively and necessarily, as we derive sensual pleasure from the scent of a rose. On these primary principles of our nature, education and accident operate to an unlimited extent; they may be cultivated or checked, directed or diverted, gifted by right guidance with the most acute and faultless sense, or subjected by neglect to every phase of error and disease. He who has followed up these natural laws of aversion and desire, rendering them more and more authoritative by constant obedience, so as to derive pleasure always from that which God originally intended should give him pleasure, and who derives the greatest possible sum of pleasure from any given object, is a man of taste.

"This, then, is the real meaning of this disputed word. Perfect taste is the faculty of receiving the greatest possible pleasure from those material sources which are attractive to our moral nature in its purity and perfection. He who receives little pleasure from these sources, wants taste; he who receives pleasure from any other sources, has false or bad taste.

"And it is thus that the term 'taste' is to be distinguished from that of 'judgment,' with which it is constantly confounded. Judgment is a general term, expressing definite action of the intellect, and is applicable to every kind of subject which can be submitted to it. There may be judgment of congruity, judgment of truth, judgment of justice, and judgment of difficulty and excellence. But all these exertions of the intellect are totally distinct from taste, properly so-called, which is the instinctive and instant preferring of one material object to another without any obvious reason, except that it is proper to human nature in its perfection to do so."

Celluloid may be mended, it is said, by wetting the edges with glacial acetic acid, and pressing them together for a short time.

A New Test for Albumen.—Salicysulphonic acid has been recommended by Mr. Roch as a certain, delicate, and convenient test for albumen (*Pharm. Centralb.*, September 19th, page 549). The albumen is said to be thrown down by the acid as a white powder, having an acid reaction, and giving with ferric chloride an intense red colour. The separation of albumen from a liquid is stated to be complete, 0·0005 gm. in 10 c.c. being distinctly recognizable. On examining urine, it is recommended to introduce a few crystals of the acid into a cubic centimeter of the liquid, and shake, when the occurrence of turbidity may be taken as evidence of the presence of albumen, since the reaction is not affected by the presence of urea, uric acid, peptones, or glucose.—*Pharm. Journ.*

FLASH POWDER EXPLOSIONS.

BY CHARLES L. MITCHELL, M.D., PHILADELPHIA, PA.

Within the last two years the community of Philadelphia has been startled by a series of fatal accidents, occurring during the manufacture of a compound used in photography, called magnesium flash powder, whereby, in all, five human lives have been lost.

The first accident occurred about two years ago at the drug milling establishment of McIlvaine Brothers, where, while a workman was engaged in grinding this powder in a peculiar form of mill known as a "chaser," the compound suddenly ignited and exploded, burning him fatally. The second accident occurred at the chemical laboratory of Messrs. Wiley and Wallace, some months later. While a lad in their employ, named John D. Cruice, was engaged in sieving this powder, it suddenly burst into a flame, burning him so severely about the face and body that he died within a few hours. The third and last accident, and the most fatal of all, the memory of which is still fresh in the mind of the public, occurred a little more than a month ago, and, singular to note, at the same place where the preceding accident had taken place. In this occurrence three persons lost their lives, Mr. Joseph Wiley, the senior member of the firm, and two of his assistants in the chemical laboratory. While handling some of this flash powder, it suddenly exploded with terrific force, killing them instantly, and badly wrecking the building. This series of lamentable and fatal accidents has served to direct public attention to the subject of "flash powders," and it has revealed dangers attending their manufacture and use which have been but little known and comparatively unsuspected.

Magnesium flash powder is a compound used in photography for the purpose of portraiture at night, and in photographing dark interiors and underground localities, in which, owing to scanty light or even absolute darkness, it has been impossible to obtain an image on the sensitive silver plate.

The introduction of magnesium flash powder as a means of photographic illumination dates back now some three years, when Gædicke, of Berlin, introduced to public notice a compound containing metallic magnesium, which, when ignited, gave a sudden brilliant and intense white light, possessing high actinic properties. Metallic magnesium alone had been used for this purpose for some time previous, being burnt in the form of wire or ribbon; but it was slow, expensive, and uncertain, and was but seldom employed. Gædicke's invention, however, employed the magnesium in the powdered form, and combined it with highly oxygenising substances, such as potassium chlorate and nitrate, for the purpose of increasing the rapidity and intensity of the combustion of the metal. The new compound sprang into immediate and extended favour, for it afforded a convenient and satisfactory means for accomplishing many results hitherto either very difficult or utterly impossible for photographers. The photographic amateur also took hold of it with his accustomed vigour, and all over the land he exercised his skill in "taking" the company assembled at many an entertainment, supper, or ball, while, on more informal occasions, he burnt his own fingers, and astonished his admiring relatives with the sudden and brilliant flashes of the compound in his endeavour to successfully accomplish home portraiture by night. A note of warning was soon sounded, however, and the first fatal accident, occurring during its manufacture, demonstrated that this new compound possessed properties which rendered it under many circumstances extremely dangerous.

Magnesium flash powder, specifically considered, comes under the heading of pyrotechnic compounds. While metallic magnesium will burn by itself when ignited, it does so with but moderate rapidity. It is necessary, therefore, in order to produce the sudden and brilliant flash of white light so desirable for photographic purposes, that the activity and intensity of its combustion be very much increased. The ingredients used for this purpose have been the same as usually enter into the composition of other forms of fireworks, namely, potassium chlorate, nitrate, permanganate or bichromate, amorphous phosphorus, picric acid, sulphur, and antimony sulphide. Gædicke's formula has always been a secret, and consequently those who manufactured flash powder have been obliged to devise formulæ of their own. The composition of these different powders has been kept secret, and it is highly probable that in many cases the ingredients have been combined with but little regard to their chemical properties, and the chemical reactions which might occur from their admixture. The inventor of the particular brand of flash powder which caused the deaths of the five persons previously noted, testified at the coroner's inquest, and subsequently in court, that "he was not a chemist," and the terrible results which accompanied this flash powder, which he had "invented," showed very clearly that it was formulated in utter ignorance of the dangerous properties of its several ingredients.

The chemical composition of many of the different flash powders in the market has been such that the resulting compounds were exceedingly dangerous in character; in fact equally, if not even more so, than gunpowder, or the fulminates, and for this reason: that a flash powder, to meet with the requirements of many photographers, must not only burn rapidly, but must "flash;" that is, the combustion must take place with such rapidity that it must be almost instantaneous in duration of time, so as to avoid the movement of the eyelids, or the changes in expression of the person being photographed. Such combustion must necessarily, for chemical reasons, be exceedingly intense, and to produce this result, chemical agents have to be employed which will liberate oxygen gas freely and in large quantities, so as to supply to the burning metallic magnesium the amount required for rapid and complete incandescence. A compound of this character is a gunpowder to all intents and purposes. When ignited with a match it bursts violently into flame, often with a puff or partial report, showing that its component gases are liberated so quickly as to produce, if the compound were in a confined space, all the effects of an explosion. These compounds are liable from their chemical nature, and from the presence of potassium chlorate, to accidentally explode or ignite under certain conditions, and may, indeed, do so spontaneously, for reasons unkown to chemical science.

The particular make of flash powder which caused the five deaths previously mentioned was known as the "yellow flash powder," or "brutem fulmen," and was manufactured for and sold by the firm of Buchanan, Bromley, and Co., of Philadelphia, general photographic stock merchants. This firm made two kinds of flash powder: the "yellow," which was composed of magnesium, potassium chlorate, picric acid, bichromate potassium, &c.; and the "violet," which was similar in composition,

excepting that the picric acid was omitted. It was claimed that the death of the boy, John D. Cruice, occurred while preparing the "violet" flash powder; but from the fact that the death of Mr. Wiley and his assistants resulted while endeavouring to destroy, some months later, some of this dangerous compound, it is highly probable that it was in reality the "yellow" powder which the boy was engaged in mixing when he met his death. Be that as it may, the combination of ingredients in each of these powders is sufficiently dangerous to render them articles exceedingly unsafe to handle, the most perilous being probably the yellow powder. This powder, as before stated, contained picric acid, magnesium, and the chlorate, nitrate, and bichromate of potassium. No one of these agents would in itself be explosive, except under extraordinary circumstances; but the combination of these different substances introduces at once a large element of danger. It is a well-known chemical fact that many metals, when in a state of fine subdivision, become rapidly oxidized—so rapidly, indeed, that the absorption of the oxygen is attended with both light and heat, particularly if the element of moisture be added. Powdered magnesium and powdered zinc, after being wet with water, have been known to become sufficiently hot to ignite material in contact with them. The admixture, therefore, of any chemical substance rich in oxygen, or holding it loosely in combination, with a readily oxidizable metal like magnesium in a state of fine powder, renders the compound exceedingly susceptible to rapid changes, and certain physical conditions, such as moisture, heat, light, and perhaps electricity, will greatly assist such decomposition. Picric acid, another element in this particular compound, is, when in a pure condition, comparatively safe, as it will burn without danger, and explodes only when heated in a confined space. That of the market is often impure and contaminated with the picrates of sodium or potassium, by-products of its manufacture, thus considerably increasing its dangerous qualities. The salts of picric acid—namely, the picrates of potassium, sodium, ammonium, lead, barium, magnesium, &c.—are extremely dangerous in character, belonging to the class of fulminates or detonators, a series of compounds unstable in character, and liable to explode with slight percussion or friction, with the liberation of immense volumes of gas. Sarrau states that the relative force of picrate of potassium when exploded, as compared with gunpowder, is as 1·98 to 1·00, almost twice as great. A mixture of 0·5 kilograms of potassium picrate and 0·5 kilograms of potassium chlorate evolves through its combustion 352 litres of gas; 1 kilogram of gunpowder evolves but 200 litres under the same circumstances.

(*To be continued*).

Photographic Society of Great Britain.—At the meeting on Tuesday, March 11th, at 5A, Pall Mall East, at 8 p.m., the adjourned discussion will take place on the paper read by Dr. Lindsay Johnson at the annual meeting; and Mr. John Spiller, F.C.S., F.I.C., will read a paper, "Experiments by Dr. Percy and Mr. George Shaw on the Chemical Phenomena of Light."

Photographers' Benevolent Association.—The address of the above has been changed to 65 and 66, Chancery Lane, W.C., and all communications respecting the Association should be forwarded so addressed to the honorary secretary, Mr. H. J. Beasley. We are requested to state that the annual meeting, which was adjourned till the 7th inst., cannot take place on this date, as the Registrar has not passed the new rules.

Notices of Books.

Jahrbuch fur Photographie und Reproductionstechnic fur 1890. Edited by Dr. Joseph M. von Eder. (*Knapp: Halle*).

The appearance of the fourth of Dr. Eder's annuals will be hailed with satisfaction by lovers of photographic science. Germany has become so much the home of original research in photographic matters, that we expect to find in such a work as that before us, which includes articles by so many leading experts, a wealth of original matter carrying our knowledge in several points a step farther than before, and our expectation is not disappointed. A feature of the work, which might be inferred from the title, is the attention which is bestowed upon giving the latest advances in the arts of photographic reproduction by printing-press methods. Amongst others, we find original articles on these matters by Hübl and Jaffe, as well as detailed accounts of processes or methods in use by Volkmer, Strasila, J. G. Albert, Husnik, and Roese, the latter referring to chromo-zincotype.

Amongst the illustrations produced by various photo-ink methods, is one in chromo-lithography, with a set of the tints used, of which there are no less than eighteen, printed underneath. The register has been wonderfully well kept, and the picture is very bright and airy.

There are about a score of these photo-ink illustrations printed by various methods and from different establishments, most of them reaching a high standard of excellence, and possessing a special interest in connection with some photographic process.

One very curious page represents fish—sturgeon and gold fish—swimming in an aquarium, and photographed by the magnesium flash. There are also several which are the work of students—they might very well be the productions of masters—at the Institute for Instruction and Research in Photography and Reproduction Processes in Vienna. A copy of an oil painting which forms one of these supplements, taken with orthochromatic collodion emulsion, is particularly charming in softness and harmony of gradation. Samples of work by the Reporter camera serve to show what really interesting pictures may be obtained in such a small compass, the photographs being only about the size of one-fourth of a quarter-plate, or half that of those recently shown by Mr. Chapman Jones as taken with his Memorandum camera. Such works illustrate the fact that there are optical reasons why that may be done with a small image which it is impossible to obtain relatively sharp with a larger one.

There are some papers of special interest on varnishes for photographic use; on artificial light, particularly various details connected with magnesium flash lamps; and on orthochromatic processes.

We do not pretend in this rapid summary to have exhausted the mention of what is useful and interesting to photographers in Dr. Eder's Annual, and the best advice we can give to those who can avail themselves of the store of information contained in the work is, to get it.

A paper on the perception of luminous radiations by the skin, as exemplified by the blind Proteus of the grottos of Carniola, has been read before the Academy of Sciences by M. Raphael Dubois. By a number of experiments upon *Proteus anguinis*, the author demonstrates that the sensibility of its skin to light is about half of the sensibility of its rudimentary eyes, and further, that this sensibility varies with the colour of the light employed, and is greatest for yellow light.

THE CAMERA CLUB CONFERENCE.

The *Journal of the Camera Club* gives the following full programme of the Conference:—Wednesday, March 19th, 8.30 p.m.—Smoking Concert at the Camera Club Rooms, 21, Bedford Street, W.C. Thursday, March 20th.—Conference and Exhibition of Apparatus at the Society of Arts, 18, John Street, Adelphi, to be opened by the President at 2 p.m. Papers to be read from 2 p.m. to 5.30 p.m. in the Theatre:—1. Capt. W. de W. Abney, C.B., D.C.L., R.E., F.R.S., Presidential Address; 2. Mr. A. M. Rossi, "The Art of Drawing and Photography;" 3. Mr. T. R. Dallmeyer, "Limitations in the Treatment of Subjects by Focus;" 4. Mr. Lyonel Clark, "The Influence of Stops on Exposure;" 5. Mr. A. A. Common, F.R.S., "Eclipse Photography;" 6. Mr. W. T. Wilkinson, "Collotype Practically Illustrated." At 8 p.m.—Exhibition of Lantern Slides in the Theatre. Friday, March 21st, 10 a.m.—Apparatus on view at the Society of Arts, and exhibition of photographs by members at the Club Rooms, 21, Bedford Street. 2 p.m.—Renewal of conference in the Theatre, Society of Arts. Papers to be read from 2 p.m. to 5.30 p.m.:—1. Official communication upon the subject of Regulations for Photographic Exhibitions; 2. Lord Rayleigh, "Photography by the Light of the Electric Spark;" 3. Captain Abney, "A Photographic Untruth;" 4. Mr. C. H. Bothamley, "The Latent Image;" 5. Mr. W. T. Wilkinson, "Photogravure, Practically Illustrated." 7.30 p.m.—Annual club dinner for members and friends at the Frascati Restaurant, Oxford Street (near Tottenham Court Road). All photographers are cordially invited to the Conference and Exhibitions. The meetings (except the smoking concert) will be open to ladies.

Specifications Published.

4,955.—*March 21st*, 1889. "Apparatus for Automatically Operating Valves." Brin's Oxygen Company, Limited, of Connaught Mansions, Westminster, and Kenneth Sutherland Murray, of 21, Redburn Street, Chelsea, London, Engineer.

This invention is intended more particularly for use with apparatus employed in producing oxygen known as the Brin process, but is not restricted thereto, and has for its object to provide means for readily reversing one or several of a series of cocks or valves used in the said process so as to produce suction or pressure as required in a series of pipes with which they are connected without stopping, reversing, or setting in motion any additional machinery. In order to abstract oxygen from the atmosphere by what is commonly known as the Brin process it is necessary to pump or otherwise deliver air through a series of pipes and retorts for a given period. It is then necessary, by means of cocks or valves, to divert the current in pipes and retorts to prevent any further admission of air, to exhaust said pipes and retorts of all air which they contain, and finally, having obtained the required quality of oxygen, to deliver it to a gasholder or other suitable receptacle.

To accomplish this automatically according to this invention it is proposed to utilize the motion of some rotating or reciprocating portion of a pump or any other suitable piece of machinery that may be employed in connection with the process, by means of which motion of rotation is imparted by means of an adjustable pawl and ratchet gearing or equivalent mechanism to a shaft either in a vertical or horizontal plane, as may be most convenient. Connected direct to this shaft, or by means of worm and worm wheel or other suitable gearing, are a series of pairs of adjustable cams arranged to act on back pressure or other valves so as to cause them to admit steam or other motive fluid to a cylinder to exert pressure on a piston, and move it either forward or backward as the case may be.

5,373.—*29th March*, 1889. "Wooden Vessels for Holding Corrosive Substances." Peter Wardlaw Turner, 38, Garturk Street, Crosshill, Glasgow, Merchant.

The separate parts of which the wooden vessel is composed (staves or other pieces) are steeped in a warm solution of melted paraffin wax, which contains enough of a foreign substance or substances to destroy the crystalline nature of the paraffin wax when cool, such as a small quantity of india-rubber or gutta percha, or both together, either of these substances, or both together, being preferable to any others. The wooden pieces, when fully saturated with the mixture, are taken out of the bath and put together to form a liquid-tight vessel, which is then shaken up with a quantity of the liquid mixture so as to form an inside skin for the purpose of further protecting the wooden vessel.

5,920.—*April 6th*, 1889. "Photographic Cameras." Claude Raymond, of 23, Boulevard de Strasbourg, Paris, Merchant.

My invention has reference to photographic cameras of the kind generally called bellows cameras, and it consists in improved means whereby these cameras can be made to expand or contract as required.

For this purpose I fit the camera with two levers or rods crossing each other in the form of the letter X, and jointed together at the middle. One end of each lever is jointed to a pivot, and the other end slides in a grooved guide. For easier manipulation of these levers one or both of the sliding ends is or are preferably fitted with a milled button carrying a pinion which gears with a rack on the guide.

The manner in which my invention can be best carried into effect will depend partly upon the size of the camera. For a small portable camera I would have one pair of the crossing levers at the top and another pair at the bottom of the camera. For a larger camera I would have a pair of crossing levers at each side, and in order to give additional strength and to dispense with the bed portion, a third pair can be placed at the bottom, but without a pinion and rack. The levers of this third pair can be ribbed to make them stronger, and there may be a boss at their crossing point to serve as a foot.

One or other of the side pairs of levers can be more or less extended so as to slightly incline to one side the plate holder or front part of the camera carrying the object glass. The levers can also have screw threaded or extensible parts so as to allow of inclining the plate holder in a vertical direction.

At the meeting of the Society for the Encouragement of Fine Art last week, at which Mr. Newman's paper, printed in this issue, was read, the slides were exhibited by means of one of Messrs. Watson and Sons' lanterns. Mr. Gale, Mr. G. Davison, and Mr. George Smith were among the photographers present.

Proceedings of Societies.

Camera Club.

On Thursday, 27th February, Dr. C. S. Patterson read a paper on "Photography as applied to Medicine and Surgery." Mr. T. Charters White occupied the chair.

The lecturer began by stating the qualities which he considered indispensable in a good medical photographer. He then gave a short resumé of the history and literature of the subject, and going on to its present development, he gave the three great directions in which it was used, viz. (1) as an investigator, (2) as a recorder, (3) as a demonstrator, giving many examples. He then considered it under its various medical departments, illustrated by lantern slides. He said that before a general audience it would be absurd to go into the photographic details of manipulation, but he would like to lay great stress upon two points, isochromatic plates and the magnesium flash lamp, both of which he found almost indispensable. He impressed on the audience, moreover, the important aid they could render to the medical photographer by influencing hospital authorities to give proper facilities for medical application of photography. The paper concluded by a short notice of the way in which this work was now gaining ground.

In the discussion which followed, Messrs. Pringle, Elder, Cooper, Andreae, Dr. Massey, and the Chairman took part.

Thursday, March 13th, will be a lantern evening. Meeting at 8 p.m.

London and Provincial Photographic Association.

At the weekly meeting on the 27th ult. Mr. H. M. Hastings occupied the chair.

Mr. Birt Acres was elected a member of the Association.

Mr. A. Haddon, at the last meeting, suggested a delicate test for grease in water, which he was unable to demonstrate then from the impurities of the water. He had brought a bottle of distilled water to the meeting. The scrapings from a piece of camphor were allowed to fall on the surface of the water, motion being at once imparted to them. By simply drawing the finger across the forehead or face, and then dipping the finger in the water, the particles of camphor instantly ceased to have movement, from the grease imparted by the finger.

Mr. F. P. Cembrano showed a foreign postcard illustrated by photography, under government sanction.

Mr. A. Haddon gave a demonstration of glass-blowing, remarking upon the usefulness of being able to make the various small glass articles required for the dark room and laboratory. The lecturer proceeded to explain the composition and varieties of glass, of which there are four kinds, German glass, soft and hard, ordinary English soda glass, lead glass, and combustion tubing. Of these the best for all ordinary work is the soft German. It is necessary to select that special variety that will stand heating and reheating. By diagrams on the black board the zones of a candle flame were explained, followed by a description of the several blowpipes in use, worked either by the foot, or blown by a tube held in the mouth. Illustrating the manipulation of the blow-pipe, the lecturer commenced by making a simple but indispensable article of dark-room use, a stirring rod. A piece of glass rod of the requisite size was cut, and one end held at the point of the flame, and fused. By revolving the rod at the same time, the end became hemispherical; the other end was then fused and flattened. If the object is simply to bend a piece of glass, an ordinary fishtail or batswing is useful. All that is necessary is to hold the tubing in the flame until sufficiently soft to bend to the required angle. A wash bottle, delivering tube, and pressure guage were then made. A piece of glass tube was taken, one end closed and rounded, and the edges of the other end rounded; this formed a test tube. The sealing of solids and liquids in tubes was next shown. For the latter, a piece of glass tubing is taken, one end closed by fusing, and rounded. This tube is then heated in the centre, and drawn out, the upper part forming a funnel to receive the liquid. To get this into the reservoir below, the bottom part of the tube is held for a short time over a flame, causing the air to expand, the liquid being drawn into the lower tube as it cools. The top part is then broken off, and the neck sealed. To weld two pieces of glass of different diameters together successfully, both pieces of glass should be from the same pot. How to make a T joint, blow a bulb, make a minim glass and bulb pipettes was next shown. The determination of the specific gravity of solutions in use, the lecturer held to be of the greatest importance to photographers. This was easily ascertained. Small glass bulbs are blown, water inserted, the neck fused and sealed, and then adjusted so that they just sink in any liquid of known strength. Ammonia, used in every dark room, was instanced. How was it possible to know its strength after the bottle in which it was kept had been opened, perhaps, as in the case of an amateur, several times? By using a specific gravity bulb, its determination was exceedingly simple. A ten per cent. solution is made up from ammonia of known full strength 880°. A glass bulb is weighted to just sink in the solution. In making up subsequent solutions, the bulb has only to be placed in a measure of water, and ammonia of any unknown strength poured in carefully until the bulb commences to sink; a ten per cent. solution can thus always be guaranteed.

In answer to the question as to the method adopted for creating the vacuum in an incandescent lamp, the lecturer, by a diagram on the blackboard, explained the principle of one of the most effective pumps known for this purpose. A glass tube is bent in the form of a syphon. At the top bend is a stopcock, to which is attached the glass bulb to be exhausted containing the filament. The vertical column is filled with mercury until it rises to the top bend; passing over this it descends by small globules to a receptacle placed to receive it. Each globule as it descends carries with it by its own weight a certain amount of air imprisoned between it and the globule following. By this means a vacuum in the bulb is almost perfectly formed. This is the Sprengel pump, in fact

The demonstration concluding at a late hour, admitted of but little discussion.

Hackney Photographic Society.

This Society held its first exhibition on Thursday last at the Morley Hall. Dr. Roland Smith opened the exhibition, and hoped it would prove of use to those present.

During the evening a "flash-light" group was taken by Mr. J. Hubert with his oxygen blow-through lamp. Among those present were Messrs. J. Traill Taylor, Henry Sturmey, G. J. Clark, and W. L. Beurle.

The members had a good show of apparatus and work, Messrs. Clarke, Hoddle, Houghton, Hubert, Dean, Roder, Gosling, Reynolds, Barton, Acres, W. Fenton Jones, Grant, and others exhibiting.

The professional element was represented in a large exhibition by dealers of apparatus.

West London Photographic Society.

At the last ordinary meeting Mr. G. F. Blackmore occupied the chair. Mr. Roe was elected a member of the Society, and Mr. Wilmer was nominated for election.

After the disposal of the formal business, Mr. Chas. Dixon's paper on "Holland House," was read by Mr. Hodges. Mr. Dixon superintended the exhibition of slides.

The paper was prefaced by a short description of the process employed in the production of the slides. They were, with the exception of a few on chloride dry plates, produced by the wet collodion process by reduction in the camera from 9 by 7 negatives, which also owed their origin to the same wet-plate method. In the case of some of the interiors, exposures of two hours had been given, and the plates were backed with wet blotting paper to keep the films moist. The lecturer then traced the history of the house from the time it first came into the possession of the Holland family in 1600 down to the present time, illustrating his remarks with a large number of interior and exterior views of the house, and of the park and grounds.

Mr. Wilson presented the Society with a number of photo-

graphic works of reference as a nucleus for the formation of the Society's library. After some discussion it was decided to refer the appointment of the Librarian to the Council for further consideration.

On the 14th March, Mr. H. Selby is to read a paper on "Stripping Films."

North Middlesex Photographic Club.

On February 24th Mr. G. Davison delivered a lecture upon "Pictures by Photography," illustrating it by about one hundred photographs taken by himself.

After speaking of the advances that photography had made and the restrictions which it imposed, he proceeded to review what are generally considered the rules of art, and remarked that exceptions to these were almost as much the practice as not, and instanced Mr. Robinson and others, who had taken some of their best pictures with the sun in front of the camera, in direct contradiction to one of the best known rules. Again, another rule was that the horizon line should not be in the centre of the picture; this, and many other rules he referred to, and had one or more pictures to prove that they might sometimes be departed from, and advised that the simplest subjects be chosen—namely, those with as little in them as possible—so that the interest might be centred upon the principal feature, and to endeavour to introduce originality and boldness into their pictures. He then referred to the faults to be avoided and merits to be sought, giving force to his words by a photograph showing each particular feature.

Monday, March 10th, will be members' lantern night. Visitors invited; ladies admitted.

Bristol and West of England Amateur Photographic Association.

On January 3rd a meeting of the Association was held in the Queen's Hotel for the lantern exhibition of slides by various members. In the absence of the president, the proceedings were conducted informally.

Several members were present, including Messrs. W. L. Bernard, J. W. Evens, M. Lavington, F. B. Bond, W. Norgrove, and W. W. Boyden, all of whom exhibited work. Mr. Boyden showed some slides on chloride plates developed with "photopel," the vivid red colour of which is quite a departure from the usual scale of tints.

The annual business meeting for 1890 was held Feb. 7th, when the President, Mr. H. A. H. Daniel, took the chair.

The president, vice-presidents, and secretary and treasurer for the past year were re-elected.

It was agreed that the Secretary be asked to write to Dr. Emerson, thanking him for and accepting his offer of "Life on the Norfolk Broads."

Mr. Brightman was requested to obtain a lantern for the Society's use from Messrs. Perken, Son, and Rayment.

Liverpool Amateur Photographic Association.

A meeting was held on the 27th of February, with Mr. Paul Lange in the chair.

The following were elected members of the Association, viz., Messrs. Hugh R. Jones, M.A., John H. Welsh, H. F. Tildesley, Geoffrey Cather, William Rock, junr., and William T. Bell.

The President announced that letters of resignation had been received from Messrs. T. H. Day and G. H. Rutter as members of the Council, and from Mr. Walter Hughes, the Hon. Secretary, and that Mr. Edward M. Tunstall had been appointed Hon. Secretary. The attention of members was drawn to the extra meeting to be held at the City Hall, Everle Street, on Thursday, March 20th, for which evening a concert was being arranged, to be followed by the President's illustrated lecture on "Norway." The President also announced that the Council had arranged for a series of practical demonstrations in photography for the special benefit of beginners.

The Council had also arranged to exhibit the pictures (sixty in number), 15 by 12, of Mr. H. Tolley, the gold medalist, of Nottingham. These would be on exhibition for a short period in the club rooms. It was hoped they would prove an attraction, as, through the exhibition of Mr. H. P. Robinson's series, thirteen new members had been induced to join the Association.

Mr. T. Sayce submitted a most ingenious hand-camera, made at a very trifling cost, and meeting all the requirements of the amateur photographer.

Other business being concluded, the general public gained admittance, and Mr. D. Lewis gave his paper on "A Fortnight in the Netherlands with a Camera," followed by Mr. W. P. Christian with "Moor and Don, or Studies in Algeria and Spain." Both lectures were illustrated with the lantern.

The Manchester Lantern Competition slides lent to the Association were then exhibited.

Sheffield Camera Club.

The first soirèe in connection with this club was held last evening at the Masonic Hall. Among those who attended were Mr. G. T. W. Newsholme, F.C.S. (president), Dr. T. H. Morton (vice-president), Mr. B. W. Winder, F.C.S., F.R.M.S. (treasurer), Mr. G. E. Malcham (secretary), Dr. Manton, and Mr. Wm. Gilley, junr. A considerable quantity of photographic apparatus was displayed. Messrs. Marion and Co., and R. and J. Beck, of London, contributed lenses, and the Eastman Company furnished some very interesting enlargements.

The President, in the course of a short address, referred to the origin of the Club, and said some of the members when they joined were novices in the art, but others were men of great experience and ability, ready at all times to give advice and valuable help to the recruits. In their Club the professional element did not enter, not that he would say one word in disparagement of the professional photographer; but he felt strongly that a society could not do well which had both the professional and amateur within its ranks. To the amateur photographer was due the credit for the great and rapid advancement of the art of photography during the last few years. Still, although there had been that advancement, the art was now only well advanced in infancy. If such rapid progress had been made in the past, who could predict what its progress would be in the future? Who could measure the great value it must become to the microscopist, the chemist, and the physiologist?

During the evening Mr. Winder, with the aid of a lantern, showed some of the members' slides. A flash-light photograph of a group was also taken by Prof. Arnold.

Bath Photographic Society.

February 25.—Annual meeting; Mr. W. Pumphrey in the chair.

Messrs. Baldwin, Cloakley, Christopher Morris, Charles Terry, and W. S. Wilkins were elected members.

The Treasurer's balance sheet showed a balance in favour of the Society, and in all respects was a most satisfactory one.

The Hon. Secretary and Treasurer, Mr. W. Middleton Ashman, read a carefully prepared and exhaustive report of the Society's proceedings.

The Chairman, in moving the adoption of the account, said the Society had cause to be very well satisfied. The principal expenses would not have to be incurred again; part was met out of the income, and the rest by a loan from officers of the Society.

The election of officers was then proceeded with, and all who served during the past year were unanimously re-elected.

Mr. Greene read a paper entitled "Photography in an Age of Movement" (see page 183). Both the instruments and examples shown were regarded with much interest.

The Secretary exhibited one of the "Collins" detective cameras, and explained the details of working it. The neatness and simplicity of this instrument were remarked upon.

The Chairman then explained the method of producing photo-micrographs. He exhibited a number of specimens and the apparatus used to produce the same.

The leading points requiring attention having been dealt

with, a brief discussion followed, in which Messrs. Ernest Pitman, Greene, and the Secretary took part.

Mr. King, in moving thanks for the papers, spoke of the advantages of such a process for obtaining permanent records in microscopy, and the work could be done of a winter evening. He also referred to the more certain determiuations of astronomers to-day than before photography was employed in their calculations.

There will be a lantern competitiou on March 26th. Slides and particulars of process should be in the hands of the Secretary the day previous.

Photographic Society of Ireland.

A few eveuings ago the members had a practical demonstration given them by Mr. James Carson, C.E. He introduced the subject by showing the utility of the several parts of the lanterns and their accessories, such as gas bottles, valves, and gauge; the differences between the "blow-through" and mixed gas jets; how to properly centre the light for dise illumination; methods of iutroducing slides into the lautern for both single and double lantern exhibitions. Mr. Carson was thanked by the meubers present, and desired to place the matter on paper to be read at some ordinary meeting of the Society.

On March 3rd Mr. J. H. Hargrave, C.E., gave a lecturette on "Lantern Slides, and how to make them." He directed attention to the methods—(*a*) by contact; (*b*) by reduction. In the first class he demonstrated the remarks made by exposing and developing two slides. In the class (*b*) he subuitted a home-made reducing arrangement, by means of which the ordinary camera was brought into play, being fixed on a substantial base-board, and focussed roughly by moving by hand, but finely in the usual manner. The negative was placed at a measured distance from the lens in a slot cut in card-board, and suitably safe-guarded. He gave much information as to his experience with plates by several makers, first dividing these plates into two classes—"chloride" and "bromide." The developing he favoured was "pyro." He devoted time to demonstrate the mounting of slides, and referred to various masks.

Dr. J. Alfred Scott added remarks as to intensification, showing a distinct preference for Monckhoven's. He exhibited a printing frame made by himself for use with quarter-plates in contact lantern plate exposure. It was so constructed as to admit of so much of the lantern plate projecting over any part of the edge of a quarter-plate as might be covered by a mask, wheu it would be advantageous to include or exclude a part of the subject in the quarter-plate as the case might be.

Photographic Club—The subject for discussion on March 12th will be "Stereoscopic Photography;" on March 19th, the adjourned discussion on "Artifical Light as an Adjunct to Daylight," will take place.

On the question of which is best for dark-room windows, paper or coloured glass, it may be said that if a satisfactory coloured glass can be got it is preferable, as the colour of paper is apt to be discharged by the continued action of daylight.—*Photographic Scraps.*

Gold Bath.—Iu au article communicated by E. Kiewning to the Dutch photographic journal *Lux*, there is a notice of what the author holds to be a remarkable receipt for a toning bath which is not liable to deterioration:—

Water	600 grams.
Chlor. gold	4 ,,
Chlor. potass.	60 ,,

After the solution is effected, 20 grs. of chemically pure chalk in the form of powder are added. Let this mixture stand for three or four days protected from the light; the bath is then ready for use. The tones produced by this bath are brown and blue, with all the intermediate tints, according to the concentration and duration of the toning. The abovementioned bath is, says E. Kiewning, of the chiefest importance in the summer, when the temperature is high, and the employment of carbonate of soda in the gold bath is, in consequence of its reduction-accelerating powers, by no means desirable.

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

J. D.—*The Ligroine Lamp* was sent off to you, per L. and N. W. R., on Monday morning. We shall be glad to hear of its safe arrival and successful employment. The Welsbach incandescent cones are easily procurable in this country, and you need not wait long for extra supplies. Wheu using part of the apparatus as a blow-pipe, a special air-jet will be required, and then silver can be easily melted.

M. P. S.—*Council Elections.* There is a mistake somewhere, twenty-one names appearing on the cover of the *Journal*. Your friend was duly nominated, but declined to serve on the council.

A. F. (Warwick).—*Gelatine brands.* Information already given by post; let us hear in the event of your having any further difficulty.

Litho.—*Albert Transfer Paper and Zincography.* It is hardly likely that the new transfer paper would be already procurable in this country. For reversing plant, apply to any optician; all you want is a good plane mirror. For etching troughs use wood, well dried and coated with melted paraffine; glass bottoms would be of no particular advantage. The sensitising bath of—

Bichromate of potash	50 grammes
Water	1,000 c.c.

is equivalent to a five per cent. solution, which you can make by disolving one ounce in a pint of water, if you have not gramme weights and litre measures. Remember to add the ammonia.

L. M. A.—See "Concise Instructions in the Art of Retouching," by Burrows and Colton—Messrs. Marion and Co. Somewhat old, but a very good book, with full descriptions and pair of negatives as frontispiece.

Collodio-Chloride.—There is no reply from Dublin.

F. C. S.—*Inactivity of Developing Solutions in Cold Weather.* We can quite confirm all you say, having tried to work this week at an uncomfortably low temperature. The image preferred to remain latent, and the naphthol developer was far behind pyro in power of development. From our own and Mr. W. K. Burton's comparative experiments, we know that there is no disadvantage of this kind in summer time.

Graphic.—*Photo Waste of the Noble Metals.* There is an error of calculation, or misprint, in the American statement, for on the data given there is an 0 too many. £2,500,000 should read £250,000. Even then it is a big estimate.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1645.—*March* 14, 1890.

CONTENTS.

THE FIRST OPTICAL LANTERN.

An able article by Mr. James Mew appears in the present issue of this journal, and includes a translation of Kircher's own description of the magic lantern, of which popular instrument he was the inventor. Mr. Pringle, at the Camera Club last week, as will be seen by the report in another column, gave currency to a rumour which had reached him that the magic lantern was first invented, as he put it, by John the Baptist, otherwise Giambatista Porta, the inventor of the camera; but any such claim can probably be sustained only by special pleading, and will not shake the title to the honour, almost universally admitted from time immemorial, to belong to Athanasius Kircher, the good and self-confident Jesuit priest. The truth seems to be that it is not easy in some cases to draw a line of demarcation between the camera and magic lantern; for instance, the largest photozincographic print in our pictorial supplement issued this week represents such a transition instrument, invented by Kircher. The solar beams are received upon pictures or inscriptions painted upon polished plates made of some not readily oxidizable metallic alloy, the composition of which is not on record; then, by means of one double convex lens for each picture, the images are projected on the walls and roof of a darkened chamber. The instrument bears a strong resemblance to a camera, and, at the same time, a strong resemblance to that optical lantern of modern times, in which the image of a brilliantly illuminated inverted opaque object is projected on a screen in a darkened room. Kircher, it will be seen, for use with this instrument, took the trouble to have the letters of the alphabet engraved bottom upwards, and then called them a "catoptric" alphabet, instead of simply telling his readers to take ordinary printed letters and turn them upside down. The other two pictures in the supplement represent a magic lantern beyond all mistake; one of them differs only in principle from the other, being fitted up, Polytechnic Institution fashion, in a second chamber. The pictures prove that Kircher mounted rows of lantern slides in long rectangular frames, as they are mounted and sold in shops at the present day.

Kircher used a reflector behind the oil light, but it was not truly optically centred, if the Italian draughtsman who shared in the production of one of Kircher's blocks can be trusted; probably, however, he cannot be trusted, for throughout the whole of the ponderous old Latin book, there are, occasionally, small discrepancies between the engravings and the letter-press. The position and description of the projecting lens are neither clearly pictured nor clearly described, perhaps intentionally; even in modern times we find inventors sometimes secretive on essential points. Some of the earliest pictures of magic lanterns in old books represent a bull's-eye lens in front of the slide, and a light behind the slide; this, there is little question, was Kircher's arrangement. The first lantern slide pictures of which any information has come down to us were not, it will be seen, of a cheerful nature; the one picture represented Father Time as a skeleton with scythe and hour-glass; the other picture represented one of the units of poor humanity roasting in eternal flames. They took life sadly in those days.

The small cut from Kircher's book, represented on page 198, in Mr. Mew's article, has been by some modern writers mistaken for a drawing by Kircher of the optical system of his lantern, but it is not so. The oval in front is not intended to represent a lens, but a piece of flat glass. The opening behind it is not intended for the passage of a lantern slide, but for the passage of air to the flame. In fact, the cut is meant to represent a lamp for illuminating objects at great distances, by means of a light suitably directed by parabolic or other reflectors.

Lord Rayleigh once said that few persons now-a-days read Newton's "Optics," yet that they are well worth perusal, and contain records of devices which are occasionally re-invented in modern times. The same remark might also be applied to Kircher's "Great Art of Light and Shade."

THE "PHOTOGRAPHIC NEWS" SUPPLEMENT.

With the present number of this journal is issued a pictorial two-page supplement, representing the first magic lantern invented by Kircher, and a transition instrument half-way between an optical lantern and a camera. These are photo-zincographic copies, on a somewhat reduced scale, of Kircher's original engravings, published in Rome in 1646, and in Amsterdam in 1671. The latter seems to be the date of the first printed publication of a description of a true magic lantern.

ATHANASIUS KIRCHER, THE INVENTOR OF THE MAGIC LANTERN.

III.

BY JAMES MEW.

In the third and last part of the tenth and last book of his "Great Art of Light and Shade," Kircher deals, it has been already said in the preceding article, with Catoptric Magic, or the wonderful representations of objects by means of mirrors. Commencing with explanations of the construction of mirrors in their many varieties—such as spherical, cylindrical, and conical—the reader next meets with a series of problems, as Kircher calls them, or propositions concerning the formation of several mechanical instruments. The first of these propositions is how to construct an alembic which, by the sole assistance of burning mirrors, can effect distillation better than by the aid of a fire. The second is how to make a machine which can light a fire on an altar at any given hour, ignite also the holy candles, and, after that, cause a fountain to rise which will turn the sacrificial flame to ashes.

The third problem will be given at full length. Its subject is how to construct an artificial lantern, by means of which any writings may be read at a long distance.

"Let," says the author, "a lantern (see fig. 1) be constructed of the cylindrical figure which is here shown in the picture, in whose base A B there must be set a concave mirror as nearly as possible parabolic, and within the focus of this mirror let there be placed the flame of a candle F, and you will have at once what you desire.

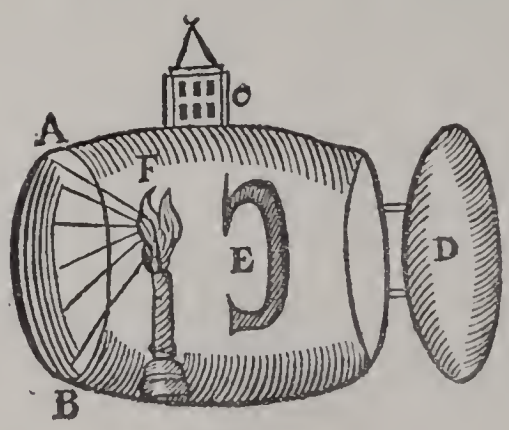

Fig. 1.

"For the light will then shine with such unusual splendour as to show without any difficulty, and by night, even the minutest letters, only to be otherwise seen by the aid of a telescope, while those who behold the flame from a distance will surely suppose it to be a mighty fire. The light will be increased if the interior of the cylinder be formed out of shining tin into an ellipse, but the figure will sufficiently explain the invention. E designates the handle, D the window opening or outlet for the light, and C the chimney."

Kircher, after referring to a chapter in a previous portion of his work, which will be given hereafter, in which an instrument, a peculiar camera, conducive to the birth of the magic lantern, is shown, goes on to say, "Since this singular invention was left by us to be amplified and adorned by other greater inventions, it has happened that many, enticed by the novelty of the matter, applied their minds to its perfection. And among the first of men to do this was a certain Dane—whom Kircher calls, somewhat strangely, Thomas Walgensten—a mathematician of no mean repute, who, after a consideration of my invention described by me as aforesaid, of the magic lantern, effected some improvements therein, and then, to his own great pecuniary advantage, sold it to different men of rank in Italy, so that in a short time the lantern was fairly well known through the whole of Rome. The only difference between this lantern of Walgensten's and my own invention was that the former showed the forms of many objects very clearly in a dark room, to the extreme admiration of the beholders." Kircher, however, also exhibited in his own Jesuit College in a dark room with equal surprise on the part of the spectators. "And it is indeed a thing well worthy of being seen," says Kircher, "when by its aid whole tragic, satiric, or other scenes are exhibited to the life."

The catoptric artifice, previously described, differs from the new lantern only in this, that in the latter case a movable light is called into use, while Kircher utilized the rays of the sun. "Everything that could be shown by the movable lantern was," says Kircher, "shown by me in colours to the life by means of the sun's rays falling on a mirror on which the forms of objects were described, and reflecting them on the wall of an inner chamber; and we also taught in the same place how, without the aid of the sun's rays, to represent objects by a concave mirror or a transparent lens. And," says Kircher, "I enter into these matters the more fully in order to make clear to the reader whence these new mysteries of the lantern have derived their origin, a lantern not undeservedly, in our own opinion, called magic and thaumaturgic, from its wondrous representations of all conceivable objects in a dark-room or in the deep silence of night." And now nothing remains but to explain in a few words the fabrication of this instrument—an instrument which, as the date is important, it is proper to say was not shown to the public in the edition published at Rome in 1646, but first appeared in that published at Amsterdam in 1671, which date, therefore, may be considered that of the birth of the magic lantern.

Let a box (see fig. 2 in supplement) be made of wood, A B C D, with an opening at L for a chimney, through which the smoke of the lantern may pass. Let the lantern K be set in midst, either suspended by a wire or on a stand M, opposite to the aperture at H, in which let a tube be fixed, and at one end of the tube, I, let there be inserted a good lens; at the other end of the tube, at H, let a plane, clear piece of good glass be fixed, on which whatever you choose has been painted in diaphanous water-colours.

This being accomplished in the chamber V X, and on its white wall the light of the lantern passing through the lens will exhibit the image painted on the plain clear glass at H (which must be drawn on the glass upside down), with the right side up, and magnified and expressed with all its different colours to the life. Note, however, that the light of the lantern must be intense, and in order to ensure this, we place the concave steel mirror before the flame, by which means the power of the light will be increased in a wonderful manner.

It remains to explain the manner of multiplying images. Between two boards neatly formed in the shape of a parallelogram let a piece of polished glass be inserted, equal in size to the opening at H; upon this glass let images of whatever kind and number you wish be painted in diaphanous water-colours, as may be seen in the parallelogram M N. This being inserted between the fissures H P, N P

* The letter P is not in the picture, and N seems to have been written for O.

and its pictures moved one after the other to the opening H, will exhibit eight different images upon the wall, whence it is clear that, if you have ready four or five parallelograms of this kind, of which every one gives different images, by help of these you may easily, in a darkened room, show the spectators whatever you will.

The exhibition will affect the beholders with greater wonder if the lantern be placed in a separate chamber, A B C D (see fig. 3 in supplement), and the little tube inserted in the wall B D at the place H, in the manner already mentioned, for then in the adjoining chamber, B E D F, on the opposite wall G, will appear as many images as have been inscribed on the parallelogram—joyful, sad, dreadful, horrible, and, to spectators ignorant of their cause, miraculous—together with such sentences and writings as have been delineated on the glass, all of which the reader will best and most readily understand from the illustration.

In the conclusion of Kircher's "Great Art of Light and Shade," is a short treatise entitled a New Cryptology, a catoptric art by which two friends, being at a distance from one another, may manifest mutually, without any obstacle or inconvenience, their hidden conceptions, and in addition thereto, show their personal presentments reciprocally by a kind of catoptric replication, and exhibit such other matters as they may desire.

This treatise is divided into two parts, of which the one part is concerned with the projection of figures to any distance by means of the sun, the other with catoptric steganography by means of a candle.

It is, says Kircher, in his preface to his new Cryptology, part of the nature of the human intellect to aspire to the attributes of the divinity, and to prosecute their attainment by daring and almost gigantic endeavour. Of these attributes, the two chief are the following, the one to penetrate into the future, and the other to manifest to those who are absent mental conceptions without, it must be understood, the aid of any human medium. Both of these, as they seem at first sight to be far beyond the bounds of natural possibility, deservedly occupy a front place in the ranks of the hidden and the mysterious. With the former, astrology is busied, of which it is unnecessary to speak here; with the latter, steganography; that is to say, the secret means of speaking at a distance. In this art, the author informs us, monarchs of the world have considered themselves especially blessed, having regard to its convenience for ready counsel, and the expeditious dispatch of necessary business. The love of the emperor Maximilian for the abbot Trithemius, at that time the sole proprietor of such a secret, is sufficiently well known.

Our concern here is with Catoptric Steganography, an art, says Kircher, entirely of our own invention, since we remember not to have read anything of the kind in any other author. An admirable art is this, and indeed worthy of the curiosity of kings, an art by which friends at the distance even of three miles may converse together unheard with security and ease. But leaving the wanderings of words, let us come at once, says the author, lest the reader should suppose we are gulling him, to our grand secret. And so we come at once, though Kircher does not, to his second chapter.

Concerning the Mirrors Necessary for Catoptric Steganography.—In Catoptric Steganography, according to the industrious Jesuit, three things are required—a mirror, a mesoptic glass or lens, and a support or stand. The mirror must be plane, not made of glass, nor of steel, but molten of metallic material. In the first place it may not be of glass or crystal, on account of the profundity of the matter rendering the mirror opaque, from which it follows that the reflected ray being refracted in too dense a medium falls upon the wall doubled—an accident which not only renders the characters indecorous, but causes also, amongst them, no insignificant confusion. Steel it may not be, for steel is well known to be impatient of all humidity. And therefore a mirror of the above-mentioned material must not be chosen as the base and foundation of our steganographic operations, for when we proceed to write thereon our mental concepts, such a mirror becomes easily infected and befouled with the juice of the corrosive ink, and will contract rust, and by no means commodiously respond to our design. And so the most suitable of all for our purpose will be a plane mirror molten of metallic material, for this will sustain the ink without any injury, and may also be polished with the least amount of inconvenience.

In the next place will be required a mesoptic glass of a hyperbolic or of a lens-shaped figure; an obtuse section as far as may be, with a diameter of half-a-palm's breadth; and happy may that man consider himself who can attain unto a hyperbolic glass after the fashion of the pupil of his own eye, for he will behold an effect ten times that of a particular lens, and thereby be astonied. The fashion of both of these glasses—the lens-shaped, and the hyperbolic—has been already treated of at considerable length,* and we know that while the hyperbolic can be used for the most remote distances, the lens will only have its effect within a limited radius, and the greater the distance, the greater also must be the hyperbole; and thus much with regard to the glass in general. For the present experiment, an ordinary lens of somewhat obtuse convexity will amply suffice.

In the third place, the support has to be considered. This should be made (see Iconism xxxiv, fig. 1) of an oblong piece of wood C D, having a fissure in its midst G H, within which the mirror A may move. The glass B and the mirror A are so furnished with joints, that they may be fixed in any part or position by versatile craft. F is the foot, or pedestal sustaining the whole machine; and F is of such a size as may be easily set in the valves of a window. This is an instrument which will be found exactly suited to the performance of any work in catoptric steganography, as will, from what follows, more clearly appear.

Of Concave Mirrors.—Concave mirrors may also prove of the greatest service in this experiment, for they increase in a marvellous manner the images of objects, and set them forth in the most perspicuous fashion. But since it is not every one who possesses mirrors of this kind, we rather use plane mirrors which are of more easy attainment. Mirrors made with a section of eighteen degrees have in this art of ours a prodigious effect, and project the shadows of things to a much greater distance. But, says Kircher, I have communicated only to a few skilled friends and acquaintances the art of applying such mirrors.

Kircher's third chapter treats

Of the distances which are required for the projection of the forms of objects.—Since no natural agent can act to an infinite distance, it follows necessarily that it must have a certain and determinate sphere for its activity, the semi-diameter of which sphere may be called the distance of the agent and

* In Book X., Part II., Chapter 8, where the matter, forms, varieties, collocations, and effects of lenses are admirably illustrated and explained.

patient, since within this distance all sensible actions of natural things are concluded. A sphere of this fashion throws off a sensible light, whilst it continually diffuses itself through a mean by uniform propagation, until, when the sensible forms of light at last are lost, it finally ceases in shade, and this sphere extends itself so much the more as the intermediate body more increases the light; but that which increases the light in the greatest degree is a lens in the form of a hyperbola, and others of this kind, as has been already described, arranged in a proportionate degree of distance between the light itself and its boundary. Reflected forms, with which we are here particularly concerned, are allotted a smaller distance than direct forms, which, having been laid down, we have the following problem presented to us.

It is required to know to what distance the reflected forms of objects may be projected. The answer is that since light is multifold, it has also a multifold reflected sphere of its diffusion. The rays of the sun diffuse reflected forms to the greatest distance, a candle less remotely. "I, myself," the author informs us, "have proved that a glass (mirror) of a half palm's size will project the forms of objects to a distance of five hundred feet, so that such forms projected into a dark room can be easily and distinctly interpreted by the bystanders." The plane mirror was, as has been said, of the magnitude of half a palm, the diameter of the round lens of one-third of a palm, and so with a proportional increment of both mirror and glass (lens) the reflected forms of objects may be still further projected in exact accordance with the additional magnitude of mirror and lens.

"Therefore, if the mirror and lens be both of eight palms, I affirm," says Kircher, "that in this case sensible forms of objects may be projected to the distance of twelve thousand feet, nor can this matter admit of the smallest degree of doubt; and this being so, I can imagine nothing more divine. For is it not a paradox, and a matter in the opinion of all incredible, that a man should speak with his friend by means only of a mirror at a distance of three leagues, should exhibit to him any figures he may desire, and send him, if he so choose, a long letter for his perusal? But that these things are as I have said, that mortal alone knows to whom alone in all the world I have communicated this, my secret."

As, however, nothing is altogether perfect in this best of worlds, so even Kircher's steganographic system is attended by some slight inconveniences. Of these the author mentions two only. They are that the forms of the reflected objects are immensely increased—so that, for example, one letter may attain the magnitude of a tower, the other that, in proportion to the distance of the images of the objects, their appearance is weaker; indeed, they wax so feeble that unless the whole room be dark, nothing whatever will be seen. If, therefore, anyone shall be able to hit upon a means by which he may reduce the proportion of these figures when seen at a great distance, and yet at the same time exhibit them clearly, he may congratulate himself on having discovered a secret well worthy of self-glorification, As for me, says Kircher, who am without the necessary leisure for such an undertaking, and destitute of the wealth which it would be likely to consume, I have hitherto failed in bringing the matter to this satisfactory conclusion. But let no man doubt that such a desirable end may be attained by the proper disposition of intermediate concave mirrors. And, concludes Kircher, I think that I have for the nonce sufficiently explained, as it were, in a preface the nature of my secret.

The next chapter—chapter four—is headed,

Of Steganographic Praxis.—We will first teach how to transmit the letters; but before doing so, it is to be noted that nothing can be written by this art of ours save upon the walls of some shady and obscure place. In a manifest light no reflected ray can be well perceived, and so neither the forms of inscriptions reflected from a mirror; but wherever a place is somewhat dark, the shadows of objects may be perceived, and they will appear with so much the more exquisiteness and minuteness as the place in which they are represented is more shady or more obscure. Whosoever therefore will desire to practise himself in this matter, before all things it is necessary (see Iconism xxxiv., figure 1), that he should inscribe with common ink, and upon a plane mirror A, whatsoever he would have appear in reflection. But since the letters he employs cannot be portrayed in their ordinary fashion, and have their erect natural and proper position upon the plane mirror, we have thought it right to append to this article an alphabet constructed as it must necessarily be to procure for him the result required. And we trust that by means of the use thereof every stumbling block which may offend him in his first essay will be wholly removed out of his path.

The letters must be inscribed on the mirror in the position in which they appear in the Latin alphabet displayed in the adjoined Iconism.

In the present Iconism we have displayed the alphabets of three tongues—Hebrew, Greek, and Latin. In these different alphabets, the upper series of every alphabet is that which is natural. The lower series represents the same alphabet written inversely, or turned upside down and the letters are to be inscribed on the mirror in the fashion in which they are here represented.

This then is to be the position of the characters in which we must write what we wish to express upon the mirror for then they will appear in their right order and position projected upon the distant wall. Suppose you are desirous to communicate a matter to a friend at an appointed hour, you will first inscribe the matter on the plane mirror in the conceived words, in letters upside down, as here are shown. Let, for instance, your communication to your friend written on the mirror be conceived in the following words:—

AD MAJOREM DEI GLORIAM.

You will write these words in the manner displayed on the mirror AS.

The words PAX VOBIS should (see Iconism xxxiv figure 2) be inscribed so that they may appear as on the plane mirror V. The figures to be projected are also to be drawn upside down, as is clearly shown in the mirrors R and N.

After the inscription of the letters in the manner indicated, the plane mirror must be continually turned about until the reflected ray falls exactly on the dark place whereon the letters are to appear. If the reflected ray cannot be seen on account of the distance, the visual ray following the path of the reflected ray, will quickly demonstrate the line of steganographic direction. The incidence of the reflected ray having been determined by this artifice, a lens must next be interposed between the mirror and the dark place or terminus in such a manner that the reflected light may cover the whole superficies

the glass. The lens must also be set in an exactly proportioned distance, which distance must be beforehand determined by observation—that is to say, by approximating or elongating the glass (lens) from the mirror, until the reflected forms of the letters appear as distinctly as may be in the position desired. And after all this has been achieved, there will be beheld within the walls of the room, if the terminus be of that nature, the whole of your concept projected, not without the astonishment of those who gaze thereon, in letters a foot and a half in magnitude, so that the whole wall of the room will be occupied therewith. for these letters will appear so much the larger as the space is more distant between the mirror and the terminus.

It is also here to be noted, that, by some unexplained artifice of Nature, the master-painter, the letters will be seen depicted with every variety of colour, which matter, as it is indeed unusual, will work the greater admiration in the minds of those who behold it.

The figure on the left-hand side of the Iconism, representing the popular idea of an angel, bears a tablet containing a Hebrew quotation, a little misspelt, from Proverbs xv. 15, which is, being translated in the English version, "He that is of a merry heart hath a continual feast."

Kircher's fifth chapter treats of the projection of figures. This is virtually the same as that of the letters. It is written, he says, in the Book of Magic, that Solomon, to inspire awe in his subjects, exhibited his figure in places from which he was himself far away. Many interpret this as a fiction of the Rabbis, but by the catoptric art, an image of oneself may be projected to a distance as easily as that of any other person. It is necessary only to draw the extreme lineaments, commonly called the profile. But experience will teach here more than many words. By Catoptrics may be explained marvellous matters in history, hitherto supposed to be the works of devils. Roger Bachon, as Kircher spells his name, was, owing to his knowledge of catoptrics, considered a necromancer.

Chapter VI. deals with coloured images. The only point of variation in the directions for producing them is, that the figure desired to be projected must be painted in transparent colours. The result is so extraordinary, that many calling themselves acute philosophers accused more than once the unhappy Kircher of dealing with the black art.

In the seventh chapter Kircher explains how motion may be communicated to his catoptric semblances. Profiles must be cut out in paper, and legs, arms, feet, hands, and head are to be attached by joints, so that they may be moved by means of strings. The bodies must be fastened by glue to the surface of the mirror. Then the shadows will be seen to move on the wall to the trepidation of all beholders. If you wish to represent flies, you must smear the edges of the mirror with honey, and you will see flies like giants crawling upon the wall. These attached to steel will follow a magnet moved behind the mirror in any direction desired.

Chapter VIII. contains the mechanism of a steganographic horologe, with which it is unnecessary to trouble the reader.

A short Second Part deals with steganographic catoptries by means of a candle. Here the praxis is the same, but the mirror different. It should be, says Kircher, of an obtuse section of eighteen degrees, or parabolic, with a lens-shaped tube in the form of an hyperbola, proportioned to the concavity of the mirror. The fantasms produced in this manner are much more formidable, and with this machine an impious man may, by means of devils described upon the mirrors, be easily restrained from the perpetration of atrocities.

Another method of presenting images by a candle is to write upon the convex superficies of a glass sphere having as large a diameter as may conveniently be gotten. Behind the sphere is set a burning torch. Images are obtained in this way more deftly, with greater certainty, and at a farther distance than by the use of the concave mirror. "But," says the author, "to leave others some room for their experiments, and to prevent our work growing to an excessive size, we willingly break off the thread of our machinations, mindful of that of Menander—

Ο σοφὸς πυλλὰ ὀλίγοις τοῖς λόγοις.

RULES FOR PHOTOGRAPHIC EXHIBITIONS.

Last week the programme of the papers to be read at the Camera Club Conference was published in these pages. It is proposed to have a discussion upon the regulations for photographic exhibitions, at the Conference, at the Society of Arts, on Friday next, with Captain W. de W. Abney in the chair.

The Club has informed a large number of photographic societies that in continuation of the Conference upon this subject, held at the Camera Club in 1888, and in view of the special interest attaching to the question at the present time, it is felt to be advisable to gather together as many views as possible upon certain leading points in exhibition regulations, with the ultimate object of removing some of the disadvantages which are generally held to attend the systems now in vogue. At the Camera Club Conference the Camera Club will bring forward a set of regulations and recommendations as a basis for discussion.

It is believed that there are at least some few points of reform upon which all who are accustomed to exhibit, or are called upon to manage exhibitions, are agreed. Much good would accrue if these conditions could be settled with some definiteness, and be adopted by the leading societies.

The following are set out as points on which there appears to be fair general agreement; upon these and all the submissions criticism is desired:—1. That exhibition authorities and societies should decline prizes placed at their disposal for the purposes of advertising. 2. That some restriction as to the number of awards is required; suggest a basis for a limitation. 3. That awards should be all of equal value. 4. That if any farther division than Art and Scientific Sections be required, the classification be of the simplest—say, *in the Art Sections:* (*a*) landscape and landscape with figure; (*b*) figure subjects; (*c*) portraiture; (*d*) architectural.

Other points upon which agreement is desirable are as follows:—1. Selection and constitution of Board of Judges for Art and Scientific Sections. 2. Announcement of judges' names as early as possible, and before entries are due. 3. The working of the system of champion classes. 4. Exhibition in competition of work by a firm, in which work several hands have had a share. 5. An intimation in the regulations that the judges are *requested* to withhold awards in cases of insufficient merit in a class or classes.

Other points:—Retouching? One picture, one frame? Diplomas or medals? Separate amateur and professional classes? Hanging committee?

Since the foregoing was in type, we have received the following communication on the same subject from Mr. Ralph W. Robinson :—

"A very able and interesting article, by Mr. G. Davison, in a contemporary, deals sensibly, I think, with the present degraded state of photographic exhibitions.

"As Mr. Davison suggests, it is time that exhibitors should speak with no uncertain voice their opinions in the matter. It appears there was once a time when it was an honour to receive an award; but now, alas! on how few of the medals scattered about with such profusion can the photographer with common sense honestly set any value. As trade advertisements, perhaps they are useful as a guarantee that the recipient has obtained a certain degree of proficiency, but to those who really know the state of affairs, what are they? The very badness of design and inferiority of workmanship of many of them are a slight on the artistic perception of the recipient, or an only too faithful testimonial to the want of taste on the part of those responsible for their issue. How long, I wonder, will the long-suffering exhibitor continue to enter his pictures for competition and allow them to be adjudicated upon by journalists and others, however eminent in their own profession, unless—which is rarely the case—they have the education and experience necessary for the true art critic? The deliberations of the Camera Club next week should do good in giving us the carefully considered views of the amateurs. Have not the leading professionals, too, something to say? It should be possible, I think—so self-evident is the undignified state into which exhibitions have fallen—for a combination to be brought about, of the principal exhibitors, to protest against present abuses. If only a dozen or twenty of the most representative men would make up their minds to united action, and refuse to exhibit, except where men of acknowledged ability as artists, either in painting or photography, will be judges, the exhibition committees would soon see the advisability and, indeed, necessity of reform.

"For my own part I would willingly see medals abolished entirely, and only the best of the photographs sent in hung. Of course, the proportion rejected would depend on the quality of work, and space at the disposal of the committee, but the standard should be a high one; and I think Mr. Davison goes under rather than over the mark, when he suggests the rejection of forty per cent. I most emphatically agree with Mr. Davison that there should be no division between professional and amateur, and no classification except into art and science divisions, and perhaps a technical division should be added to include all photographs not shown as works of art, or as of a scientific character. Most interiors, photographs of machinery, *copies* of paintings and other works of art, and similar subjects, would be included in this division. With regard to the fusion of amateur and professional classes, I believe it is fallacious to argue, as some do, that it is unfair to the amateur to make him compete on equal terms with the professional. On the contrary, the professional has many disadvantages, except in portraiture. He must attend to business for the greater part of his time—which many amateurs need not do—and can devote his leisure only to art study. I believe, too, that it has been an invariable result of the mixture of commercialism and art that one or the other has had to suffer.

"I would suggest that instead of awarding medals, the judges should weed out all inferior work and reject it, and from the photographs exhibited select a few of the very best, to be purchased by the Society holding the exhibition, to form a permanent collection, to the lasting honour of the producer, an encouragement to do good work, and, as time goes on, to form invaluable historical records of the art progress of photography."

CHROMO-PHOTOGRAPHY IN THE PRINTING PRESS.

In our notice of Dr. Eder's annual in last week's issue we had occasion to refer to one of the supplements or illustrations with which it is enriched, an illustration printed in coloured inks, and resembling in all respects a bright and airy sketch in water colours. The fact of producing a coloured illustration by means of selecting portions of a negative for printing each with a separate tint, or in some parts with several tints overlaid on the same part is, of course, not new; but when any particularly striking production is seen, there are naturally enough enquiries as to the means by which it has been accomplished, and as in the subject of the present notice, the process is one which is scarcely known in this country, some details of it may be interesting to our readers.

We gather from the annual containing the illustration, and from other sources, that the plates employed by Messrs. Wezel and Naumann, of Leipzig, are prepared as follows :—Lithographic stone is partly dissolved and partly reduced to a pulp by digestion in hydrochloric and sulphuric acids. To this pulp is added a mixture of solution of asphaltum and resin and a small quantity of oil. By this means a mixture of fatty or resinous salts of lime and sulphate of lime is formed. After evaporating the excess of acid a dilute solution of soda is added, and warm zinc plates are covered with a fine spray of the mixture. The plate thus coated with a film of artificial lithostone, is afterwards treated in the same way as an ordinary lithographic stone, except that in place of nitric or hydrochloric acid, phosphoric acid mixed with dilute gum arabic is employed.

Plates thus prepared have yielded as many as 6,000 impressions, and we learn that the process is used to the almost entire exclusion of other processes by Messrs Wezel and Naumann, who have over thirty steam presses doing various lithographic work.

As the film of stone is thin it is recommended to avoid as much as possible having to make corrections. If, however, any are necessary, the place is washed with turpentine, and is then lightly rubbed with pumice powder and water. When dry it is again lightly rubbed with dry pumice powder, care being taken not to lay the zinc bare.

If any correction has to be made after etching, a solution of citric acid, of about one-third strength of that used for stone, is employed, and the spot may then be worked upon again. Dirty corners or patches are best rubbed away with oxalic acid. If by any mischance a place has been laid bare on the zinc it is treated with gallic or tannic acid.

The process as described, it will be seen, is applicable to all lithographic work. In the example before us, the registering of the different plates is so perfectly performed that we cannot detect any fault in that respect, and the total result is the production of a charming chromo-lithograph from a photographic negative.

PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Electro-Chemical Etching Process for Hard Metals—Retouching Negatives—Developers for Flashlight Negatives—Fixing with Magnesium Chloride.

Electro-Chemical Etching Process.—For the production of photo-mechanical blocks, zinc plates are almost exclusively used to receive the transferred image, which is etched into them by means of acids. This process has been very much perfected of late, as it is well known; but where harder metals have been tried for the same purpose, it has always been found exceedingly difficult to etch them as cleanly as required for the various photo-mechanical printing processes. To attain the desired effect, it was necessary to use very strong etching solutions, which attacked the metal unequally, destroyed the fine lines, and produced rough edges. This is now obviated by a new patented "electro-chemical hard metal etching process," which is worked commercially by a trading company at Berlin under the firm of "Electrochemische Graviranstalt." The advantages of this process consist in the fact that it is not only possible to readily work hard metals useless for the ordinary etching process, but that also very good etchings may be produced on curved or cylindrical surfaces. A short description of the *modus operandi* of this establishment may be interesting to some of your readers. The etching is done in a stoneware trough; the etching fluid is a diluted solution of an acid, rendered a good conductor of electricity. For the production of the electrical current a dynamo machine of about 200 ampères is used. The hard metal plate is first well polished, and then the transfer is made on it. The latter is dusted with resin powder in the ordinary way. The surplus of the powder is first wiped off and blown away, and then the rest of it, adhering to the lines and surfaces of the transfer, is melted. This is done by placing the plate on a roasting iron and heating it by means of a Bunsen's burner until, by an evenly black colour of the transferred impression, it is evident that the whole of the remaining resin powder has been melted. The metal plate, the back of which has been protected by asphalt varnish, is now placed in the bath, the composition of which is a different one according to the metallic alloy used. As an electrode on the one hand the hard metal plate itself is used: on the other hand a carbon plate is arranged parallel to the metal plate. The surface of the hard metal plate is of course directed to the counter-plate. If the circuit be now completed, the unprotected spaces of the metal are attacked by influence of electro-chemical decomposition. Where the metal plate dips in the liquid, small bubbles arise, and on the plate bubbles appear, forming a whitish scum. If after a short time the plate is removed, it will be found covered on the unprotected parts with a whitish mass, *i.e.*, a metallic compound. If the latter is rinsed off under the tap, it will be observed that the pure metal is already bitten-in to the thickness of a sheet of paper. As in the case of ordinary zinc etching, the plate is removed from time to time, dried, re-inked with fatty ink, dusted with resin, and the latter melted superficially. After the electrolytic etching process is finished, the asphalt film is removed from the back and the edges of the plate, and the latter made ready for use by sawing, filing, and cutting.

Retouching Negatives from Lead-Pencil Drawings.—The following method has been devised, and is a thoroughly certain and excellent one, by an experienced retoucher, Mr. H. Lenhard. It will be of special value to those retouchers who work in collotype and zincography, as they have in hand many lead-pencil drawings. To make the rendering of such a drawing true to nature, and upon a purely white ground, the following method should be used. Zinc-white, finely rubbed down with water—to which some albumen or gum solution is added, in order to insure to the colour a certain degree of permanence—is applied to the varnished film of the negative, which may be either a wet collodion plate, or a gelatine dry plate, and the colour is spread by means of two badger-hair brushes (so-called dabbers) by even strokes downward and from right to left, or *vice versa*, so as to form an entirely equal and well-covering layer over the varnish film. After drying, the negative is placed on the retouching desk, and a mirror is placed beneath it, in order to enable the retoucher at work to see the most delicate lines of the drawing, and by means of a pointed wooden pencil (beech-wood), the drawing is touched up in all its lines. By this means every line becomes uncovered and remains sharp, whilst the ground retains its full covering power. Of course the printer must treat such negatives delicately, because the zinc-white film is easily damaged by rubbing. The laying on of the covering ground requires some practice.

Developers for Flashlight Negatives.—We learn from the *Wochenblatt* that Professor Eder, in his new book, "Photography by Magnesium Light," recommends the following developers for flash-light pictures:—

1.—*Pyro Developer.*

A.—Sodium sulphite	... ...	100 grammes
Pyro	... ...	11 ,,
Water	... ...	500 c.c.
Concentrated sulphuric acid	...	6 drops
B.—Cryst. soda	... ...	50 grammes
Water	... ...	500 c.c.

Just before use, not sooner, 20 c.c. of solution A and 20 c.c. of solution B are mixed with 20 c.c. of water.

2.—*Hydroquinone Developer.*

A.—Hydroquinone	... ...	10 grammes
Sodium sulphite	... ...	40 ,,
Water	... ...	400 c.c.
B.—Potassium carbonate	... ...	20 grammes
Water	... ...	20 ,,

Before development 20 c.c. of solution A are mixed with 20 c.c. of solution B. This developer can be used repeatedly, and it is recommended to add a small quantity of fresh developer, but not before the development has been nearly finished.

Fixing with Magnesium Chloride.—Magnesium chloride ($Mg\ Cl_2$), which, as the older operators will remember, served as a useful addition to the collodion, by which the vigour of the negative was increased, and the solarisation of the sky prevented, has of late been tried by Herr R. E. Liesegang as a fixing agent for gelatino-chloride paper. This experimenter found that prints on this paper were completely fixed if treated with a diluted solution of this salt, and that they were not at all reduced in vigour, as is the case with hypo, ammonia, and sulphocyanide of ammonia. The fixed prints kept well; but as the gelatine of the film is slightly attacked by the salt, it is advisable to add a small quantity of alum to the bath. "Perhaps," says the author, "the magnesium chloride, on account of these properties, can be used for fixing photographs in natural colours."

Notes.

The latest photographic curiosity is the rhombohedral camera of Professor Cohn, of Breslau, by which a picture can be taken while the eye is regarding it in the glass screen. This is effected in the following way:—Two rhombohedra of glass are placed in a special chamber just behind the camera lens, by which means two images are thrown upon the upper and lower halves respectively of the ground glass screen, the eye looking along a path between the two rhombohedra. To use the instrument a sensitive plate is put in place of the upper half of the ground glass. When a sharply defined image has been obtained upon the lower glass, an instantaneous shutter is released in the interior of the camera in front of the upper rhombohedron, and the picture is obtained on the sensitive plate.

The competition in the insurance world to obtain new "lives" is so keen that many contrivances are adopted on the part of agents to ingratiate themselves with possible insurers. The great point is to get an introduction, and, after a little agreeable conversation, to artfully bring up the subject of life insurance and its incalculable benefits by a sort of side wind. One of the most successful agents, who does a large business in the provinces, finds a photographic outfit one of the most useful baits he has ever tried. In calling upon the various farmers, what can be easier than to talk to the farmer's wife or daughters about photography? The matter once started, the next thing is to produce the camera from the gig, and proceed then and there to photograph the members of the farmer's family. "If," as the agent shrewdly remarks, "the farmer has got no family, then I commence talking about his favourite horse, dog, or cow, and the photographs, so far as I am concerned, are quite as good as those of human beings."

Of course the photograph once taken, a second visit is a necessity in order to exhibit the proof, and in this way friendly relations are built up. But one thing the agent informs us is indispensable. The ladies must be flattered; hence an arrangement with a skilful retoucher is indispensable. This makes photography rather a heavy outlay, but the commission paid by insurance offices is now-a-days so large that, though the enterprise is purely speculative, it pays in the long run.

Professor Romyn Hitchcock, in the *American Monthly Microscopical Journal*, gives some valuable hints as to the use of coloured screens in photomicrography. The blue produced by ammonio-sulphate of copper was formerly used, but when colour sensitive plates were introduced yellow screens took the place of blue, because it was found that many specimens had yellow, red, and brown parts which were not well photographed with blue light. The colour and thickness of the screen both require attention. If it be too thin the blue light is not sufficiently cut off. In particular cases an almost monochromatic yellow light is desirable, as when it is desired to obtain sharp outlines of deeply stained objects regardless of structural details.

But generally a rather broader spectrum range is desirable, for the light employed should correspond to the different colours or shades of colour of the object. It is owing to neglect of this consideration that we often see photo-micrographs which are mere silhouettes, while the objects show much more structure to the eye. This is frequently observed in photographs of such structures as the tongue and sting of a bee, and legs of insects. In other preparations, in which the colour is a stain-brown or red, for example, the fault lies partly in the exposure, which, in many cases, is insufficient to give more than outlines and blank interiors. This is frequently noticeable in photographs of bacteria. By a proper choice of a screen, if a screen is required, a photograph should show any object as clearly as we can see it in the microscope. Colour-sensitive plates may be said to be indispensable in the photography of rock sections with polarized light.

It is curious to read in Mr. W. P. Frith's "Reminiscences" how photography, now used so extensively by the police in the detection of criminals, was anticipated by the pencil. Mr. Frith gives two examples. The first relates to an experience of Mulready, who, while walking down the Bayswater Road in 1805, was stopped by a foot-pad armed with a pistol. The artist had no choice but to comply, and, on reaching home, drew the man's face very carefully, taking the drawing to Bow Street. Within a fortnight the man was captured, his apprehension being due entirely to the picture. The second instance relates to Mr. G. B. O'Neil, who was robbed of his watch while looking at the time under a gas lamp near Kensington Church. The time for observation was very short, but the artist was able to make a drawing, which he gave to the police. The man was soon after caught, and at his trial the drawing was produced, and the likeness, together with Mr. O'Neil's recognition, was sufficient to convict him. Mr. Augustus Egg, R.A., also made a drawing in connection with a robbery at his house. Unfortunately the drawing was not that of the thief, but of his dismantled room, with himself standing ruefully gazing at the scene.

From a discussion on a paper read by Mr. W. Lovibond at the Chemical Society on a new method of colour analysis by means of the tintometer, it appears that women, in regard to eyesight, are vastly superior to men. Mr. David Howard, who presided, remarked that in all his experience he had never met with a colour-blind woman, and did not believe that one existed. This opens up a new sphere of woman's work. Where nicety of vision in regard to tints is required, women certainly should be employed.

THE CRYSTAL PALACE PHOTOGRAPHIC EXHIBITION.—I.

The Photographic Exhibition this year at the Crystal Palace contains more pictures than did the Exhibition of 1889, and a smaller show of photographic apparatus. The pronounced novelties in apparatus placed on view are not numerous, but the most interesting feature to the landscape photographer is the evidence of a growing tendency to substitute aluminium for brass, wherever possible, in lens mounts and cameras. The recent improvements in the manufacture of aluminium on a large scale have, according to a statement made some months ago by Sir Henry Roscoe at the Royal Institution, reduced the price of aluminium to twenty shillings a pound.

Messrs. Watson and Son have fitted up an aluminium turn-table to some of their well-known "Acme" cameras, thereby obtaining a palpably great reduction in weight; this reduction, they state, amounts to three-quarters of a pound in a half-plate camera; and in a whole-plate camera, to seventeen ounces.

The same firm has also on view a heavy studio camera and stand, with exceptionally quick screw focussing motions, and fig. 1 will help to explain the principle on which the ponderous camera can be tilted upwards or downwards by the operator. The base of the camera is represented by N K, and W V represent the ends of two wooden bars affixed thereto. A E represents an angular piece of wood, which by a screw motion can be made to slide backwards or forwards horizontally along the top of the stand, whilst the camera base N K is so hinged that it cannot move horizontally. Under these conditions, when A E is moved in the direction indicated by the arrow in the cut, the bar V rises and the bar W falls, and the camera is tilted accordingly; if they be moved in the opposite direction, the end N of the camera will rise, and K will fall. The camera has a large turntable, with spanners of suitable dimensions, and works firmly.

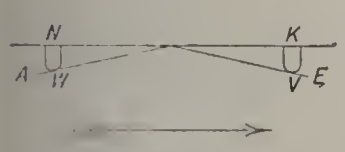

Fig. 1.

The chief feature of the exhibit of Mr. Fox Shew is, of course, his well-known hand-camera, but he has two novelties in the shape of lens shutters. One of these, which he calls "The Eclipse Repeating Shutter," is represented in fig. 2. It has an adjunct which is a blessing, namely, an arrangement by which it can be fitted on to lens hoods of different diameters; this arrangement consists of a compressing ring and an india-rubber washer. The shutter has a pneumatic release, does not require setting, and will work in any position.

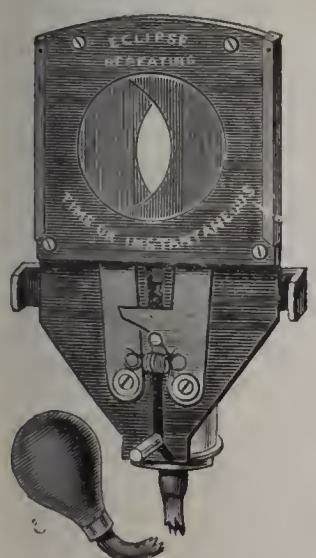

Fig. 2.

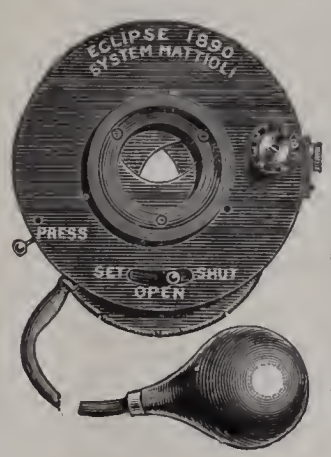

Fig. 3.

The other shutter, fig. 3, exhibited by Mr. Shew, is the invention of an Italian, Signor Mattioli. Mr. Shew calls it "The 1890 Eclipse Shutter." Its mechanism consists chiefly of three sectors, which open concentrically, and are actuated by a revolving flat ring, which travels round and opens or closes them. The shutter has a strong spiral spring with little play; each moving part of the shutter has little work to do, and this principle favours rapidity of action. The following are some of the advantages which Mr. Shew states to belong to the shutter:—(1) It can be fitted in the centre of the lenses, at the back, or on the hood as required; (2) It is of very high rate of speed, due to an entirely new system of propelling disc; (3) It can be adjusted to eight different speeds as well as for time exposures; (4) It is perfectly smooth and free from vibration in its action, whether at full speed or slow; (5) It is smaller and more compact than any shutter in the market, being at the same time very strong, and not liable to be affected by any change of climate—a shutter uncovering a lens for 8 by 5 measuring only 3½ inches diameter by ½ inch in thickness; (6) It is provided with a rotating diaphragm plate corresponding with the stops of the lens; (7) Owing to an improved method of releasing valve, the ball or pear of the pneumatic release is considerably smaller than usual, and instantly refills itself; (8) It is provided with a trigger, which may be used in lieu of the pneumatic release for box detective and other hand cameras; (9) The mode of manipulating the shutter is engraved on the face, thus dispensing with loose instructions.

Messrs. Smith and Beck exhibit their recently introduced aluminium mounts for lenses, and which will effect a considerable reduction in the weight of the apparatus of landscape photographers, more especially of those who adopt the wise system of travelling with plenty of lens power. The aluminium mounts are one-third the weight of brass mounts. There are difficulties in working aluminium. It "drags" under the tool, as does pure copper, so has to be turned slowly under some lubricating medium; for aluminium, paraffin is the medium selected. There is a difficulty in soldering it, which has been partially overcome by Cowles and others. Messrs. Beck and Co. inform us that, "under certain conditions the metal can be soldered; but joints cannot be made sufficiently sound to bear tube drawing. Where tubes are required, they must be drawn out of solid castings, and the results are not even then always as satisfactory as might be wished. Another difficulty in working the metal is that of obtaining a good surface." Aluminium is reasonably free from liability to attack by any chemical substances it is likely to meet when it is in the form of fairly cared-for lens mounts. The lenses, mounted as described by Messrs. Smith and Beck, have iris diaphragms, graduated to indicate the apertures recommended by the Photographic Society. The same firm exhibits its "Pecrops" tourists' camera, one of the features of which is, that it does not rack out, but pulls out, and can then be clamped at once, so that time is saved by the user.

Mr. Stanley exhibits a convenient combined rocker and developing-room lantern, the principle of which may be explained by the aid of fig. 4. In this cut, E E E

represent the red glass front of a developing-room lamp, through the bottom and inclined window of which the rays from the light A fall upon the mirror N M, and are reflected upwards through the glass platform F H F; on this platform the glass developing dish is placed; red light thus passes from below through the negative in course of development, so that the amount of density it is gaining can be continuously watched. Some light from the upper part of the lamp falls at the same time upon the upper surface of the plate in the dish. A rocking motion is given to the platform by means of the pendulum H K. At M the mirror is held by a hinge; a little chain is attached to the other end of the mirror, N, by the aid of which chain the mirror can be raised or lowered, and hooked so as to rest at any required angle.

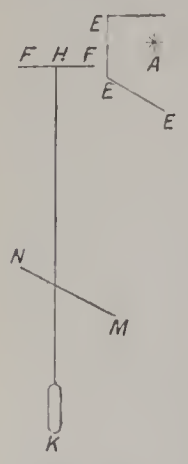

Fig. 4.

Mr. Stanley also exhibits a new magnesium lamp, invented by Mr. Ferrero, intended for the illumination of negatives which have to be copied in the camera, and for other purposes. Fig. 5 will help to explain its principle. In this cut, H N is a sheet of ground glass, closing the major opening of a horizontal pyramidal chamber made of tin, whitened inside. A is a wheel carrying a coil of magnesium ribbon, which is paid out by hand. W W is a small sheet of glass, with a small circular piece of white paper affixed to it at K to prevent the direct rays of the light M falling upon the sheet of glass H N. The rays can thus reach it only by reflection from white surfaces, by which means the illumination is more equalised. When in use, a spirit-flame is constantly burning at the mouth of the tube whence the magnesium ribbon enters the lamp, so that should the magnesium light go out, it is soon re-lit.

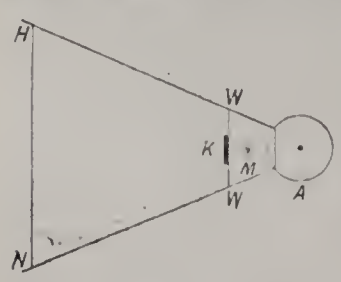

Fig. 5.

The tops of Mr. Stanley's folding-stands are made on the principle indicated by fig. 6, in which D is the wooden top of the fork of one leg, and K E the brass slip attached thereto. B is a part of the stand head, and A B a brass cone on which the fork of the leg bears in use. This conical form is given to the brass peg A B, we are told, to prevent K E from springing to B, and in prolonged use the latter always finds a part of the peg to bear against, instead of touching a flat portion of the stand head proper, in which latter case the stand would be less rigid.

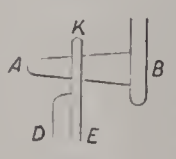

Fig. 6.

Photographic Society of Ireland.—A lantern meeting will be held on March 27th, and on April 11th Prof. J. H. Stewart will take as his topic, "The Stop, and the Optical Centre."

Last Friday night the machine camera invented by Mr. Friese Greene and Mr. Mortimer Evans was exhibited in the library of the Royal Institution after the close of the usual Friday evening lecture. The instrument attracted much attention.

PHOTOGRAPHY IN FRANCE.

French Photographic Society—Exposure Shutter—Developer in Tablets—Halo and Means of Preventing it—Orthochromatism.

Exposure Shutter. — A communication was received from MM. Marillier and Robelet, introducing the instantaneous shutter of R. Blänsdorf. This instrument is truly simple and ingenious. The length of exposure is regulated by a fan which may be changed at will for one of larger or smaller size, as the exposure is desired to be comparatively long or short. The resistance offered by the air to the speed of the fan is greater or less as the surface of the vanes is more or less extended. If the apparatus is well constructed, apparently it should not alone work with almost chronometric exactitude, but should be free from the danger of getting out of order.

Developer in Tablets.—This developer, the composition of which is not stated, is presented in the form of tablets, or pastilles. No weighing is required; it is sufficient to know that for a given quantity of water a certain number of the pastilles will be necessary. Several members of the Society have experimented with these tablets and find them very satisfactory.

Theoretical Explanation of Halo, and the Means of Preventing It.— By a singular coincidence communications have been received at the same time from M. Cornu, of the Institute, and from Messrs. Lumière and Son, of Lyons, relating to the same subject, "The Cause of Halo." From the explanations given, it appears that there are rays which are totally reflected after falling upon the inner surface of the glass. The fact is verified by using a luminous point on a black background. This spot is photographed, and the image shows an aureole or halo round the luminous spot. M. Cornu endeavoured to suppress the halo by covering the back of the glass with a varnish composed of essences of cinnamon or of clove in which a piece of glass is placed, and other essences are gradually added until the glass ceases to be visible. We have then a liquid the refraction index of which is the same as that of the glass. This varnish is blackened with lamp black, and is applied to the back of the plates with a brush. The rays traversing the thickness of the glass are thus entirely absorbed; there are no longer any reflections, and the halo is suppressed. The unfortunate thing connected with this remedy is, that it is not very practicable in application. It is unfortunately difficult to replace this coating by a sheet of paper or by any other black surface, for optical contact is indispensible in order to suppress the halo. To arrive at the desideratum, we ought to be able to manufacture an adhesive black material, the index of which is equal to that of glass, and which might be applied immediately to the back of the glass, thus realising optical contact. In this way the employment of the proposed remedy would be easy.

Contretypes in China Ink.—M. E. Vallot showed a very successful contretype obtained with liquid China ink. It had been produced in the following way. A glass plate covered with bichromated gelatine had been exposed to the action of light under a negative for the desired time, and then developed in water blackened by liquid China ink. The gelatine not indurated by the light imbibed the liquid, and finally an excellent negative was obtained. The same operations may be gone through by immersing the exposed gelatine in a colouring bath of any tint, but it is necessary to use permanent colours if the negative is not

to be liable to fading. This process shows that there is no necessity to use a plate containing silver bromide in gelatine; certainly such a plate may be used if the silver compound is first dissolved in hyposulphite of soda. The plate is then well washed, sensitised in solution of bichromate of potassium, and, after drying, exposed under a negative, and developed in a colouring bath. A perfect contretype is thus obtained.

Practical Orthochromatism.—M. Lèon Vidal—in view of the interest excited amongst the members of the Society by divers presentations relating to orthochromatism—thought it desirable to explain that this art, which consists in reproducing in grey tones (monochrome) the various tonalities of coloured objects, is practically easy of application provided that one is somewhat initiated in the knowledge of the question. In the first place, we should know what are the cases in which orthochromatism is necessary. Generally, he said, it is useless, when working from nature in taking landscapes and buildings, to employ orthochromatic plates. It is sufficient to be furnished with pellicular screens coloured with aurantia of different degrees according to the subject, and a little practice soon teaches what is the depth required for the particular case. In photographing interiors, orthochromatic plates are often necessary, especially for such subjects as fruits, flowers, pictures, and designs in coloured material. In this case, however, the employment of screens is still indispensable, and it is very rarely that their use can be omitted. Now, it is inexact to say that for coloured objects we may use with success one sole orthochromatic preparation. Preparation of eosine, erythrosine, and chrysaniline, may do for reproductions where yellow, green, and orange are the dominant colours; but where red is dominant, it is absolutely necessary to have recourse to other preparations, notably chlorophylla cyanine, or to a mixture of erythrosine and cyanine. The best thing to do, then, when not engaged in some definite work for which ordinary commercial plates may be suitable, is to make orthochromatic plates oneself, by preparing them for the particular kind of work to be done. Nothing is easier or simpler than the preparation by the bath method, and he asked himself in vain how it happens that so few persons have, up to the present, thought of preparing their photographic palette. For our own part, says the author of the communication, we continue to make various preparations for the purposes of our work, and we succeed with the most complete facility. The conclusion arrived at is, that except for special cases, it is better worth while to prepare oneself the plates that may be required, than to use commercial ones, and that it should be remembered that more often than not the screen alone suffices, and that its use is indispensable for correcting tonality, even when using orthochromatic plates. By the aid of lantern slides M. Vidal showed results obtained with and without screens on orthochromatic plates, as well as on ordinary ones, and called attention to the very feeble difference existing between views of the same subject taken by him on ordinary and on orthochromatic plates when used without a screen.

The meeting terminated with the exhibition of some very fine lantern slides by M. Bagnet and M. Balagny.

Leon Vidal.

The Earl of Crawford and Balcarres has closed and dismantled the observatory at Dun Echt, which has been so well-known to all astronomers for many years past, and has presented all the instruments and the astronomical library to the Royal Observatory at Edinburgh.

Specifications Published.

5,374.—*March 29th*, 1889. "Photographic Printing." William Walker James Nicol, Mason College, Birmingham, Doctor of Science, Lecturer on Chemistry.

My invention has for its object the production of photographic pictures or images in silver on paper, wood, or other surfaces.

For this purpose I apply to paper or other suitable material, a coating of a ferric salt, alone or mixed with the other salts hereinafter specially mentioned; the surface thus prepared is sensitive to light. The ferric salt used may be that of any of the organic acids afterwards mentioned, which prevent the precipitation of iron by ammonia; or it may be any other ferric salt sensitive to light, and the precipitation of the iron is in this case prevented by the addition of a sodium, ammonium, or potassium salt of one of the organic acids, which prevents the precipitation of iron by ammonia, and this may be employed either in the solution with which the paper or other material is coated, or it may be added to one or other of the solutions subsequently used. The surface sensitive to light is then exposed to the action of light under a negative or other screen of similar character, when after some time a faint image becomes visible. It is then brought in contact with a solution containing silver nitrate or the other salts of silver (subsequently mentioned) dissolved in ammonia, to which has been added potassium oxalate, or the other salts mentioned later, which may tend to increase the rapidity and vigour of the development, alter the tone of the finished picture, or prevent the precipitation of the iron by the ammonia. The print is then washed in water to which has been added ammonia, and a salt of one of the organic acids, which prevents the precipitation of iron by ammonia. A subsequent washing in water, followed by drying, completes the operation.

Hitherto no means have been known by which, when using ferric salts as sensitisers (*i.e.*, for coating the paper), and developing with solutions containing silver salts, a print could be obtained, the tone of which was such that toning with gold or other metals, followed by the use of sodium-thio-sulphate, could be dispensed with; I therefore greatly simplify the operations involved, and add to the permanency of the finished print. According to my invention, I use paper, wood, glass, woven or other material, the surface of which I prepare and

render sensitive, by applying to it in any convenient manner a solution prepared in one of the following ways :—

1. I make a solution of normal ferric sodium citrate ($Fe\ Na_3\ (C_6\ H_5\ O_7)\ 2$) containing twenty per cent. of the salt as expressed by the above formula, and add to it five per cent. of normal potassium oxalate ($K_2\ C_2\ O_4$), but I do not confine myself to these exact proportions; they may be altered according to the vigour and tone desired in the resulting picture. In place of the ferric sodium citrate mentioned above I sometimes use other salts as follows :—Ferric ammonium citrate or ferric potassium citrate or the corresponding salts of tartaric acid, also ferric tartrate and ferric citrate, and I sometimes use a mixture of these ferric salts with citric or tartaric or oxalic acid, or the salts of these acids with potassium, sodium, or ammonium. I have also been very successful with solutions of ferric salts which are precipitated by ammonia either alone or with one or other of the above salts and acids. Thus I have obtained excellent results with the following :—

2. I make a solution containing five per cent. of normal ferric oxalate ($Fe_2\ (C_2\ O_4)\ 3$), and five per cent. normal ferric tartrate ($Fe_2\ (C_4\ H_4,\ O_6)\ 3$), and one per cent. of tartaric or oxalic acid ; in this case the precipitation of the iron is prevented by modifying the developer or subsequent solutions as stated below. I do not, however, confine myself to these exact proportions, as they may be altered according to the effect desired, as stated above. In general, however, I prefer to use one or other of these solutions, the composition of which I have stated in full. In some cases depending on the nature of the surface to be coated: if, for instance, it be glass, wood, or cloth, thickening material, such as gelatine, starch, arrowroot, or gum-arabic may be added to the above solutions; usually this is not required for paper. The paper or other surface prepared with one or other of the foregoing solutions is dried, and is then ready for use. After exposure to light in the usual manner I apply to it the developing solution.

I use solutions of various soluble salts of the metals of the alkalies or ammonium. I have been most successful with the following—viz., potassium, sodium, or ammonium, oxalate, acetate, borate, citrate, or tartrate, either alone or mixed together.

1. Thus, with paper sensitised with No. 1 solution, for cold blue-black tones I prefer a solution containing—(*a*) 20 per cent. potassium oxalate ; 1·5 per cent. silver nitrate, the precipitate formed being nearly dissolved by the addition of ammonia. (*b*) For black neutral tones :—10 per cent. potassium oxalate ; 1·5 per cent. silver nitrate. (*c*) For sepia tones :—7 per cent. borax ; 1·5 per cent. silver nitrate. In both cases ammonia is added as above.

2. When the paper is sensitised with No. 2 solution I prefer a solution containing—(*a*) 15 per cent. potassium citrate ; 10 per cent. sodium acetate ; 1·5 per cent. silver nitrate ; or (*b*) 15 per cent. potassium citrate ; 10 per cent. potassium oxalate ; 1·5 per cent. silver nitrate; ammonia being added in both cases as above.

The developing solutions 1, *a*, *b*, or *c*, may be used with paper prepared with sensitising solution 2, if the prints, after removal from the developing solution, are placed for a short time in a solution prepared thus :—

Clearing solution—20 per cent. solution of citrate or tartrate of potassium, sodium or ammonium rendered distinctly alkaline with ammonia. When greater contrast is desired in the print I obtain this by adding an oxidising agent to the developer, preferably a salt of chromic acid in quantities of from 2 to 10 c.cms. of a 5 per cent. solution of potassium chromate to the litre of developer. I do not confine myself to any definite temperature of the developer, though I prefer to use this at the temperature of the air. The developer may be applied to the printed surface in any convenient way.

After treatment with the developer the print is washed in successive changes (*i.e.*, till iron and silver salts are removed) of the washing solution. I prepare this as follows :—Washing solution—A 25 per cent. solution of sodium citrate is mixed with an equal volume of strong ammonia solution. This is then diluted with ordinary water in the proportion of 150 c.cms. to every 10 litres of water. Potassium or ammonium, citrate, or potassium, sodium or ammonium, tartrate, or sodium, potassium tartrate, may be used in place of the sodium citrate in the above.

The prints are then washed in water and dried.

Having now particularly described and ascertained the nature of my said invention, I wish it understood that I do not confine myself to the mixtures mentioned, or to the exact proportions of the ingredients given therein, but employ on occasion other mixtures and proportions of the salts particularly mentioned as suitable for my purpose, nor do I confine myself to aqueous solutions of the said salts, but may for the purposes of preparing the sensitising and developing solutions use other solvents where these are permitted by the chemical nature of the salts employed, and I therefore claim as my invention as follows :—

1. The use of paper or other surfaces coated with ferric salts as described above, to be used for the production of photographic images in silver, along with the class of developing solutions already given and particularly referred to in my second claim.

2. The use of solutions of silver salts dissolved in ammonia in conjunction with salts of the alkalies or ammonium with oxalic, acetic, boric, citric, or tartaric acids, for the purpose of producing on paper or other surfaces previously coated with ferric salts sensitive to light, images in silver which are of such a colour as not to require toning with gold or other metals.

3. The combined use of ammonia and a potassium, sodium, or ammonium salt of citric or tartaric acid, in a solution used for washing prints obtained on surfaces coated with ferric salts, and developed with solutions of silver salts in ammonia.

4. The use of the solutions—sensitising solutions 1 and 2. Developing solutions 1 *a*, *b*, and *c* ; 2 *a*, *b*, and *c*. Clearing solution ; washing solution in the way and manner substantially as described and set forth in the foregoing.

5. The use of an oxydising agent, such as chromic acids or any of its salts, in a developer prepared as described and set forth.

4,716. *March 18th*, 1889. "Photographic Cameras." James Yate Johnson, 47, Lincolns Inn Fields, London, Gentleman, communicated from abroad by Henri Pusset, of 48, Rue de Bondy, Paris.

An improved photographic camera, according to this invention, is provided with a magazine containing a number of sensitive plates which are capable of being pushed towards the front by a spring. These sensitive plates are separated from each other by plates of ebonite or other material not liable to be affected by the chemicals employed in the developing process, which may be performed in the interior of the camera, as hereinafter explained. The plates are pressed together by the action of the spring, and a partition working in suitable guides so as to push forward the plates without inclining or tilting them may be interposed between the plates and the spring at the back.

To charge the magazine with plates a slide at the back is drawn out so as to disengage a sliding cover which, being drawn back, horizontally exposes the interior of the magazine so that the plates can be inserted, after which the magazine is closed by returning the slides to their original position. When a plate has been exposed, it is pushed by means of a flexible slide or curtain into a light-tight bag underneath the magazine. The plate can then be passed through an opening in the lower part of the back into a dish on the bottom of the camera, in which it can be developed, the process being watched through an opening covered with ruby glass in the top of the camera. The interior of the camera is lighted during this operation by means of one or more ruby glass windows or openings in the side or sides. These openings may be provided with dark slides or shutters.

The developer is introduced into the dish through a rubber tube fitted to a short tube attached to the bottom of the dish. This short tube protrudes through an opening in the bottom of the camera so arranged as to admit of the necessary movements of the dish.

The camera is provided with a sliding shutter, which is

retained in the closed position by a spring catch. A rubber spring tends to pull down the shutter and uncover the lens. By means of a rod the spring catch can be caused to release the shutter, which thereupon descends and uncovers the lens. A pin on the shutter then comes in contact with a horizontal rubber spring or band, the elasticity of which causes the shutter to rebound and return to the closed position, where it is retained by the spring catch. The shock is absorbed by a spring provided for the purpose.

To exclude light from the magazine the flexible slide or curtain hereinbefore referred to is arranged to close the opening between the magazine and the camera, and extends downwards through an opening in the bottom of the magazine sufficiently to cover the opening hereinbefore referred to in the lower part of the back of the camera. The opening in the bottom of the magazine for the passage of the shutter is closed by a spring shutter when the slide or curtain is drawn up. This flexible slide works in a vertical groove in the front of the magazine, and in a horizontal groove in the top of the latter.

The camera may be provided with two focus finders, in which the image is projected by a lens on to a mirror which reflects it on to ground glass screen in the usual way. One of these focus finders is used for pictures taken with the longer axis of the plate vertical, the other serving for pictures taken with this axis horizontal. The apparatus is further provided with a focus finder of special construction, composed of a convex mirror receiving light through an opening in the front of the camera, and which can be seen through an opening in the top of the camera. A small hole is formed in the centre of this mirror, and a thread or wire extending diagonally across the opening in the front carries a register mark, such as a small glass bead. In order to direct the camera on an object it is held under the arm in such a position that the register or bead coincides with the hole in the centre of the mirror. This mirror may be made of glass tinned or simply blackened at the back.

On Thursday, March 20th, there will be an exhibition of lantern slides at the Society of Arts in connection with the Camera Club Conference.

Photographic Club.—On Wednesday, March 19th, the adjourned discussion will be held on "Artificial Light as an Adjunct to Daylight"; March 26th will be the monthly lantern meeting.

Travellers in Russia are now obliged to have their photographs annexed to their passports. The photographer, however, rarely has any good fall to his lot without having to pay some compensation for it. The Russian law will soon impose a stamp duty upon eartes-de-visite.

Sheffield Photographic Society.—An exhibition of photographic slides has been given at the Montgomery Hall, in aid of the building fund of the Public Hospital and Dispensary. The slides were mostly the work of members of the Society, the majority being of local interest, and were exhibited by means of a powerful lantern belonging to Mr. W. D. Forsdike. The slides were described and commented upon by Mr. Alleyne Reynolds. The first series of photographs consisted of views in Sheffield, and most of them instantaneous street scenes. Following these were a number of pictures taken in the suburbs, and afterwards photographs of Derbyshire views were exhibited. The exhibitions concluded with a number of miscellaneous views.

A London Summer Photographic Exhibition.—Mr. Kenric B. Murray, Secretary to the London Chamber of Commerce, sends us information about a proposed city summer photographic exhibition, under the auspices of the Photographic Trade Section of the London Chamber of Commerce. He says that it has been decided by the Photographic Trade Section to organise an exhibition of photographic apparatus and pictures, to take place in the centre of the City of London from the 1st to the 15th June next, and that it is believed that one of the largest of the City Companies will kindly give the Section the free use of its hall and rooms for this purpose. The undertaking has a long list of "patrons," headed by the Lord Mayor.

Correspondence.

THE ROYAL METEOROLOGICAL SOCIETY.

Sir,— At the ordinary meeting of the Society to be held by kind permission of the Council of the Institution of Civil Engineers at 25, Great George Street, Westminster, on Wednesday, the 19th inst., at 7 p.m., the following papers will be read:—

"A Brief Notice respecting Photography in Relation to Meteorological Work," by G. M. Whipple, B.Sc., F.R.Met.Soc.; "Application of Photography to Meteorological Phenomena," by William Marriott, F.R.Met.Soc. These papers will be illustrated with lantern slides.

After the reading of these papers the meeting will be adjourned, in order to afford the Fellows and their friends an opportunity of inspecting the exhibition of instruments illustrating the application of photography to meteorology, and of such new instruments as have been invented and first constructed since the last Exhibition.

The Exhibition will, at the request of the Secretary of the Institution of Civil Engineers, be open in readiness for their meeting on Tuesday evening, the 18th inst., and will remain open till Friday, the 21st inst.

William Marriott, Assistant Secretary.

30, *Great George Street, Westminster, S.W., March*, 1890.

THE LANTERN SOCIETY.

Sir,—The adjourned general meeting of the above Society will be held in the Regent Street Saloon of the St. James's Hall on Wednesday, March 19th, at 7.30 p.m., for the purpose of considering the rules drawn up by the provisional committee.

T. H. Holding, Secretary *pro. tem.*

46, *Chesilton Road, Munster Park.*

Proceedings of Societies.

Photographic Society of Great Britain.

At the meeting of this Society held on Tuesday evening, the 11th inst., the chair was occupied by Mr. J. Glaisher, F.R.S., President.

Mr. G. L. Addenbrooke, who had been announced to open the discussion on Dr. Lindsay Johnson's paper, adjourned from the previous meeting, sent a letter regretting his inability to be present, and giving his views on the subject. He thought that the scheme for an Institute proposed by Dr. Johnson could only be accomplished either by obtaining a charter for the Society, and granting diplomas for which fees could be charged, or by munificence of private donors.

A letter from Dr. Emerson was also read, in which he said that he thought the proposed Institute ought to be independent of any other body, such as the authorities of South Kensington. He had no idea of sharing rooms with any other Society, but would like the Institute to have its own premises, in which there ought to be a library, a laboratory, space for exhibitions, a dark room, &c., as well as a museum. There should be courses of lectures, and those who attended them should be furnished with diplomas of the Society, but for the first year or so members of the photographic societies should receive diplomas without qualification. As to the Society's Journal, he thought that in it the art side of photography had been sadly neglected, and that there should be associated with the Editor some one specially qualified and interested in that department. The management of the proposed Institute should be entrusted to amateurs and professionals who were practical men, and those who merely took up photography in a *dilletante* spirit should be excluded from office.

Mr. W. S. Bird said that they had to consider whether a scheme could be drafted that would be capable of being put into effect. He thought that in the first instance a subscription list should be opened. If members came forward so that they could start with £2,000, they could appeal with much better grace either to the City Companies or to the public. Dr. Johnson, he knew, felt strongly that with a proper programme help might be obtained from the City Companies,

Mr. T. Scamell thought that before going to the public for money they ought to have some notion of the probable cost of the building. It seemed to him that £10 a head from every member of the Society would go but very little way towards the expense necessary. If, however, he were furnished with details as to the size and number of rooms required, he would calculate something like what the cost might be expected to be.

Mr. W. E. Debenham thought that it was not desirable to offer a bait to persons to join the Institute by proposing to confer diplomas without examination or qualification. Diplomas were supposed to represent some ascertained competency, and he thought it not dignified to use them in the way proposed.

Mr. W. Bedford said that an ideal had been placed before them, and if that ideal was pitched rather high, it was perhaps as well that it should be so. The first question was whether a charter could be and should be obtained. Before any appeal was made either to the public or to the City Companies, the Society ought to be in a position to show that the Institute proposed to be formed would really advance photography. Photography, he thought, might very well lay claim to a share in the public munificence, although for his own part he would rather work on the basis of improving the present position of the Society.

Mr. Chapman Jones understood that some of the speeches implied that the Institute was to have power to license photographers.

Mr. Bird said that it must not be supposed that any compulsory powers would be vested in the Institute, but he was quite certain that traders and photographers would consider the diplomas valuable, and would obtain them. In any case, it would take several years to carry out such a programme as had been sketched out.

Mr. T. Sebastian Davis said that although it was desirable to have the Exhibition premises and the meeting and other rooms in the same building, it might not be absolutely so, and it might be found more practicable to get the premises they required separately.

The Chairman said that it might be an instruction to the council to ascertain the cost and the probability of obtaining a charter, and this course was approved.

Mr. John Spiller, F.I.C., F.C.S., read a paper on "Early Experiments by Dr. Percy and Mr. George Shaw on the Chemical Phenomena of Light." Having been a pupil, assistant, and friend of Dr. Percy, he had been trusted by his executors with his photographic note-book. Mr. Shaw, too, had given free permission to use the notes. Mr. Spiller wrote on the blackboard the following table, showing the direction of the experiments made, some of which dated back as far as 1844 :—

First Set of Experiments.

a	AgCl in air
b	,, ,, hydrogen
c	Moist AgCl in air
d	,, ,, ,, nitrogen-K in tube
e	,, ,, ,, ether vapour

Second Series.

1	Dry AgCl in dry chlorine
2	,, ,, ,, ,, nitrogen—K and CaCl in tube
3	,, ,, ,, iodine vapour
4	,, ,, ,, air with phosphorus
5	Silver foil in dry chlorine

Third Series.

I.—Dry AgCl in dry Cl
II.—AgCl in moist Cl
III.—Dry AgCl in dry air

The expressions K in tube, K and CaCl in tube, meant that there was potassium to absorb oxygen, and chloride of calcium to absorb moisture sealed up in the same tube as the silver chloride. These substances were not, however, in contact with the sensitive substance, but were enclosed in a sort of chamber in the tube, and packed in with asbestos. The result of these experiments was, that after exposure to light, the AgCl in the tube marked *a* of the first series had undergone the least change of the set, whilst if there was any difference in the others, that in the hydrogen had been the most affected. In the second series, it was noted that the silver chloride, which was reduced by the action of light, became reconverted into the original compound when put away in the dark. The chloride in tubes 2 and 3 became chocolate brown, and the iodine present in No. 3 did not retard this change. In No. 4 tube, the chloride darkened considerably, and to some extent even in the dark. In No. 5, the silver foil acquired a beautiful iridescence by exposure to light. In the third series, the last tube No. III. rapidly changed colour, and of the others, No. 2 (that containing moist chlorine), was more quickly darkened in the light, and more rapidly bleached in the dark than No. I.

The Chairman called attention to the fact that the April meeting would be held on the 15th, and not on the customary second Tuesday in the month.

Mr. F. F. Baggalley was elected a member of the Society.

Camera Club.

On Thursday, March 6th, Mr. Andrew Pringle gave an address on "The Optical Lantern." Mr. Francis Cobb occupied the chair.

Before the lecture a handsome testimonial, consisting of a silver jug and three goblets, was presented by the members to Mr. E. G. Spiers, as a friendly recognition of his valuable services as late Hon. Secretary to the Camera Club Company.

The Secretary handed round a copy of the work called *Giphantia*, bearing the date 1761, in which was found the singular forecast of photography read at a previous meeting. The book, which had been lent by Mr. A. C. Lyster, is a translation from the French work *Giphantie*, by Tiphaigne de la Roche, published at Cherbourg. The Secretary also handed round a convenient little actinometer, arranged as a small printing frame, in which a little scale of letters of different densities, printed on silver paper, served as the indication of sufficient exposure for printing in platinum. He believed that the instrument would be brought out by the Platinotype Company.

Mr. Charles White also exhibited a series of photographs bearing on the subject treated of at the previous meeting, "Photography applied to Medicine and Surgery." The photographs showed in succession the means adopted for patching up and giving artificially a normal appearance to the face, in the case of a patient who had suffered severe ravages from cancer.

Mr. Andrew Pringle said that for some years he had made a variety of experiments in relation to the optical lantern, and had gained a certain amount of experience, especially in regard to the lime light. He would not deal with the historical part of the subject that evening, but would remark, in passing, that he had been told that the optical lantern was first invented of John the Baptist—that is to say, by Giambatista Porta. The condenser, provided it be large enough for the slide, cannot be too small ; a 3½-inch condenser will cover an ordinary lantern slide with a circular mask, but not if the slide have an oblong mask. The diameter of the condenser should be slightly greater than the diagonal of the mask. The smaller a condenser can be made, the shorter will be its focal limit, and about 2½ or 2¾ inches is about the nearest a lime light can be brought to it with a reasonable amount of safety. Nine out of ten of the condensers now in the market consist of two plano-convex lenses, mounted with their curved sides towards each other. Herschel's condenser consisted of a slightly meniscus and a double convex lens ; the double convex lens was mounted in front, and the meniscus behind, with its concave surface towards the light. He did not know that one of these condensers was better than the other. Then there was the triple condenser, due to the optical ingenuity of Mr. John Traill Taylor, and which picked up a considerable percentage of the rays from the source of light, which percentage would otherwise have been lost in space. This plan, however, lengthened the focus of the system. Mr. Dallmeyer had made a condenser which he (Mr. Pringle) had not tested against any other, and the Camera Club possessed one of them. Any person using the lantern would not be far wrong in using the first and commonest of the condensers he had mentioned, for it was the best all-

round condenser, and the one he almost always used. The projection lenses should give a flat field, and be of sufficient diameter to transmit plenty of light ; lenses for ordinary lantern views work at not less than *f*/4. As everywhere in optics it is a case of compromise : as the aperture is enlarged, definition is sacrificed ; and as the lens is stopped down, light is sacrificed, and better definition obtained. When oil is used in the lantern a good draught of air is necessary, and the air channels must be of larger size than necessary when the lime light is employed. He knew no reason why lanterns should be made of such enormous size as at present, whereby they had become so bulky to carry anywhere, as to make life not worth living. Here the speaker exhibited a small lantern made by Messrs. Newton and Son ; also another and smaller one made by Mr. Beard. As to the cottages sold by some makers to produce dissolving effects, he felt great respect for those who could afford to buy them ; as for himself, he did not feel inclined to use these enormous edifices ; they might be useful to professional lecturers, for to give dissolving views the register must be everywhere perfect, and great care taken beforehand in preparation. Mr. J. Malden had the most perfect lime light arrangement for such lanterns that he had ever seen, but a vast amount of preparation was necessary, and his (Mr. Pringle's) remarks that evening were not intended for professional lecturers at all, but for those who used lanterns for home purposes. The speaker then said a little about the history of jets, beginning with that invented by Canon Beechy, in which oxygen was driven up through the centre of an argand oil flame, and acted upon a ball of lime suspended within the flame. He next described the blow-through and mixed gas jets, and he spoke of a mixed jet in which he used common gas from the main at the ordinary pressure thereof ; in this he used a specially small nipple, and obtained quite as much light as from a blow-through jet, and the light was concentrated on a smaller area. He next exhibited a mechanical device, consisting of a cut-off for economising gas ; he said that one of the same kind, but slightly differing in form, is made by Mr. Steward. The gas in jets, he continued, must not travel round any sharp corners, or the flame will roar, and the "way" inside the pipe must be smooth everywhere. He believed that there were, practically speaking, only two kinds of lime cylinders in the market, namely, Nottingham limes and the composition limes ; the first is the best except for blow-through jets, which require a softer lime. The composition limes are usually very truly turned ; but the Nottingham limes are badly turned as a rule, so lose much of the advantage they would naturally possess, otherwise they would be the best for mixing jets. He had tried various substitutes for limes, but, in his hands, they had all been utter failures. The oxygen obtained direct from chlorate of potash was usually the best ; but within the last month or two Brin's had been improving a great deal. He had found Beard's regulators to be excellent, and said that they are now in use nearly everywhere ; he had never used the early ones, but spoke of those with recent improvements. As for lantern-slide carriers, he would rather have none of them ; he did not know any better than Chadwick's for the single lantern ; he thought Beard's to be the best for the dissolving lantern. Mr. Cembrano had brought a carrier that evening to the meeting, and which had been invented by Mr. Cowan ; he had never seen it before, and no doubt it would be examined by the members present. The nature of the screen used is very important ; with a bad screen at least twenty-five per cent. of the light may be lost to the observers ; if any light can be seen behind the screen, that is so much light lost to the spectators. A properly plastered wall is the best screen. For a flexible screen he recommended one coated with a size charged with zinc white ; it must not be a shining screen, neither must it be too thin, for then much of the light will be lost by absorption. For darkening a room in daylight, Clarke's patent shutters are the best. An open stage to the lantern is almost a necessity. Mr. Newton has made a lantern which can be turned up in a moment, if necessary, so as to point to the ceiling, and the image can then be thrown on the wall by means of a mirror or prism ; this device is useful to show objects which must be kept in a horizontal position.

Mr. Beard then exhibited Hardwich's ether tank at work.

Mr. J. Traill Taylor said that the triple condenser caused an enormous increase in the illumination of the projected image, and that all the best American lanterns had triple or quadruple condensers. He was having apparatus constructed to make oxygen on the spot, and to supply it automatically to the lantern at proper pressure and in proper quantity directly it was evolved. He was aware that apparatus to do so had been invented in Manchester, but it was large and cumbrous. He then described means he had devised to get a parallel beam for polarisation by a reflecting bundle of glass plates ; he placed a concave lens in the conical beam from the condensers.

After some remarks from other speakers, and a reply from Mr. Pringle, a vote of thanks was passed to the latter.

The Chairman said that the tilting of the lantern was nothing new ; he had seen it done some years ago at the Society of Arts.

London and Provincial Photographic Association.

At the meeting on the 6th inst., Mr. R. P. Drage occupied the chair.

Mr. F. York sent to the meeting some lantern slides of French make, showing an opaque deposit on the inside of the cover glasses, which were detached for inspection. A letter from Mr. York accompanying the slides stated that he had received them from an old lanternist in Trinidad, who attributed erosion to the extreme humidity of the climate during the summer months. Government lenses were similarly affected, and had to be repolished. Mr. York also stated in his letter that during his stay in the West Indies he saw some plates packed face to face separated by pieces of cardboard at each end ; between the plates a network of fungoid growth had sprung up, due to the same cause.

Mr. T. E. Freshwater stated that he had seen a great many lenses that had been sent from Barbadoes to this country to be repolished. In every case they were of foreign manufacture. He knew of no instance of English glasses being affected in the same way.

On the subject of a remedy for condensation on lantern slides, Mr. A. Haddon suggested the removal of the free alkali from the surface of glass by boiling. Glass so treated would not be so liable to condense moisture with change of temperature.

The Chairman asked for the best method of removing carbon images from opal plates.

The general opinion was in favour of rubbing with very fine silver sand or emery powder.

Mr. A. Haddon would soak the plate in hot water, then pour over it strong hydrochloric acid, giving the plate a good wash afterwards.

Mr. F. P. Cembrano showed a lantern carrier made in brass, from a model designed by Mr. A. Cowan, and exhibited by him at one of the meetings of the Association.

The competition pictures were exhibited. The conditions, as previously announced, were that the prints should all be from three negatives selected by the members, and that any printing process might be employed. All the members present, except the exhibitors, acted as judges, each member having three votes, with the result that two awards fell to Mr. F. P. Cembrano, and one to Mr. J. B. B. Wellington.

Sheffield Photographic Society.

At the last monthly meeting, held at the Mason Hall, on Tuesday evening, Mr. B. J. Taylor occupied the chair.

The judges' awards in lantern competition for the best series of six slides was announced as follows :—"In the opinion of the judges no set of slides was of sufficient merit to take the first prize ; the same was, therefore, withheld." The second was awarded to Mr. W. T. Furniss, who also secured the prize for the best slide in the competition. The whole of the slides were afterwards passed through the lantern.

Mr. G. Bromley gave a demonstration and lecture on the new benzoline saturator, as an adjunct to the optical lantern. He commenced by showing the working of the oxy-hydrogen mixed jet light. Having explained the details

and points requiring care and attention, he passed on to the ether light, explaining the method of charging the saturator and connecting the tubes. The lecturer showed that no fear of explosion need be entertained ; that a "suck-back" could not happen, providing pressure was maintained on the oxygen gas, and the chance of firing the saturator minimised again by carefully draining away the fluid not soaked up by the stuffing in the saturator tubes. The best light was obtained when just short of hissing at the jet, and it could be maintained at equal brilliancy by slight attention from time to time to the cylinder key and turning the lime. Attention was next drawn to the benzole and benzine saturator—firstly, the method of charging was shown, next the warming appliance for increasing the volatilisation of the fluid, and lastly the connection with the gas and lantern jet. It was explained that a jet with larger aperture could be used with this light than was practicable with ether, but on application little, if any, difference was seen in the brilliancy. Gasoline could, with advantage, be used in place of benzine, and altogether the process, as compared with ether, was more economical ; if anything, the light was more intense and penetrating, and certainly, in the hands of the operator, produced the best results, the ordinary mixed jet being inferior to ether, although it had many good points in its favour. The same slides were used in each case, so that the comparison should be equal and fair.

Lewes Photographic Society.

A meeting was held on the 4th inst., the President in the chair. Two new members were elected.

A vote of condolence with the widow and family of the late Mr. Simon Norman was passed.

The slides sent in for the first quarterly competition were passed through the lantern, and the awards of the judges were as follows :—Class 1 (landscape)—Mr. A. H. Webling ; Class 2 (architecture)—Mr. Percy Morris ; Class 3 (any other subject)—Mr. G. E. Constable. There were fourteen sets sent in from seven competitors.

A special general meeting is to be held to-day, to consider the question of carrying out a photographic survey of the district, when a paper on the subject will be read by the Hon. Secretary.

East Dulwich and Peckham Photographic Society.

A meeting was held on March 7th, Mr. F. W. Edwards in the chair, when hand and detective cameras were the topic for consideration.

Amongst the specimens on view were Fallowfield's "Facile" and Abraham's "Ideal." Another exhibit was a shutter, for which the advantage was claimed that it could be regulated for speed, as the setting was automatic. A camera which was introduced resembled, in appearance, a walking stick. It was made entirely of metal, was light, and yet, when set up, very rigid. Furnished with a ball and socket joint at the top, it is easily opened and closed.

The Society having decided to exhibit at the Crystal Palace Exhibition, the members brought a good number of photographs to the meeting.

Dundee and East of Scotland Photographic Association.

March 6th.—General meeting, Mr. D. Ireland in the chair.

Eleven competitors entered for a lantern-slide competition. The votes having been scrutinised, the following were declared the prize-winners :—First, Mr. D. Ireland ; equal seconds, Messrs. J. R. Stewart and A. Wilson ; third, Mr. V. C. Baird.

Mr. A. Stewart gave an account of his visit to Western Norway in the s.s. *St. Sunniva*. After a few introductory remarks he showed a number of lantern slides, with descriptions.

G. D. M.—Your reply to Mr. Pringle includes answers to criticisms, by different persons, of your utterances made in another journal, which criticisms many of our readers have not seen.

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the Photographic News, Messrs. Piper & Carter, 5, Furnival Street, London.

All Communications, except advertisements, intended for publication should be addressed to the Editor of the Photographic News, 5, Furnival Street, London, E.C.

Senoj. (Malvern).—*Exhibition Announcements.* If you are a member or exhibitor of any one of the leading photographic societies, especially those publishing a list of members like the Parent Society, you will be sure to receive a notification of all forthcoming exhibitions. Without being so, you must take the trouble of watching the advertisements and special announcements. The Pall Mall Exhibition always receives at Michaelmas, and opens a week later.

J. D.—*Fuel for the Ligroine Lamp.* Ordinary benzoline is the liquid now recommended for charging the boiler ; it is not necessary, therefore, to look about for a product of exceptionally low boiling point, such as gasoline, although this was specified in the first published account. We are glad to hear of the apparatus coming safely to hand, and regret that your second letter could not be answered last week.

J. C. J. (Nice.)—*Developers for Prints on Gelatino-Chloride Paper.* The hydroxylamine developer (see page 197 of the Year-Book) answers very well for the alpha paper of the Britannia Company, Ilford. You have the choice of two qualities, rough or smooth.

R. L.—*Flash Powder Explosions.* The dangers to which we directed attention some months ago have received an awful exemplification in the article on page 191 of last week's News. By the incautious admixture of magnesium powder with picric acid, chlorate of potash, sulphide of antimony, &c., five lives in all have been sacrificed in America, enough to preach a warning to those who ignorantly deal with such detonating substances. With magnesium alone projected through a spirit flame, all such terrible disasters may be avoided, but it is well, even then, to keep a vigilant look-out for dropping fire.

L. T.—*Price of Platinum.* Owing to the demand for electrical purposes, superadded to the use of this metal in photography, the price of platinum has recently advanced. At the sale of Dr. Percy's effects last week twenty-eight ounces realized £55 3s., and this included some scrap; so that £2 per ounce is about the lowest quotation at the present time.

A. M. (Bootle).—*Test for Alums.* It is, perhaps, immaterial whether you employ potash or ammonia alum ; but they may be distinguished by warming up the solution with caustic soda, when the latter will give off the odour of ammonia. A negative result is here sufficient to indicate potash alum. The sulphate of alumina is more strongly acid.

D. H. M.—*Blisters on Bromide Paper.* The fault is most likely inherent to this particular lot of paper, which was coated too dry, and so the attachment of the gelatino-bromide coating is imperfect. From your description there is nothing wrong either in the chemicals or manipulation. Albumenized paper sometimes fails from the same cause.

C. J.—*Collotype Films.* Gelatine sensitized with a five per cent. bichromate solution, and if you want extra insolubility add a small quantity of chrome alum dissolved in acetic acid to the softened gelatine. Read up Mr. Bolas's Cantor Lectures, of 1884 (*Society of Arts Journal*), or get Mr. W. T. Wilkinson's book, published by Messrs. England Brothers, Charles Street, Notting Hill, W.

J. W.—*Surfacing Carbon Prints.* Finding that the lustre is too great when transferred and dried upon glass, could you not squeegee down upon a slightly grained zinc plate, or even try a very finely ground glass ?

Received.—The *Procès Verbaux et Resolutions* of the Paris Conference, and Programme of the Fourth Annual Conference of the Camera Club, to be held on the 20th and 21st inst., at the Society of Arts, under the Presidency of Captain Abney.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1646.—*March* 21, 1890.

CONTENTS.

ALUMINIUM IN PHOTOGRAPHIC APPARATUS.

ALUMINIUM, which was first isolated by Wöhler, in 1827, seems destined to play an important part in the photographic apparatus of the future, because of its lightness as compared with brass, and because of its recent fall in price, due to improved methods of manufacture on a large scale.

Aluminium does not rank with noble metals, such as gold and platinum, since it is more easily attacked by chemical reagents; for instance, it is acted upon by acetic and several other vegetable acids; this, however, is not particularly in its disfavour, for the same may be said of brass, the alloy with which it will have to compete. Pure air, wet or dry, has no action upon it, but the same cannot be said of wet air containing ammonia, and it must be remembered that ammonia is practically always present in the air of towns, also in the country over manured land. If any traces of chloride of aluminium be left in the metal, due to its method of manufacture, the metal is less stable and more easily attacked by damp and by certain chemical reagents. According to Deville, neither sulphur nor sulphuretted hydrogen has any action upon pure aluminium, either at ordinary or at somewhat high temperatures; but according to Fremy, aluminium decomposes sulphide of silver by uniting with the silver and setting free the sulphur. Sulphuric acid, concentrated or diluted, has little or no action upon aluminium, especially when the metal is pure, neither does nitric acid act upon it at normal temperatures; at the boiling temperature it dissolves it slowly. Hydrochloric acid dissolves the pure metal slowly, and the impure aluminium rapidly; alkaline solutions act upon aluminium rapidly, at the same time liberating hydrogen. When the sample of aluminium contains traces of iron or sodium, it is more readily attacked than otherwise by the solutions of certain metallic salts. A solution of common salt, hot or cold, has little or no action upon aluminium. The metal is attacked somewhat by soap. Commercial aluminium is never chemically pure, but usually contains a little silicon and iron; of late manufacturers have been more successful in eliminating the iron, the presence of which deteriorates its colour. Certain gases are occluded by aluminium, and from it carbonic acid and hydrogen have been extracted.

Aluminium has a bluish white colour, will take a beautiful matt surface, and can be polished and burnished under a suitable lubricant; when pure it has no smell, but when rich in silicon exhales the odour of siliuretted hydrogen. It is easily forged, rolled, or beaten into leaves, and the leaves will burn with a most brilliant light in oxygen gas. Aluminium is easily drawn into wire or tubes, but requires annealing afterwards to become flexible once more; the tenacity of the wire, according to Fremy, is half way between that of zinc and tin, but increases when the metal is hammered. Barlow found the tensile strength of aluminium to be twelve tons to the square inch. It is exceedingly sonorous, and some of its alloys are particularly suitable for church bells. Its melting point is between those of zinc and silver.

At present, the most useful alloy of aluminium in the arts is that with copper, namely, the well-known aluminium bronze, which is tougher than gun-metal, and takes a polish resembling that of gold. The alloy likely to be most useful in photographic apparatus must be one not seriously above the weight of pure aluminium, and a good one for the purpose consists of ninety-five per cent. aluminium and five per cent. silver. We have reason to suppose that some of the aluminium now used in photographic goods on sale in the market is slightly alloyed with another metal, which we guess to be possibly silver. An aluminium-silver alloy in the proportions just stated possesses, according to Tissier, an elasticity which is wanting in the pure metal, also a greater hardness and capability of being polished. An alloy of aluminium with German silver has excellent physical properties, and as this alloy is in the market, it may probably be that used in the portions of photographic apparatus. Any alloy of real silver and aluminium is attacked somewhat by sulphur.

At present, we know of no evidence that aluminium will prove less durable than brass in photographic apparatus, especially if the apparatus be kept dry, and in as pure an atmosphere as possible. Should any

evidence be found, after lapse of time, of galvanic action between an aluminium milled head and an interior brass screw, the action can probably be stopped by keeping the camera in a dry place.

THE CRYSTAL PALACE PHOTOGRAPHIC EXHIBITION.

II.

Before closing the notice of Mr. W. F. Stanley's exhibits, Mr Ferrero's dark slide and changing box combined, for celluloid films, represented in fig. 7, claims attention as a

Fig. 7.

useful appliance for the photographer, provided extended experience in working with it should prove that it has all the merits claimed for it by those who place it on public view; so far as can be ascertained from a passing inspection, we see no reason why it should not fulfil their claims, which are:—(1) Extreme simplicity and absence of anything liable to get out of order; (2) the films are put into the carrier just as they are taken from the packet, no shields or metal frames being required; (3) the films are moved by the fingers—no reliance is placed on springs or the action of gravity, which so often fail to act in changing boxes for glass plates; (4) two qualities of films can be carried in one carrier, and either can be picked out for exposure as required; (5) the operation of changing the films is done in a few seconds, whilst the filling or emptying of the carrier is infinitely more simple than with roller slides.

This Ferrero's film carrier is intended to enable the photographer to carry and to expose two or even three dozen films without having recourse to a dark room. It consists of a box, the front of which is fitted as a dark slide. Inside box a loose board, actuated by a spring, presses the films towards the rebate, whilst a light papier-maché board divides the film which is being exposed from the others, and a similar board placed behind the unexposed films divides them from those which have been exposed. When the film has to be changed, the opening of the lid causes the pressure board to be drawn back to the bottom of the box, thus leaving ample space in which the films can be changed. Attached to the carrier is a bag having two holes, in which the thumb and forefinger are inserted for changing the films. The two finger holes are provided with elastic bands, which exclude all light from the interior of the bag when the fingers are inserted.

Messrs. D. Noakes and Co. have a good show at the Exhibition, and some men at work in the actual manufacture of the mounts of lenses, and other varieties of brass portions of instruments. Moreover, in the evening, when the great display of lantern slides is going on in the adjoining theatre, Mr. Noakes gives a small show of his own at his stall, and employs the limelight for the purpose.

This firm exhibits the simple little gas regulator pictured in fig. 8. It is virtually a fine-adjustment tap, which, when in use, is screwed into the back of the ordinary jet-cock; the rough adjustment is first made with the latter, and the fine adjustment afterwards made with the little regulator; when the regulators are once set to suitably and delicately balance the gases, operations can be carried on for a long time with the ordinary cocks before a fresh adjustment of the regulators becomes necessary. The object of the regulator is to economise gas, and to stop any hissing of the flame. Interiorly it consists of an acute cone working within a similar cone.

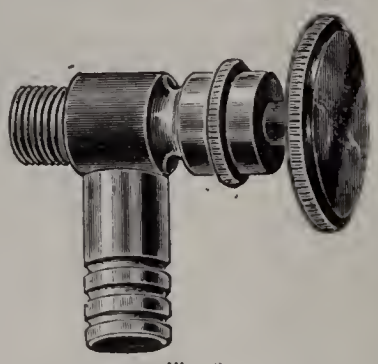

Fig. 8.

The "key camera," fig. 9, as sold by Messrs. Noakes and by the Platinotype Company, is also on view. Some

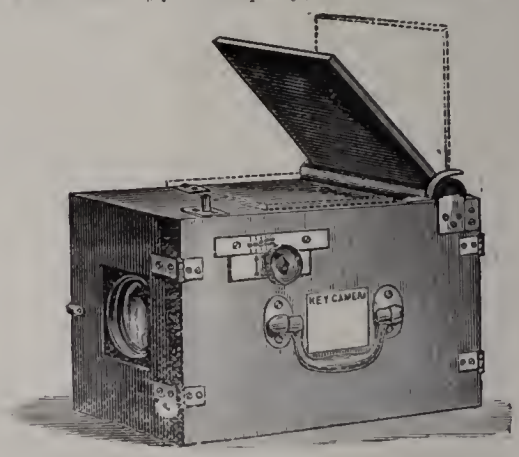

Fig. 9.

improvements have been made in it since it was first exhibited at St. James's Hall last year, as described in these pages at the time. The improvements consist of small modifications to prevent, within certain limits, its getting out of order when carelessly manipulated. The main principle of this ingenious instrument is, it may be remembered, that the plates are kept in little cases which may be carried in the pocket; the plates are introduced into the camera and removed therefrom by passing through a kind of "tap" with an excessively long slot in it.

Fig. 10 may interest lovers of the ideal who have never been behind the scenes at theatres, to see by what methods fairy-land is brought within the view of ordinary mortals, and to give some glimpses, in this matter-of-fact, vulgar age, of the times when fairies danced in the forest glades, and imps swung upon the aspen sprays. It is a limelight lantern, of not particularly romantic form, with a disc in front, carrying circles of glass of different colours. By turning the perforated disc, the stage can be illu-

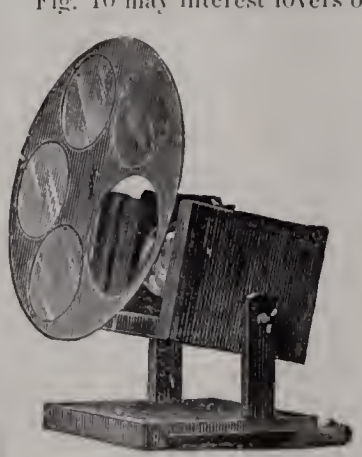

Fig. 10.

minated with any desired colour at the will of the operator.

Messrs. B. J. Edwards and Co. have a stall at the Exhibition in illustration of the results obtainable by orthochromatic photography, and among the most remarkable are yellow daffodils, blue hyacinths, violets, and lilies of the valley, in a yellow vase, taken on isochromatic and ordinary plates. They also exhibit photographs of paintings, in which orthochromatic methods are so valuable, and their isochromatic specimens on view include portraiture, landscapes, and copies of paintings, by leading photographers: also transparencies, lantern slides, and negatives showing difference between isochromatic and ordinary processes. Among these are copies of a painting in the National Gallery, "Bacchus and Ariadne," by Titian (Signor Morelli), and of an oil painting, "Grapes and Oranges."

Messrs. G. Houghton and Son exhibit dark-room specialities, and give occasional demonstrations of the working of Mr. Friese Greene's sensitised cards, in which the positive image is developed upon the card itself, so that no mounting is necessary, and all the operations are finished expeditiously.

Messrs. Sands and Hunter have an exhibit of good photographic apparatus, but no special novelty this year. They have a permanent stand at the Crystal Palace, consisting of a glass case full of photographic appliances.

Sir David Salomons exhibits a rocking-table of a compact nature, with the weight ingeniously placed altogether out of the way of the operator when the latter is performing developing work. Mr. E. G. Platt exhibits photographic brass work: Messrs. Pearson and Denham a reducing camera and circular bellows camera; Mr. W. R. Baker a satchel camera and walking-stick stands; Messrs. Trevor and Co., photographic wrappers; Messrs. Benham and Froud, a dark room lamp with parabolic reflector; Mr. W. F. Slater, picture frames; Mr. A. Clarkson, limelight apparatus; and Messrs. T. Riley and Son, a detective camera. Mr. Henry Crouch exhibits a four-fold stand, with thumb-screws to tighten up the parts; these are easy to manipulate, but are sometimes absent in this class of stand to gain an advantage in packing. Mr. W. Sparks exhibits albums, screens, and frames; Mr. W. Scorer, cameras and lenses; Messrs. T. W. Couch and Co., frames and mounts; Messrs. E. Mander and Son, frames and screens; Messrs. Taylor, Taylor, and Hobson, lenses; the Platinotype Co., platinum prints with demonstrations of the process; Messrs. J. Theobald and Co., lithographic lantern slides with operators at work; Messrs. Justin, Bros., a camera stand of spiral metallic ribbon, which packs into a small case measuring about 8 by 4 inches; and Messrs. Sharp and Hitchmough, photographic apparatus in large variety.

Every evening a lantern entertainment is given at the Palace, with the powerful limelight lantern in charge of Mr W. Brooks. As the screen is a long way off, a projection combination of longer focus and larger aperture than usual is employed. All through the evening last Tuesday the jets were worked without any "roaring," nor was there a hitch of any description.

The following is the list of prizes awarded at this Crystal Palace Photographic Exhibition of 1890:—

Gold Medal for Best Alcove.—Lafayette, Dublin.

Club Challenge Cup.—The Birmingham Photographic Society.

Open to Professional and Amateur Photographers.—Class A, (Sec. 1) Green Bros., Grasmere—Silver medal for alcove. Bronze medals, Class A—(Sec. 1), Anty and Ruddock, Tynemouth, for 560 and series; (Sec. 2) Lyd. Sawyer, Newcastle, for 469; (Sec. 3) Richard Keene, Derby, for 948 and series; (Sec. 3) Henry W. Reeve, for 1,186 and 1,179; (Sec. 5) James E. Goold, Newcastle-on-Tyne, for 568; (Sec. 5) Symonds and Co., Portsmouth, for 1,176; (Sec. 7) Gambier Bolton, Camera Club, for screen, 12; (Sec. 8) J. Pattison Gibson, Hexham, for 470 and series. Class B (Sec. 1). W. W. Winter, Derby, for 199; R. Faulkner, Baker Street, Portman Square, W., for 1,170; B. Scott and Co., Carlisle, for 1,177; T. F. Goodwin, 63, Anerley Road, S.E., for 489 and series; (Sec. 2) W. J. Byrne, Richmond, for 517; (Sec. 6) F. W. Edwards, Peckham Rye, S.E., for 616. Class C (Sec. 1), Frank Sutcliffe, Whitby, for 1,164; R. H. Lord, Cambridge, for 1,143; (Sec. 3) Arthur H. Carnell, Plymouth, for 1,057; (Sec. 7) Walter L. Colls, Barnes, for 1,139; (Sec. 8) Thomas Scotton, Derby, for 1,001; (Sec. 9) H. J. Godbold, St. Leonard's-on-Sea, for 1,166. General—George Thompson, Liverpool, for 222.

Open to Amateurs Only.—Lady Amateur Class (Silver medal)—Miss Clarissa Miles, Malmesbury, for 80, 81, and 82. Bronze medals—Class AA (Sec. 1), G. H. Catt, Spettisbury, Dorset, for 1,225; (Sec. 3) Court Cole, Folly Bridge, Oxford, for 891 and 892; Rev. W. Mann, M.A., S.C.L., Bristol, for 1,322; (Sec. 5) Martin J. Harding, Shrewsbury, for 870; T. J. Bright, Gipsy Hill, for 862; Surgeon A. G. Newland, I.M.S., for 1,035 (for photographs taken under great difficulty); (Sec. 8) J. L. Mackrell, Fairfield, Liverpool, for 256 and 257. Class AB (Sec. 2), J. E. Austin, West Court, Detling, Maidstone, for 814 and 815. Class AC (Sec. 1), E. C. Middleton, Birmingham, for 414. General—W. Jerome Harrison, Birmingham, for 401 to 406.

The judges also recommend that a complimentary medal be awarded to Mrs. Rejlander for the exhibit of her late husband's art studies.

Owing to the large number of lantern slides in competition, awards in the Lantern Division cannot be published this week.

PHOTOGRAPHY AT THE ROYAL METEOROLOGICAL SOCIETY.

Last Wednesday night a meeting of the Royal Meteorological Society was held in the theatre of the Institution of Civil Engineers, Great George Street, Westminster, with Mr. Blanford, F.R.S., in the chair. In another part of the building was an exhibition of instruments illustrating the application of photography to meteorological purposes; also an exhibition of photographs of meteorological phenomena.

Mr. G. M. Whipple, Superintendent of Kew Observatory, read a paper on "Photography in Relation to Meteorological Work," which was much to the same effect as the memoir he read some months ago before the Photographic Society, and the same illustrations were given by means of the optical lantern, which last Thursday was worked by Mr. Wainwright.

Mr. William Marriott then gave an address on "The Application of Photography to Meteorological Phenomena," during which lantern views from the same negatives from which the chief prints in the adjoining exhibition were taken, were projected on the screen, so that the facts represented could easily be explained to all the listeners present before they inspected the exhibition itself. Some of these photographs were exceedingly curious. One represented hanging against a partition the clothes of two men who had been struck by lightning, but fortunately not killed; one man's trousers had been torn to shreds, whilst one leg of the nether garments of

the other man, simply was less injured, but had the knee taken out, and showed indications of the flash having passed zig-zag fashion from one leg to the other. Some boots burst in all directions formed pitiable objects in the foreground. The old story of lightning sometimes impressing the picture of an adjoining tree upon the body of a person struck by the flash seems to have been founded upon an actual natural fact, for the photograph of the arm of a boy who had been struck by lightning was shown, and it had picturesque arborescent markings burnt on the skin, such markings as inaccurate observers might hastily conclude to represent the branches of a real tree. An excellent photograph representing gigantic icicles hanging from the branches of trees was shown; it had been taken by the Rev. F. W. Stow. Some photographs of clouds taken by M. Paul Garnier, at the Observatory, Boulogne-sur-Seine, near Paris, were also shown, and were considered by the speaker to be the finest specimens of that class of photographic work which the Meteorological Society had yet seen. Photographs of floods, tornados, lightning flashes, and of trees broken by rime frost were among those shown. One photograph showed how a broken tree carried by a tornado had with its stem speared a horse in the side and killed the poor animal: and another, how pieces of straw carried "end on" by a tornado had been partially driven into trees, so as to stick therein like nails. Dr. A. Riggenbach, of Bâle, had sent some photographs of cirrus clouds, which he had taken by means of their reflection from the surface of Lake Sarnen, when he could not get them so well by direct means. He attributed the greater ease in photographing to the partial polarisation of the light by water; this we think to be an error, and that no evidence has yet been produced that polarised light acts differently from other light on photographic films.

THE CAMERA CLUB CONFERENCE.

Yesterday afternoon the third annual Camera Club Conference opened in the hall of the Society of Arts.

Capt. W. de W. Abney, in the course of his presidential address, stated the fact that colour-vision is three-fold with a normal eye, and he thought that the same principle may, perhaps, apply to the sensitive photographic plate. The eye is sensitive to red, green, and violet, and many intermediate visual colours may be compounded of two or more of these three colours. A sensitive plate may be said to take the place of the retina, and the sensitive salts used, to a colour perception. He thought that the photographic spectrum norms of sensitiveness are analogous to the spectrum norms of colour-perception in the eye, or, in other words, that a photographic plate has, in reality, only one, two, or three colour-perceptions, and that all sensitiveness to other colours is due to only partial response of this vibrating molecule to wave-lengths, which differ slightly from those with which it is in accord. A study of the simple mixture of the natural salts favours this view, and he believed that by using this as a working hypothesis, a better understanding of the apparent vagaries in the extent of sensitiveness will be attained. Recently, in *The Standard*, an announcement had been published that the problem of photography in natural colours had just been solved, and that, too, by a printing process. Dr. Eder's name was coupled with this statement as endorsing the discovery, otherwise he (the speaker) would more readily have supposed it to be a specimen of journalistic credulity. Photography in natural colours has long been a fact. He argued that a printed photographic image in natural colours cannot be produced on an elemental substance, so a compound substance must be used. With chloride of silver, as he had proved and published long ago, the spectrum exercised reducing action at one of its ends, and an oxidising action at the other. When photographs in natural colours are obtained, the difficult problem of how to fix them remains. Fixing means the removal of something still sensitive to light, and this removal must at once change the colour, if the colour has been produced by chemical change. If the colour is produced by altered molecular arrangement, that molecular arrangement must also be destroyed by white light. The existence of the power of fixing such images is therefore improbable. He did not believe in the discovery of any really practical method of producing permanent photographs in natural colours.

Mr. A. M. Rossi then read a paper on "The Art of Drawing and Photography," which was followed by a brief discussion, in which Messrs. Adcock, Davison, Dresser, Newman, and Major Nott took part.

Mr. T. R. Dallmeyer then read a paper entitled "Limitations in the Treatment of Subjects by Focus," in the course of which he argued that two of the points set forth in the memoir of Mr. W. K. Burton, read recently before the Camera Club, were erroneous. He said that it is a scientific mistake to state that a photographic lens cannot give a sharper image than does the eye. The authority of Helmholtz was against the assertion, and so were his (Mr. Dallmeyer's) experiments. In testing the matter, it is necessary that the photograph and the view shall be examined under the same angle. Mr. Burton had also stated in effect that the eye will give as perfect a representation as a lens of a near and distant object when viewed at the same time. Mr. Dallmeyer disputed this, and said it was impossible, except by artificial means. To try the experiment fairly, the eye and lens must be placed under the same conditions, and if the eye be stopped down by placing in front of it a moderately large pinhole in a screen, near and distant objects can be seen at the same time with considerable sharpness.

In the course of the discussion upon this paper, Captain Abney expressed the opinion that a good photograph must be sharp all over, and be viewed at the same angle as was the original subject; the eye will then, when viewing one part of the photograph, see the rest of it with the same "fuzziness" as in nature under like conditions.

Mr. A. A. Common, F.R.S., gave a summary of his paper upon "Eclipse Photography," in the course of which he expressed the opinion that eclipses in the future can be observed and photographed by much simpler appliances than heretofore. He suggested the use of one large heliostat, which then would be the only instrument requiring astronomical adjustment, and with it but one driving clock would be necessary for the purposes of the whole expedition. The whole of the different observations could then be made by the aid of the heliostat. The idea, he said, is not new, for small heliostats have been used for somewhat similar purposes, but the impediment of so working on a large scale has been the difficulty of obtaining a plane mirror of sufficiently large size. Now, it is possible to construct a mirror to serve the whole of the instruments. By the adoption of this plan the enormous weight and quantity of packages now taken out by eclipse observers would be greatly reduced.

Mr. Albert Taylor said that during the recent eclipse of the sun, the Americans took out some interesting instruments. Professor Todd took out a large polar axis, eleven feet long composed of two great tubes side by side, and provided with several supports. On this great polar axis he fixed all his twenty-seven instruments.

The President remarked that Mr. Common had for some time past been using mirrors in which the proportion of aperture to focal length was greater than had ever been seen before; he tested his own mirrors, and they were perfection itself. He had just been talking in a jaunty way of making a twenty-inch flat mirror; the difficulties in the way were enormous, but if Mr. Common were to say that he would make a three feet plane mirror, he would afterwards do it. He (Capt. Abney) believed that Mr. Common had found out how to overcome one of the greatest difficulties opticians had in making large flat surfaces.

Mr. H. Trueman Wood then took the chair, and Mr. W. Wilkinson gave a demonstration of the working of the colloty process, and gave explanations of the chief points connected therewith.

To-day (Friday) the Conference will be resumed in the Hall of the Society of Arts at two o'clock. One of the papers is by Lord Rayleigh, on "Photography by the Light of the Electric Spark," relating chiefly, in all probability, to some expe

ments of his recently performed at the Royal Institution, in which the drops into which a large vertical jet of water burst, at some distance above the nozzle of the delivery pipe, were proved to amalgamate to a certain extent by the proximity of a neighbouring electrified glass rod. The great water-jet is exceedingly sensitive to electrical action, indeed more so than a gold-leaf electroscope; the drops showed a tendency to amalgamate even when the rod was excited at a distance from it of several yards. To photograph the varied dimensions of these drops, an extraordinarily short exposure was necessary, and this was effected by means of a single spark from a powerful battery of Leyden jars—the means, indeed, by which Fox Talbot half a generation ago, in the same theatre, photographed printed matter upon the rim of a rapidly-revolving wheel.

This evening the annual dinner of the members and friends of the Club will take place at the Frascati Restaurant, Oxford Street, London.

PHOTOGRAPHY IN NATURAL COLOURS.

Last Tuesday's *Standard* contains the following telegram from its Vienna correspondent:—

Dr. Eder, Professor of the Photographic Institute of Vienna, has announced that a photographer named Veresez, living in Klausenburg, Transylvania, has succeeded in solving the problem of photographing in natural colours. Up to the present, only the shades between deep red and orange can be retained, and even these, if exposed to the light, fade in from two to three days; but the experiments are being continued, with good prospects of complete success.

The *Standard* has a leading article upon this telegram, in which, on the face of it, there may be nothing which photographers have not known for years; the only thing which suggests that there is something new in the invention but missing in the telegram is, that Dr. Eder gives the weight of his name to something which has been done.

Some correspondence about this telegram has since been going on in the *Standard*, in which journal, on Wednesday, the following letter appeared over the initials A. J. M.:—

I have read with much interest your leader on "Photographing Natural Colours," as well as the telegram from your Vienna correspondent, and, comparing the two, I cannot help feeling that you think rather too much of Herr Veresez's discovery, for it appears that all he has done as yet is to get red and orange, which may be only a lighter or brighter shade of red. Now, if this is the extent of his "discovery," I can claim to have done as much, and more, in time so remote as to make me feel that I must have passed the "bloom of youth." In the early days of photography, I had much experience in the Daguerreotype process, and have often produced portraits in which, while the black coat has been black, the face has been a natural flesh tint, and the background or sky a clear light blue. This has occurred mostly when the light was particularly actinic; it was the result of no discovery, but came naturally, and if there should be any others still living who practised that ancient art, they can doubtless testify to a similar experience. It is my belief that the only way in which photographing natural colours can ever become an accomplished fact is by the discovery, not of a method of producing mere colour by light, for that has been done again and again, but of a sensitive film that will give the complementary colours, so that the red would give in the negative an equally decided or undecided green, and the blue a corresponding orange; then in printing from such a negative the colours would be again reversed, and so faithfully portray the original natural colours. But of such a discovery your correspondent gives not a hint. You refer in your article to our greatest authority in these matters, Captain Abney, and one would much like to know what he thinks of the "discovery."

Yesterday the following letter from Capt. Abney appeared in the *Standard*:—

In your Leader of yesterday, and in your Correspondent's letter signed "A. J. M." of to-day, a reference has been made to myself as regards Photography in Natural Colours. May I be allowed to say that the description given by your Vienna Correspondent of the discovery made by Herr Veresez is not such as to favour the idea of any advance in such a branch of photography having been made? Photography in natural colours has been an accomplished fact for years past; but to render such colour permanent and unaffected by exposure to white light is a problem which is almost, if not quite, on a par with that of perpetual motion from a physical point of view. I am dealing more fully with the question to-morrow in my Presidential Address at the opening of the Camera Club Conference at the Society of Arts, and will not anticipate my remarks.

Yesterday also, J. T. wrote to the *Standard* as follows:—

I have shared in "J. M.'s" experience. A really good Daguerreotype always seemed to bear a suspicion of colour, and once, by purely accidental circumstances, I obtained veritable colours. I remember it was an Autumn day, one-half the overhead sky was bright, but angry clouds, from which came frequent electric discharges, obscured the rest. My sitter was gaily attired in a black silk gown, checked with green, red, and a narrow yellow stripe. All being ready, the then rather impertinent warning was given, "Now, madam, sit still if you please, and don't wink." The roar of the rain was at hand, the cap was removed, when the lightning and thunder crash came simultaneously. My subject jumped up with a squeal, and ran away to the house. I had little thought of anything but a failure, the exposure having been interrupted. My astonishment was great, on "bringing out" the picture, to find I had a beautifully delicate, naturally coloured Daguerreotype. I kept my treasure, and many saw it; but after some months the colours faded away. On mentioning these circumstances to a clergyman, he told me that, whilst receiving lessons in photography at the Polytechnic Institution, London, during a violent thunderstorm, a coloured image was imprinted, not upon the plate, but upon the lens of the instrument. These, and other facts with which I am acquainted, seem to point to electricity as a means of producing naturally-coloured pictures.

Yesterday we received a letter on various subjects from Dr. Eder, in which he said nothing about any recent great discovery in photography.

A New American Photographic Journal.—We have received No. 1 of *The Photographic Globe*, a monthly journal, devoted to the artistic and scientific advancement of photography, edited by Maximilian Toch, and published by the Photo. Globe Publishing Co., New York. The editor says:—"In adding another journal to the sterling issues of its kind, we beg to make our obeisance, and repeat the words of the old proverb: 'There can never be a superfluity of good things.' . . . It will be our aim to publish succinctly the discoveries and inventions as they are produced, and to lay aside those intricate, abstruse, and subtle topics which to the majority of the profession are unintelligible." The frontispiece is a print on "Diamond Extra Brilliant Pense Albumen Paper," from a negative by E. C. Dana.

Exeter Hall Camera Club.—A photographic society thus entitled has been formed in connection with the Central Y.M.C.A. The Club has been divided into two sections, to one of which ladies will be eligible for membership. The following advantages and privileges, amongst others, are offered to members:—Use of dark rooms to be constructed in basement at Exeter Hall; popular and instructive lectures on photography; out-door excursions for the study of landscape photography; facilities for exchanging photographs, and purchasing apparatus and chemicals at cost price; and periodical exhibitions by members, besides ordinary meetings from time to time. Those desirous of becoming members should communicate with Mr. G. J. Ingram, Hon. Sec., Exeter Hall Camera Club, Exeter Hall, Strand, from whom also full particulars may be obtained on enclosing a stamped directed envelope.

PHOTOGRAPHY IN ROME.

The Association of Amateurs of Photography in Rome, located in Via Poli, 25, publishes every two months a *Bulletin* of photographic news interesting both to the amateur and the professional. The *Bulletin* was born on the 15th May of last year. The number for January of the present year contains a photographic illustration by Carlo Rocchi, of a highly picturesque character, taken from the plantations of chestnut trees which surround Rocca di Papa—of this the heliotype has been executed by Martelli. The number also gives a report of the proceedings of the general assembly held on 26th January in the present year, an article on orthochromatic plates by E. and F. Boissonas, some photographic *causerie* or chit-chat by Giovanni Gorgiolli, together with a bibliography and occasional notes of a varied character.

The assembly held on 26th January was presided over by Augusto Ducros, the vice-president of the Association. Carlo Rocchi read a paper in which, after mentioning the friendly relations which subsisted between the Society at Rome and the Societies of Florence, Naples, and Milan, he stated that strangers interested in photography passing through Rome might avail themselves of the hospitality of the society of which he was a member, and obtain photographic assistance and appliances of which, as travellers, they might be destitute. The following were then formally elected members of the council of administration of the Association:—Don Antonio Ruffo, Augusto Ducros, Ing. Giovanni Gargiolli, Carlo Rocchi, Don Prospero Colonna, Cav. Enrico Valenziani, Edoardo Kowalsky, Conte Guiseppe Primoli, Bruto Marini.

The article which its author, with sufficient modesty, calls Photographic Chit-chat, is the continuation of another which treated of the relations of photography to painting and sculpture. That architecture also may be profited by the camera is, says the author, sufficiently clear. The reproduction of monuments, with their details of geometric design and accurate perspective, may be of the greatest service to the architect; but careless pictures, such as those too often seen in the shop windows, are worse than useless. Before all things, it is necessary that the photographic artist should be an adept. "How often," says Gargiolli, "is an eyesore found in a falling monument, in hanging columns, in a disfigured capital, in a door or window larger below than above, not to mention false and badly arranged effects of light and shadow, defects not indeed of photography, but of the photographer."

To enumerate all the useful applications of the photographic art to the reproduction of machines and instruments of every kind, and the many advantages it might lead to in the industrial arts—as, for instance, in the matter of furniture and decoration—would, says the author of the article, be too long a matter for the present *Bulletin*. He particularises, however, the great use of photography in obtaining enlargements of pictures of microscopic preparations. The secrets of the world of the infinitely little are hereby laid bare to the interested spectator. Medicine, surgery, anatomy, botany, mineralogy, and all the natural sciences have in the application of photography their firmest and most useful support. Suppose, says Gargiolli, we have a case of building; suppose the engineer has to furnish the directorate with a relation of his monthly progress. What could do this better than a photograph of the edifice at the end of every month? This would show at a glance its exact state and advancement, and finally, when all these pictures were collected together at the conclusion of the work, they would give an exact chronological story of the whole construction.

In the army, photography would be of the greatest service if the principal officers were previously instructed in a special photographic school. It would afford an exact and complete view of forts, bridges, trenches, and other military appliances, of the position of the troops, and of the different localities, for the Ministry to consider at home. I am of opinion, says the author, "that the army would derive no small advantages from a rational exercise of photography, a fact which is demonstrated by the dispensations made in this regard already by the military councils of many nations. What has been said of the army applies equally well, in the author's opinion, to the navy. But he says, photography is with us in no great credit; it is considered generally a mere trade if exercised by the professional, or if by an amateur a mere diversion for idle people. "This," says he, "is false, aye, most false." And, he adds, the absolute negligence of our Government in this respect is deeply to be deplored. In Vienna, Berlin, and other great towns, institutions for teaching photography are provided by their governments, universities, so to speak, furnished with cabinets, laboratories, and everything which is theoretically or practically necessary to the development of the art, while we Romans have nothing. Such instruction cannot, in the opinion of Gargiolli, be given adequately by the professors of physics in the lyceums and universities. Their pupils could obtain little more than a superficial smattering, a collection of wandering, disconnected ideas from the few lectures on photography that any professors would be able, having regard to their other duties, to deliver. But if the government were to establish a school of photography the different parts of the Ministry—as those connected with war, the navy, public works, agriculture and commerce—would all be interested in its maintenance. All these might avail themselves of its services. Even the police might gain something by the detection, through its means, of a criminal, a "person wanted."

"Then could the Government," says Gargiolli, "have such photographs as it desires properly executed, and not be obliged to content itself with such daubs and enormities as are at present too often the result of the labours of the first photographer who happens to be at hand. The Ministry of Public Instruction would find their advantage therein with the production of ably executed works, which might serve for schools of industrial art and academies of design."

The author concludes this interesting article with two scenes from his own experience. He wanted to obtain, on one occasion, permission from the Ministry of Public Instruction to execute photographs of certain monuments for his own private use and gratification. He obtained, after some little delay, a reply that it was impossible to give him a general licence, but that he would be allowed to copy any specified objects if he would first give notice of such objects to the Ministry, and afterwards send them copies of the photographs taken. "I had," says Gargiolli, "no objection to parting with the photographs, but was not altogether content with the other condition, not being a photographer by profession, but a mere amateur who desired the beautiful without any prospect of profit." On another occasion, seeking a photograph of some object of public art which pleased him, several were brought to him by the seller, but all so vilely done, either from a bad

position or a bad light, or a deflection of the vertical lines. that he proposed to take a picture for himself: but as this was strictly forbidden, he departed, shaking the dust off his feet against all monopolies of professionals.

CHROMO-PHOTOGRAPHY BY BLOCK PRINTING.

Referring again to the illustrations in Dr. Eder's annual, we find—in addition to the zincographic print from 18 plates, which we described last week—two further examples of printing in several colours on the same paper. In both of these cases there is the important fact that block printing in high relief is the process employed, and some interesting details concerning each method are to be found in the work in which they are contained.

The first example to be noted is a copy of a subject printed in red—or rather a sort of terra-cotta colour—and black. It represents a figure in arms on horseback, and is a very effective production. There are three impressions—one of the subject in black outline; one of the general terra-cotta tone, which in the finished print covers all but the high lights; and one of the two combined. The method by which the separate negatives are obtained from the parti-coloured original is ingenious though simple, and is described by Professor Roese, of the Imperial Printing Establishment in Berlin, from whose account we extract the following details.

For coloured reproductions, as many negatives are taken as there are colours to be used. For the purpose of producing the particular illustration under discussion, two negatives are made. The one negative—that for reproducing the black outlines—receives a very long exposure, and is best effected with an orthochromatic plate. By this means the red terra-cotta colour produces so much effect on the negative that it classes with the white, and leaves the black lines remaining wherewith to produce the zinc plate that is to print black. For the "tone plate," on the other hand, such a short exposure is given that only the white lights show distinctly, and the red is classed with the black.

In this way are made facsimile reproductions either of the original size, or on a smaller scale, from coloured wood engravings. In the Imperial Printing Office in Berlin there is a large collection of reproductions from coloured works, as well as black and whites, of the old masters in wood engraving:—Jan Livens, Hans Balding Grien, H. Burgkmaier, Albert Durer, Joh. Vechtlin, Lucas Cranach, Andrea Andreani, Tobias Stimmer, Urse Graf, H. S. Beham, Schauenfelein, Altdürfer, &c.

The other example of chromo-zincotype contained in the book is a print in four colours, reproduced from a sketch in oil colour by Kotschenreiter. The print is by Meisenbach and Schmaedel, of Munich, who use the word "autotype" in connection with the zinc-etching processes that they employ. The picture represents a weather-beaten head, and is very effective both in drawing and suggestive colouring.

On the subject of autotype colour printing—by which, as above mentioned, the idea associated in the minds of English readers with the word autotype must not be connected—we have an article in Dr. Eder's book by G. Fritz, Technical Inspector of the State Printing Office in Vienna. Much more highly than black and white reproduction, says he, must be esteemed prints in chromo-autotype, for by its application it is possible to secure a truer representation of the originals, both in drawing and correct rendering of colour, than by any other method hitherto known. Water colour drawings, however, lend themselves better to reproductions, by the block photo processes, than do oil paintings. The latter often require a large number of colour plates, and to represent their solid effect many tones must be overlaid on the same place, whilst water colour paintings and other pictures that are painted in a similar style, are, on account of the generally transparent character of the tones, much better within the reach of the typographic printer's art. Each method of printing has its own characteristic, and typographic or block printing is less suited than the copper etching, lithographic, or collotype methods for representing the deep, powerful, solid effects commonly found in oil paintings.

ANOTHER PHOTOGRAPHIC SURVEY.

The Manchester Amateur Photographic Society has inaugurated a photographic survey of Manchester and Salford, and its Secretary has sent the following letter to each of the members of the Society:—

"Dear Sir,—I beg to inform you that the Committee are now making arrangements for carrying out this scheme. April and May being considered the best months for taking street scenes and some of the objects suitable for the survey, it is imperative that operations should begin at once. At the present stage I cannot give you details of our plans, as these will depend upon the number of volunteers we get to assist us. It is intended to photograph street scenes, prominent buildings, market places, railway stations, churches, interiors and exteriors, old bits of architecture, interesting nooks and corners, especially those doomed to early demolition, parks, historical residences, including those in the surrounding neighbourhood of Manchester and Salford, and having connecting associations; also instantaneous views, such as Fairs and 'High Change;' in short, anything that will record the city and borough and the habits of the people, as they are to-day.

"I need not point out to you that this is a vast undertaking, and one that will require our full strength. But we are a large Society, and if every member will take his share of the work, the divisions will be very small. If, however, it be left to a few to perform, the survey will be a burden. I hope you will do your best to obviate this by helping us.

"To take an ordnance map and cut it up into slips, giving a piece to each member to mark his circuit, would be rather arbitrary in a voluntary work of this kind. It is considered better to leave it to the members to photograph whatever and wherever they choose, and to send in the results for selection by the Committee. But apart from this, the Committee will collect the names of all the places and objects to be taken, and make an allotment to each member, for which he will be held responsible to photograph at his earliest convenience.

"In the binding of the survey, the artist's name will be written under the print, and at the completion the negatives will be returned to their respective owners. I shall be glad to communicate with any member respecting the scheme, and hope to give fuller information in the next number of the *Record*.

"Will you kindly give your best consideration to the questions at foot, and let me have your replies not later than Monday's post, and oblige,

"John Wilcock, Hon. Secretary.

"335, *Moss Lane East, Manchester, March 6th.*"

THE SIZES OF PHOTOGRAPHIC PLATES.*

BY J. CRAIG ANNAN.

The question whether the sizes of plates and papers at present adopted by British manufacturers are the most economical that could be devised, is a subject worthy of careful consideration.

How the present sizes came to be fixed I do not precisely know. The terms whole-plate, half-plate, and quarter-plate have the ring of a convention about them, and may have been fixed by some photographic parliament in days long gone by. Plates $8\frac{1}{2}\times6\frac{1}{2}$ were the largest size prepared for Daguerreotypes, and probably were then known as full plates, and this may be the origin of the term. Other sizes appear to have been designed by the makers of cameras in a haphazard way, as their fancy or expectancy of custom led them. What I wish to discuss to-night is, whether the proportions of length and breadth in the standard sizes of British plates are the most economical that could be devised? I think most certainly they are not, and I would like very much to see this subject taken up by the International Congress which is to meet this year in Brussels; for the double reason that an international series of sizes might be fixed, and that they should be arranged on some reasonable basis.

In a communication to this Society about five or six years ago, the late Mr. Norman Macbeth, R.S.A., laid down a rule to find the best proportions of length and breadth for a picture, the resulting proportions being $\sqrt{2}\times1$.

Now, while maintaining that the ultimate proportions of a print must depend entirely on the composition of the picture, I have become firmly convinced that this shape is the most useful and economical that could be found for general work.

Compare this size with those in use.

$\sqrt{2}\times1 = 1{\cdot}41\times1$	$8\frac{1}{2}\times6\frac{1}{2} = 1{\cdot}31\times1$
$15\times12 = 1{\cdot}25\times1$	$7\frac{1}{2}\times5 = 1{\cdot}5\times1$
$12\times10 = 1{\cdot}2\times1$	$6\frac{1}{2}\times4\frac{3}{4} = 1{\cdot}37\times1$
$10\times8 = 1{\cdot}25\times1$	$6\frac{1}{2}\times4\frac{1}{4} = 1{\cdot}53\times1$

A glance at the list shows that nearly all the sizes are less oblong than the Macbeth proportions, the modified half-plate $6\frac{1}{2}\times4\frac{3}{4}$ being nearer it than any other. Consider for a moment, and I think you will find that in nine cases out of ten in trimming a print from a 15×12, 12×10, or even whole-plate negative, you have to cut more off the breadth than the length to make the shape look pleasant, and that a half-plate oftener than any other size is a suitable shape as it stands.

Compare this size also with the artists' canvasses which have the largest sale.

$\sqrt{2}\times1 = 1{\cdot}41\times1$	$10\times7 = 1{\cdot}43\times1$
$18\times12 = 1{\cdot}5\times1$	$20\times16 = 1{\cdot}25\times1$
$14\times10 = 1{\cdot}4\times1$	$18\times14 = 1{\cdot}28\times1$
$12\times8 = 1{\cdot}5\times1$	

These two last sizes are for portraits, head and shoulders, and are of course squarer than an average picture would be.

And now I wish to point out the most interesting and useful feature of this shape, which is that, when it is doubled, the relative proportions are precisely maintained. $1 : \sqrt{2} :: \sqrt{2} : 2$.

You will at once see the manifold advantages of a series of plates based on a principle such as this. And as this paper is not intended to go fully into the subject, but is written more for the purpose of raising a discussion on what I consider a most important matter, I will conclude by giving a list of sizes on the lines which I would like to see carried out. Of course if an international series were fixed, they would be worked out in the metric system.

$4\frac{1}{4}\times3$	$12\times8\frac{1}{2}$
$6\times4\frac{1}{4}$	17×12
$8\frac{1}{2}\times6$	24×17

As the sizes become large, the difference between them is too great, and intermediate sizes would be required.

7×5	20×14
10×7	28×20
14×10	

* A communication to the Glasgow Photographic Association.

PEOPLE WITH DOUBLE FACES.

Mr. Napoleon Sarony's observations on the human countenance, to a *New York World* reporter, run thus:—

"Perhaps you are not aware of the fact, but, unless you are entirely different from the rest of humanity, one side of your face is unlike the other. Doubtless nine persons out of ten would not notice the difference, but it is there, and if you make a careful study of the profiles of your friends' faces you will find it in a more or less marked degree in every instance.

"This peculiarity of nature was called to my attention when I entered the practice of photography. Previous to this time I had been an artist and lithographer, and naturally had been led to study the human figure with more or less care. I had discovered this incongruity of nature, if it may be so called, but it was not until I began posing models before the camera, and had every line of the face emphasized, that this idiosyncrasy became more apparent to me, and I set to work to discover the cause; for, of course, there is a cause for everything, the human face included.

"My first discovery was that the difference in outline lay almost invariably on the two opposite sides of the nose. The right side, for instance, might be pure aquiline, and the left show a decided inward curving line. This difference I found in many instances had been caused by accidents, such as had been received in wrestling, falling, being struck by a ball, or other misfortunes which youth is heir to. There is an indentation on one side of my own nose, caused by a blow from a ball, and it renders the expression of one side of my face almost entirely different from the other.

"But accident is not the principal cause of these facial differences in humanity. Not by a great deal. It traces way back to the cradle. Mothers find that their infants will remain quieter when they are sucking their thumbs, and for peace in the household they very often lay the foundation for what becomes a deformity in after life.

"Let me explain: Baby lies in her cradle as still as a mouse. Her chubby little thumb is held between her rosy lips, and the forefinger is pressing the cartilages of the nose on one side. It is that little forefinger that is doing all the mischief, for it is slowly, but surely, pressing the cartilage out of shape. If drops of water wear away a stone, surely constant pressure will indent a human face."

Photographic Club.—March 26th, monthly lantern night; April 2nd, "Standard Solution and the Expression of Photographic Formulæ."

A MODIFIED COLLODION EMULSION.

BY A. PEEBLES SMITH.

That collodion methods are but little used in the production of lantern slides by amateurs goes without saying. "Takes too much time—costs too much." One might say that emulsion making was the thief of time, and chemicals. It is not only this; but time is the thief of emulsion, especially in the amateur's hands, as he can only use a small portion at a time, and the emulsion becomes of the consistency of water with age—entirely useless. To gain time and prevent collodion emulsion from sinking into the silver waste, or oblivion, and to show its cheapness, is the purport of this article.

Before acquainting the reader with the rapid ten-minute method, possibly a description of the actual practice heretofore indulged in, and its subsequent cutting down in time, and the preserving of one's good nature would be of interest.

In the first place, to make an emulsion by collodion methods, it is essential we have some bromo-iodised collodion. The formula in use is as follows:—

Collodion.

Alcohol	1½ ounces
Ether	2¼ ,,
Gun-cotton	40 grains
Iodide of ammonia	15 ,,
Bromide of cadmium	54 ,,

First take the alcohol and dissolve the iodide in it. Take next your bromide and grind it in a mortar, adding a few drops of distilled water. Now pour the combined alcohol and iodide gradually into it, grinding constantly until nearly all the bromide is taken up. A slight precipitation occurs, but if well ground will be very small, and of no serious consequence. Gradually add the ether to the alcohol, iodide, and bromide, shaking it with a kind of circular motion. Add the gun-cotton; filter it through a tuft of cotton saturated with alcohol, and put away to ripen for a week. If white iodide is used, and the collodion does not become a deep cherry colour, by adding two or three drops of iodine the collodion will be in prime condition for sensitising.

Sensitising.—Dissolve in a test tube by gentle heat 75 grains of nitrate of silver in one dram of distilled water, adding 4 drams of alcohol, which has previously been heated in another test tube. Now go into your dark-room, and by orange light gradually add the alcoholic solution of silver, giving it a vigorous shaking after each addition, finally rinsing the test tube with 2 drams of alcohol and adding it to the emulsion. After shaking well, add to the finished emulsion three drops of nitric acid. Care must be observed to keep silver solution heated, else precipitation will be the result, and though it may not spoil the emulsion, the bromide of silver formed will be in a very coarse state, making it useless for lantern positives.

It will be observed from the foregoing that to make an emulsion we merely make bromo-iodised collodion and sensitise it. In other words, we take the collodion of the old wet process and fire the silver bath into it. Well-ripened bromo-iodised collodion can be obtained in eight-ounce bottles from any of the leading photographic stock-houses, at a less cost to the purchaser than the amount of bromides, iodides, ether, and alcohol, necessary to the making of the same amount of collodion. Provided with an eight-ounce bottle as above, take four ounces of its contents and follow the instructions given in this article about sensitising, and the result is a collodion emulsion which should not have taken more than *ten minutes* to complete. Emulsion so made does not keep for any length of time: nor does the amateur so wish it, as he is compelled to work spasmodically.

Make the emulsion the evening before the day you intend using it. Secure a slab of plate glass; level it, covering its surface with well cleaned albumenized glass, 3¼ by 4. Measure out 1½ drams of emulsion; pour in the centre of each plate. When the surface becomes tacky, wash in two or three changes of distilled water; allow the plates to soak for two minutes in a tincture of quinine of the following strength:—

Water	5 ounces
Tincture quinine	2 drams

Wash again in distilled water, and dry by gentle heat. When dry the plates are ready for exposure. The albumen solution is made by dissolving the white of an egg in three pints of water, and filtering through cotton saturated with alcohol. It is best to filter the emulsion at the time of coating the plates. If four ounces of collodion make more emulsion than can conveniently be coated for use the following day, cut down the formula, preserving the proportions, thereby saving loss of emulsion and time in coating plates.

Having exposed the plate, we now take up its development. The exposure should be about four times as long as that given a very slow gelatine plate. One point to be remembered in the development of collodion emulsion is that it cannot stand a very great amount of alkali. The slides shown at the Society of Amateur Photographers were developed with eikonogen in the following proportions:—

Eikonogen	2 grains
Water	1 ounce

The alkali was *one drop* of a saturated solution of carbonate of soda. Previously to applying the developer, the plate was soaked in a solution of alcohol two parts, water one part. After fixing and washing, the plate is intensified with pyro and silver, as used in wet process, with proportions as follows:—

A.—Pyro	24 grains
Citric acid	24 ,,
Acetic acid, No. 8	¼ ounce
B.—Nitrate of silver	40 grains
Citric acid	10 ,,
Water	8 ounces

If old ferrous oxalate developer is used, no intensification is necessary; but eikonogen tones are unsurpassed, even by the carbon process.—*American Amateur Photographer.*

North Middlesex Photographic Club.—On Monday next, March 24th, Mr. Smith will give a lecture on "Micro-Photography," and illustrate it by means of the optical lantern. Visitors invited to attend.

Social evening, Nov. 25.

Notes.

In France the study of composite photography has been taken up with great enthusiasm, the specimens exhibited in the International Exhibition giving some remarkable results, as we mentioned some time ago. A very thoughtful article appeared in *La Nature* recently, and is well worth perusing by those interested in the subject. The method pursued in France differs considerably from that first put forward by Mr. Francis Galton. Mr. Galton produced his composites in the printing-frame; the French workers produce theirs in the camera by a succession of exposures. The writer's theory is this:—The variations in the features of each photograph being given an insufficient exposure, do not print; the features which are common to all the photographs receive the proper exposure because they occur again and again. Hence these salient lines alone printing, we get the type of the particular collection of individuals. An objection has been raised to this method on the ground that the plate becomes more sensitive the more often it is struck by feeble light; consequently those portraits last exposed will have a predominant influence in the final result.

This objection, the author shows, by a series of experiments difficult to explain without the diagrams and pictures which accompany the article, has no force if the operations be conducted properly. The conclusion the writer comes to is that the larger the number of subjects in each composite, the greater the probability of obtaining a real type. When a small number—say three—is taken, there is a risk of generalising too much, and as the exposure in each case is but a third of the normal exposure, it is sufficiently long to give details which are not common to these faces, and the consequence is we get not a combined result, but a super-imposing of the three. A very brief exposure is insisted upon as indispensable to obtaining a trustworthy result.

A new work on London is about to be brought out by the Religious Tract Society, and the editor has made an application for permission to inspect and photograph certain of the charters and documents in the Guildhall Library. The application was granted by the Court of Common Council at its meeting last week, and under the directions of the town clerk such charters and records as may be desirable will be photographed. This application suggests the propriety at some time of setting up a proper studio at the Guildhall Library, and of appointing an efficient photographer. At the present moment we know of more than one illustrated paper which would be glad to have photographs of old engravings and wood-cuts for reproduction, were it not for the trouble and expense of employing a photographer. If an ordinary business charge were made for such copies as might be required, the expenses of a Corporation photographer would soon be paid. There are many other useful things which such an official could perform, and the City might do worse with its superfluous cash than devote a portion to such a purpose.

The question is sometimes asked, why do some photographers so excessively retouch the negative as to in many cases effectually destroy the likeness? An excellent answer is to be found in a little story which has found its way here from America. A lady of an uncertain age, and still more uncertain looks, interviews a photographer's youthful assistant on the subject of being photographed, upon which there is the usual stipulation made that payment must be in advance. Lady: "But suppose I pay for them and don't like them, what am I to do?" "Don't know, ma'am; Mr. Blank is out just now, but he'll be in soon, and will tell you." "That seems to me a very queer rule; you ought at least to guarantee satisfaction." "Yes, but you see, ma'am, there ain't no way to keep pictures from lookin' like the people." Truthful lad! But this was in the old days. It is now quite possible to keep the pictures from looking like the sitters. We retouch.

The Oberammergau Passion Play is enacted the first year of every decade, and thousands will flock to the Bavarian Hochland in May, on the 26th of which month the performance—we presume we must call it—takes place. Whatever may be the feelings of the audience, the performers at least conscientiously regard the affair in a religious light, and so sacred do they think it that they will not allow the Crucifixion scene to be photographed or otherwise depicted. In this they show better taste than did the American minister who lately preached on Mars Hill—where St. Paul preached his sermon to the Athenians—and had himself photographed in the act!

According to the *Globe*, the head waiter at a long-established and well-known restaurant is a capable amateur photographer. The fact has come out *apropos* of some pictures which appeared in the *New York Herald*, "by which William's genial countenance was grievously libelled in six several pictures." The *Globe* recommends the "waiter-photographer" to have his revenge on the *Herald* artist when he comes to the restaurant again, and "shoot" him—photographically, of course—on the feed. We may remark, *apropos* of that mysterious man the waiter, that the oddest discoveries are apt to be made concerning him. We recollect finding in the head waiter at a quaint old inn at Canterbury an accomplished microscopist, and an authority on infusoria. With all his scientific reputation—for he was well known in London—he was modest, and gratefully took his tip in the proper professional manner.

GRADE IN PROFESSIONAL PHOTOGRAPHY.

BY H. COLEBROOK.

Scarcely another business can show so many widely distinct and varied grades as photography, and a study of no mean interest may be found—to those who care about such things—in the links and connections which bind the highest to the lowest, the Court photographer to the beach-man, wide as is the difference between them. It would almost seem, from the countless numbers of existing grades, that each professor of the art finds for himself an original position, so forming a grade of his own; and further, were it possible for a man to ascend, by gradual progression, through these many divisions, from the lowest degree to the highest points, it may be imagined that the extent of his improvement would scarcely be patent to himself. It is only by selecting, for comparison, points fairly wide apart, that any real difference can be appreciated. The comparison of the two extremes would present something truly striking, but the gradual course through all would give little or no idea of progress in photography. There is the difference of taste, the difference of education, the difference of position, opportunity, capital, all influencing that widest difference of all between good and bad photography. For illustration take four representatives from the two extremes, and two intermediate stages.

The "beach-man," as he has already been called in this article—though merely for distinction—will perhaps be better recognised from his description than from his name. There is nothing extraordinary in his being found by the sad sea waves, there is something even appropriate in it. He has many points in common with the seafaring man. His general appearance hardy and weather-beaten, his most prominent feature partaking of the beacon description, his eyes bearing that almost barometrical indication of too much "wet," the effect of shingle and sand giving him a walk peculiarly his own, all proclaim the man. His general standpoint is between two bars—viz., the harbour-bar, if there be one, and the refreshment bar, which there is sure to be. He moves amongst the crowd of pleasure-seekers, bearing in his hand a specimen of work—to the public, a beautiful collodion positive; to the initiated, a silver print set off by a remarkably bright brass mat and tray. His voice, though husky, is skilled in smooth phrases; he is also skilled in argument. He need be, for though his specimen meets with general admiration, the completion of an order is generally accompanied by a little altercation and a large amount of abuse on the part of the customer. His posing is simplicity itself, and the adjustment of his instrument perfectly bewildering in its celerity. The number of his journies to the inland bar would require a clever mathematician to calculate. This is such an undoubted fact, that the ordinary Table of Solubilities appears incomplete without the following item:—

	Temp.	Water	Temp.	Alcohol.
Cash Receipts.	Immaterial.	Insol.	At all T's.	Highly Sol.

His education, taste, and capital may be algebraically expressed as x, y, z, an equation with three unknowns; but whatever else may be urged against him, it cannot be said he lets his opportunities go by. His position must be represented in the trade as zero. The above, of course, is a specimen of the lowest of his class. To say that an honest, conscientious positive worker is not to be found would be extreme, but they are unique in their rarity, and generally seek a quiet spot, where their names cannot be tarnished by the juxtaposition of their unworthier brethren, who, as a class, must be mildly considered as degenerate. Leaving the beach-worker to revel in his alcoholic propensities, and ascending to the nearest quiet street, the representative of the second grade makes his appearance in rather an eccentric manner. Advertisements varying in number from ten to thirty appear in every available space, in shop-window, door, and on the walls of the building, setting forth that artistic portraits can be had beautifully finished at 5s. 6d. a dozen. It is said that a romance repeatedly told becomes gospel in time, even to the romancer. It may be so with these advertisements, the proprietor really believing that what he is continually advertising is indisputably correct. His window is a marvel of uniformity and variety, both. Rows of cartes and cabinets, tier upon tier in symmetrical profusion, lay claim to the one, while the other is evidenced by the wide range of tones, the faces ranging from ghastly to tropical; the mixture of subjects from the sweep to the ballet-dancer; and lastly, the positions, many and easy, the ballet-dancer in particular looking excessively comfortable with one foot on a very high chair. Within we have a good example of that style of unarrangement known as unstudied. Framed pictures lie about as specimens of "Our Club Portrait." The proprietor is suave and polite; his being no grammarian forms not the slightest check to his volubility. The studio is a trifle bare, but with everything in its place—in fact, everything seems to have taken root and grown there. The instruments are in the fullest sense of the word adjustable, though seemingly of an automatic adjustment. Leaving the pose to the operator, it becomes merely a question as to whether you shall hold a lean pedestal up, or whether the pedestal shall hold *you* up. The pedestal being the shakiest, you take the safest course, and after a few mystic "passes" the operator retires to develop. The result is more than successful—it always is—so after a few business formalities have been gone through, and you have resisted the temptation to "Try our Club," you leave, a happy man. In a few weeks' time you are probably a wiser man, and if there is any inclination left to try the effect of any sort of club, without doubt it will be a war club.

Doubling the price of the foregoing example will give us a representative of the third grade, but luckily price will not form the only distinction here. A strong impression that a plain reproduction of a face is not the sum total of artistic portraiture, will be found to exist. The uniformity and variety of the window may be nearly gone, but, strangely enough, there remains something attractive in its arrangement. The quantity of specimens being considerably diminished, the quality is the more apparent. The work shows signs of careful finish, and there is a softness, and roundness, that the eye rests on with pleasure, after its former experience. There is still a uniformity—a pleasing one—in the tone and depth of printing, and a decided taste in the selection and character of the specimens shown. The same principles are found to exist inside. You are not told what a splendid portrait you are sure to obtain, but there is an evident anxiety to prove it, and when you see that there are few or no "clubs" about, you feel there is a possibility, or even a probability of it. Politeness and suavity still exist, but of a more intelligent and educated order,

and this with the trouble and pains that are taken, cause you to breathe as though in a purer atmosphere. There is, perhaps, an eyesore here and there; a straining after unnatural effect, a tendency to bury the sitter in accessories, a want of character, a want of simplicity and greater breadth, but on the whole there seems an upward tendency, and the impression left is certainly more complimentary to the photographer and his art.

The fourth grade has already been spoken of as the "Court" photographer, though this is also merely for distinction, for although many high class photographers have had something of Court work, yet there are many who have not. As I speak of a class, Court must, therefore, be understood in a general sense. There is, or ought to be, a sensation amounting almost to awe in approaching this class, who have reached the summit of many a lesser man's ambition—a feeling that patent leather, and a little more polish, will not be inappropriate. I will endeavour to step lightly and with circumspection.

The first point that would strike an outsider would be the fact that advertisement is either entirely absent, or nearly so. This may prove many things, but amongst others, certainly a sense of security and prosperity, it being unnecessary to attract custom by anything approaching vulgar display, an excellent guarantee that this class do not seek, but are sought. To say that their show rooms, reception rooms, dressing rooms, and studio exhibit taste of the highest order; that even fashion finds its way into their sacred precincts—that everything is of the completest—all this would be superfluous; and to hint at the presence of anything partaking of ordinary vulgarity would be simply to call into requisition sal volatile and eau-de-cologne, and other revivifying necessaries. Though many a lesson might be learnt from these things, they do not form the fairest subject for comparison. The work itself is, of course, the actual test, and this may be seen by all in the form of pictures of celebrities. I do not mean to say that this work is of the highest order of artistic merit—far from it; but as I am speaking of the work of a class, I wish to take a general sample. Something even the reverse of artistic might be found in many, but there is one grand point, that as a whole they exhibit judicious use of the materials of a picture; there is that combination of tasteful simplicity and worth that stamps the photo as coming from one who has an intelligent appreciation of the powers of photography. Much might be claimed in favour of their subjects, but were these subjects submitted to the ordinary retoucher, photographs of very ordinary mortals would be the result in nine cases out of ten. Posing in the hands of this class becomes easy and natural, even though in some cases it be rather studied; but the same pose on an unsuitable subject, in the hands of one of the lower orders, becomes such an awful and horrible perpetration, that it is a wonder that the friends of the latter subject do not take sudden and immediate revenge. The imitator doubtless has the same idea, but without the feeling that prompted it, and herein lies the strongest distinction of all, for were there no room for the influence of thought and feeling, then a distinct line might be drawn to represent the limit within the reach of all, bearing little or no room for comparisons.

Now, by joining these four examples, and carefully filling in the space between each, an uninterrupted succession of degrees will be shown from first to last, each degree at the same time possessing *something* original and distinct. From this I want to show that, collectively, progress is evidenced; individually, the reverse. Take, for example, the case of a man starting a business in one of the intermediate stages. He will naturally open according to his ability, but will have still more regard for his capital and surroundings, this point governing his charges. If he be a conscientious worker, he will give full value for money. Having established a connection—which, needless to say, will take time—can he advance his prices so as to improve his work? for he cannot do it otherwise. But rarely; for he cannot do this without a general upset of his whole business, and a fresh start, as it were, on a new basis. On the other hand, there are many things likely to influence him in lowering his prices, and unfortunately the work does not at first follow (it must eventually), thereby bringing his downward influence to bear on his brethren of the same degree. Thus a process of filtration is continually going on, swelling the lower ranks enormously, and leaving the higher ones clear and free, with every prospect of a brilliant future. And then—well, for the peace of mind of the many—"When things get to the worst, they generally mend."

CELLULOID OR CELLONITE?

A suit that the Celluloid Manufacturing Company, of New York and Newark, began a year ago against the Cellonite Manufacturing Company, Wilmington, for infringement of copyright, has been decided by Justice Bradley, of the United States Circuit Court of New Jersey, in favour of the plaintiffs. What makes the suit remarkable is that it has caused the respective publishers of Webster's and Worcester's dictionaries, and of Chamber's "Encyclopædia," to remove the word "celluloid" from the class of words that were heretofore considered public property. The Wilmington Company makes a substance that is similar to celluloid, and have put it on the market under the somewhat similar name of cellonite. The New York and Newark concern at once brought suit to restrain the rival firm from using the word, asserting that the word "celluloid" was a noun of its own creation; that it had copyrighted the word as a trade mark, and that the use of a word in any way similar was an infringement of this copyright. The Wilmington Company offered the dictionaries as evidence that the word was public property. Lawyer Cox, for the plaintiffs, set up the claim that the dictioners had no right to include the word in their publications, and that such unlawful publication could not affect the copyright rights of the plaintiff. He meantime laid the matter before the publishers of the dictionaries, and the latter promptly revised their latest editions. They published the word in its alphabetical place, but with an explanation that it was a private trade mark. Lawyer Cox and the publishers are now trying to introduce a substitute word that may be used by anybody without affecting the copyright, and that will enable the dictionary publishers to continue to print a description of what the substance called celluloid in trade is. Justice Bradley's decision gives the plaintiff exclusive use of the word "celluloid" as a trade mark, and also of its corporate name, and grants a perpetual injunction against the use by anybody of any name in any manner resembling celluloid. A suit is now pending against a prominent retail business house in New York for selling cellonite for celluloid, and also for permitting customers to leave the shop under the impression that cellonite was celluloid. The Celluloid Company assert that this also is an infringement of their copyright.—*Invention.*

To Wash Negatives Quickly.—Place the negative under the tap, and turn the water on so that it will fall with considerable force. Hold the plate diagonally, and turn it round occasionally. While the water is falling on it, go over the surface with a camel-hair brush or a soft sponge, always moving from centre outwards to margin. In a few minutes the hypo will be eliminated.—*Photographic Scraps.*

FLASH POWDER EXPLOSIONS.*

BY CHARLES L. MITCHELL, M.D., PHILADELPHIA PA.

Explosive compounds are defined to be certain bodies which possess the property, when heated or set on fire, or from some other cause, of being converted from their solid or liquid state into gases in an almost immeasurably short space of time, such gases during their chemical conversion liberating heat, and in consequence highly expanding, and through this expansion exerting a great pressure on their surroundings. This conversion is accompanied by a detonation, which in its proper sense is called an explosion. Explosive compounds are divided into two classes. In the first class, designated as "detonators" or "shattering compounds," of which nitroglycerine is an example, the explosion is effected in an immeasurably short space of time, and all parts of the substance decompose simultaneously, thus making the initial pressure of evolved gases the maximum one, and producing the most powerful impression upon closely adjacent bodies. The second class, of which gunpowder and blasting powder are illustrations, are called "disintegrating compounds." The explosion of these proceeds progressively by combustion, and their gases gradually accumulate until the resistance to them gives way.

Of all the salts formed by pieric acid, the picrate of magnesium is probably one of the most dangerous, and, no doubt, caused the last explosion of the series mentioned. It is a well-known fact that chemical combination and decomposition will take place when two different substances are simply mechanically mixed together, and allowed to remain undisturbed for a period of time. Considering these facts, there is no doubt that, if pieric acid and magnesium were placed in intimate contact with each other, as would occur when used as component parts of this flash powder, and then allowed to remain undisturbed for some time, chemical combination would ensue, with the formation of picrate of magnesium. Another fact in connection with this is that powdered magnesium is quite hygroscopic, and has a tendency to cake together in loose masses, or adhere to the sides of a bottle, if exposed to a moist atmosphere. Pieric acid, when powdered, is also rather sticky in character, and it can be readily seen how, if these two substances existed together in a mixture, they would be attracted to one another; then, given the elements of time, moisture, and perhaps some slight warmth, and chemical combination would inevitably occur. That this is not pure theory, but fact, can be substantiated by a fact lately mentioned to the writer by Professor Henry Leffman, of this city, in a personal conversation. He stated that some time previously, while microscopically examining a sample of this "yellow" flash powder, he was surprised to notice an entire absence of metallic magnesium the yellow crystals of pieric acid being alone prominent. On dropping the powder into water, however, an abundant sediment of metallic magnesium was deposited, showing its presence; and a closer examination of the powder showed that particles of magnesium were completely enveloped in a yellow coating of pieric acid. Of course these circumstances afforded a most fruitful opportunity for the conversion of the two substances into the explosive picrate of magnesium, and there is no doubt whatever in the mind of the writer that such combination actually took place.

The presence of this dangerous chemical, probably in considerable quantity, was undoubtedly the cause of the last accident at the laboratory of Wiley and Wallace. It was testified at the coroner's inquest that the victims of the accident were engaged at the time it occurred in emptying some of this "yellow" flash powder into a drain, for the purpose of getting rid of it. They had just returned from court, where Mr. Wiley was defendant in a suit for damages brought by the relatives of the boy, John D. Cruice, and his assistants were witnesses, and no doubt impressed by the evidence of the dangerous character of this powder, as brought out during the trial, determined to remove it out of harm's way as soon as possible. There were some seven or eight pounds of this powder, contained in a large bottle, still remaining in their cellar, which had been made some eighteen months previously, and had remained undisturbed all that time. It is not known to a certainty what was the immediate cause of the explosion. Neither fire nor chemicals were known to have been present. Water had been thrown upon some of it: but experiments subsequently made proved that the addition of water to the compound would not generate sufficient heat to ignite it. The most reasonable explanation, therefore, and probably the only one that can be offered, is that the pieric acid and magnesium had, through long standing, become converted into their resulting salt, and that by some accidental jar, or perhaps in shaking or knocking the bottle to loosen its contents, a portion of the picrate was detonated, causing the detonation of the entire mass, and the consequent terrific explosion. That it was a detonation, and not merely a sudden ignition of the mass, is proved by the fact that the bodies of those killed were not in the least burned or charred, but of course greatly mangled from the force of the explosion. Mr. Wiley's body in particular was found only after some search, and then it was discovered tightly wedged in an empty barrel, dismembered and horribly mangled. In the two previous accidents the victims were simply burned through the sudden ignition and partial explosion of the compound, and their bodies accordingly were marked by great eschars where the flames had reached them; but in the last accident a perfect detonation occurred. This was due probably to the fact that thorough chemical combination of the pieric acid had occurred through length of time. The other accidents occurred during the mixing of the fresh powder, and the injury caused was more due to an intense combustion of the magnesium and chlorate, an explosion of the second class only taking place.

It is evident from these fatal accidents that this particular compound, the "yellow" flash powder of Buchanan, Bromley, and Co., was a substance possessing properties even more dangerous than dynamite, and one that was alike unsafe to make, to use, or to keep. To sell such an article, therefore, for ignorant and unskilled persons to use, or to induce anyone to attempt its manufacture, places a terrible responsibility upon those who knowingly undertook such a risk. The testimony at the coroner's inquest upon the first victim revealed fully the dangerous character of this compound, and if its vendors had possessed but an ordinary regard for human life and safety, they would have promptly withdrawn it from the market. A plea of ignorance is, therefore, useless, and they stand convicted before the bar of public opinion of causing, through cupidity and reckless defiance and disregard of public safety, the death of five human beings, with its attendant train of widowed

* Concluded from page 192.

wives and orphaned children. Not many men would consider this a satisfactory exchange for a few paltry dollars.

The death of Mr. Wiley and his associates, though greatly to be deplored, was largely the result of their own imprudence, and sadly illustrates the fact that men will, through familiarity and frequent handling of dangerous substances, often become almost insensible to the risks of their occupation, and take chances that they would probably counsel others to avoid.

As before mentioned, a curious fact is, that at the time this accident occurred, the firm of Wiley and Wallace were engaged as defendants in Court of Common Pleas, No. 2, in a suit for damages brought by the relatives of the boy John D. Cruice. The case of Cruice v. Wiley et al, will long be a "cause celebre" in judicial records, not so much from the legal features attending its trial, although the case was somewhat unique, but from the tragic features which brought it to such a sudden termination. It is almost unprecedented in the annals of medical jurisprudence, and a very extraordinary fact, that the three individuals who had testified in open court that this flash powder compound was not dangerous and not explosive, should, within a few hours after so testifying, and within a short time after leaving the court-room, be hurled into eternity by the explosion of the very mixture they had endeavoured to prove harmless. As an expert witness for the prosecution, it became necessary for the writer to express a decided and positive opinion upon the dangerous nature of this flash-powder mixture, and during cross-examination the following quotation from Eissler's work on "The Modern High Explosives," was cited, more particularly in reference to such combinations with potassium chlorate :

"In mixing these compounds great danger is attendant, and too much circumspection cannot be used. They explode instantly upon any violent stroke, very often by friction alone ; sometimes spontaneously, as when in a state of rest, and no known cause for their combustion can be ascertained. Many are deluded as to its safety by so-called experiments with freshly-made powder. Manufacturers of the compound may attempt to show its safety by hammering it and cutting, and similar tests ; but let the powder be exposed to the natural atmospheric action, attract some moisture, then get dry, and the least friction or blow will cause an explosion."

Viewed in the light of the subsequent tragedy, these words seem almost prophetic ; yet little did the writer think, at the time when he cited them as evidence, that so soon and so impressively would their truth be demonstrated. Verily, "truth is often stranger than fiction."

It seems hardly necessary now, in view of all that has been cited, to raise a note of warning in regard to the use of these flash-powders, but the statement has already been made that, whilst this particular compound was unsafe, other compounds are harmless. The writer wishes to state emphatically, therefore, that in his opinion *all forms of flash-powders are dangerous*, the difference between them being only in the degree of danger involved. As had been said, they are composed of substances prone to rapid decomposition when in contact with each other ; they are liable to form new compounds, often possessing dangerous and unknown properties. Their combustion is attended with an intense amount of heat, involving risk from severe burns, and they are liable to spontaneous explosion or ignition. This danger is greatly augmented when they are made or kept in mass, and the probable reason why a greater number of fatal accidents have not occurred is because the powders have been mostly made in comparatively small quantities and put up in separate packages, each containing but a few grains of the mixture. A simple mixture of magnesium and potassium chlorate, which has been claimed to be harmless, has been known to explode under percussion, and there is probably no compound of this character which does not possess some elements of danger.

The use of these powders will and should be entirely abandoned, for there are now equally satisfactory and much more safe methods of producing the same result. The different forms of magnesium lamps now on the market, in which the powdered metallic magnesium is thrown into the flame of an alcohol lamp, gives a form of illumination which is quite as efficient photographically, and, what is equally to the purpose, it is perfectly safe ; it has been claimed by some that the combustion of the magnesium, when used with this lamp, was not as rapid as when the flash powder was employed, and in consequence certain instantaneous effects could not be obtained. In the writer's opinion, it would be much better, then, to abandon this class of work entirely, rather than run the risk attending the employment of such dangerous compounds ; moreover, he considers that these objections are mostly imaginary. In Charles Lamb's "History of Roast Pig," it is related that the inhabitants of the country deemed it necessary at first to burn down a house in order to roast a pig. In course of time they discovered, however, that much simpler and less dangerous methods would answer equally as well. It is hoped, therefore, that the time will soon arrive when the photographic public will discover that magnesium can be employed for purposes of illumination without using compounds which are akin to gunpowder and dynamite in their dangerous properties.

THE FIRST OPTICAL LANTERN.

Kircher knew the use of projection lenses for the optical lantern, because, in his older book, he pictured such lenses in the plate representing the apparatus in which the solar rays were used for the illumination. Yet in his later work, printed at Amsterdam, he pictures his magic lantern without projection lenses in front ; hence, last week we hazarded the guess that perhaps he left such lenses out of the diagram on purpose, especially as there is evidence that over some of his discoveries he had a somewhat secretive disposition. However, this supposition is rather hard upon Kircher, for no first-rate man of science or man of fine feeling would give, under the guise of publication, a method which would not work to the best advantage so far as his knowledge went. More probably the true explanation of the matter is, that Kircher's projection lenses were not of suitable focal length for the new conditions under which he worked with the whole apparatus in a small room, so he then threw shadows of lantern pictures upon the wall by means of an optical system entirely behind them, as represented in these pages last week ; if so, the means he used were not unlike the optical system of the lantern of the London policeman. Kircher's pictures had never before been published in this country, nor had Kircher's detailed description of his magic lanterns been previously circulated in the English language.

Patent Intelligence.

Specifications Published.

2,983.—*February 20th*, 1889. "An Improved Lantern." Tom Bell Burns, Camelford, Cornwall, Ironmonger and Manufacturer.

This improved lantern can be made of any shape and fitted with glass, mica, or horn panes, or glass globes, or any other contrivance for allowing the light to pass through; the upper part of the lantern having an opening for inserting a kettle, can, bottle, or any other receptacle for holding fluids or food, and which is heated by means of a candle, lamp, or other heating apparatus. The can, bottle, kettle, or other receptacle can be carried inside the lantern, if required, for the purpose of keeping the fluid or food warm. The opening in the upper part of the lantern is fitted with a door either hinged or sliding, or other suitable contrivance to prevent the wind from blowing out the lamp or candle.

3,279.—*February 23rd*, 1889. "Flashing or Continuous Lights." Frederic William Hart, 8 and 9, Kingsland Green, London, N.E., Manufacturer of Scientific Instruments.

I would here premise that in Patent No. 356, January 9th, 1888, there is described by me in reference to fig. 3, a chambered plug into which falls the magnesium or other inflammable powder from the hopper above, and on turning the plug half-way round, the contents are discharged into a container below; one, two, or more charges could be introduced, according to the volume of light required, the volume and power of the air blast being regulated as set forth by figs. 4 and 5 of the said Patent. Now in the apparatus about to be described, instead of the chambered plug discharging the powder into a container for holding one or more measured charges, I discharge the powder direct from a plug, tube, or other container, surrounded by a barrel or sleeve, to which is attached a hopper or reservoir of the powder communicating with the chambered plug, tube, or other coutainer, or the two fittings may work together over a port or ports, after the manner of the slide valve of a cylinder, so that alternate flashes of light can be given like the discharge from the exhaust tube of an engine, or the hopper can be allowed to remain over one port, and thus give forth a continuous stream of inflammable powder through the aid of air from a fan, bellows, or gas bottle under a regulated pressure. In the case of circular plugs or tubes, instead of the plug or tube turning, the barrel or sleeve with a covered hopper may turn on the plug or tube; the hopper or sleeve is fitted with means to ascertain when the reservoir of material is becoming exhausted. In cases where india-rubber injection balls or bottles are used for compressing air for the discharge of the inflammable matter, the valves of the Patent No. 356, 1888, are used for the purpose therein set forth. For igniting the inflammable matter the pairs of flames are arranged in line thus = = = =, one, two, or more, with intervals so that there is free access of air or oxygen in all directions. When gas is employed the burners are disposed on an adjustable frame also movable on a joint for fixing, so that the light can be directed at any angle from the horizontal to the vertical position, the hopper and container for the inflammable material travelling therewith, so that the discharge tube remains always in line with the igniting burners, so as to produce at pleasure innumerable combinations for dot and dash signals.

In combination with a flashing lamp or lamps for photographic, scenic, signal and other purposes, I employ portable reservoirs of inflammable gas for igniting purposes, and where numbers of separate flashes are required simultaneously, also separate chambers of air or oxygen gas, each under regulated pressure adjusted to the number of lamps and resistance to be overcome.

3,465.—*February 26th*, 1889. "Reproducing Pictures and Designs." Henri Jules Le Boulch, Versailles, France.

By my invention a simple sheet of paper is used in place of stones, or copper, or other plates ordinarily used for the reproduction and multiplication of designs of different sorts, such stones or plates only being required to obtain, in the first instance, the design upon the simple sheet of paper.

I take a sheet of transparent paper or other sufficiently transparent material, and I print upon it from the original stone or plate containing the design, and I retain this printed sheet until copies are required, when I transfer the design upon it to the surface of a stone or other suitable support. For printed or lithographed composition or designs, I make the print upon paper coated with a gelatinous layer, and I then pass it through a bath of solution of bichromate of potash, or other suitable bichromate having the property of rendering gelatine insoluble; and I dry the sheet, expose it to light, then soak it in water until the parts forming the original design completely disappear, then dry it and treat it as a photographic negative. Or, instead of the process just described, the design may be put upon a sheet of paper coated with bichromated gelatine, then exposed to light, developed in water, dried, and then treated as a photographic negative. The gelatinised paper may be replaced by any other kind of sensitised paper capable of giving a negative in the same way.

Or the design may be printed upon a sheet of paper with gelatinous or mucilaginous ink, the sheet being then placed face downward upon a surface of stone or zinc well covered with black ink, which adheres to all the sheet except the gelatinous or mucilaginous design, and passed through a press, the print being then dried and developed in water, the gelatinous or mucilaginous design being washed away, and a negative being thus obtained from which proofs can be produced.

By writing upon ordinary paper with ink of the same kind, and treating the sheet in the way just described, a *facsimile* negative is obtained, from which proofs can be obtained in the same way.

Or a negative may be obtained by writing directly upon the paper or other material with gelatinous or mucilaginous ink slightly acidulated, treating the surface with greasy matter, then washing and inking the surface, and printing from it.

Or a sheet of glass or paper may be coated with white varnish, the print or sheet carrying the design being laid in contact with the varnish, and the other side of the paper support being oiled; the whole is then soaked in water, and a positive is obtained from which a negative may be made in the manner already described.

What I claim is:—

The methods of reproducing pictures and other designs substantially as described.

4,169.—*March 9th*, 1889. "The Manufacture of Aluminium." John Leman Eckersley Daniel, 3, Victoria Street, Westminster, Electrical Engineer.

My improved process, which is based on the well-known laboratory experiments of Bunsen and St. Claire Deville, has for its object the manufacture of aluminium on a commercial scale, certain improvements being made in such experiments, as hereinafter described, to enable the manufacture to be successfully carried out.

In this process aluminium is produced by electrolysing the double chloride of aluminium and sodium, and means are provided for maintaining the bath at all times in a uniform state or condition.

The inventor claims:—

1. Maintaining a constant and continuous replenishment or regeneration of the bath with chloride of aluminium as fast as it loses the same while undergoing electrolysis.

2. The construction and use of apparatus, substantially as described and shown by drawings, for the continuous manufacture of aluminium on a commercial scale.

5,067.—*23rd March*, 1889. "Photometric Apparatus." John Methven, of the Gas Light and Coke Company's Works, Nine Elms, Surrey, Associate Member Institute of Civil Engineers.

My invention relates to that class of photometric apparatus which are known as jet photometers, the object of the invention being to render these apparatus more accurate and reliable than heretofore.

It is a well known and accepted fact that jet photometers, as at present constructed, are not to be relied upon to give an

accurate indication of the quality of the gas to be tested, and the reason for this is, that not only the apparatus, but the gas itself, are more or less seriously affected by changes in the condition of the atmosphere, both as regards variations in temperature, and in the barometrical pressure.

It will be evident, then, that to obtain perfect accuracy in indicating the illuminating power of the gas, two conditions are necessary, viz., a constant temperature and a constant barometrical pressure.

Now, my invention consists in the means whereby these two conditions are practically provided for.

In carrying out my invention, I make use of the ordinary jet photometers, whether they are constructed to indicate the quality of the gas used by maintaining a constant height of flame, and observing the pressure required to produce that height of flame; whether they are of a construction to indicate the quality of the gas used by maintaining a constant pressure, and observing the height of the flame produced by such constant pressure; or of any other form or description of jet photometer, where a jet flame is used for the purpose of a photometer.

For the purpose of maintaining an uniform temperature of and within the apparatus, I enclose in a water jacket the whole of the gas way and the tank or vessel containing the water used for indicating the pressure of the gas within the instrument, and which is commonly known as a King's gauge. The water within the jacket I keep at a constant temperature by means of circulating tubes attached to the water jacket, and heated by a jet or jets of gas. These tubes project through the box in which the instruments are generally placed for the protection from draughts, and the heating jets may be brought into contact with them when desired.

A thermometer is inserted in the water jacket and in the gas way of the instrument, so that the temperature can be always ascertained.

In this way, the temperature of the gas in the gas ways, or measuring parts of the apparatus, can always be maintained constant.

A thermometer will also be placed in the box, so that the general temperature in the box may be the same as the water jacket.

Alterations in the barometrical pressure of the atmosphere affect not only the volume of the gas in the measuring chamber of the instrument, but also the combustion of the jet flame.

For instance, with a prevailing high barometer, the volume of gas within the measuring chamber, or, in other words, the volume of gas passing through the instrument, as indicated by the pressure recorded by the "King's gauge," is compressed; consequently, the quantity of combustible material passing through the jet to form the flame is such that a longer flame is required to consume it. The reverse is the action of a prevailing low barometer. The volume of gas passing through the instrument, as indicated by the pressure recorded by the gauge, is expanded; consequently, the quantity of combustible material which forms the flame is less, and the flame is of necessity shorter.

The means which I use to provide for changes in the barometrical pressure consist of a movable scale, by means of which I am enabled to ascertain what should be the height of the flame, according to the barometrical pressure for the time being.

The scale is attached to a frame secured to the top of the instrument just beneath the socket of the jet burner, and which extends upwards in front of and behind the jet flame. The back of the frame is fixed at about two inches from the centre of the flame, and the front portion at any distance being a multiple of the distance the back is from the centre of the flame. On the front portion of the frame is engraved the scale. The centre portion of the front of the frame, which is made of coloured glass, arranged to be adjusted by a screw arrangement, is moved up or down the frame in guides provided for the purpose, so that the top edge of the glass may be brought to the mark on the scale indicating the height of the barometer for the time being.

The height of the flame will be ascertained in the usual way, by sighting the top edge of the movable blue glass, the top of the flame, and the line fixed on the back of the frame. The position of the line on the back of the frame is arrived at when the instrument is rated by comparison with the results of the standard photometer. Having adjusted the height of the flame, the readings of the instrument may be regarded as indicating the correct illuminating power of the gas by observing the pressure necessary to give the adjusted length of flame. When the instruments are designed to indicate the quality of the gas by maintaining a fixed pressure, and observing the height of the flame produced by such constant or fixed pressure, the scale indicating the length of the flame may be marked on the movable blue glass, and which may be adjusted in like manner to the scale indicating the barometer for the time being; the length of flame will thus have the necessary correction for the barometer prevailing.

I may also use, to provide for changes in the barometrical pressure, a scale which I apply outside the ordinary scale on the dial of the instrument, and which supplemental scale may be worked round the dial by means of a screw which projects through the side of the box.

The supplemental scales I use result from observations extending over a long period of time, and, by taking a reading of the barometer, and bringing zero on the scale to the division at which the pointer of the instrument is arrested, the exact quality of the gas in candle power can be read off.

Instead of moving the scale, I may secure it on the dial, with zero point on the scale corresponding to zero on the dial. Then, taking the reading of the barometer, I make the corresponding reading on the scale zero for the time being, and adjust the quantity of float water in the instrument to bring the pointer opposite such division. In this manner I start with the proper correction according to circumstances.

In these last-named means for providing for variations in barometrical pressure, in which the scale is used as a supplemental scale to the dial of the instrument, or is attached to the zero end of the dial, the results obtained are equivalent to those obtained by altering the height of the flame, but in the latter case the correction is made on the pressure indicated by the pointer of the "King's gauge."

5,218. *March 26th*, 1889. "Expansible Opera and like Glasses." Caroline Spilsbury Pocock, 2, The Elms, St. Anns Hill, Wandsworth, Surrey, Gentlewoman.

So far as can be judged by the drawings, this instrument closes in an exceedingly neat manner, and the mounting might possibly be made to suit a miniature binocular camera. The inventress thus describes the arrangement.

According to the usual construction or arrangement of opera glasses, field glasses, and the like, whether used alone or in combination with views, boxes, or cases, the cases have been of circular form telescoping one within the other to close them to reduce their bulk or occupy less space than when drawn out.

Now the object of my invention is to dispense with these cases which telescope within one another, and use a flexible or yielding body which is compressible, such as leather, or waterproof canvas, or other similar material affixed to the frame composing the object glass and field glass ends, said leather or canvas connection being of tapered form, so that when the object glass frame is expanded or drawn away from the field glass end, the article has the appearance of an ordinary leather or canvas bound metal frame.

To the field or large glass end I arrange a hinge joint to each half of the opera glass, and by leaves or strips hinged thereto, and slotted, I can by a pin connected to the frames of the object glasses retain the object glasses at the required distance, or expanded from the field or larger glass end, the end of the slot in the side strips having a kink in which the pin becomes lodged to retain the article in an expanded form.

The object glasses may be carried in a separate frame to that carrying the pins, and by means of a central screw the focussing can be adjusted.

The parts between the object glasses and the field or larger glasses may be provided with springs to push the object glasses into an expanded condition, and the slotted frames which would limit the extent of expansion can also be arranged for retaining the article in a closed state.

5,525. *April 1st*, 1889. "Photographic Hand Cameras." Denis McNamara, 25, South Terrace, Inchicore, Dublin, Engine Fitter.

Its novel features are, first, a dry plate is changed and placed in focal position and the shutter set, by the one movement, thereby preventing the possibility of exposing the same plate twice over through inadvertence or otherwise; secondly, the one button or knob serves all purposes, viz., for changing dry plate, for setting and discharging the shutter. Hence the advantage by which a number of dry plates may be exposed in very rapid succession.

In outward shape it consists of a rectangular box or case, one end of which is recessed to receive the lens. Within said case is a grooved box open at the side next to the lens, its depth a little more than double that of the sensitised plates, of which it is capable of holding twelve or more; each of the latter is inserted in a thin metallic sheath; midway on the inside of the two opposite walls of said box is formed a horizontal groove parallel to the axis of the lens, through which is passed a thin metallic plate or partition dividing it into two compartments, the upper for the unexposed, and the lower for the exposed plates, and on which it is capable of sliding; the ends of said partition are attached to the walls of outer casing, and a slot is cut in the former sufficiently large to allow one plate with its sheath to drop through at a time from top to bottom compartment. Immediately beneath partition and in said bottom compartment is a rod, one end crossing said slot, so as to prevent a plate from dropping through, and is kept in position by a spiral spring; the other end passes through wall of outer case at the end opposite to the lens, and terminates in a joint, to which is attached a lever actuated by a bar placed longitudinally on the outside of camera, one end bearing at right angles against said lever; the other terminates in a knob or button, which is used for setting and discharging the shutter, and also for changing the dry plates. On the bottom of the outer case is a sliding cover through which the grooved box is charged with dry plates. In doing so the plates are placed in their grooves in the lower chamber, the camera being inverted according as grooved box is moved along the partition; each time a plate comes over the said slot it drops through into the upper compartment, the rod being kept back so as to clear the slot by pressing upon the knob during this operation.

The instantaneous shutter is inside the camera. A nozzle or rim is formed at the back of the lens, on which is fitted a cap capable of opening by a hinged joint at the bottom, and actuated by a spindle, one end of which passes through the outer wall of camera, terminating in a cross-piece forming a T with said spindle. At one end of said cross-piece, at right angles to it, and parallel with wall of outer case, is secured or formed a thin flexible arm of spring steel, the end of said arm resting upon a ledge or stud when the shutter is closed; the other end of cross-piece, forming a crank with said spindle, is used for the purpose of opening the cap by means of a hook hinged on to a sleeve, and kept in position by a flat spring. Said sleeve is capable of sliding upon the bar, to which is attached knob or button heretofore mentioned, and is actuated by a spiral spring slipped over said bar, one end bearing against the sleeve, the other against a movable pin for regulating the speed of the shutter. When said bar is pushed forward by the knob the sleeve and hook are carried with it, the spiral spring becomes compressed, the hook coming into contact with cross-piece, and having a wedge-shaped end, loops on to it; when the finger is removed from said knob the latter returns to its original position, being acted upon by the spiral spring in grooved box, the hook retaining its hold upon the cross-piece: the shutter is now set.

To discharge the shutter, the knob is pushed in the opposite direction, thereby bringing a thin flat projecting piece secured to said bar into contact with flexible arm resting upon projecting ledge, which yields by its flexibity, and is pushed off said ledge; the spiral spring now acting on the hook shoots it forward, thereby turning round the cross-piece with it, and opening the cap; when said cross-piece arrives at a certain angle the hook slips off, but the momentum imparted to the cap causes the latter to strike an elastic band or spring which causes it to rebound and lock itself once more on projecting ledge.

To change a plate, the knob is pushed forward, the shutter becomes set as before, the bar bearing against the end of lever draws out the rod in grooved box, and a plate is dropped into bottom compartment; the pressure of the finger is now removed from said knob, and the spiral spring brings back said rod into its original position, but the latter, when returning, comes into contact with the top edge of plate which has just dropped, and pushes it forward, and being in its groove it carries the entire grooved box along the sliding partition until the next plate following up drops a short distance down into slot in partition, and rests on top of rod; said plate becomes jammed in the slot by the pressure of the rod still bearing on top edge of plate in bottom compartment, thereby keeping the plate steady for exposing.

The plates when dropping would be liable to stick after being jammed in the manner described. To overcome this, the partition where it is attached at both ends to camera is made to slide longitudinally through a short distance. A lever is hinged on inside to wall of camera, one end bearing against a stud on partition, the other end against a similar stud on rod; when the latter is drawn out the said lever moves the partition, the grooved box remaining stationary, and liberates the plate which had been jammed in the slot, thereby allowing it to drop freely, said partition being brought back again to position by a spring.

An indicator is attached to camera for the purpose of registering the number of exposed plates. It consists of a flat graduated bar connected to grooved box, and capable of moving in a guide on the inside of camera, with a hole in the latter, forming light-tight communication with said guide, and through which the number of exposed plate can be read from the outside.

5,287.—*March 27th*, 1889. "Focussing Field, Marine, and Opera Glasses." Samuel Joseph Levi, Optician, and Ernest Carre, Clerk, of 40, Furnival Street, Holborn, London.

Our invention relates to an improved focussing motion for field, marine, and opera glasses; and it has for its object to enable the glass to be more quickly and easily adjusted, which is of importance, especially when, as in the case of a horse race, the object viewed is in rapid motion, and its distance from the observer is therefore constantly and quickly varying.

The invention consists in substituting for the ordinary screw motion, a motion worked by a wheel, or preferably a pair of wheels, turning on a transverse axis at right angles to the line of motion of the central sliding spindle, and of such diameter as to be readily worked by the pressure of the thumbs when the instrument is held by both hands, as race glasses are usually held. Each wheel acts on the sliding spindle through a pin or stud projecting laterally from the sliding spindle through a longitudinal slot in its guide tube, the said pin or stud engaging in a radial slot in the inner face of the wheel. Or instead of a slot, each wheel may have a crank pin fixed to its inner face, the said crank pin being connected with the stud on the sliding spindle by a short connecting link. Instead of wheels small levers may be used.

6,353.—*April 13th*, 1889. "Photographic Apparatus for Tourists." Samson Albert Darier-Gide, 4, Rue Bellot, Geneva, Switzerland.

This invention can be adequately explained only by the aid of diagrams.

19,691.—*December 7th*, 1889. "Photographic Cameras." Oscar Freeworth, of Lenkerbad, County Wallis, Switzerland, Gentleman.

The inventor claims:—

1. In photographic cameras the arrangement consisting essentially of a prism and eccentric discs which, when the prism is turned, force the bellows, which are held firmly against the prism by means of springs, away from the prism.

2. In connection with the arrangement described in the above claim, the employment either of plate or film-frames connected with each other, or, in case of sensitive paper, of rollers.

Correspondence.

A PHOTOGRAPHIC SCHOLARSHIP.

Sir,—May I beg you will insert enclosed correspondence in your next issue? The matter appears of sufficient interest to require public discussion, in order to arrive at the best method of disposing of the gift in question.

I may say that my own feeling is to offer the sum as a scholarship, to be competed for by examination amongst the students of the schools of photography at the Polytechnic, South Kensington, &c., and that the earning of such scholarship should carry with it the necessity for a year's residence and study at one of the best schools of photography on the Continent.

I venture to think this method would tend to elevate the art-science, and place it on a level with other special subjects which are already similarly endowed. John Howson.

My dear Sir,—In looking over the programme of the Conference I see amongst the agenda, a proposal to abolish trade medals at exhibitions. Now, though I hold views on this subject opposed to yours, I am quite ready to admit that general feeling is against me; and that being so, it is manifestly for the benefit of photography that my views should be put aside, and trade medals should disappear. Therefore the Britannia Works Company will, in future, abstain from offering any such medals. This I hope will be some little help in clearing the way for a prompt and easy settlement of the question, as my firm is one of the principal offenders. I take this opportunity of recording my earnest conviction that, however ripe the time may be now for such a sweeping change, in the past the giving of trade medals has served a good purpose, by stimulating competition, and bringing to exhibitions good work which would have been absent in many cases without such inducement. I claim, moreover, to have credit given us for a real desire to further the art of photography, as well as our own ends, in what we have done in the past. To prove that we have been and are to a great extent disinterested in our motives, I am pleased to inform you that the Britannia Works Company have generously placed at my disposal the sum of £100 per annum for three years as a scholarship to be used as may best seem adapted to further the interests of either the art or science side of photography, with an expression of preference for the science side. To the Camera Club, as the leading spirit in all forward movements in the art, I desire to transfer this generous gift, and I trust the Conference will see their way to accept it, and that we may conjointly be able to dispose of it in a fitting way.

Brokenhurst, Ilford, March 10th. John Howson.

G. Davison, Esq.

Dear Sir,—The Committee of the Club discussed the subject of your kind offer at their last meeting on Thursday last, and requested me to thank you for your generous proposition. At the same time it was thought that the best way of applying the gift—or, rather, the best course to adopt—would be to place the fund entirely at the disposal of a committee or trustees formed independently of any *one* society, but rather from the Photographic Society of Great Britain and other leading societies conjointly. A representative committee formed in this way would probably be able to suggest a method of applying such a fund to advantage, either by offering inducement for research and experiments in certain directions, or for original work of value in any way bearing on the advancement of the science or art of photography. G. Davison.

Camera Club, March 14th.

To John Howson, Esq.

Photographic Society of Great Britain.—Technical meeting, Tuesday, March 25th, at 8 p.m., at the Gallery, 5a, Pall Mall East.

Sheffield Camera Club.—At a meeting held on March 12th, Mr. H. W. Smith, representative of the Eastman Company, Ltd., gave a lecture on "Enlargements on Bromide Paper." After detailing the most suitable lights and developers, he gave a practical demonstration on the Eastman paper, explaining the process step by step.

Proceedings of Societies.

Camera Club.

On Thursday, March 13th, lantern slides were shown at the Camera Club. Mr. Webber occupied the chair.

The Hon. Sec. handed round some collotype prints on Japanese paper and satin by Mr. W. K. Burton. Some fine Japanese paper, intended for experiment, were distributed to those desiring pieces.

Professor Stebbing exhibited some collotype prints brought from Paris, which had been produced by M. Balagny. Some of these were on rough-surfaced papers. Mr. Stebbing stated that within three-quarters of an hour of giving a negative to M. Balagny, about twenty prints were given to him. He thought that M. Balagny would introduce his method into England, and he saw no reason why the amateur should not have his own machine at a cost of about £4, and make his own collotype reproductions.

A show of lantern slides was then given; altogether, about 200 slides were brought or sent up by Messrs. W. M. Robertson, Lane, Elder, Seyd, Ellis, Laurie, Fitz-Payne, Howlett, and Grimshaw.

The subject on Thursday, March 27th, will be "Platinotype Possibilities," when Mr. W. Willis will read a paper. Meeting at 8 p.m.

London University College Photographic Society.

March 11th.—Dr. R. T. Plimpton in the chair.

Dr. N. Collie, F.R.S.E., read a paper on "The Chemistry of Photographic Developers." The simplest form of development was first noticed, where a ferric salt has been reduced by light to a ferrous salt, when the nearly invisible image can be made visible by washing with ferricyanide of potassium, or treating with a silver or gold salt, which metals are deposited where the iron has been reduced, thus developing the image. The development of the visible image on the photographic plate was then noticed, and it was pointed out that in this case, as only an infinitesimal quantity of haloid salt of silver undergoes change during exposure to light, development has to be carried on in a different way from that already noticed. The alkaline developers—pyrogallic acid, hydroquinone, and others—were next mentioned. These developers are characterised by their great affinity for oxygen, and differ from ferrous sulphate, the reaction of which with nitrate of silver was discussed, in being able to reduce the haloid salts of silver. The actual chemical change which takes place when a plate is developed by any of these substances was shown to be the same. It is a case of reduction of the silver salt by the developer, but, as the developer contains no silver, the only way in which the image can be built up is by the further reduction of the silver salt in the film. The question why silver is deposited on one part of the film and not on another, thus forming the image, is explained by the assumption that electro-chemical decomposition occurs. It was finally pointed out that in all ordinary cases of development a reducing substance was necessary, and usually the greater the reducing power the more powerful the developer; and, as there are numberless substances amongst organic compounds which possess this reducing power in a greater or less degree (phenyl hydrazine was shown as an example), the choice of new developers is, probably, by no means limited.

In the discussion which ensued, Mr. E. S. Worrall criticised eikonogen as being admirably adapted for certain kinds of work, but, to get a good negative, he preferred the yellow image obtained by using the old-fashioned pyro developer.

The next meeting will be held on Tuesday, March 25th, which will be a lantern night, and the last meeting this term.

Derby Photographic Society.

The monthly meeting was held at the Rooms in Derwent Street on Thursday last; Mr. A. B. Hamilton presided.

Mr. Bankart, of Leicester, gave a lecture on "Development," and exhibited a number of his negatives.

London and Provincial Photographic Association.

At the meeting on the 13th inst. Mr. L. Medland occupied the chair.

The evening was devoted to judging lantern slides put in for competition by the members. The slides were all made from three quarter-plate negatives chosen for the purpose, which were passed to each intending competitor in turn. The subjects were:—"Land's End, Seascape," "Old Houses at New Lyn," and "Children Gathering Seaweed." The slides were projected on the screen side by side from two lanterns supplied and manipulated by Mr. T. E. Freshwater, the slide judged to be the best being left on the screen until displaced by one voted to be better.

At the conclusion it was found that Mr. J. B. B. Wellington's slides had taken first place in all three subjects, and also the second place with two of the subjects, Mr. D. W. Atkins taking the other. Mr. Wellington's slides were made from collodio-bromide plates. Mr. D. W. Atkins used gelatine plates. The competition was an exceedingly close one in several cases, and created a great amount of interest among the members.

West London Photographic Society.

A meeting was held 14th March, Mr. E. W. Foxlee in the chair.

Mr. H. Selby gave a paper and demonstration on "Eastman Stripping Films." The lecturer said although condemned to die a natural death, owing to the introduction of celluloid films, yet stripping films, in the hands of careful workers, presented few difficulties, and were undoubtedly superior to glass in the matter of portability, storage, and immunity from damage if dropped. He attributed his early failures to neglect of the instructions issued by the Company. He seldom dealt with more than two films at a time. The great point was not to leave the film more than ten minutes in washing water after development and fixing. After that time he placed them in an acid bath composed of acetic acid 10 minims, water 10 ounces, in which they were left all night. Films so treated always stripped without trouble. It was very essential to have clean glass. He did not use rubber solution, but polished the glass with French chalk, employing a thin collodion made by the Company. His mode of working differed from that recommended by the Company in the following particulars: he did not strip the same evening as he developed; he never used rubber solution; he did not place the film on glass support under water, it being easy to avoid bubbles without so doing; he never used glycerine and alcohol, and did not varnish the gelatine skin.

In the course of the discussion which ensued, Mr. Hazeon said he had developed only five films, given him by a friend. He had used neither skins, collodion, or rubber solution, but he succeeded in stripping all of them without mishap.

Mr. Wilson, in developing Kodak films, used a weak solution of sulphuric acid and water. He sometimes left them several hours under pressure, not allowing them to dry; they then always stripped. He rather liked the operation of collodionising and coating with rubber, and therefore employed both solutions, although sometimes with the rubber there was a tendency of the film to stick locally.

Mr. Stein had found the film negative detach itself from its skin sometimes, and that when collodion had been employed.

Mr. Rickford wished to know why hydroquinone rotted the film. It did not seem to do so in all cases.

Mr. Wilson had found the films melt away in a hydrokinone developer, which, however, contained caustic soda.

Mr. Hodges considered a roll-holder and films far more convenient on tour than plates: the negatives, owing to the absence of halation, were fully equal, if not superior, to those on glass. They also were very suitable for enlarging, the mat surface backing producing a very soft effect. By copying a small transparency in the enlarging camera the film side out, and enlarging on transferotype paper, or a stripping film, enlarged negatives could be readily and cheaply produced.

Mr. Roland Whiting wished to know whether the film would give a good bite to the retouching pencil. The collodion surface seemed to be very glossy.

Mr. Foxlee thought the collodion film a very valuable part of the process, and Mr. Hazeon ought to attribute his success to sheer good luck. The collodion not only protects the stripped film, but holds it together while upon the glass, and to avoid risk it was better to employ a preliminary coating of rubber solution. In very refractory cases he had used *boiling* water with success, which could have done without a rubber substratum. Damp sometimes caused the insoluble chromated emulsion to affect the soluble substratum of gelatine; difficulty in stripping them occurred; the weak acid solution, however, remedied this defect. He did not leave the films under pressure more than ten minutes. It was a mistake to leave them soaking after fixing, because the pyro exercised a tanning action on the soluble gelatine, and if the film were allowed to dry before stripping, the difficulty of stripping would be greater. He had never found the films become detached, and was at a loss to assign a reason.

Mr. Hodges thought it might be due to the presence of grease, or to careless squeegeeing.

The next meeting will be on March 28th, a lantern night, when friends are invited.

Glasgow Photographic Association.

March 6th.—Mr. William Lang, jun., F.C.S., in the chair.

A paper on "The Sizes of Plates" (see page 220), by Mr. J. Craig Annan, was read, and a discussion followed, the general outcome of which was that if an adjustment should be made, it should be done on an international basis.

A picture taken by an automatic photographic apparatus was afterwards shown to the members. It had evidently been taken on a wet plate, but particulars of the apparatus itself had not been given in sufficient detail to explain the *modus operandi*.

Mr. Patrick Falconer followed with a communication—"A Neglected Dry-plate Process," showing results obtained by the method, both transparencies and negatives. The process in question is one put forward by Mr. Hannaford in 1861, where the sensitised collodion plate, after being washed, is coated with a preservative of white of egg to which a certain amount of nitrate of silver has been added, and the albuminate of silver formed dissolved in ammonia. Mr. Falconer has worked the process for twenty-five years. The speed of the plate would appear to be very rapid, Mr. Falconer and the President having made transparencies shown at the meeting on the screen by means of the Association's lantern, when the exposure behind a negative did not amount to more than a second or two in front of an ordinary batswing burner. The image was brought out by means of eikonogen, and afterwards strengthened by means of pyro, citric and glacial acetic acids, and silver.

Several photographic novelties were shown, and an exhibition of transparencies by means of the Association's lantern concluded the evening's programe.

Photographic Society of Ireland.

A meeting was held at the Rooms, Dawson Street, Dublin, on the 14th inst., with Mr. Greenwood Pim in the chair. After election of four new members,

Mr. Louis Meldon read a paper on "Shutters." He said that he would confine himself to observations on instantaneous work, and the lenses most suitable. Having explained the working of the Wilson chronograph, which he used as his timing apparatus, he went on to say that shutters might best be classified relatively to the position they occupy when used with the ordinary form of doublet lens: 1st, on the hood of the lens; 2nd, between the two combinations; 3rd, immediately behind the lens; 4th, immediately in front of the plate. The fourth class he intended at once to dismiss, for, although its position was in many respects the most favourable of all, the advantages were much out-balanced by the inconvenience due to the large size of the apparatus needed. An ideal shutter, he said, was one which, if it were possible, would open to its full aperture suddenly, and without lapse of time, and, having remained open a certain time, would close suddenly

again. Mr. Meldon, having considered most of the instantaneous shutters in general use amongst photographers, proceeded to describe his own, and passed through the lantern some specimens of its work.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

A MEETING was held in the Mayor's Parlour, Old Town Hall, on March 12th, Mr. S. S. PARTRIDGE in the chair. Mr. Thos. Scotton was elected a member of the Society.

The silver and bronze medals were presented to the successful competitors in the lantern slide competition—Mr. Porritt and Mr. Joliffe respectively. The competition for silver and bronze medals for enlargements offered by Mr. F. Pierpoint was declared void, in consequence of the number of entries not complying with the conditions. The competition was postponed until the October meeting, when silver and bronze medals will be offered by Mr. Pierpoint for the best enlargement, members to enter not more than three specimens for competition. The medals are offered on condition that not less than three compete for the silver, and five for the silver and bronze medals.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

THE annual dinner was held at Beale's Restaurant, Holloway, on the 15th inst., Mr. J. HUMPHRIES, F.S.A., in the chair.

The usual loyal toasts having been honoured,

Mr. J. W. MARCHANT proposed the toast of the evening, "The North Middlesex Photographic Club and its Officers," which was responded to by the

CHAIRMAN, who briefly sketched the position of the Club, and alluded to the ability and energy displayed by the council and hon. secretary (Mr. G. R. Martin) in the past year, and to the successful manner in which the arrangements in connection with the recent exhibition of photographs and soirée had been carried out by them. The roll of membership had increased, as also had the finances of the Club. The lectures and demonstrations had been well attended.

Mr. BROCAS (Holborn Camera Club) acknowledged the toast of "Kindred Societies."

Mr. G. R. MARTIN (hon. secretary), who replied to the toast of "The Press," said he was glad of the opportunity of stating how much the Club was indebted to the Press in reporting their meetings.

Mr. DAVALL, senr., responding for "The Visitors," referred to the wonderful advances made in photography, particularly in the astronomical direction.

During the evening, a varied series of vocal and instrumental music added to the entertainment.

The *menu* card consisted of an original design by Mr. Saville, photographed and finished by Mr. Beckett, both members of the Club.

THE PHOTO-NEPHOGRAPH.—In the exhibition at the Meteorological Society, was Captain Abney's photo-nephograph, or cloud camera, which Mr. Whipple described as an apparatus not yet fully developed. He said that its object is to obtain simultaneous instantaneous photographs of the same cloud from two or three stations situated at a distance from half a mile and upwards from each other. These simultaneous pictures are then utilised for determining the positions of clouds above the surface of the earth, and so obtaining a knowledge of the upper currents of the air, their direction and motion at heights far above those at which anemometers can be placed, and in places where they may be supposed to be unaffected by the irregularities and eddies formed by excrescences, such as hills and valleys, which modify the contour of the earth's surface. At Kew, two cameras fitted to theodolites are erected on stands half a mile apart, but electrically connected by an underground telegraph wire. Each camera is provided with an adjustable instantaneous shutter, which can be manipulated by an electric current at the will of the directing operator. The *modus operandi* is as follows:—A first points his camera at a selected cloud, and then having instructed the observer at the remote station B, through a telephone, as to the direction in which he should place his instrument, releases both shutters at the same instant of time, so obtaining a pair of pictures in which the stereoscopic effect affords the required data.

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London

M. E.—*Asbestos Wicks.* We have had no experience with asbestos wicks, but imagine that they would not be less liable to clog, for a carbon deposit would be formed at the top, and entail the necessity of occasionally igniting the asbestos to get rid of it. Try the experiment for yourself, either with the loose fibres or a strip of asbestos cloth.

C. N. W.—*Photogravure Details.* Try to attend the practical demonstration to be given at the Camera Club Conference this afternoon, about 5 p.m., at the Society of Arts. You will be admitted on signing the visitors' book.

RETOUCHER.—*The Address of Herr Fritz Luckardt* is Hotel National, Vienna. You will find an account of his studio and special device for glazing the roof in the article, "Fritz Luckardt at Home," at page 460 of our vol. xxv.

R. B. B. (Dennistown).—*Etching of Glass.* There are two methods: the first, producing "satin effects," is done by hydrofluoric acid alone. For a dead-white etching, make a mixture, in a gutta-percha or lead bottle, of very finely powdered fluor-spar with enough strong oil of vitriol to form a thin paste, and allow time for the acid to decompose the calcium fluoride. Write with a quill pen or small brush dipped in the fluoric ink on the glass direct, without either wax or varnish for protection. After a few minutes' contact, wash off and dry with filter-paper. A small proportion of precipitated sulphate of baryta is sometimes added to thicken the ink before use, and give more opacity.

V. R. (Malta).—*Method of Reviving Daguerreotypes.* The best process is by immersion in a very weak solution of cyanide of potassium, watching carefully until the image is just cleared, and then quickly washing under a tap, with final rinse in distilled water. Allow to dry spontaneously in the air.

M. F.—*A Small Studio.* The information you require is given in Mr. H. P. Robinson's little book entitled "The Studio; and what to do in it," published by Messrs. Piper and Carter. A very compact form of studio was described by Dr. John Anthony, at the April, 1870, meeting of the Photographic Society. See the *Journal* of that date. But the details of construction must always be to some extent governed by local circumstances. You might be able to build one for the sum named, but the calculation would be rather close.

H. B.—Your letter received, signed, and passed on to the Kingsland Branch.

M. E. P.—The *Crystal Palace Exhibition* remains open until Saturday, 29th inst. The lantern display is better than ever; two new lenses, of three inches clear aperture, with big lime lights, project the image upon the screen, which is said to be 35 feet in diameter. The amplification is therefore about 140 times. Ask Mr. Brooks to let you see the apparatus.

D. W.—Received the four cabinet vignettes. They are, indeed, excellent, and we will write you respecting them in the course of a few days.

F. S.—*Iris Diaphragm.* The only objection arises from the chance of grit getting into the working parts; but against this you may put down the loss of time in changing the sliding diaphragms, and the possibility of leaving them behind, or of dropping them into long grass or heather in the field.

E. P.—*Fading of Silver Prints.* The liabity to change has been vastly over-rated, for if carefully fixed and thoroughly well washed, finishing off with hot water, the longevity is quite remarkable. We have seen some notable instances lately of good prints not appreciably affected in thirty years.

Several other corespondents in our next.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1647.—*March* 28, 1890.

CONTENTS.

THE INVISIBLE PHOTOGRAPHIC IMAGE.

THE nature of the invisible photographic image being unknown, the wisest course is to weigh all the different hypotheses at present in existence, and not to try to raise any one of them to the level of a kind of Athanasian Creed which must not be denied without the individual falling under the ban of heresy. Mr. Bothamley did not do this in his paper read before the Camera Club Conference, still there may be no harm in pointing out some of the arguments in favour of the dynamical hypothesis of the nature of the invisible image.

The chemical hypothesis is that the molecule of bromide of silver is decomposed by the action of light. The dynamical hypothesis is that it perhaps is not decomposed, but that the interatomic vibrations of the molecule are modified, and that the affinity of the bromine for the silver is thereby somewhat weakened by the action of light, so that the developer acts more easily thereupon, and decomposes the modified molecule more quickly than if it had not been acted upon by light.

The initial effect of the light is undoubtedly of this kind, because an instantaneous action is unknown to science; every decomposition requires time, for all nature works as if upon springs. A bottle of mixed hydrogen and oxygen gases, for instance, cannot be exploded all at once; experiment has proved that a portion of the mixed gases remains unburnt. On these principles the dynamical hypothesis is certainly to some extent true, even if the chemical hypothesis should be the true one in relation to the final phenomenon of an invisible image on the plate when the latter is ready for development.

In the abstract of the paper given last Friday by Mr. Bothamley, the main argument against the dynamic hypothesis was, that if light merely modified the motions of the constituents of the molecule, in the course of months or years the motions would resume their original character, and the fact would be indicated by the dying out of the invisible image on the plate, so that no picture could be brought out by development.

For the sake of simplicity in illustration, two atoms only may be assumed to be in a state of some kind of vibration in relation to each other, and to place a definite picture in the mind's eye, we will compare these two atoms with the sun and the earth, calling the sun an atom of silver, and the earth an atom of bromine.

Leverrier first proved that the orbit of the earth varies with time, in consequence of perturbations set up by the planets. At the present time the path of the earth round the sun is nearly circular, and at midwinter the earth is nearly ninety-one millions of miles from the sun; but when the orbit was at its greatest eccentricity the earth was nearly ninety-nine millions of miles from the sun at midwinter. One period of great eccentricity began 240,000 and ended 80,000 years ago, and is one which is quoted by Dr. Croll and others in support of the astronomical theory of glacial epochs, a theory more generally accepted by scientific men than any other. In the thousands of consecutive years during which the earth is at midwinter more than, say, four millions of miles from the sun than at present, it neither breaks away from the sun, which would correspond to the decomposition of our imaginary molecule, nor does it come back in a few months or years, or hundreds of years, to its present path round the sun.

The objection may be raised that in the matters of weight and speed it is not fair to compare the infinitely great with the infinitely small, but the response is that little is known about atoms; nobody has ever seen one, nor is much known about the immense forces which control their motions. Professor Tyndall often amused Royal Institution observers by bursting bombshells by means of the molecular force exercised by water when in the act of freezing.

The argument was put forth at last week's Conference that there is no doubt as to the decomposition of the molecule, because of the smell emitted by large

numbers of bromide plates when exposed to strong daylight at works where they have been spoilt in the course of manufacture. Nobody denies, however, that light, when it acts long enough, may set up chemical decomposition, though this is not so clear in the case of absolutely pure iodide of silver when not in contact with any other chemical substance, so far as man can surround it with such conditions.

Mr. Carey Lea, who accepted the dynamic hypothesis soon after it was first published by its two originators, has changed his opinion at least three times as to the nature of the invisible image, and there would be nothing surprising if he changed it again next week. This is to his credit; it proves him to be a philosopher who does not dogmatise, but changes his opinions from time to time as newly revealed facts come under his notice.

One of the functions of trained scientific men is that of experimentally investigating such problems as these, and much chemical and mathematical investigation will have to be brought to bear upon the particular question now under notice. The chemist may hereafter tell us what is given off by bromide plates when exposed to sunlight, and the mathematician may bring evidence to bear as to the possible duration of modified interatomic motions, assuming such to exist. Professor Dewar took up safe ground when he stated that it is an exceedingly difficult task to determine what takes place when light first strikes a photographic film. Professor Meldola is to lecture on this subject a few weeks hence at the Royal Institution, and what he has to say thereupon cannot fail to be of interest.

THE CAMERA CLUB CONFERENCE.

The First Day's Proceedings.

A report of the first day's proceedings of the Camera Club Conference was published in these pages last week, and to-day we add a brief portion of Mr. Rossi's paper read thereat, as follows :—

Mr. Rossi on "Photography and Drawing."

Mr. Rossi, in the course of a paper on the above subject, said :—

The marvellous perfection to which photography has risen, and the facilities that she offers us, have so minimised the long and tedious years of an art education, that a youth born an artist can now accomplish, in as many months, that which would have taken him so many years to learn before photography.

The three great components that constitute an artist are design, drawing, colouring. By design we understand the idea, the scheme, the conception that an artist wishes to express. This is a creative faculty, and, like colour, cannot be taught; if it is to some extent acquired by tuition, it will be destitute of individuality and void of originality. Drawing is the necessary foundation of painting, without which it is impossible to obtain the images of things or their action, their just proportions, expressions, or animation.

This knowledge, though infinitely easier to some than to others, can be sooner or later acquired, and by practice can be perfected. Colouring, as we said before, is an instinct born with us. Every man has a genius—the evil, the dormant, the sluggish, and the bright genius that inspires in our works that mysterious breath of the spirit that makes us see lovely images. Unfortunately for many, their mind has been unable to carry them beyond the borders of the boundless area of mediocrity to get a glimpse of the glorious fields of immortality. Nevertheless, their academical education has not been lost, for it has given them experience, which has convinced them that a true artist now is not made at an academy, or in any of the numberless schools where young people flock by the hundred to the destruction of art, but by going to nature ; and if such youths who can from nature's inexhaustible book get inspiration and learning, devoted themselves to art, it would be a blessing for all connected with it. Michael Angelo called with Vasari one day on Titian, at the Belvidere at Rome, to see a picture of a naked figure of Danea. Many of the guests began to praise the work highly, as do people when the artist is present, and Michael Angelo, when all had left, declared that the manner and colouring of Titian pleased him greatly, but that it was a pity that the Venetian did not study drawing more, for if, he added, the artist had been as aided by art and knowledge of design as he had by nature, he would have produced works that none would surpass.

I would ask you, if an artist of Titian's gigantic powers lived now, and had produced a picture of a naked figure, would he have incurred the criticism that his great brother artist passed upon him? I think not; for conscious, as great men generally are, of the weak point in their works, he would be sure to use all the legitimate means in his power to secure a correct outline before applying to it his fascinating powers of painting. I can therefore well imagine a nineteenth century Titian taking a good photograph of *that* he has conceived with his imagination, and tracing it on his canvas to his size before painting from his model, and thus he would be sure to produce that which the modern Michael Angelo would admire, not only in the manner and colouring, but also in the drawing. It is indisputable that photography has destroyed all conventionality and mannerism in art, and has shown us the correct way of drawing, by placing before our eyes the true forms of lovely things and of all things.

Mr. Rossi concluded his paper by expressing his firm belief that the only teachable part of art, which is drawing, is sinking with the rising of photography, and, in his humble belief, the days are not far off when a youth, born with artistic instincts, in a few months of mechanical instruction can be his own teacher, and photography will be his academy.

The Second Day's Proceedings.

The second and last day's proceedings of the Conference began last Friday morning in the hall of the Society of Arts, London, under the presidency of Capt. W. de W. Abney.

Discussion on Regulations for Photographic Exhibitions.

Mr. George Davison read a variety of papers and letters upon photographic exhibitions, in the course of which he stated that the following opinions had been expressed by various societies and exhibitors at a representative conference in 1888 :—

1. *Length of Notice.*—Unanimous that long notice should be given.

2. *Previous Announcement of Judges.*—The meeting at the Camera Club in 1888 was unanimous in favour of early announcement of judges' names, and there was a large preponderance of replies from influential exhibitors consulted in which the same view was definitely taken.

3. *As to Classification.*—Opinions divided, but considerably in favour of classification by "subject."

4. *Awards or no Awards.*—A large majority of opinion that awards are generally desirable at photographic exhibitions.

5. *As to Frequent Exhibition of Prize Pictures.*—The 1888 meeting decided by a large majority in favour of a champion class; but there was a very large preponderance of opinions from leading exhibitors that medalled pictures should only be restricted by a time limit varying from one to three years from date of first exhibition.

6. *As to the Amount of Work to be Performed by the Exhibitor.*—All the written opinions urged the necessity of selection, exposure, development, and printing being the work of a competitor, a fair sprinkling making an exception as regards mounting. The meeting added a unanimous resolution that where competitive exhibits were the work of more than one operator, the same should be notified in the catalogue.

7. *Judges for Art Section.*—The 1888 meeting preferred, by a majority, that the judges in the Art section should be "photographers, admitted authorities on the artistic side of photography," rather than solely "artists recognised in the artistic world."

8. *Judges for Scientific Classes.*—Unanimous that experts only be adjudicators.

Other points which were unanimously agreed upon were as follows:—

9. All awards should be of equal value.

10. The granting of large numbers of awards, and the acceptance by exhibition authorities of prizes offered for the purposes of advertising, greatly to be deprecated.

11. That some limit be imposed upon the number of photographs to be accepted from one exhibitor.

He added that opinions on some of these points had since been modified, and that the discussion thereof would be useful.

As recommendations the Club put forward the following suggestions:—(*a*) That the power of rejection of inferior entries should be rigidly exercised; (*b*) that with reference to Rule 6 greater effort should be made to encourage the exhibition of photographs, specimens, and other things illustrating the application of photography to various sciences and industries; (*c*) that retouching be declared; (*d*) that proper and full provision be made for re-packing pictures for transit; (*e*) that a small charge for wall space—minimum 2s. 6d. for 10 square feet—be made; (*f*) that the number of photographs sent in to any one section by each exhibitor be limited; (*g*) that each photograph in the Art section shall be separately framed.

Any distinction between amateur and professional in photographic exhibitions is considered absolutely unnecessary, and greatly to be deprecated.

The Club looks forward to a time when it may be possible to dispense with awards entirely, and would approve of an exhibition in which no medals were offered, but in which greater stringency was exercised by the committee of selection, so that the honour of being hung would constitute an award.

Mr. Mansfield, president of the Dublin Photographic Society, objected to the formation of a champion class at exhibitions.

Mr. Davison found the objection to a champion class to be general. He added that Mr. Robinson had written, stating the best exhibition system to be that of the Photographic Society of Great Britain, that champion classes are objectionable, and that he thought that the disqualification of photographs which have previously taken one prize would amount to giving place to second-rate pictures. He objected to a division between amateurs and professionals, but thought that if one were made, it should be absolute. He likewise thought that excessive retouching should be discouraged. Mr. F. Hollyer wrote that the champion demon should be knocked out; he had known many champions in his time, and they all drank themselves to death. Mr. Sutcliffe wrote that all prizes should be declined which savoured of trade, and that a total of about ten medals should be given to each five hundred exhibits. Judges' names should be published from the outset, that photographers might know whether to exhibit or not. He was in favour of separating amateur and professional work at exhibitions. Messrs. Cembrano, F. Evans, and others had also written on the subject. The Camera Club found the number of awards to be out of all proportion to the number of photographs exhibited, and that they were seldom withheld. The secretary to the Photographic Society of Great Britain wrote that the council hoped that the step taken by the Club would lead to some general agreement, and hoped that the suggested regulations for exhibitions would be drawn up somewhat on the lines of the annual exhibition of the Photographic Society.

The Rev. F. C. Lambert would like to gather general opinions on several points, and thought that rules and recommendations should be separated. He did not wish the idea of classification to be suppressed for photographs which were not upon attractive subjects, for then the latter would have little chance of being recognised. He thought it to be undesirable that editors should be judges, and that all the work over the photographs on view should be done by the exhibitor or exhibitors. On the principle of "one day's work one day's pay," he hoped that no picture would receive a second award, and that there should be some time limit; for instance, it might be a rule that photographs exhibited should have been taken within the previous twelve months. There might be one champion class once a year, but he should prefer the abolition of champion classes altogether. He thought that in judging, technical excellence should weigh somewhat, but artistic excellence chiefly.

Mr. C. W. Hastings said that it was all very well for the Camera Club to lay down rules, but could provincial societies adhere to them? He suggested that a permanent photographic exhibition committee should be formed in London, that the councils of the Camera Club and Photographic Society should be drawn upon for such committee, and that the presidents of provincial photographic societies should be members thereof; there should also be local provincial exhibitions and sub-committees. No picture should take a second prize, and permanent judges should be appointed. All medals and diplomas should come from the permanent committee. Champion classes had been established to keep out "pot hunters."

Mr. W. D. Welford wished to try to represent the feelings of the provinces in the matter. He agreed with the principles expressed by the Camera Club, but thought that it would not be safe to pass the rules and recommendations as they stood, because they would be thought impracticable, for exhibitions in the provinces ran on different ground to those in London. One of the aims of provincial exhibitions is to educate the public as to the claims of artistic photography; it is also necessary that they should pay, and the rules before them would prevent exhibitions being held. Practical and not ideal rules were required, especially as there are more exhibitions in the provinces than in London. Everything seemed to depend on the judges, and that the exhibitors should have confidence in them. He thought that editors should not be judges, because they might have to express opinions elsewhere on the exhibits; he also thought that technique should not be entirely lost sight of in judging. To abolish all classification was too sweeping a change, and he did not see what

gain there would be to art by making a distinction between the amateur and the professional photographer.

Mr. A. Maskell was opposed to any system of prizes, awards, or judges, and if the Camera Club did not have them, he could not see why it should try to lay down rules on these subjects for others. He objected to advertising prizes. He should like to see an annual *salon* or academy, at which it would be an honour to have pictures hung on its walls, and the judges—that is to say, the hanging committee—should be mainly sought from without. In the arts, much work is done by assistants; and in photography, in which so much of the work is mechanical, he did not think this matter was one which need be inquired into. He hoped that the term "amateur" would soon be disused. At all international exhibitions photography has been placed in the background, and the exhibits put in any out-of-the-way places; and photographic meetings seem to be recognised by an ignoring press as dealing neither with mechanics nor with art.

Sir David Salomons objected to landscapes and portraits being classified under the same heading; he did not see how they could be compared in giving one award. As for those firms who offered trade medals, he never bought goods of them, and he advised his friends to take the same line of action. If judging went only upon artistic merits, technical photography would soon go down hill. Nine out of ten photographers admitted retouching to be necessary in portraiture whenever there was no power to select the subject, and landscapes could often be improved by introducing clouds; so photographs produced on such lines ought not to be disqualified.

Mr. H. Trueman Wood thought the classification of the Photographic Society to be good, and that it had worked well. The rules before them, he thought, should be referred back to the Camera Club Committee, which could then be guided by the light thrown upon them by that discussion.

Mr. Davison then gave his personal views, which were, in reply to Mr. Lambert, that he thought it to be far easier for the judges if there were no classification. As to Sir David Salomon's objection, there was a provision in the rules, for the judges had the power of deciding how many awards should be made. Some workers produced but one or two artistic pictures in a year, and the competition system prevented some of the best work being exhibited. A suggestion had been made that in judging, attention should be "chiefly" instead of entirely given to artistic merit. He thought that the two things—technical and artistic merit—could not be separated. Some of the suggestions of Mr. Hastings deserved consideration. Mr. Welford had argued that classification would interfere with the success of local exhibitions, but he (the speaker) did not see that at all; he agreed with the ideas of Mr. Maskell, and was of Mr. Trueman Wood's opinion that the matter had better be postponed.

Mr. Macey Wright wished to know if all editors were to be excluded from being appointed judges.

The President replied that the rule was meant to apply to the editors of photographic newspapers. As to Mr. Maskell's remarks, if the Photographic Society was not recognised by the scientific press, it was entirely its own fault, for when scientific papers were read before it, some of the members said that they were too abstruse and had better be taken somewhere else.

The report was then referred back to the Camera Club Committee.

Lord Rayleigh on "Photography by the Light of the Electric Spark."

Lord Rayleigh, Secretary to the Royal Society, and Professor of Natural Philosophy at the Royal Institution, said that in response to an invitation from their Hon. Sec., he had attended to describe his experiments upon the above subject. He had had occasion to photograph the drops into which jets of water burst soon after issuing from a nozzle or from a hole in a plate, and the jets under examination varied from $\frac{1}{2}$ inch to $\frac{1}{30}$ inch in diameter. They were in a state of unstable equilibrium, for the tendency of such cylindrical bodies of water is, to separate into drops bearing a tolerably definite relation to the diameter of the particular jet. He then projected upon the screen by means of the lantern a photographic picture of that part of the jet at which it breaks into drops. As the drops are sometimes at the rate of about 100 per second, to photograph them sharply the time of exposure must be limited to a great deal less than $\frac{1}{1000}$ of a second, and in some cases to $\frac{1}{10000}$ of a second. A very great degree of luminous intensity in the images thrown upon the plate is therefore necessary, and he did not think that this could be obtained by means of ordinary photographic appliances. He added that "the spark is taken between brass balls enclosed in a magic lantern. The light issuing from the condenser, still slightly divergent, falls at a distance of sixteen feet upon a large single lens of about ten inches diameter, which plays the part of a field-glass. The photographic lens, a large portrait combination by Dallmeyer, is situated about seven feet behind in the image of the lantern condenser as formed by the field-glass, and is just large enough to include it. The jet to be photographed is placed parallel to the field-lens, and as near as conveniently may be upon the side next the photographic camera. The preliminary focussing of the image upon the ground glass cannot well be effected by the light of the sparks. For this purpose a candle, which may stand in front of the lantern condenser, is substituted." To get the spark, he used the large battery of Leyden jars at the Royal Institution, charged by a powerful Wimshurst's electrical machine. All along, his principal difficulty had been that of getting enough light, for, in these very rapid exposures, the effect of the light upon the eye seems altogether greater than, and out of proportion to, its effect upon the photographic plate. A great deal, however, can be done by varying the development, and by subsequent intensification. Each drop, as it comes off, is connected by a ligament to the main jet; this ligament then breaks, and forms itself into a little drop behind the big one, and, as it travels faster than the larger one, comes into collision with it. He described the effect of weak electrical action upon the sensitive part of these nearly vertical fountains, which is where they break into drops, and how electricity caused a number of the drops to coalesce into one large blob.

Mr. Charlton Wollaston thought that perhaps the experiments revealed the cause of the large size of drops of rain during a thunderstorm, and that electrical influences might have something to do with the formation of waterspouts.

Mr. Trueman Wood had seen the experiments at the Royal Institution; he had also tried to repeat the experiments at home, and he had been struck by the small amount of light available; he had been much struck by the feebleness of the photographic effect, as compared with the brightness of the image on the screen. A great amount of concentrated light was necessary to get any image at all. Could any estimate be made of the length of time of duration of the spark?

Another speaker asked if Lord Rayleigh had photographed drops when falling on a surface and breaking into splashes.

Mr. Elder thought that the brightness of the spark increased with the amount of self-induction in the circuit.

Sir David Salomons said that the spider, in spinning its web, exuded a viscous substance which aggregated into beads; he thought that perhaps by the means described such facts could be photographed, and additional information obtained about insects and animals.

Lord Rayleigh replied that no doubt electrical influence had to do with the big drops in which rain fell during thunderstorms. If, instead of placing a weakly-electrified body near the jet, a strongly-electrified one were used, the dispersion of the jet was increased instead of diminished, for the drops, being similarly electrified, then repelled each other, and did not collide. When moderately electrified, they united instead of rebounded, and it seemed as if some kind of a disruptive discharge took place. It is not clear to which of these causes the big drops of rain during thunderstorms are due. He had not yet attempted the photographing of drops splashing upon a plate, for to make the exposure at the precise moment when a drop fell on a plate was a difficult matter. He doubted if increased induction would give a brighter light, but had not tried it. He had not exact measures of the periods of the electrical sparks he used. An American professor had done some work in estimating the period of electrical sparks, and

had proved that very small sparks had periods going down to one-millionth of a second, or less.

The President said that photographing by the electric spark had been done in the old Daguerreotype days, and that he had repeated the experiment at the Royal Institution, but he used a reflector instead of a condenser to concentrate the light from the flash. He had also tried to ascertain the duration of the light, and made out that it was certainly less than $\frac{1}{100000}$ part of a second. The late Professor Guthrie and himself had begun the investigation of splashes; but the death of the former broke off the experiments.

Captain Abney on "A Photographic Untruth."

Mr. H. Trueman Wood then took the chair, while the President read a paper on the above subject.

Captain Abney said that the particular photographic untruth with which he had to deal was the untruth in form which a photograph gives when judged by the effect of light and shade. He had placed a white cylinder in a perfectly dark room, then had illuminated it from one direction only, and had found that the effect varied, according to the angle at which the light fell. Such illumination made the photograph of a man's face longer from front to back than it should be, and photographers, by a kind of instinct, seemed to try to get rid of this by extra illumination of the side. He had used exact measurements in his experiments, and had come to the conclusion that photographic gradation is never right. Photographers had long ago found out that they could not use the same mode of lighting as the painter.

Mr. C. H. Bothamley on "The Latent Image."

Mr. C. H. Bothamley gave an abstract of his paper on the above subject. He said that the physical theory of the latent image is, that when light falls on a sensitive plate, the molecules on which it acts are thrown into a state of unstable equilibrium, so as to be afterwards more readily affected by a reducing agent. If so, the disappearance of the latent image ought to be spontaneous, and he took it that the disappearance of the latent image is not spontaneous. Carey Lea, once one of the foremost supporters of the physical theory, had recently thrown over the last vestige of evidence in its favour by showing that silver iodide has the power of absorbing a considerable quantity of free iodine. After the exposure of the plate to light, the iodine is re-absorbed, and the plate comes back to its normal state. The perfectly pure haloids are not changed by light, but in the presence of moisture they are decomposed under luminous action. The dark solid substance formed under such conditions is probably not metallic silver, because it is difficultly attacked by nitric acid. He thought that the chlorine and the bromine liberated by light united with the gelatine, for he had failed to obtain evidence of the liberation of bromine in the free state upon the exposure of the plate to light. Exposed plates had been kept for months in some cases, and in some other instances for two or three years before development; if, then, the change set up by light had been merely throwing molecules into a state of unstable equilibrium, it was highly probable that in all that time the plate would have gone back to its original condition. He had repeated the experiments of others, and had found that bromine destroyed the latent image, but that it was extremely doubtful if even the strongest nitric acid would do so. Mr. Carey Lea had proved that marking a plate with a weak solution of hypophosphite of soda, also of certain other salts, would produce a latent image which could be made visible by development. He (Mr. Bothamley) had found that a plate so treated acted in every way the same under chemical reagents as a normally exposed plate. Pressure, or rather shearing stress, will produce a latent image, which is destroyed by bromine and certain other reagents; evidently stress produced the same substance in the film as did light. He thought Hodgkinson's and Meldola's views as to the chemical constitution of this substance to be extremely improbable; he thought that no oxychloride was present, but some reduction compound of silver. The investigations of Mr. Spring, of Liege, might have some bearing upon the problem of the effect of shearing stress upon a photographic plate, for Mr. Spring had found that substances which expand when they combine, form a compound which is decomposed under pressure.

Mr. John Spiller said that free bromine is given out when dry plates are exposed to light. Last summer he was near a stack of condensed plates exposed to sunshine, and the smell of bromine was nearly strong enough to knock a man over. He thought that experiments as to how long a Daguerreotype plate would keep between exposure and development would have some bearing on the subject.

Another speaker stated that Dr. Eder had recently published that the effect of shearing stress can be reversed by exposure of the plate to light.

Captain Abney had had more than nasal proof that the substance liberated by light from photographic plates is bromine. Nitric acid was the most doubtful of the oxidising agents for destroying the image. In the old wet plate process it was easy to develop an image on iodide of silver, then to dissolve it with nitric acid, and afterwards to develop the image again upon the same plate, and so on for a long time. The term "latent image" should not be used, for there is no latent image; the term "photographic image" would be better.

Mr. Bothamley thought smell to be an unsafe guide as to the substance thrown off by dry plates exposed to sunshine; it might possibly not be pure bromine, but a compound containing bromine.

Mr. W. T. Wilkinson on "Photomechanical Printing."

As the last item of the Camera Club Conference programme, Mr. W. T. Wilkinson gave a practical demonstration of the photogravure process. From the nature of the case demanding excessive care at each stage of the operation, and the late hour at which Mr. Wilkinson was called upon to give his explanations, the circumstances were not favourable to the production of a good result, and so it happened that the final printing process was never reached. Commencing with a clean copper plate, the speaker said that the first step was to lay the ground or "grain" the surface; this he did by shaking up a quantity of finely-powdered resin in a capacious box, lifting the lid to insert the plate, and allowing the resinous particles to settle like so much dust upon its surface. The attachment was secured by a spray producer, or the newly-invented "air-brush," finishing off on a hot plate. Upon this grained surface a reversed carbon print from a transparency was laid down, and then developed with hot water in the usual manner, the paper backing being removed, and all the soluble gelatine washed away in water heated to as high a temperature as the hand could conveniently bear. This done, the surface was rinsed with methylated spirit to quicken the drying, and then a resist varnish of gum dammar in benzole was applied. Now the plate was ready to be etched, and for this purpose it was laid face upwards in a dish and treated with an alcoholic solution of perchloride of iron. This latter salt slowly attacked the copper through the varnish layer, the iron salt having the effect of hardening or tanning the gelatine film, and the spirit induced a more regular action than could be got by the use of an aqueous solution. It required some experience to know how far to carry this etching process, and the margins had, of course, to be protected by asphalte during this operation. The plate was now ready, after washing off the ferric salt and cleaning away the carbon pictures and resinous coating, to be inked up and mounted for the production of successive impressions. This part of the process was "taken for granted," inasmuch as time had not permitted the operator to get a sufficiently deep etching; but Mr. Wilkinson showed some other plates, previously manipulated, which, in this respect, he regarded as perfectly satisfactory.

The Camera Club Dinner.

Last Friday night the annual dinner of the members of the Camera Club, and their friends, was held at the Frascati Restaurant, Oxford Street, London, under the Presidency of Captain Abney.

After the toasts of the Queen, the Prince of Wales, and the members of the Royal Family, Professor Meldola proposed that of "Success to the Camera Club," coupled with the name

of the President of the Club, Captain Abney, upon which the company struck up "For he's a jolly good fellow," and they gave him their emphatic assurance that there was no division of opinion upon that point.

Captain Abney, in response, said nobody could accuse him of too much partiality for the Club, for his attendances at its meetings had been few and far between, and he felt that he had not done his duty. The Club had been prospering; it had now nearly 600 members, and more papers were read before it than at any other ten photographic societies in Great Britain put together. Through the action of the Camera Club the Customs' examination of dry plates had been greatly facilitated, and now dark rooms for the proper examination of such plates had been provided at our various seaport towns. That day it had been seen that the Club had taken a step in relation to photographic exhibitions, and the Club had started the one man exhibitions. He hoped to see the time when no medals would be given at exhibitions, and that the simple fact of permitting photographs to be suspended on the walls would be considered sufficient honour. Soon the Club would enter into new premises with full accommodation, with eight or nine well-fitted dark rooms, also with workshop, laboratory, studio, enlarging room, and last, but not least, a billiard room. Nothing went into its journal but original matter; he had been editor of the journal of another society for several years, but had never found any committee or anyone to aid him with original matter. He would propose the toast of "The Photographic Societies of Great Britain and Ireland," coupled with the names of Mr. Mansfield, president of the Photographic Society of Ireland; Capt. Mantell, honorary secretary of the Photographic Society of Great Britain; and Surgeon-General Ranking, the representative of the Photographic Society of Leamington. He thought that the improvements, if any, in the Photographic Society of Great Britain had been due to the action of the Camera Club; he felt this to be a rather doubtful compliment, but he meant it.

Mr. Mansfield, in response, remarked that he thought all the photographic societies at a distance from London were grateful to the Camera Club for bringing them together; otherwise they would have been less able to make their voices heard in the management of photographic affairs, as exemplified in the discussion on exhibitions that day.

Capt. Mantell stated that an unexpected honour had been thrust upon him that evening, and had he known it beforehand he should not have enjoyed his dinner so thoroughly, but he was sure that all who had attended the Conference that day must have been thankful for all the work it had done.

Mr. M. Smith said that the Camera Club was a social organisation, and had social gatherings each year to which it invited a certain number of visitors. Among their visitors that evening were Professor Meldola, M. Paul Nadar, of Paris, M. Lafort, Mr. Rossi, Mr. Chapman Jones, Mr. H. Bothamley, Mr. W. T. Wilkinson, Mr. W. H. Harrison, Mr. Welford, Professor Stebbing, of Paris, Mr. H. Harriden, Mr. A. Cowan, Mr. Turner, Deputy Astronomer-Royal, Mr. O. Smith, of Stockholm, also the manager of the Nobel Explosive Co., and Mr. Mead, of the Alpine Club. He would couple with this toast the names of M. Nadar, Mr. Mead, and Mr. Frank Braine.

M. Nadar, who spoke in French, said that it was difficult for him to speak English, and that he wished success to the Camera Club.

Mr. Mead responded that his knowledge of photography in Switzerland for many years consisted in stumbling over the legs of camera men at Swiss Hotels; of late years, however, he had stumbled on higher ground, and photographed several Swiss peaks.

Mr. Braine explained that he was a bashful and retiring man, and that he had brought a friend to return thanks for him; that friend was Mr. Edwards. He had met Mr. Edwards on board the French steamboat between St. Malo and Dinan. The friend then told a story, not strictly photographic, about a man with a pickaxe.

Sir David Salomons then proposed "The Press," coupled with the names of Messrs Harrison, Hastings, Sturmey, Wright and Horsley Hinton. He was not in favour of anonymous journalism, and thought that every article should have the name of the writer appended thereto.

Mr. Macey Wright responded, that in making a speech he felt like the man who, when going to bury his wife, remarked, "I cannot go in that carriage with my mother-in-law; if I must, I must, but you will quite spoil my day's pleasure." He was glad to hear that the Camera Club was going into new premises, and thought that the Provincial Press would be ready to aid it in giving publicity to its ideas if country newspapers were regularly made acquainted with its desires in that respect.

Mr. W. H. Harrison agreed with Sir David Salomons in not being in favour of anonymous journalism; he also thought, with the Camera Club, that the editors of photographic journals should have nothing to do with exhibitions or other executive work in photography, on which they might afterwards have to comment in another capacity; they should stand outside such work as free and independent spectators. In like manner, he thought that public workers in photography, who posed before the public as men submitting to free and impartial criticism, should not in their private capacity be shareholders in newspapers. He was glad to see the culture and education which characterised the proceedings of the Camera Club, and that it had an excellent honorary secretary, for those experienced in the working of organised bodies were aware to what a large extent their prosperity is due to the capacity of the working secretary.

Mr. Hastings was pleased to hear about the new premises, and hoped that the new home of the members would be in every way a credit to the Club.

Mr. Sturmey's connection with photography had been a short one; he, too, thought that articles should be signed. He then told some anecdotes about the errors of amateurs, and entered into some details relating to his journal.

Mr. Horsley Hinton made some brief remarks, which were imperfectly heard at the other end of the room.

Mr. Herbert Harraden then sang a song, "The Photographic Fiend."

The President next gave the toast of "The Officers of the Camera Club," coupled with the names of Mr. Ferrero, managiug director of the Camera Club; Mr. George Davison, honorary secretary; and Mr. Asbury Greene.

Mr. Ferrero felt more at home in reminding members about arrears of subscription, than in making after-dinner speeches, but the greatest pleasure next to doing one's duty was to know that it was appreciated. He spoke highly of the work done by his predecessor, Mr Spiers.

Mr. Davison said that without such work for the Club as that given by Mr. Ferrero, all would come to a standstill. His (Mr. Davison's) own work was easier because more interesting; he had an interest in his kind friends of the Camera Club, but regretted being kept somewhat from the study of photography. The summer months, however, for which they were pining, were coming.

Mr. Asbury Greene, as one of the original members of the Club, would be glad to do all he could for it in the future.

Mr Charters White told a humorous anecdote or two, after which the company separated,

---

Cleanliness in Photography.—On one occasion Lord Palmerston was asked for his definition of dirt. He promptly replied that it was matter in the wrong place; so if, after a peep into your neighbour's dark-room, you see pyro, soda, and other chemical stains in stream-like courses on the outsides of bottles and graduates, then you can draw a direct conclusion that the operator or his assistant is negligent, and it is impossible for him to get perfect negatives. The matter on the outside of his bottles will, while handling, drop into his developer, thereby causing streaks, stains, pin-holes, and an endless train of other evils which will sometimes work an irreparable injury to a properly posed and well-lighted negative. —B. F. M'Manus.

ON DIFFERENCES OF COLOUR-SENSITIVENESS AT DIFFERENT TIMES.*

BY PROF. H. W. VOGEL.

It is recognised that the quality of the light varies considerably in the course of a day. According to the height of the sun and the more or less murky condition of the atmosphere, a greater or smaller proportion of light is received direct from the sun on the one hand, or reflected from the sky on the other hand. As one or other of these sources of illumination comes into play, the character of the light changes in a noteworthy manner. So long as we worked with collodion plates and iodide of silver, it was the indigo coloured light that was essentially important (spectrum line G). Violet and ultra-violet light, which would also come into the reckoning, are, in fact, so little reflected by solid bodies, that the said rays need not for ordinary subjects be taken into account, although in photographing heavenly bodies they play an important part.

Since the introduction of dry plate photography, the maximum of activity is removed towards the bright blue (half-way between the lines F and G), and at present the photographic intensity of the light depends upon the quantity of bright blue existing in it.

With the introduction of colour-sensitive plates the matter again undergoes an important change. Since it has become possible to prepare plates which are from six to ten times as sensitive to yellow as to blue, the amount of yellow and yellowish green present plays a most important part. I made the observation so long ago as the year 1874 that the chemical action of the solar spectrum varies considerably at different times, especially towards the ends—that is to say, the violet and the red and yellow. I was working with colour-sensitive plates, and found this effect even with the sun at the same height and the weather apparently similar.

In the year 1875, during my voyage to the East Indies, I made a set of spectrum experiments in the Red Sea and Indian Ocean with collodion plates, the sensitiveness of which was about equal to yellow and blue. Five photographs of the spectrum were taken daily. On one day I found that the action of the yellow greatly exceeded that of the blue, and this in the afternoon and at midday, as well as in the morning. This can only be explained on the assumption that on that particular day the yellow light in the atmosphere was very overpowering, for what reason I know not.

Since colour-sensitive plates have come into regular use, it has happened to me that in photographing the same object under apparently similar conditions as to weather, the colour-sensitiveness of the same plates has shown decided variations. It has happened that a bouquet of flowers, which, at the Imperial Technical High School, has served as a test object for colour-sensitive (cosine silver) plates, against the ordinary plate, would sometimes show a very striking difference between the action of the two, whilst at other times the difference would be exceedingly slight.

Finally, I observed that colour-sensitiveness showed to least advantage on those days when, with a half-veiled sun, a sort of greyish light prevailed, in which objects appeared without brilliancy. All the phenomena considered, it seems that the intensity of different coloured light in the atmosphere, even when there is no difference perceptible to the eye, varies considerably. Sometimes the red and yellow predominate; sometimes blue. In the latter case, the effect of colour-sensitiveness is least noticeable. Further experiments on the subject are in course of being made.

* Translated from the *Jahrbuch für Photographie*, 1890, for the PHOTOGRAPHIC NEWS.

SEVERE TESTS OF COMPRESSED GAS CYLINDERS.

THE Scotch and Irish Oxygen Co., of Polmadie, Glasgow, ask us to publish the following interesting account of the severe testing of compressed gas cylinders, which appeared in *The Glasgow Herald* of March 13th:—

A series of experiments was conducted yesterday at Stevenston by the Scotch and Irish Oxygen Company, Limited (Brin's Process), for the purpose of demonstrating the absolute safety of their cylinders for containing compressed gases. It will be remembered that a fatal accident occurred to the foreman of their Works at Polmadie by the bursting of a cylinder some six weeks ago, and the impression was conveyed to the public that the explosion was due either to some defect in the cylinder, or to its strength being overtaxed by being charged to an excessive pressure.

A thorough investigation was, however, made into the cause of the accident, and the facts disclosed left no doubt that it occurred through a mistake on the part of the unfortunate man himself. It was clear that he had introduced oxygen into a cylinder which was already partly charged with hydrogen, these gases forming an explosive mixture when brought together. One fact especially which pointed at once to this conclusion was that the main portion of the exploded cylinder, found almost on the spot where the accident occurred, was almost too hot to be touched; whereas, the portions of cylinders which have since been intentionally burst by being subjected to excessively severe treatment were found to be perfectly cold. In consequence of this erroneous impression it was thought advisable to subject the cylinders to an exhaustive series of tests, so as to prove beyond dispute that they are thoroughly adapted for the purpose of carrying the gases, and capable of withstanding the most extreme amount of rough usage to which they can possibly be subjected during transit from place to place.

The cylinders used are of different sizes, varying from 1 foot long by 3½ inches diameter to 6 feet 6 inches long by 5½ inches diameter. They are made of mild wrought steel ¼ of an inch in thickness, and before being used each cylinder is subjected to a hydraulic test of at least twice its working pressure, and is afterwards stamped with the pressure to which it was subjected, the date of the test, and the test mark. The cylinders are re-tested periodically, and for the purpose of safety the custom of the Company has been to paint those for the different gases in distinctive colours, so as to avoid the danger of mixing. As a further precaution, every cylinder which is brought into the works after having been in use, is at once emptied.

To make the recurrence of such a misfortune as the recent accident absolutely impossible, it has been decided to adopt a left-handed thread for the valves on the hydrogen and coal gas cylinders, so that by no possible inadvertency can they be filled at the oxygen pump. A number of experiments were made about ten days ago which gave excellent results. A 6 feet 6 inch cylinder, weighing about 1 cwt., was twice raised to a height of 35 feet, and

dropped horizontally upon a solid iron block 12 inches square and weighing 3½ cwt., each blow bending it to the extent of about three-quarters of an inch. It was then dropped vertically on to its round end, having a clear fall of 31 feet, when it was found that the impact had only flattened a part of about the size of a pennypiece. It was next placed across the iron block, and an iron weight of 6¼ cwt. dropped on to its centre from a height of 35 feet, the blow crushing in the side to the extent of ⅞ of an inch. The cylinder was subsequently placed on two iron blocks, set 4 feet 1 inch apart, so as to support the ends, and the same weight again let fall upon it from the same height, with the result that it was bent 4¼ inches from the straight, but did not explode.

Another cylinder was afterwards tried in the same manner, with the exception of the crushing blow, and in this case even a more satisfactory result was obtained, as it was bent to the extent of $7\frac{5}{16}$ inches by the bending blow, and still remained intact. A smaller cylinder, measuring 31 inches long by 5½ inches diameter, containing 17lb. liquefied carbonic acid gas, was also dropped crossways and vertically from the same height, and was afterwards flattened to the extent of 1¾ inches by dropping the 6¼ cwt. weight upon it, without injuring it otherwise than in shape. Each of these tested cylinders was subsequently found to contain the full quantity of gas, and to be perfectly sound. Yesterday's experiments were of a similar character, and were equally satisfactory. A 6ft. 6inch cylinder, weighing 107lb. including the contents, was dropped four times across the iron block from a height of 35ft., these trials producing a bend of 2⅛ inches. It was also allowed to fall on its end, with little perceptible result. A smaller cylinder was treated in the same manner, and sustained no greater injury than a few dents.

From these particulars it will be seen that the tests were eminently satisfactory, for it is inconceivable that such cylinders during transit could undergo anything like the severe treatment to which they were subjected, while it was evident that they still possessed a considerable reserve of strength.

PHOTOGRAPHING A SPEAKER'S GESTURES.

About a year ago, Mr. Edison became intensely interested in instantaneous photography in its possible availability in connection with the phonograph, and at once began an exhaustive series of experiments in that direction. The first thing was to develop the possibilities of the camera as to rapidity of exposure, and an elaborate system of experiments was begun to try if possible to photograph a rifle bullet in its passage through the air at its maximum initial velocity of 5,000 feet a second. To do this successfully no known mechanical means were adequate—5,000 feet means 60,000 inches, an inch being about the length of a rifle bullet. But to secure a perfect picture of a bullet moving at this extraordinary velocity it must apparently be at rest, and hence the actual time of exposure must be brought down to incredibly infinitesimal limits.

The great inventor at once harnessed the lightning to do the work, and before the camera arranged a series of vertical wires so fine as to be practically invisible, and so connected that the breaking of any one of them would complete an electrical circuit and furnish an illuminating spark for the two-hundredth of a second. At first the experiments seemed to be fruitless, as the rapidity was such as to exceed the limits of sensitiveness of the plate in the camera; but weeks of careful experiment brought a solution in a new combination of sensitising chemicals by which even this infinitesimal period of time sufficed for a perfect image.

But a new difficulty arose. The slight imperceptible tremor of the room in which the experiments were conducted, caused by the motion of the machinery and dynamos in another part of the building, was sufficient to destroy the sharpness and value of the photographic image. This was overcome by erecting a special building for the purpose, and placing the camera on a pier of solid masonry running down to the primitive rock. Then, and then only, it was that success attended the experiments.

But the reader will doubtless ask the question, *Cui bono?*—what possible good was it to get a picture of a rifle bullet showing the condensation of air in front of it, the vacuum behind, and the air eddies that were thus created? Much every way! Not only as a practical means of studying the best form for a bullet in overcoming the resistance of the air, but more especially as a means of developing the great idea that Mr. Edison had in his mind of bringing photography to bear as an adjunct to the phonograph. He thought that if a speaker's personality could be brought before the eye by means of photography and the stereopticon while the phonograph was bringing the subject-matter before the ear, that an important end would be gained, and to accomplish this the elaborate series of experiments was planned and carried out. The result has been the most marvellous success and the most wonderful machine it is possible to conceive.

Let the reader imagine a popular lecturer, preacher, or orator delivering an address. In front of him, at the so-called reporters' table, are two small machines, one the well-known phonograph, and the other an ingenious piece of mechanism by which photographs of the speaker are taken in succession with enormous rapidity—at intervals, let us say, of from one-eighth to one-twentieth of a second, and suppose both these machines to be at work silently recording both the uttered speech and the personal appearance of the speaker at each fractional part of a second. The results thus obtained may be sent to any desired point, and the photographs thrown on a screen by an ingeniously contrived piece of mechanism. Thus the exact appearance of the speaker, with all his gestures and play of features, are exactly reproduced, while the phonograph simultaneously delivers the speech. The interval between the successive photographs is so infinitesimal that the screen picture is apparently a living one, moving, gesticulating, and apparently uttering the words which, in fact, are spoken by the phonograph. The greatest difficulty experienced by Mr. Edison in his experiments was the synchronization of the two instruments, so that the utterances of the phonograph should exactly coincide with the gesticulations; but this was finally overcome, and the experiments were crowned with the most perfect success. What the commercial value of the invention may be is yet to be decided. It cannot fail to be intensely interesting as an exhibition feature, but whether it will fill a useful niche in the every-day life of the world is another question entirely.

Mr. Edison is not pushing the matter at present, being absorbed in his experiments on electrical traction for street cars. When that problem is decided he may bring this new invention prominently before the public. We wait.—*New York Herald.*

MOUNTING LANTERN SLIDES.

So far as we can gather, there are only two reasons for, or advantages to be gained by, the system of what is generally called uniform mounting: facility in carrying on the operation consequent on the use of mats already cut, and the pretty appearance of a set when so mounted. The first is unworthy a moment's consideration; and anyone who would let it influence him had better at once turn to some other hobby, or wait till he can mount his slides by a "drop a nickel in the slot machine." A good deal can be said in favour of the other reason, as the chief aim and object of at least a large quantity of the photography of the present is to satisfy the craving for the beautiful; and if the disadvantages of uniformity under circumstances where it should not be sought, were not out of all proportion greater than its advantages, we should not have so much to say against it.

So long as the results of photography were merely curiosities, people were content with simply wondering how such things could be, and even the initiated were too much intent on improving the technical to give much consideration to the artistic; but now that the technical has reached a stage only a little short of perfection, photography is more and more assuming in men's minds its true position—not itself an art, but only the means by which artistic results may be produced. In other words, and words more especially applicable to our purpose, lantern slides are gradually becoming less and less looked at and thought of as photographs, and more and more regarded as a means of producing on a large scale projections that shall be in the truest sense of the word pictures. We are aware that there is at present a school, or a few weak enthusiasts who would fain be considered such, which sneers at rules of composition and canons of art; and, perhaps, for them, and the kind of work they show, when they do show anything, rules, laws, and canons are not needed. But the great body of sober-minded artists, the men of light and leading, both ancient and modern, have given, and are giving, ample evidence of their faith in what may be said to be the great principles of light and shade, and composition.

We may take it for granted that a very large majority of the lantern slides that are made, except by those professionally engaged in their production, are from negatives not especially taken for the purpose, and, consequently, better suited for either upright or horizontal pictures. From negatives of 4 by 5 and under, the positives, as a rule, are printed by superposition and, of course, by reduction in the camera from larger sizes. Now, it will be evident that if the composition has been good for an upright or a horizontal picture, and the whole plate filled, an equally good composition cannot be made to fill the square opening of the regulation mat, and the attempt to do so can only result in the cutting out of material necessary to proper balance, excessive and often, in consequence, offensive foregrounds, weakly-placed horizon lines or vanishing points, and other equally objectionable faults.

But we may ask, why should lantern pictures be square, or nearly so? Artists of the brush are deservedly credited with a fairly good appreciative taste in such matters, and we are within the mark in saying that less than one per cent. of the frames that adorn our galleries, either public or private, are of that form, and even of those few, for most of them there is some special reason for the choice of the direct square.

The true artist, then, in making lantern slides from his ordinary negatives, will arrange so that the longest side of the composition shall come just within the regulation mount, as uniformity in the length or height is easily obtainable, and of course let the sky and foreground take care of themselves. In mounting he will, of course, see that the mat is suitable to the horizontal or upright so made, and although the slides may not look so pretty when simply looked at, they will, when on the screen, fully reward him for all the extra trouble he has taken.

But, notwithstanding those facts which "are chiels that winna ding," we know that there are some who, octopus-like, will continue to cling to "the good old size and shape," and as they, if they are not to fall behind, must cease to be content with photographs and strive after pictures, the following suggestion may help them to make a fairly satisfactory compromise.

If the stickler for the regulation mount believes in the adage, "whatever is worth doing, is worth doing well," he will not mind a little additional trouble and a little extra expense in carrying out his desires. Before going to the field, he should mark off, by a heavy pencil line, a direct square on his focussing screen. If, say, his camera is an $8\frac{1}{2}$ by $6\frac{1}{2}$, a square of six inches will be suitable. He should then take all his pictures in duplicate, the first filling the full size of the plate, and the second confined within the limits of the square. He should remember also that faults in composition are more noticeable on a large than on a small scale, and take especial care in the arrangement of the second exposure. In this no pains should be spared, and no time grudged or thought misspent, and an exposure should never be made on a subject that is not in every way satisfactory. Better a clean plate than a picture that needs to be apologised for.—*The Beacon.*

Devon and Cornwall Camera Club.—On Monday, 17th, at the Athenæum, Plymouth, Mr. S. Weekes passed through the Club lantern about two hundred slides of his own making and from his own negatives, making appropriate remarks upon each. The lecturer led the company from Plymouth to the South of France, thence to Venice, Rome, the Italian Lakes, Switzerland, and back to Devon and Cornwall, winding up with groups of persons associated with the Club either as members or friends.

The Sizes of Photographic Plates.—In one part of the final report of the International Photographic Congress at Paris, dealing with the question of "Uniformity of Dimensions of Plates," a normal international plate 18 by 24 centimeters ($7\frac{1}{8}$ by $9\frac{3}{8}$ inches about) was adopted. The division 12 by 18 centimeters was also adopted, and the divisions and multiples of 18 by 24 centimeters. In the matter of sizes of lantern slides, the form $8\frac{1}{2}$ by 10 centimeters ($3\frac{1}{2}$ by 4 inches about) was adopted by a vote of 18 to 13. Another size proposed was 9 by 12 centimeters, but was not adopted because it was thought to be too large. The screw for attaching the camera to the tripod was also considered, and the following size was adopted: Its diameter shall be 9·5 millimeters, with a thread cut an isosceles triangle of 55 degrees opening running to the summit, not more than 1·6 millimeters deep, and having a pitch of one-sixth of its height. This is the $\frac{3}{8}$-inch screw of the English system of Whitworth, adopted by the Photographic Society of Great Britain in 1882. For the attachment of lenses of different sizes to the same camera, a system of universal screws was adopted upon the same system as that mentioned above, and with sufficient play to allow easy working. The screw flanges for all new lenses made in the future are recommended to be cut with exterior openings having 10, 50, 75, 100, 125 millimeters.—*Anthony's Bulletin.*

Notes.

The likeness of the new German Chancellor, General von Caprivi, to his predecessor, Prince Bismarck, is a happy coincidence. Prince Bismarck used to have a double, who was accustomed to sit to unscrupulous photographers in Berlin, and whose photographs were sold as those of the Chancellor. This fraud went on for some time, but was at length discovered, and the "double" found his way to durance vile. Those who wish to turn—we will not say an honest penny—will probably be tempted to pass off the photographs of the old Chancellor for those of the new one. We mention this so that purchasers may be on their guard.

A lady correspondent of an evening paper has made the astonishing discovery that the portraits of curates and other smaller religious lights are not only exhibited in suburban shop windows, but command a ready sale. The announcement is rather late in the day, as from the earliest photographic times a suburban photographer invariably seized upon the countenances (if he could get them) of the local ministry, both of the Church and Dissent, as a good advertisement. But the lady writer goes a little further; in fact, she has a "good idea," and has come forward to assist ladies of limited means. Her suggestion is that a number of ladies should form themselves into a company for the sale of curates' photos. She is confident the profits would exceed all expectations, as the number of ladies of all ages who are ready to expend their spare cash in purchasing the photos of their pet parsons is very large. Moreover, the young ecclesiastics themselves, in so good a cause, would willingly "countenance" the work. There is, unfortunately, a frivolity about this last observation which makes one doubt the sincerity of "A Feminine Observer," for so the writer signs herself. We are really afraid she is having, under the guise of philanthropy, a quiet laugh at the curates.

At last the automatic drop-a-penny-in-the-slot photographic apparatus is an accomplished fact. At present it has its habitat at West Bromwich, where a demonstration took place the other day, and as the circumstance has been narrated in all its details in the financial papers, we may take it that the patent will occupy the attention of a limited liability company. Mr. G. A. Sala—who, like a true journalist, has always his imagination on tap—sees possible drawbacks in the invention. He entreats the patentees very properly to guard against the following contingencies:—First, the malevolent small boy suddenly crying out, "Shove in your mouldy coppers!" or "Hi, there Mister!" just as you have begun to stand motionless; second, a violent fit of sneezing or coughing; third, the uncalled-for interposition of an entire stranger, who, at the critical moment, pops his head over your shoulder, grinning horribly, and gets photographed for nothing on the unhandsome and untradesmanlike plea that it is "the same concern." Mr. Sala has really spotted the initial difficulties in the way of the success of the apparatus, and it will be interesting to see how they will be overcome.

A photographer in one of the large provincial towns has found his business greatly increase, and his photographs more pleasing to his customers, since he has employed a young lady of prepossessing appearance to assist him in the studio. When a nearly full face is required, and the eyes are to be turned in the direction of the camera, he gets the young lady to take off the cap. If the best view of the features necessitates looking away from the camera, the lady assistant plants herself at the required spot, and with pneumatic attachment makes the exposure all the same. The essential point is that the sitter shall turn his eyes towards the fair asistant. We use the word "his" advisedly, as we are not ready to believe the plan would answer so well with feminine sitters.

Sterne's oft-quoted sentiment, "they order these things better in France," has received a fresh exemplification from a photographic point of view. In a recent murder case which has just excited some attention in Paris, the victim, Hippolyte Richard, was by profession a canvasser for photographers. With that nice discrimination and attention to details so peculiar to the French mind, his arrangement with his employers was based upon the distinctions which exist between the representatives of various classes; that is to say, a customer was not a customer and nothing more, but varied considerably in value according to his or her position and notoriety. In fact, a sort of tariff appears to have been established, of which the following formed the leading items:—For every deputy he introduced he was to receive 5 francs; for a senator, 3 francs; for a negro potentate, 10 francs; for an actress taken in ordinary costume, 20 francs; and for an actress taken *decolletée*, 20 francs. We in England have not yet approached this perfection of tabulation.

It is impossible to exaggerate the future importance of photography in regard to astronomical observations. At no distant date the world will be spotted with observatories all filled with photographic appliances, and all collecting records of the heavens, which will be of the utmost service when compared together. The latest additions to the world's observatories comprise one at the Vatican and one recently established by the Catholic Mission at Madagascar, where a building has been erected on a hill about 4,000 feet in height, and situated a short distance to the east of Tananarivo. The first-named, so far as astronomy is concerned, will concern itself principally with celestial photography. In the second a photographic telescope for solar observations will be provided.

CHILDREN.

BY A PHOTOGRAPHER.

M. Legouvé, writing of Madame de Staël, informs us that she died talking. When her friends were nervously solicitous to exclude visitors who, moved by affection, or fashion, or curiosity, or, lastly, by a common but ghoulish gluttony of distress and agony, pressed for admission to the bed-chamber in which the accomplished authoress lay dying, she is reported to have rebuked them, and to have insisted on her visitors' admission. "Let them come in," she cried, "let them come in; I thirst for the human face—*J'ai soif du visage humain!*"

This thirst for the human face, which Robinson Crusoe must have felt in its deep desire and insatiable longing, expresses, undoubtedly, one of the most ardent passions of humanity throughout all time. We have all a thirst for the human face; but the photographer is perhaps possessed by it in an exceptional degree, and has been known, whether as professional or as amateur, to undergo considerable risks in his attempts to quench it. Our memories are green of the gentleman who proposed, in defiance—or rather, perhaps, in ignorance—of the Koranic law, to take a portrait of the Sultan of Turkey.

In what considerable measure this thirst is shared at the present day by the general public, any reflecting observer may find out by taking up his position in front of a stationer's shop in a popular thoroughfare—say, for example, in Regent Street—where the photographs of celebrities of the season are exposed for sale. There the hero or heroine of the hour, strong man or fashionable woman, convicted murderer or military chief, draws the noses of the crowd in such close proximity to the glass of the shop window, that a greasy film soon settles upon the pane, only to be rubbed off by a fresh band of inquisitive investigators. "No mere curiosity, however, is this," say the amiable apologists of human nature; no silly love of distraction, no empty frivolity of idleness. No! the street crowd of which the component elements are only too familiar, is thirsting for the human face, because it is thirsting for the human soul! It may be so; but is the photographer similarly affected? It is extremely doubtful. In the case of children, the contrary has been too often the case with him. He has thirsted for the human soul, because he has thirsted for, and failed to obtain, the human face. Failing to take the child from life, he has yearned to take life from the child.

The charms of infancy have been in every age and country a subject on which prose writers and poets have been allowed to dilate without let or reprehension. Euripides, in his "Meleager," a piece which the public, and especially the male adolescent portion thereof, will regret to hear has been lost in the lapse of time, has not omitted to give vent in verse to the following ideas, which Stobæus, the author of the Latin Anthology, has been kind enough to preserve: "Sweet is the sun's light, sweet is the sight of a calm sea, or a mighty river, or a land in spring—a thousand other things are sweet—but believe me, there is nought sweeter than to see, after a life of celibacy, beautiful children flourishing in our home." This sentence seems somewhat strange—strange enough, indeed, to cast a doubt on the authenticity of the fragment—when it is remembered that Euripides was a confirmed misogynist, and "said things" about women which it would be painful to repeat in any publication laying claim to an iota of respectability.

The charms of infancy and of childhood have inspired poets of imagination all compact to sing of the fair heads, the curly hair, the sparkling looks, the rosy lips, and the smiling cheeks—poets apparently oblivious or ignorant of the constant worry, the strange perversity, the nocturnal peevishness, the mulish obstinacy, and the congenital deceit—from the days of Euripides till the days of Victor Hugo, who has distinguished himself in some degree as the children's poet. The *Orientales* and the *Contemplations* savour much of this simple theme, and a poem of two dozen lines is devoted to the description of a child dreaming of sand full of diamonds, and other strange matters—perhaps the result of an overburdened stomach—in a soft cradle set in the secure shadow of the maternal bed. There have been photographers, it is whispered, who devoutly wished that the condition of the poet's child was chronic in the infantile world—that children, if not dreaming, might at least be continually asleep. They would not, they believe, under these conditions, have been called upon to take their portraits, or if they were, it might have been done with ease.

But to photograph a child awake! This is the work, this is the labour. A man must be to the manner born to accomplish this. I speak of the past rather than the present, but the present is not all plain sailing. The strange difficulty of the undertaking, the indomitable perseverance which it requires, can scarcely be conceived by the outside world. It is hidden from all save those unhappy ones who have experienced it.

The greatest reverence, says a celebrated satirist, is due to the child. I fully concur with the justice of this observation in the abstract—but Juvenal was not a photographer. If he had been, and had been asked—we will suppose—to take the portrait of his friend Sempronius's little boy, and had maintained his reverence for that child unimpaired after the operation, I should hold a higher opinion of Juvenal. Job is commonly credited with the virtue of patience; he did not, indeed, manifest this virtue to any very great extent when he cursed his day—nevertheless, the patience of Job has passed into a proverb. I trust I shall not be accused of irreverence when I say that to take the portrait of a child requires something more than the patience of Job.

Bairns, says a Scotch proverb invented before the days of photography, are a blessing; to the photographer they are only too commonly—well, to avoid any strong language, I will say—the reverse. They cannot and will not be taken, and, like the child of Themistocles who governed his mother, who governed her husband, who governed Greece, their will is supreme. Not that there is not plenty of counsel on the subject how the thing is to be managed; but it is like that of the conjuror who professes to tell you how to do it. In the moment of need the counsel pierces your hand, or slips from you like uncertain quicksilver. For instance, there are some counsellors who will talk of an infant, wholly forgetting the great reverence due to it, as if it were a dog or a horse. You must study—say these wise ones—its points; you must approach it gradually, or like an old acquaintance (imagine any child of ordinary capacity being deceived by so transparent a device); you must show a love for it; this is indeed a trial; and you must stroke it down, and talk sympathetically to it.

A gentleman who speaks, as it were, *ex cathedra*, says: "I find the following method most successful in dealing with this difficulty. On the arrival of the youthful sitters in the studio, I place them at once in the proper focus, and,

after a general adjustment, leave them to themselves during the time I make the requisite preparations." Now, as to the proper focus, it is quite certain that those children, unless children of a wholly abnormal character, would quickly move out of it; and as to leaving them to themselves—well, I have had my own experiences. There is a tale of a child, who, being left to itself, was incontinently poisoned by drinking a solution of cyanide of potassium. "Then," says the gentleman, "I finally adjust the children according to my already preconceived ideas, and attract their attention." Quite so! Various methods of doing this have been suggested and proved in practice futile. One will tell you to move about some showy toy or other, a certain way of putting the child on wires throughout the sitting; another will counsel you to imitate the mooing of a cow, the buzzing of a bluebottle, or the barking of a dog, careless of the ridiculous loss of dignity which is thereby incurred by the artist, and all too frequently to no purpose. The ordinarily lively child will, by such ill-judged proceedings, be transformed, as by some unholy spell, into stone; it will regard all your dramatic endeavours with concealed indifference, or with a calm and open contempt; it will assume a suspicious, if not a sulky expression. The graceful forms which we are told all children unconsciously assume will, by some prepense malice, some instigation of Satan, be wholly absent in this child; and when, after endeavours frittered away, and wasted energy, after much loss of time and more loss of temper, you at last, in sheer despair, say, "Now is the time!" and uncover the lens, the probability, amounting almost to a certainty, is that the child will have moved, and a satisfactory picture will not have been obtained.

There is a photographer, an intimate friend of mine—a man of considerable skill—a man, I may say, for I knew him well, of genius, kind, amiable, gentle, and long-suffering, whose evil lot it was, some years ago, to be asked to take a picture of oh, such a sweet child! But a difficulty occurred at the very outset which should have been, but unfortunately was not, a warning to that artist. The sweet child, the dear artless little thing, a boy in his tender nonage, stoutly refused to go to the photographer's studio, and insisted, like a young sultan, on that artist being brought to his own apartment. A doting mother, to whom the child's will was law, in her earnest desire to possess a picture of her darling, gave way to this arrangement, not, indeed, being able to do otherwise; for as soon as an expedition was proposed to the studio, the little tyrant filled the neighbourhood with loud lamentations. And so the photographer came, with all appliances and means to boot, into the nursery. Trailing, not, indeed, as Wordsworth imagines, clouds of glory, but a little go-cart attached to a string from an adjoining apartment, this interesting child approached the artist, and leisurely examined him with much the same kind of sympathetic and interested curiosity as is shown to the student of human nature by that portion of the public which, on a Bank Holiday, delights itself with a prolonged examination of the monkeys in the Zoological Gardens. After this examination was concluded the photographer, anxious to propitiate the subject of his future proceedings, fumbled in his pocket and produced a parcel. "What is that?" said the infant. "That, my dear, is a box of sweets, which I shall have the pleasure of giving you if you are a good boy"—and here he arranged his camera—"when I go." "Give it me, then," said the boy, "and go at once!" "There are," says Cicero, "children who need the bridle, there are others who require the spur." Evidently this child was not to be included under the latter category. My friend—my injured friend—never confided to me whether he was in a pet at this precocious *enfamure*, or whether he had some doubt as to the propriety of giving to posterity the portrait of so impolite an infant; but it is certain that he then and there collected his chattels together and took his departure, probably with the indignant Gloster, in Lear, saying, *sotto voce*—

"I shall see
The winged vengeance overtake such children!"

There was a piece of mechanism—not yet quite extinct—employed in photography known as the head-rest. It was probably so named on the *lucus a non lucendo* principle. Now this is an instrument which even adults are not altogether disposed to look upon with delight. Its screws and articulations give it an uncanny appearance; it is suggestive in some remote way of a dentist's chair. The child, as a rule, rebels against it at once. Instances have been known in which children have been thrown into strong convulsions by an injudicious appliance of this machine. Some kindly intentioned French person once patented a special head-rest for their proper use. Its distinctive feature was the greater curvature of those long thin branches, which convey to the fanciful observer the idea of the tentacles of a squid. These branches, by a neatly worked movement like that of calipers, embraced both sides of the infant's head, underneath its hair. The writer—he mentions the fact with a feeling of fervent gratitude—has had no experience of the effect upon the child of this mechanical construction, but the inventor thereof was clearly not altogether sanguine about its success. He speaks with no manner of certainty, but he speaks as one who has suffered, and he speaks without the reverence recommended by the Roman satirist. By the use of this instrument, he says, the portraits of these little devils (*ces diablotins*), who are the curse of the photographer of every country and of every time, may *perhaps* be taken successfully.

It is told in the "Memoirs" of Alexander Dumas, concerning the savages of Florida, that when they were especially wroth with a prisoner, and anxious to torture him in the most prolonged and painful manner, they committed him to the care of a select circle of women and children, who, in the cruel subtilty of their devices for ensuring the highest amount of agony, left nothing whatever to be desired. It is the unhappy experience of a large number of professional photographers that the children of savages are not by many lengths in advance of the children of civilization in the capacity of the latter to inflict mental pain.

The Daguerre Monument.—We have received several letters criticising rather severely the design for the Daguerre monument. The general tenor of these communications is that Daguerre is placed in too subordinate a position, and that the female figure and the sphere are too prominent. In regard to these critics, we would state that we agree with them as far as the published designs are concerned; but we understand that we must withhold our judgment until Mr. Hartley has finished the large clay model which he is now working upon at his studio. This model is soon to be placed on public exhibition in New York, and all interested will have an opportunity of seeing it. The changes made in the model are: reduction of the size of the sphere, elevation of the sphere, an increase of the size of the head of Daguerre to one and a-half life-size, and the total height of the monument will be sixteen feet from the ground.—*Anthony's Photographic Bulletin.*

PHOTOGRAPHY IN GERMANY.

BY HERMANN F. GUNTHER.

Professional Development—Flat and Greyish Platinotypes—Price of Albumen Paper — Influence of Development on the Deposit on Negatives—Quinol Developer with Calcium Bisulphite — Platinum Toning for Gelatino-Chloride Paper.

Professional Development.—In order to ascertain what developer is chiefly used by the German professional photographers, and to give a correct idea of the mode of development in general every-day practice, the editors of Liesegang's *Photographisches Archiv* have sent round inquiries among the most eminent photographers in Germany and Austria, and the results of these investigations have been published in the last few issues of that interesting journal. In the first place, the following two facts have come out: that the ferrous oxalate developer is still used by about two-thirds of the German photographers, and that next to it the new eikonogen developer has found the most numerous and most exalted followers. The pyro developer seems to be employed by only a small number of practitioners. As to the eikonogen developer, the following communications are of special interest. A court photographer of Wiesbaden says: "It allows a shorter exposure than any other I know of; it gives fine details, works neither too monotonously nor too hard, and develops quickly. In the studio, I expose, even on dull winter days, with an aplanatic lens, full aperture, for less than one second, and in summer a quarter of a second is enough. I use the following composition:—

A.—Distilled water (hot)	1,500	c.c.
Chem. pure sodium sulphite ...	100	grammes
Eikonogen	50	,,

This stock solution must be kept in a dark-coloured bottle with glass stopper, and in a dark room in which no acids and no ammonia are kept.

B.—Distilled water	500	c.c.
Chem. pure potassium carbonate ...	75	grammes

(Stock solution 2). Mix 3 parts of A with one part of B just before use. This developer can be applied to from three to five plates the same day, if well protected against air and light. Wash the plate, if sufficiently developed, under the tap by means of the ball of the hand: harden it in a five per cent. alum bath for one minute, wash again thoroughly under the rose by means of the ball of the hand, and fix in—

Water	800	c.c.
Hypo	200	grammes
Bisulphite of soda (chem. pure) ...	40	,,

Another court photographer, of Altenbourg, proceeds as follows:—12 grammes of eikonogen in crystals are finely pulverised in a porcelain mortar, and the resulting powder is poured into a funnel the aperture of which is plugged with cotton, neither too loosely nor too firmly. On it are poured 50 grammes of sodium sulphite, also pulverised, and the funnel is filled up with 750 c.c. of distilled water. During filtering the sediment in the funnel is repeatedly stirred with a glass rod, and, after the liquid has run through, about 8 to 10 c.c. of bisulphite lye of 118° F. are added to it, by which its colour is almost entirely destroyed. Then into the same funnel, directly on the slight sediment left, 38 grammes of chemically pure soda (calcium) are poured, and the funnel is filled up with 250 c.c. of distilled water, which dissolve the last traces of the eikonogen, sodium sulphite, and soda. This second filtered liquid is then poured into the first one, and the whole well shaken. In this way the developer (in all 1,000 c.c.) is ready for use within fifteen minutes without the use of boiling water. It keeps well for a long time. If applied when freshly prepared, it works a little softer than when it has been kept for some time. A third photographer, of Hirschberg, says: "The eikonogen developer usually gives beautifully clear, though vigorous, negatives, with perfect details in the deepest shadows; indeed, such as are hardly obtainable by means of any other developer. I proceed as follows:—

I.—Sodium sulphite	200	grammes
Distilled water	3,000	c.c.
Eikonogen	50	grammes
II.—Carbonate of soda	150	grammes
Distilled water	1,000	c.c.

I mix 3 parts of solution I. with 1 part of solution II. The fixing bath consists of:—

Hypo	250	grammes
Sodium sulphite	50	,,
Water	1,000	c.c.
Concentrated sulphuric acid ...	8 to 10	,,

For developing, I take at first an old solution, and allow the plate to remain in it until the image has come out about thirty to thirty-five seconds; then the old solution is poured off, and replaced by a fresh one. The image must be rather vigorously developed, because it is reduced a little in the fixing bath.

A Remedy for Flat and Greyish Platinotypes.—Those who work the platinotype process with hot development will from time to time make the unpleasant discovery that the prints, though they appear vigorous in the fixing bath and in the washing water, become flat and grey after drying, at least if looked at by reflected light; by transmitted light they appear vigorous, as before. This is probably caused by the fact that the hot solution of oxalate of potash, and, later on, the hydrochloric acid of the fixing bath, destroy the size of the paper, and the platinotype is consequently caused to sink into the paper. In this case the following method, recommended by Hans Lenhard, of Vienna, can be used with good results:—In 1,000 c.c. of water 125 grammes of pure gelatine are melted as usual, and the solution is gradually brought up to the boiling point. After the gelatine solution has been taken from the fire, 125 grammes of pulverized alum are added, and dissolved in it with perpetual stirring. Of this solution one part is diluted with two parts of water; the mixture is poured into a flat dish, and the latter kept warm in the water bath. In this warm solution the platinotypes are immersed, and allowed to remain for some minutes. They are then put for some time in a dish with cold water, and afterwards dried between sheets of blotting-paper. It will be found that after this treatment the prints appear vigorous again by reflected light. This additional sizing of the platinotype paper has, besides, the advantage that to the positive retoucher the work is made easy, because in this state the paper does not suck up the colour so eagerly as before.

Rise in the Price of Albumen Paper.—Some weeks ago several manufacturers of albumen paper—among these the "Vereinigte Fabriken photographischer Papiere," of Dresden—sent out a circular, in which was announced that on account of innovations requiring the utmost care in the production of photographic plain paper, as well as of the albumenised paper, the price of this latter would be raised

in future ten per cent., *i.e.*, by ten marks the ream. This announcement seems to have influenced the fraternity very disagreeably, for in the last meeting of the Photographic Association of Berlin, where the affair came on for discussion, reference was made to a business report of the "Vereinigte Fabriken," according to which the financial result for the year 1889 allowed the distribution of a dividend of 19 per cent., whilst the dividend which has been paid to the shareholders for the year 1888 amounted only to 10 per cent. The question was raised, "How do the two facts harmonize, and wherefore the rise in the price of a product after a dividend last year raised by 9 per cent.?" It was recommended to professional photographers to turn themselves more and more to the gelatino-chloride papers.

Influence of Development on the Fineness of the Deposit on the Negative.—To ascertain whether the mode of developing exerts any influence on the fineness of the deposit or grain of the negative, Dr. Miethe made the following experiment: A gelatine plate was exposed at a distance of thirty-eight inches from a stearine light for ten seconds, and then cut into eight pieces, which were developed separately in eight different solutions, consisting of ferrous oxalate, pyro, and quinol developers of varied proportions. All the plates were developed until they began to turn grey when looked at from the back, and were then fixed in the acid fixing bath. After drying, the single strips were compared under the microscope. It was not observed that the fineness of the deposit was different on the various plates; on the contrary, in all the films about the same quantity of coarse grain was found intermixed with the finer grain. It is, however, just this coarse grain to which the greater sensitiveness to light must be attributed. This may be perceived by the fact that if a very briefly exposed plate is forced in development, the image will be formed almost entirely of the coarser grain. Now, since in the case of instantaneous exposures generally strong developing solutions are used, it appears that this has given rise to the error that the size of the grain depends on the composition of the developer, and that a finely-grained negative might be produced by slow development. An over-exposed plate, the coarse grain of which has been already "solarised," will therefore, however it has been developed, always show a finer grain than a briefly exposed one.

Quinol Developer with Calcium Bisulphite.—Photographic tourists will always find it a great convenience to be able to carry a large quantity of developing solution in a concentrated condition sufficient for a large number of plates. The following method is recommended by A. von Loehr. Four small bottles are filled with the following ingredients:—1. A small bottle with 100 c.c. of a concentrated solution of calcium bisulphite. 2. A small bottle with 100 c.c. of a solution of caustic soda, 1 : 10. 3. A small bottle with 25 grammes of quinol. 4. A small bottle with 10 c.c. of a solution of potassium bromide, 1 : 10. This quantity is sufficient for one hundred quarter-plates. Development is carried on in the following manner. To 100 c.c. of water, 4 c.c. of calcium bisulphite solution are added, and 1 gramme of hydroquinone is dissolved in it. On the other hand, 4 c.c. of caustic soda solution are diluted with 100 c.c. of water. The two solutions can be kept for a long time, and are to be mixed in equal parts just before development.

Platinum Toning Bath for Gelatino-Chloride Paper.—Mr. A. Stieglitz gives in the photographic Year-Book (Eder) for 1890 the following directions relating to the platinum toning bath, which has been mentioned in this journal on a former occasion. The following solution is made up:—

Solution A.

Oxalate of potash	90 grammes
Monopotassic orthophosphate ...	45 ,,
Distilled water	1,000 c.c.

Solution B.

Potassium chloroplatinite	1 gramme
Distilled water	20 c.c.

Before toning, three parts of solution A are mixed with two parts of distilled water and one part of solution B. The bath keeps for one hour, but after half an hour it should be intensified by the addition of a few cc. of solution B. The prints, which should be barely over-printed, are washed two or three times, and then placed in the bath, film side up, until they show a violet tint by transmitted light. This requires one or two minutes in summer. Then they must at once be thoroughly washed, since otherwise the whites will appear yellow after fixing.

Fixing and washing performed as usual. To impart to the prints a matt surface, they are squeezed on to ground-glass, which they will leave, after drying, with a matt surface of sepia tone. To attain black tones, a few cubic centimetres of a saturated solution of nitrate of lead should be added to the toning bath, and the prints must be printed very deeply.

WHAT PHOTOGRAPHY WILL NOT DO.

Under the above heading Captain Abney writes as follows to the *Daily Graphic* of March 24th:—

The jubilee of photography is past, and we have had recounted in public journals, almost *ad nauseam*, what photography has already done, and there has been a little prophesying of what we may expect it to do in the next fifty years, but there has been no one bold enough to tell us what it can't do. I am going to take upon myself the *rôle* of prophet, and mention one or two advances which photography cannot make, although it is popularly believed that these will become *faits accomplis* in the not too-immediate future.

Photography in Natural Colours.—The question is often asked, "When will photography in natural colours be found out?" Had the question been put, "When will photography in natural colours be commercially practicable?" or, "When will portraits in natural colours be feasible?" the answer to be given is, "Not before the centenary." Photography in natural colours has been effected, but by a process so tedious and long in operation that it can never become of the least practical value. Becquerel, Niépce de St. Victor, and others have produced photographs on silver plates in the camera approximating to the colours of objects, and the writer has produced the whole spectrum in its hues, though dim, on collodion plates, but all have been effected by means of what is known as the printing-out method, *i.e.*, by making light itself do the whole of the work on the plate, instead of merely imitating it, and obtaining the final result by means of development. Such a process, when used in the camera, is necessarily extremely slow—so slow, indeed, that only with a very bright light illuminating the object, and by an exposure sometimes extended over days, any coloured image at all can be produced. This method is, therefore, completely out of court as a practical process for obtaining portraits, and is many times worse than the Daguerreotype process in its early days, when a sitter had to endure being screwed up in a head-rest for an hour or so in bright sunshine. From a theoretical point of view, what has been done is interesting, but at present, at all events, it remains only as a scientific curiosity. To enable it to be of any practical value, exposures must be short, and this entails the after process of development. Light may so sift and shake the matter on which it falls that it aggregates or disintegrates into minute particles of such a size

that the light reflected from them shall be of that particular colour which falls upon them; but it can scarcely be conceived, though a short exposure may so change some small portion of the matter on which it falls, that a subsequent action produced by purely chemical means, as is the case in development, can continue to produce the same necessary aggregations or disintegrations of the particles. Again, with the results that have been obtained, the permanency of the images is but short, as they will bear no subsequent exposure to white light, the colours vanishing rapidly. From what has been said, it is apparent that photography in natural colours is out of the range of practicability with the present known substances which are sensitive to light, and it is unlikely that any substance will be discovered sufficiently sensitive to enable it to be carried out by a printing-out process, and we have seen how unlikely it is that any developing process can succeed.

Transmitting the Photographic Image to a Distance.—The transmission of photographic images to a distance by electrical means is also popularly believed to be within the range of practicability. The transmission of sounds by a telephone, and their reproduction by the phonograph, have seemed to the lay mind, and even to minds which are not lay, to be akin to the transmission and reproduction of photographic images. Had a little more thought, however, been expended on the subject, it would have been seen that the conditions of the two were totally different. The phonograph enables sound to be reproduced by means of lines or points marked on a sheet of foil, the depth of sound being indicated by variations in depth and breadth of the furrowed line. In a photographic image one is not dealing with anything that can be represented by a line, but only by a surface. There are two systems which may be employed to produce the effect of light and shade lying on a surface, but even then the two systems blend together by the fact that the continuous surface at one end of a telegraph wire has to be represented at the other by lines more or less closely ruled parallel to each other. Bains's system of the transmission of handwriting by telegraph may be modified to reproduce a photographic image. In this system, the paper, with the writing to be transmitted, was placed beneath a pointer connected with the telegraph wire, and made, or broke, electrical contact, according as the blank paper or the writing came beneath it. The paper at one end moved at a fixed rate, and at the other the paper was made to pass beneath a pointer at a similar rate. At the other end, and when contact was made, or broken, at the one station, similar contacts were made at the other, marking the paper when contacts were made. By passing the sheet of paper on which the writing was made in parallel lines beneath the pointer, evidently a sort of *facsimile* of the writing was produced. By a modification of this plan, a photographic print might be, in a measure, reproduced; for instance, by causing the lights and shades of a photograph to offer more or less resistance to the passage of the current. By this means, greater or less blackening of a properly prepared paper might be caused, and produce lights and shades represented by parallel lines.

A Dream and Nothing More.—The use of selenium, which alters its resistance to the passage of a current according to the intensity of light acting on its surface, has also been suggested as a sensitive surface. This sounds very nice, but unfortunately, a telegraph wire will not discriminate between the currents transmitted from one part of a surface and another. Hence, its connection with the telegraph wire for this purpose is useless. By acting somewhat on the same plan as that adopted by Bains, an image thrown on such a surface might be roughly transmitted, but it would bear but little resemblance to a proper photograph, and it is doubtful whether it would be practically, or even scientifically, of any use. Other plans based on the same principles might be suggested, but they all must fail, and until such a time arrives that one small wire will transmit an infinite number of small currents coming from different parts of a surface, and record them simultaneously on a surface at the other end of the wire, in proper order and magnitude, the idea of practical photography at a distance is a dream, and nothing more.

Light and Shade.—One more point is that photography can never be strictly truthful as regards light and shade. If the high-lights in a photograph be accurately depicted on a paper print, the shades will be found wanting in correctness. This is an inherent defect in photography, even when black-and-white have only to be reproduced. But besides this we have another inherent defect, in the difficulty in portraying colours in proper relation to one another. A photographic plate is more sensitive to some colours than it is to others; and although modern improvements have lessened this defect, and may still further minimise it, yet the want of truth in rendering shades correctly must always remain. Perpetual motion will probably be a thing of the past when truth in photography is still non-existing.

Notices of Books.

Platinum Toning. By Lyonel Clark, C.E. (*London: Hazell, Watson, and Viney*, 1890.)

This little book, which is clearly written, and contains instructions put into good form for practical purposes, consists partly of information which has already been published in the *Journal of the Camera Club*. The only thing publicly wanting in relation to Mr. Lyonel Clark's method of toning, seems to be some series of exact experiments from which some idea can be gained as to the comparative resistance of platinum-toned and gold-toned photographs to destructive chemical reagents, all other conditions being equal. At present no figures on this point are before the world.

In an appendix to the book Mr. Clark gives the following useful details from French sources, about photographic residues:—

"I advise all photographers, however humble their output, to save their residues—not that that they can expect to recover the whole 97 per cent., but they would certainly get a return of something like 80 per cent.

"From the following table, the result of careful analysis made by MM. Davanne and Girard, we can see exactly where the different losses take place:—

	Silver per cent.
Draining papers	1·028
First and second washing waters before toning	52·860
Hypo bath	32·100
Washing water of fixed proofs	4·110
Cuttings and clippings	4·570
Remaining on proofs	3·100
Loss	2·232
	100·000

"It will be at once seen that the majority of the silver is found in the preliminary washing waters and the hypo bath, being about 85 per cent. of the whole; so that if we only manage to save a fair proportion of this, we shall effect a notable economy in our nitrate of silver bill.

"A sheet of paper measuring 17¾ by 22 will take up about 37 grains of silver—say 36; and we should easily be able to recover of this about 27 grains; or, in intrinsic value, for every ten shillings' worth of silver we should get back seven-and-sixpence from our residues—on the whole, not a bad return."

After giving one of the methods of recoving silver from washing waters and clippings, Mr. Clark says:—

"The old hypo baths cannot of course be treated in the same way, since chloride of silver is soluble in this menstruum; neither can zinc very well be used to precipitate silver, as sulphide of zinc appears to be formed in the

operation. The usually adopted plan is to add liver of sulphur, and throw down the silver in the form of the sulphide, which is next roasted to free it from the sulphur, and then fused. There are two drawbacks to this method: the stench produced thereby is beastly and even injurious, and the roasting of the residue is nearly as inodorous, and if not properly carried out—that is to say, if any free sulphur is left—explosions may occur when the mass is fused. If this system of treatment be resorted to, the precipitated sulphide should be sent direct to the refiner's.

"But the simplest and perhaps best way is Davanne's method. This simply consists in immersing a plate of copper in the hypo bath, and letting it stand for about four days. Silver is gradually deposited on the copper, whilst the copper is dissolved in the liquid. From time to time, therefore, the copper plates, which are simply stood up against the side of the tub, should be brushed; the metallic silver will then gradually settle to the bottom, and when sufficient has been collected it can be filtered and washed. The dried filtrate consists of metallic silver mixed with a little copper, and can of course be at once converted into silver nitrate, contaminated with a little copper, giving it a bluish colour. This colour will cause no harm to the print, as it is soluble; but if it is very strongly present, it can be got rid of by adding gently silver oxide in the manner described in the preparation of silver nitrate."

Specifications Published.

6,385.—*April 13th*, 1889. "Stereoscopes and Cameras." Harry Ransom, 47, Friars Street, Sudbury, Suffolk, Cabinet Maker.

The inventor claims:—

1. A photographic camera adapted to take stereoscopic pictures and to be used also as a stereoscope.

2. In a combined camera and stereoscope a chamber adapted to hold a screen of ground glass or the like in either of two positions, according as the screen is being used as a focussing screen for the camera, or a light-diffusing medium or back for stereoscopic pictures.

3. In a combined camera and stereoscope having a chamber as described, providing the said chamber with a pivotted reflector for reflecting light on to the pictures when the apparatus is used as a stereoscope, and for closing the said chamber when the apparatus is used as a camera.

4. In a combined camera and stereoscope, a screen having springs which serve to maintain the said screen in position, and, when the apparatus is being used as a stereoscope, as a holder for the pictures.

5. A combined camera and stereoscope, the lens carrying sockets of which are adjustable relatively to each other.

6. The combination with the apparatus hereinbefore described of the dark slide or plate-holder, having a central slide or partition adapted to press against the backs of the sensitised plates and hold them firmly in position in the slide, the plates being introduced into and removed from the slide at one end.

6,585. *17th April*, 1889.—"A New Use for Gelatine." Richard Henry Brunton, 21, Wellington Street, Strand, London, Civil Engineer.

The object of this invention is to manufacture tablets suitable for advertising purposes, whereby the tablets are produced in relief.

The inventor takes a model of the tablet he wishes to reproduce, such model having whatever undercut or relief may be required in the tablet; from this model he obtains a mould in gelatine; he then takes fine plaster of Paris reduced to a liquid state, to which he adds a small quantity of alum, which tends to produce a hardness of surface in the cast. Liquid plaster thus prepared is then inserted into the various interstices in the mould (which is conveniently effected by a brush), and subsequently (with the fingers) tow or other fibrous material as near the surface of the mould as may be found practicable; layers of canvas or equivalent material are then placed over the whole surface and a framework of wood. Liquid plaster is now washed over the surface, and when it sets all the materials become incorporated, and the tablet is removed from the mould in one piece, and then painted and decorated to suit requirements, as fancy or taste may dictate.

6,686.—*April 18th*, 1889. "Photographic Cameras and Lenses." Thomas Rudolph Dallmeyer, 25, Newman Street, Oxford Street, London, Optician, and Francis Beauchamp, Hope College, Whalebone Lane, Chadwell Heath, Essex, Engineer.

Our invention relates to photographic cameras and lenses.

Heretofore in applying a lens to a camera for which it has not been specially fitted, it has frequently happened that the diaphragm slot does not occupy its proper position, owing to the fact that the lens, when screwed up, has not been turned quite far enough, or has been turned too far, and in order to remedy this defect it has been necessary to alter the lens mount to adapt it for the camera. The same difficulty has also existed when applying a shutter to a lens.

The object of our invention is to provide means whereby a lens or shutter can always be caused to assume its proper position without the necessity for special adjustment, and to this end it comprises the improvements hereinafter described.

According to our invention the flange on the camera into which the lens is screwed is provided with an adjustable ring or collar, having a slight longitudinal movement upon the said

flange, so that it can be adjusted to the proper position to cause the diaphragm slot of the lens to occupy its proper position when screwed up.

In practice we prefer to adjust the ring or collar upon the exterior of the flange by means of screw threads, but it may be provided with a series of inclined teeth, or arranged in any other suitable manner.

In cases where a shutter is to be screwed into the front cell of a lens, the latter can be provided with a ring or collar of similar construction.

The inventors claim :—

1. The combination with a photographic camera or lens of an adjustable ring.

2. A photographic camera, the lens carrying flange of which is provided with an adjustable ring.

3. A lens having an adjustable ring or rings thereon substantially as described.

6,999.—*April 26th*, 1889. "Magic Lanterns." Charles Gray, 11, Crooked Lane, King William Street, and Henry Kemp, 7 and 8, Thavies Inn, both in the city of London, Opticians.

Our invention relates to magic lanterns for producing dissolving view effects. In dissolving view lanterns as heretofore constructed, it has been usual to provide each set of lenses with independent illuminating apparatus, which arrangement, when oil lamps are used for effecting the illumination, renders it necessary to place the lenses side by side.

According to our invention, we employ one set of illuminating apparatus in connection with two or more sets of lenses, whereby we are enabled to place the said lenses one over the other, and thus produce an oil illuminated lantern which is more compact than those heretofore constructed.

In carrying out our invention, we advantageously place the lamp or other illuminating apparatus upon a movable platform or stage, by means of which the said illuminating apparatus can be placed in connection with either set of lenses. The said platform is advantageously moved by means of a rack and pinion, but any other suitable mechanism may be employed for the purpose.

In some cases we use only a single condenser, which is placed on the platform with the illuminating apparatus, and is moved therewith so as to operate in conjunction with either set of magnifying lenses.

Although we prefer to arrange our improvements in a lantern in which the several sets of lenses are arranged in a vertical line, it is to be understood that our said improvements are equally applicable to lanterns the lenses of which are placed in a horizontal line.

The inventors claim :—

1. A magic lantern having two or more lenses, and a single lamp or illuminating apparatus, the said illuminating apparatus being mounted upon a platform adapted to be moved so as to bring it opposite to either lens.

2. In a magic lantern, the illuminating apparatus of which is adapted to be moved to bring it opposite to either lens, mounting the condenser so that it will move with the said illuminating apparatus.

3. In a magic lantern, mounting the lamp or other illuminating apparatus upon a platform adapted to be moved vertically in guides by means of a rack and pinion, so that the said illuminating apparatus can be placed opposite either lens.

7,905. *May 11th*, 1889.—"Measuring Distances of Objects." Charles Francis Martin, of the 2nd Battalion The Highland Light Infantry, Depôt Hamilton, Lanark, Lieutenant.

My invention relates to means of measuring distances of objects, as for range finding, topographical surveying, and such like purposes. By means of a suitable mirror or prism, I determine a station whence the distant object appears at or about right angles to a second object. I then pace or measure a base in the direction of the second object until I come to another station whence some other distant third object is at or about right angles to the second object. At this last station I hold a double sight of known width at such a distance from the eye, that I see both the first and the third objects coinciding respectively with the two slits or points of the double sight ; then, by a simple proportion, I compute the distance of the first object from the first station, for, as the known width of the two sights is to the ascertained distance of the sight from the eye, so is the paced or measured base to the distance required. The prism or mirror, the double sight, and a tape or other measure for ascertaining the distance of the sight from the eye, may all be accommodated in compact form for the pocket.

173. *4th January*, 1890.—"Holding and Exhibiting Photographs." Frederick Kitto, 3, Lower Union Street, Torquay, Devonshire, photographer.

My invention relates to improvements in apparatus for holding and exhibiting photographs and other like views, and is intended for the purpose of using up photographers' waste plates by mounting photographs thereon by optical contact or otherwise.

The invention consists of a frame to receive a photograph, view, or any picture, with the back portion glued to the frame to fix the aforesaid photograph or view in its desired position.

The frame is constructed of leather, cloth, linen, wood, metal, or of any other suitable material, with any degree of elaboration on the frame.

The object of my invention is to fix the photograph or view in the frame, or to fix a view or picture on the glass, after or before the glass is fixed in the aforesaid frame.

The inventor claims :—

1. The combination of the apparatus for holding and exhibiting photographs and other like views, and for using up photographers' waste plates, by mounting photographs thereon, or by optical contact or otherwise, as described and according to drawings.

2. The frame to be of any shape or size, and to be constructed of any suitable material.

616. *Jan. 13th*, 1890. (Communicated from abroad by Georgina Newton, of No. 6, Avenue du Bois de Boulogne, Paris, France, Gentlewoman.)—"Improved Pocket Lamp." Charles Denton Abel, 28, Southampton Buildings, Chancery Lane, London, Consulting Engineer.

This invention relates to an improved construction of apparatus in which are combined in a compact form a lamp and means for automatically igniting the same. The cylindrical lamp vessel is filled with a suitable porous material, such as cotton wool, which is saturated from time to time with paraffin on unscrewing the bottom, and the said lamp vessel is so arranged that on turning the bottom cap in the contrary direction to that in which it unscrews, it will cause the lamp vessel to revolve in the casing. At one side of the latter a flat channel is formed on the outside, and through the open lower end of the passage is inserted a strip of cardboard or stiff paper, on one face of which are deposited small quantities or dots of combustible compound, such as is used for matches or fusees, situated at equal distances apart. On the top of the lamp is fixed a piece of wire or strip of metal which, at each rotation of the lamp vessel, has its projecting end brought sharply against one of the dots of material, to thus cause its ignition, whereupon the resulting flame ignites the wick of the lamp.

611.—*January 13th*, 1890. "Magic Lanterns and Apparatus relating thereto." William Charles Hughes, Brewster House, 82, Mortimer Road, Kingsland, Middlesex, Manufacturing Optician.

This invention can be adequately explained only by the aid of diagrams.

765.—*January 15th*, 1890. "Plate-Changing Apparatus." Newnham Browne, 73, Cheapside, London, Fellow of the Institute of Patent Agents. Communicated from abroad by Friedrich Auguste Fichtner, of Elisenstrasse, 6, Dresden, Altstadt, Saxony, Cabinet Maker.

The invention relates to an arrangement or apparatus for application to photographic cameras carrying several plates simultaneously (such, for instance, as are known as detective cameras) enabling an exposed plate to be rapidly changed for a fresh or unexposed plate, so that a fresh exposure may be made with a loss of a few seconds only.

Correspondence.

A PHOTOGRAPHIC SCHOLARSHIP.

Sir,—May I trespass again on your space to make an alternative proposal for the disposal of the above. At the Camera Club Conference on Friday it was proposed that an annual exhibition of photographs should be held, on the lines of the Royal Academy or Paris Salon, where the hanging of a picture would be its own reward. The only difficulty in the way was want of funds. Now, if such a scheme is carried out, I may say that the Britannia Works Company will be most happy to place their gift at the disposal of the committee that might be formed for the purpose. If others who have hitherto limited their efforts to raise photography to a higher status to mere talk, should follow the admirable practical example, there is no reason why both the suggestions put forward should not be carried out. Then we may see our art science rank with other branches of learning which have endowments for the furtherance of their study, and adequate rewards for those who excel therein. John Howson.

Ilford, 22nd March, 1890.

CHALLENGE CUP COMPETITION AT THE CRYSTAL PALACE.

Sir,—Would you kindly insert the enclosed in your next issue, and oblige James Brown, Edgar G. Lee,

Hon. Secs. Newcastle-on-Tyne and Northern Counties Photographic Association.

[Copy of a letter sent to Messrs. G. B. Wollaston and J. F. Peasgood, Photographic Exhibition, Crystal Palace, London.]

Gentlemen,—Confirming my telegram of the 19th inst., I am instructed by our exhibitors, whose names are appended at foot, to formally protest against the award in the Challenge Cup Competition, on the ground that, from authoritative information in our possession, a portion only of our exhibits was brought under the notice of the judges.

A large portion of our pictures having been excluded from the competition, as we *know* to be the case, we hereby demand an explanation, and unless that explanation is satisfactory, we insist upon the entire Cup Competion being re-judged.

A copy of this letter is being sent to each of the photographic papers. Edgar G. Lee, *Hon. Sec.*

Mosley Street Café, Newcastle-on-Tyne, 21st March, 1890.

Exhibitors' names :—Auty & Ruddock, T. Galloway, J. P. Gibson, J. E. Goold, Edgar G. Lee, W. Parry, J. Pike, H. R. Procter, H. G. Ridgway, Lyd. Sawyer.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

Sir,—In connection with our forthcoming Photographic Exhibition, kindly permit us, through your columns, to announce to intending exhibitors that we have, in their interest, decided to extend the date for sending in application forms from April 1st to April 7th. Pictures must, as previously advertised, be in our hands by the 10th prox.

James Brown, Edgar G. Lee } *Hon. Secs.*

The Photographic Society.—The following are the present officers of the Photographic Society. *President*—James Glaisher, F.R.S., F.R.A.S. ; *Vice-Presidents*—Capt. W. de W. Abney, C.B., R.E., D.C.L., F.R.S., T. Sebastian Davis, F.C.S., H. P. Robinson, John Spiller, F.C.S., F.I.C. ; *Treasurer*—Walter S. Bird, 74, New Oxford Street, W.C. ; *Members of Council*—G. L. Addenbrooke, W. Bedford, Valentine Blanchard, Lyonel Clark, Francis Cobb, Alexander Cowan, Thomas R. Dallmeyer, Major L. Darwin, R.E., G. Davison, W. E. Debenham, W. England, J. Gale, H. Chapman Jones, F.I.C., F.C.S., Sir George Prescott, Bt., Sir David L. Salomons, Bt., J. W. Swan, M.A., F.C.S., J. Traill Taylor, Leon Warnerke, H. Trueman Wood, M.A. ; *Hon. Secretary*—Capt. A. M. Mantell, R.E., 8, Mansion Row, Old Brompton, Chatham ; *Assistant Secretary*—Edwin Cocking, 52, Pall Mall East, S.W.

Proceedings of Societies.

Photographic Society of Great Britain.

The monthly technical of this Society was held on Tuesday evening last, the 25th inst. The chair was occupied by Mr Arnold Spiller, F.C.S.

The Assistant-Secretary, Mr E. Cocking, having noticed that the subject of the fading of silver prints was under discussion, and having an illustrative specimen in his possession, had notified to members that the subject would be presented, and had brought the specimen with him. It had been taken only four years since, and had been printed upon commercial ready sensitised paper, and toned with the acetate bath. The print had faded very badly ; whereas another print made thirty-one years ago, and toned with the mixed hypo and gold bath—the print having been mounted in a similar frame to that containing the faded one, and hung on the same wall—was still in good condition.

The Chairman believed that there were some makes of cheap albumen paper which were very conducive to fading. About five years ago he was using a cheap kind of albumen paper, and had since found that all the prints that he could trace as having been printed on that sample had faded considerably. Some of the prints even showed distinct signs of fading within two months of their being executed. The paper had a strong smell. Unmounted prints of that lot had not faded so much as the mounted ones, but the former had the advantage of having been kept in a drier place.

Mr. Atkinson mentioned that in a part of Spain where the atmosphere was generally very moist, prints had been found to fade very rapidly.

The Chairman asked whether it was known, with any certainty, that encaustic paste has a preservative effect? He had a particular collection of photographs, all of which had faded except three. Of these three, one was a carbon print, and the two others had been treated with encaustic paste.

Mr. W. Bedford said that encaustic paste was not a complete protection. He had in his possession three prints that had been treated in that way, one of them by Adam Salomon, and they all showed signs of fading.

Mr. A. Mackie said that Mr. A. L. Henderson had used a sort of varnish consisting of a weak solution of gum dammar in benzole, and had found that prints so protected and exposed side by side with others not so treated had stood much better. He would enquire whether there were not two kinds of fading, one kind showing itself by partial disappearance of the image, and the other by a yellowing of the lights.

The Chairman said that the yellowing of the lights was due to a silver compound not dissolved out in the fixing bath. The presence of this compound could be detected in a fresh print by applying a dilute solution of sulphide of ammonium.

Mr. Bedford enquired whether the addition of carbonate of ammonia to the fixing bath, which had been proposed as a remedy for the kind of imperfect fixation referred to, had proved to be a complete success?

Mr. John Spiller said that ammonia dissolved nearly, but not quite, the whole of the silver compounds. The only substance which he had found to completely remove the silver was cyanide of potassium ; this must be used in a very dilute state —half a grain to the ounce was sufficient.

Mr. T. Sebastian Davis said that at the present time a great many negatives were made very thin. That was a condition which was conducive to fading of prints made from them, as a good vigorous image could not be obtained. Printing in sunlight also gave a much more permanent print than could be got by printing in the shade. The use of sodium acetate in the toning bath resulted from some experiments made by Mr. Hannaford and himself. Too much soda had been added when making up the alkaline bath then in use, and Mr. Hannaford put in some acetic acid to counteract the alkalinity. He then observed a characteristic effect upon the tone of the prints, and afterwards acetate of soda was used direct.

Mr. Mackie enquired whether there was any characteristic difference of tone obtainable with the different salts added to

neutralise the gold. He could not discover any difference when all were stopped at the same stage. He had used carbonate, borate, tungstate, and acetate.

Mr. Davis considered that borax gave a blue tone more readily than acetate, but there was a great differance in the keeping power. A borax bath should be used directly, whereas an acetate bath was better for being kept for twenty-four hours.

Mr. W. E. Debenham said that he found it stated in books and periodicals that the active condition of gold in a toning bath lasted until the metal was precipitated. His own observations, however, led him to the conclusion that the gold passed by keeping into a state when it would tone, if at all, only with extreme difficulty, and that whilst still in solution. On the other hand, even a dilute solution of gold might tone actively, although partial precipitation had taken place. This was shown by the alkaline process with carbonate of soda and citric acid, recommended by Hardwich at about the end of the year 1858. It was directed to heat the solution until a bluish colouration showed the commencement of precipitation, and the bath on cooling down was then found to be in vigorous toning condition.

The Chairman said that toning baths appeared to get soonest into condition as the acid of the added salt was weak. Hypochlorous and carbonic acids were amongst the weakest acids known, and baths made with carbonate of soda, or hypochlorite of lime, were the soonest ready for use.

Mr. John Spiller then showed a collection of about forty photographs which had been made from twenty-five to thirty-one years ago by direction of the War Office; none of them showed any fading. They were not a picked lot, but the whole of the set that he possessed. The practice in making these prints was to use purchased albumen paper, and to float it on a fifty-grain bath. The toning was done with bicarbonate of soda, and the fixing in fresh hypo. Washing was effected by means of a trough in which the prints were swirled round by a stream of water, and with an intermittent syphon discharge they were drained occasionally during the course of the washing. A false bottom of zinc pierced with holes prevented the prints from sticking to the vessel when it was emptied of water. After a time the prints were taken out, and left to soak in dishes during the night; the prints after drying, were mounted with warm glue beaten into a froth like shaving paste. The mounts used had been, according to the date, of four different colours, and were not all from the same manufactory.

Mr. Bedford thought that thorough fixing was of more importance than long washing. He had two hypo baths in use; the first contained a solution of one part of the salt to five of water. The prints were removed from this bath to one containing one part hypo to ten of water. Both baths contained liquid ammonia in the proportion of eight minims to the pint. It had been said that citric acid in the paper hindered the toning. In his experience, the effect was just the contrary. In reply to questions as to the preparation of the paper, he stated that he first floated upon a fifty-grain bath—which must be quite neutral—and then, after removing the surface liquid by drawing the paper over a glass rod, it was floated for half a minute upon a second bath containing thirty grains of nitrate of silver, and a like quantity of citric acid, to the ounce. Paper thus prepared would keep good for months. The second bath did not require to be replenished with silver, but only with citric acid, which was added in the proportion of five grains for every sheet of paper that had been floated.

Mr. England said that a difficulty had been found in keeping celluloid films, except those of small size, flat in the dark slides. He had found that if a slight curve were given to the film it would maintain its position, and he had, therefore, had strips put in the dark slides, which made the film slightly concave towards the lens. The ends of the film with a whole plate were about one-eighth of an inch in advance of the centre. This concavity also was useful in bringing the ends more in focus at the same time as the centre of the field. He had particularly noticed this when using a rapid rectilinear lens.

Mr. Debenham said that there was a certain amount of distortion when a curved plate was used with a non-distorting lens. In ordinary cases it might not be sufficient to show, but in architectural subjects, when filling the plate to the margin, it might do so. With an ordinary single lens the distortion would be increased, but with an orthoscopic lens the distortions might be made to nearly correct each other.

It was announced that at the next technical meeting, which will take place on the fifth Tuesday in April, the subject of Celluloid Films will be discussed. Mr. T. S. Davis also promised to make some experiments on the lines indicated by the discussion of this evening, and bring up the results on that occasion.

London and Provincial Photographic Association.

March 20th.—Professor E. Stebbing, of Paris, in the chair.

The Circular issued by the Camera Club Conference, with reference to the Regulations for Photographic Exhibitions, was taken into consideration. The members were of opinion that it was little use attempting to frame regulations, as each committee managing an exhibition would make its own conditions, leaving it to the public to accept them, or refrain from exhibiting, as the case might be. About many of the questions asked, it was impossible to give a decision, as so much depended upon circumstances. With regard, however, to some of them, they thought that (1) Exhibition authorities *should* decline prizes placed at their disposal for advertising purposes; (2) That awards should *not* be of equal value; (3) That there should be a class for *un*-touched pictures; (4) That it was not desirable to stipulate that each picture should be in a separate frame; (5) That all pictures should be judged on their merits, and that there should be no distinction made between amateur and professional exhibitors.

The Chairman exhibited some very good collotype prints by Balagny, of Paris. The negative of one of the subjects was by himself, and such was the rapidity of the process, that within forty-five minutes of placing it in M. Balagny's hands twelve collotype proofs were produced. The Chairman also passed round some photochromic prints by the Zurich Photochrome Co. They were printed from stone, the bitumen process being employed.

The "International Photographic Union" was referred to by the Chairman, who said that any members of a photographic society joining it would be welcomed by their continental brethen. Ladies were eligible, and there was no subscription.

Replying to a question as to the popularity of eikonogen in Paris, the Chairman said that it was not in popular favour. Hydrokinone was the favourite, and was very economical; he had developed about nine hundred whole-plate negatives at a cost of about twelve shillings.

A discussion on orthochromatic photography, and the ease with which plates could be prepared, brought the meeting to a close.

Liverpool Amateur Photographic Association.

On the evening of Thursday, 20th March, the members and friends, to the extent of four hundred and thirty, held their first "Ladies' Social." Although the Association has been in existence since 1863, the experiment of a ladies' evening had not been before attempted. The large hall—the "Eberle"—was occupied to its utmost capacity. The first hour was devoted to a vocal and instrumental concert, at which some of the leading local amateurs kindly assisted. This portion of the entertainment was under the guidance of two musical members, Messrs. Arnold J. Cleaver and F. K. Glazebrook, who are able photographic workers; they both secured medals at the Society's last Annual Members' Competition.

The entertainment concluded with the President's "Lecture on Norway." This included 130 views taken last June by the speaker, Mr. Paul Lange. The descriptive matter was entertaining and instructive. Many of the scenes depicted were hand-camera exposures, giving the daily life of the people of Norway, and there were general views of mountain, glacier, and river scenery. The pictures were shown to advantage on a 16-feet opaque screen, with Messrs. Archer and Sons' long-focus 12-inch lenses.

THE LANTERN SOCIETY.

A REPRESENTATIVE meeting was held last week at St. James's Hall, when a set of rules was adopted. The programme of the Society's work is to embrace, amongst other things, the interchange or provision for an interchange of slides between members in town and country, concessions in the shape of special terms from makers and dealers in slides, lanterns, and apparatus, together with an interchange between various clubs of exhibitions.

The following is the list of the council as far as appointed :—*Chairman*—the Hon. Slingsby Bethell ; *Vice-Chairman*—Mr. T. H. Holding ; *Secretary and Treasurer*—Lieutenant C. E. Gladstone, R.N., Northwood Hall, Rickmansworth, together with Messrs. G. S. B. Cresswell, E. Hall, N. Mackin, Maw, A. N. Shepperd, and E. R. Shipton.

The annual subscription is a guinea, the entrance fee a guinea, and for country members it is 10s., and 10s. ; but all joining the Society before October 1st are admitted without entrance fee, and all subscriptions will free members up to October 1891.

PHOTOGRAPHIC SOCIETY OF IRELAND.

AT a meeting of the Photographic Society of Ireland, held on the 24th inst., the chair was occupied by Dr. J. ALFRED SCOTT, Vice-President ; and Mr. J. Joly, M.A., delivered a lecture entitled "Among the Alps with a Camera." The photographs were taken *en tour*, commencing at Brunnen, on Lake Lucerne. The places, heights, and valleys of interest were numerous, and the chief of them were exhibited either as reductions or contact lantern slides, and comprised about seventy-two views, and included well-known mountains, glaciers, and passes. The exposures were varied from one-eighth of a second, with a small stop, to whatever the light indicated for the foreground. In this latter particular assistance had been gained by resorting to the standard tables now published by various authors. The camera, 7½ by 5, was supplied with a Dallmeyer R R Landscape Lens. The plates used were Wratten and Wainwright's. With regard to development, pyro was first tried, but afterwards discarded, and hydrokinone entirely used.

To get the best results Mr. Joly developed by the "partial" method, recommended by Dr. P. H. Emerson and Capt. Abney. The sky and bright lights, as from snow, were first brought up, and development of them stopped by plunging the plate in water. The development of the foreground is then proceeded with by dipping and brushing on a stronger developer, *i.e.*, a weak developer is used in the first part of the process ; when detail is obtained the development is equalised by putting the plate backinto the developer for a mouent ; washing and fixing complete the process.

The details were good, while the snow, glaciers, and skies were excellent. Instances of passing mists, or uonntain tops peeping through clouds, showed that the lecturer and his fellow-traveller (Mr. Dixou) had displayed taste in selecting their views, and judgment as to exposnre and development.

PHOTOGRAPHIC CLUB.—The subject for consideration on April 2nd will be "Standard Solutions, and the Expression of Photographic Formulæ." Bank Holiday outing at Godalming.

BECQUEREL is sometimes credited by his friends to be the first who photographed the solar spectrum. The spectrnm was first photographed by Ritter, and abont the same time, quite independently, by Wollaston.

M. H., Dublin.—Soune parts of your MS. just received are illegible, and soune incomplete.

M. GOUPIL, Havre.—We hope to publish your interesting communication next week.

THE publication of some notices of books, apparatus, and other matters is postponed until our next issue.

THE PHOTOGRAPHIC NEWS will be published on Thursday next, on account of the Easter holidays. All communications should therefore reach the office not later than Wednesday morning.

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London

UBIQUE (Co. Wexford).—*Photographic Trebles and Doubles.* "How to take a treble image of one and the same person playing at Chess?" is your question. All depends upon the position occupied by the players. If you mean to have three figures—say, right and left profile and front face (of the same individual) seated around the table, and supposed to be playing a two to one game—then we should be inclined to take the chess board and central figure by one exposnre, a side player against the same backgrounnd by a second exposure, and reverse this plate for the third figure. Is this an answer? For, to reply literally, a Victoria camera with three lenses would give at once "a treble image of one and the same person." But this, surely, is *not* what you mean? There is no difficulty in taking "doubles ;" such, for instance, as "Rejlander the Artist introdncing his friend Rejlander the Volunteer," or "The Painter and his Critic," now in the Crystal Palace Exhibition (screen 20) ; but the addition of a third figure, at what is ordinarily the point of junction, is not so easy of accomplishment.

W. S.—*Hydrometer Test for Silver Baths.* Under ordinary circumstances it *is* sufficiently reliable both for the printing and collodion baths. Take the specific gravity of the newly-made solutions, and maintain this uniformly by the addition of fresh nitrate of silver. This is not quite exact, for the accnmulation of alkaline nitrate in the solution is not taken account of, although it must slightly affect the hydrometer indications ; but for practical purposes this interference may be disregarded.

L. T. E.—*Chromates versus Bichromates in Gelatine.*—We are not aware of any experiments showing the comparative sensitiveness of such preparations ; but Mr. W. T. Wilkinson asserted last week, at the Camera Club, that it *was* desirable to add ammonia to the bichromated gelatine, which would of course determine the formation of a neutral chromate in the film, and that he, in practice, fonnd this to be a decided improvement.

M. F.—*A Small Studio.* Further particulars go to you by post, together with a letter of introduction.

J. D.—*Incandescent Lamp.* Received your letter, and we will bear it in nuind. No news since our interview.

INVERNESS.—We are returning yonr photographs with a private letter.

J. E. M.—*Photography in Natural Colours.* We think the case has been well stated by Captain Abney ; and, until further evidence is forthcoming, we must suspend our judgment. One can hardly say that it has been confirmed by Dr. Eder.

M. P.—*Blisters on Albumenized Paper.* Have you tried to overcome this difficulty by adding a small quantity of methylated spirit to the silver bath? This might tend to diminish the solubility of the albumen. Use about one ounce of spirit per pint of silver nitrate solution, which had better be mixed of full strength to compensate for such dilution.

E. G. (Barnet).—*Isochromatic Plates.* The evideuce is open to inspection at the Crystal Palace Photographic Exhibition, Block G ; but bear in mind that to-morrow will be the last day.

L. A. (Devonport).—*Collodio-Chloride Prints : Want of Density.* This method, like the old Wöthlytype, was always supposed to be best fitted for the production of delicate prints, and does not lend itself so well to the printing of dense negatives.

RESIDUES.—*Reduction of Silver by Iron.* Zinc is a much better reducing agent, and the difference of cost is not worth consideration. Iron only very slowly reduces the nitrate of silver, whereas zinc does so immediately, being a more highly electro-positive metal.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1648.—*April 4, 1890.*

CONTENTS.

"GIPHANTIA" INVESTIGATED.

SOME weeks ago, a communication was made to the Camera Club about photography having been foretold in an old book called "Giphantia," published in 1761. Long ago, in the old wet-plate days, this matter attracted the attention of the photographic press, and one writer, whose utterances we have recently tried to rediscover, but failed, sent to one of the photographic journals some strong reasons or statements questioning the antiquity of "Giphantia," or the extract therefrom; therefore our reports of the statements made at the Camera Club in relation to the book were cautiously worded.

As the exceedingly curious matter deserved investigation, we have since, by examination, found that the British Museum Library contains three editions of the book, all, so far as antique appearances go, bearing external evidence of being old and genuine. The first of these, entitled "Giphantie," is in French, and bears the date of 1760; it is anonymous, and purports to be published at "Babylon." The second is also in French, is dated 1761, and purports to be published at *La Haye* by Daniel Monnier. The third is an English translation, with the following words on the title page:—"Giphantia: or a view of what has passed, what is now passing, and, during the present century, what will pass in the world. Translated from the original French, with explanatory notes, London. Printed for Robert Horsfield, in Ludgate Street, 1761." The anonymous translator dedicates this edition to "The Hon. Miss Ross." On the leaf opposite the title page is written:—"This book belongs to Twickenham, and taken from thence June ye 1st, '99.—F. Howe." Some members of the Camera Club state that another edition of the work was published at Cherbourg.

The authorities of the British Museum ascribe in their catalogue the authorship of the book to Tiphaigne de la Roche, and state that the two French editions, which are first mentioned in the preceding paragraph, were in reality published in Paris. Barbier's *Dictionnaire des Ouvrages Anonymes*, vol. ii., page 544, published in Paris in 1874, ascribes the authorship of "Giphantie" to Ch. Fr. Tiphaigne de la Roche, and gives the date of the book as 1760, so fully recognises its genuineness; and it is probable that, on the authority of Barbier's book, the name of Tiphaigne de la Roche is applied to the work in the British Museum catalogue of printed books. Vol. III. of the *Bibliotheca Britanniea*, published in Edinburgh in 1824, catalogues the English edition of "Giphantia," so that the work was certainly in existence before the advent of the Daguerreotype, collodion, and gelatine processes; consequently the work may be regarded as not of recent date. Under these circumstances, we now quote in full the remarkable passages contained in the book:—

I saw, out of a window, a sea which seemed to me to be about a quarter of a mile distant. The air, full of clouds, transmitted only that pale light which forebodes a storm: the raging sea ran mountains high, and the shore was whitened with the foam of the billows which broke on the beach.

By what miracle—said I to myself—has the air, serene a moment ago, been so suddenly obscured? By what miracle do I see the ocean in the centre of Africa? Upon saying these words, I hastily ran to convince my eyes of so improbable a thing. But in trying to put my head out of the window, I knocked it against something that felt like a wall. Stunned with the blow, and still more, with so many mysteries, I drew back a few paces.

"Thy hurry," said the Prefect, "occasions thy mistake. That window, that vast horizon, those thick clouds, that raging sea, are all but a picture."

From one astonishment I fell into another; I drew near with fresh haste; my eyes were still deceived, and my hand could hardly convince me that a picture should have caused such an illusion.

"The elementary spirits," continued the Prefect, "are not so able painters as naturalists; thou shalt judge by their way of working. Thou knowest that the rays of light reflected from different bodies make a picture and paint

the bodies upon all polished surfaces, on the retina of the eye, for instance, on water, on glass. The elementary spirits have studied to fix these transient images; they have composed a most subtile matter, very viscous, and proper to harden and dry, by the help of which a picture is made in the twinkle of an eye. They do over with this matter a piece of canvas, and hold it before the objects they have a mind to paint. The first effect of the canvas is that of a mirrour; there are seen upon it all the bodies far and near, whose image the light can transmit. But what the glass cannot do, the canvas, by means of the viscous matter, retains the images. The mirrour shows the objects exactly, but keeps none; our canvases show them with the same exactness, and retain them all. This impression of the images is made the first instant they are received on the canvas, which is immediately carried away into some dark place. An hour after, the subtile matter dries, and you have a picture so much the more valuable, as it cannot be imitated by art, nor damaged by time. We take, in their purest source, in the luminous bodies, the colours which painters extract from different materials, and which time never fails to alter. The justness of the design, the truth of the expression, the gradation of the shades, the stronger or weaker strokes, the rules of perspective—all these we leave to nature, who, with a sure and never-erring hand, draws upon our canvases images which deceive the eye, and make reason to doubt whether what are called real objects are not phantoms which impose upon the sight, the hearing, the feeling, and all the senses at once."

The Prefect then entered into some physical discussions, first, on the nature of the glutinous substance which intercepted and retained the rays; secondly, upon the difficulties of preparing and using it; thirdly, upon the struggle between the rays of light and the dried substance; three problems which I propose to the naturalists of our days, and leave to their sagacity.

Meanwhile, I could not take off my eyes from the picture. A sensible spectator, who from the shore beholds a tempestuous sea, feels not more lively impressions; such images are equivalent to the things themselves.

The Prefect interrupted my extasy. "I keep you too long," says he, "upon this storm, by which the elementary spirits designed to represent allegorically the troublesome state of this world, and mankind's stormy passage through the same; turn thy eyes and behold what will feed thy curiosity and increase thy admiration."

Charles François Tiphaigne de la Roche was born at Montebourg in 1729, and died on the 12th August, 1774. He was a doctor of medicine and a literary man, and chiefly made his mark in the world in the latter capacity. He took his degrees in the University of Caen. His works are little known, and but few of them preserved in this country; most of them are of an idealistic nature. Giphantia is the name of an island which the author supposes to have been given to supernatural beings one day before Paradise was closed on the ejection of Adam. He wrote a few scientific works: one of them, entitled "Physical Observations on Agriculture, Plants, and Minerals," was published in 1765.

Why does not the Photographic Convention, which meets at Chester this year, arrange for an excursion to the top of Snowdon? It may be years before it is within the same moderate distance thereof.

PHOTOGRAPHY IN SWEDEN.

The *Fotografisk Tidskrift*, or Photographic News, published at Stockholm under the management of Albin Roosval, presents its readers in last month's issue with a pictorial supplement of no mean interest. In the course of every year six illustrations at the least accompany this publication. The present picture, says the paper, will show what we are able to accomplish by aid of the newest and possibly most important of the means of photographic printing. The picture is a *phototype* taken *direct* from a negative after nature by a new method elaborated by Axel Lagrelius, with the assistance of a lithographic institution, representing a country scene with figures. A man is shown reclining under a tree by a river-side watching the approach of a boat containing a man and woman to the shore. In the foreground are reeds, sedges, and other water-plants. On the spectator's right is a pier or boat-house. The whole presentment is soft and delicate, and the process is said to be quick and cheap.

At a meeting of the Society at Stockholm on the 19th February, under the presidency of H. Gilden, the following were elected members:—John Höjer, Max Sievert, Henrik Rosen, C. G. Engström, C. Johansson, M. E. Bäckström, B. W. Lundin, A. F. Höglund, A. Lindstedt, H. G. Öhrling, K. Salin, O. Lindberg, Feyehting, Victor Berg, E. Lundström, C. Akrell, F. Almgren, Professors Montan and Retzius, C. G. Rude, a photographer of Christiana, and the Court photographer, M. Hansen.

Professor Hasselberg gave a lecture at this meeting on some experiments of the elder Draper, chiefly derived from "Draper's Scientific Memoirs." The "Scientific Memoirs" or experimental contributions to a knowledge of radiant energy, written by John William Draper, M.D., LL.D., the celebrated President of this Faculty of Science in the University of New York, were published in England in octavo in 1878, and are sufficiently well-known.

The most interesting part of this work, which engaged the attention of Professor Hasselberg, is perhaps "on the analogy between the phenomena of the chemical rays and those of radiant heat," extracted from the *Philosophical Magazine* of September, 1848.

The editor, Albin Roosval, exhibited during the meeting a collection of photographs, executed and presented to the Society by Christensen and Sörensen, of Silkeborg, in Denmark. These photographs were copied on aristo paper manufactured by that firm, and some specimens of this paper were submitted to the members of the Society for experiments.

Numa Petersen showed a flash-lamp of French construction. This apparatus, which has the form of an ordinary note-book, gives a strong light, sufficient to illuminate a small group in a room, and will supply twenty flashes uninterruptedly, one after the other, in the space of one minute. It contains a benzine lamp, lucifer matches, and magnesium powder, and is ready for use on any occasion. The cost for every flash is a mere trifle. The whole apparatus may be purchased for 10 kronor, or about 11s. 1½d.

The rest of the number is made up of the usual answers to correspondents, reviews of works treating on photography, an article on composite photography after J. T. Stoddard, and an announcement of an amateur photographic exhibition in Buda-Pesth; this exhibition, commencing on the 15th of April, will remain open till the conclusion of May.

PHOTOGRAPHIC PRINTING, OUTDOOR AND IN.

BY C. BRANGWIN BARNES.

It has often been a matter of considerable surprise to me that so many photographers should still conduct their printing in the open air. From the earliest days of photography it has been a recognised fact that the operating, or taking the negative, is more likely to prove a success in a studio than the open, but for some occult reason which I have never been able to discover, the subsequent operation of printing from the negative has always been looked upon as a very minor detail, requiring but little skill and capable of being conducted anywhere, and preferably on the leads or in the back yard or garden. Now a very little consideration will prove that this idea is an erroneous one, and that the erection of a studio for printing under glass, or the conversion of some part of a room into the same, will amply repay its primary cost, and that in a very short space of time. The advocates of open air printing will no doubt allege that prints are obtained more rapidly out of doors, and it is a fact that such might be the case if (Oh, those dreadful if's!) we had a climate where bright, dry weather was the rule, and rain, fog, and mist, the exception; but such not being the case, I contend that so far from time being gained by printing out of doors, the boot is decidedly on the other leg, as more prints can be obtained under glass, and, what is perhaps more to the purpose—where such a thoroughly conscientious set of human beings as photographers are concerned—the number will not only prove to be greater, but the general quality better. A terrible amount of time is lost to the out-door printer in rainy or showery weather; each little downpour necessitates the covering up of all the frames, and if the shower threatens to be prolonged they all have to be rushed indoors and wiped, and await another glimpse of brightness; and with such weather as we usually get at this time of the year, the covering and uncovering and taking indoors and out again of two or three hundred frames necessitates some considerable waste of time. In foggy or misty weather the moisture in the air condenses rapidly on the glass and materially retards printing, added to which the damp atmosphere also affects the sensitised paper, causing it to print red and weak. Occasionally a shower comes on so quickly that the frames are swamped before the printer can cover them, and a few drops of water find their way round the glass to the film side of the negative; the paper sticks and either necessitates the varnish being soaked off, or, in the event of the plate not being varnished, it requires re-immersion in hyposulphite of soda, followed by washing and drying: loss of valuable time again. Add to this the fact that the frames have to be hurriedly scrambled up, and that occasionally one falls to the ground and reduces the negative to fragments, such negative in nine cases out of ten being the most valuable one in print, and I fancy we have a strong argument in favour of inside printing.

In the summer, when we have less rain, the dust plays havoc, entailing constant dusting of the outsides of the frames, and even then it manages to get inside while the print is being examined. Then think of the numerous breakages caused by sudden change of temperature; a negative is brought in from a temperature of, say, 28°, the frame opened and the paper changed in a room warmed to about 50°, and it is then sent out again to be printed: there is a sudden ominous click, and the negative displays a crack from one side to the other.

All this might be avoided by printing under glass, and a printing studio can be erected at a very trifling cost when compared with what is cheerfully paid for the one in which the operating is performed. I have seen an arrangement which admirably answers the purpose required, in use at one or two studios I could mention, and which I may briefly describe as follows: A few boards are run out level with the sill of a back window to form a sort of flooring, and a glass roof is run from the level of the top of window sloping down to the end of the boards; this is extended about four or five feet on each side of the window opening, and is capable of receiving a considerable number of frames, which are thus protected from the rain, mist, dust, and change of temperature, added to which the printer is always at hand close to his work, and has not one half of the running about to do that falls to the lot of his brother who has to do his printing in the garden or on the leads. Platinotype and carbon printing benefit from this method of proceedure even more than albumen silver, or gelatino-bromide.

Should a bright sun glare upon the glass, a covering of white tissue paper is an advantage, as sun printing soon damages gelatine negatives. In the little island of Malta I have seen printing carried on through a covering of calico, so intense was the power of our best friend, the sun. However, it is a rare thing to get very much sunlight here in England, so it is advisable to fix even the tissue paper in a way that it can be easily removed and replaced. An excellent way is to stretch it upon little wooden squares just fitting into each pane of glass, and fastening with a button on either side, although one or two panes might always be kept covered during the bright weather for the purpose of printing the vignettes, which are always softer through tissue paper than when the aperture is uncovered. The best man to commission to erect the printing studio or box is one who is in the habit of building or glazing greenhouses, as they have a way of keeping out the water that the ordinary run of builders seem to be ignorant of, and it is necessary that such an erection should be water and dust tight.

A PHOTO negative bath dish has been patented by Mr. John R. Moeller, Grand Island, Neb. This is a dish with vertical end and side ribs, integral transverse ledges at the lower end of the end ribs, and a corrugated partition, to support a number of negatives in a single dish so that they will not bear against each other, while their lower edges will be held above the sediment in the bath.—*Invention.*

Nature calls attention to an "Album" which has been sent to it, containing reproductions of photographs taken in Celebes. "The collection has been formed," it says, "by Dr. A. B. Meyer, director of the Zoological and Ethnographical Museum of Dresden, and includes thirty-seven plates, on which about two hundred and fifty reproductions are printed. In 1870 and 1871 Dr. Meyer spent some time in Celebes, and the greater number of the photographs which have been reproduced he brought back with him. Others he has received from friends. We cannot say that the process employed has always yielded perfectly satisfactory results; nevertheless, the 'Album' contains many representations that cannot fail to interest students of anthropology and ethnography. There are groups of portraits from northern, central, and southern Celebes, and any one who carefully studies them will find that they give him a very vivid idea of the various types of the native population. The tables are accompanied by short explanatory notices, some of the best of which are by Dr. J. G. F. Riedel, Utrecht. The work is edited by Dr. Meyer, and issued by Messrs. Stengel and Markert, Dresden."

PHOTOGRAPHY IN HABANA.

The *Photographic Bulletin*, which is published monthly in Habana by the well-known depôt of photographic effects superintended by J. S. Lopez and Company, has already reached the last number of its eighth volume. Of this last number the most interesting contents are articles on eikonogen, contretypes, transparencies for the lantern on gelatine plates, and practical demonstrations.

The author of the article on eikonogen tells of his experience of this new developer, of its action on different combinations, and of its value, as he conceives it, in comparison with other agents. On the whole, he is of opinion that not enough is known of eikonogen to furnish matter for a definite and conclusive verdict, but so far as he has yet gone in his experiments, such hopes as he has formed about it have not been disappointed.

The exact place which eikonogen has to occupy in the photographic laboratory has yet to be determined; but there is no doubt in the mind of the writer of the article in the *Bulletin* that it presents brilliant qualities for the display of the most delicate details in the deepest shadows, requiring, as a rule, less exposure than is necessary with hydrokinone.

Discussing the various external forms of eikonogen, he says it presents itself sometimes as a grey crystalline powder; at others it discovers a deep, dark red with intersections; and again, at others, a colour known as *cenizas de rosas*, or ashes of roses. The colour of the solution differs, of course, according to the colour of the substance itself, and the experimentalist may obtain a dark vermilion, an intense green, and a green primrose, besides other still paler hues. The article, which is a long and interesting one, goes on to treat of the solubility of the agent, which, it says, varies about as much as its colour. As to the quantity of eikonogen to be employed, the author is of opinion that the published formulæ usually state an excess of what is actually required. In our own experiments, he says, we have found that a very small quantity of alkali gives results far superior to those obtained by a more concentrated solution. The nature of the alkali is unimportant. A caustic alkali may be used with the eikonogen, or a carbonate of potash or sodium. A formula for eikonogen is given by the writer, which, he says, produces peculiar clearness and brilliancy in the shadows. This formula is as follows:—

Sulphite of soda (cryst.)	...	...	194 grains
Carbonate of potassium	...	...	15 ,,
Carbonate of sodium ...	...	...	32 ,,
Water	...	...	8 ounces

The solution must be preserved in a well-stoppered bottle, and when required to be used, to every ounce of the solution must be added 6 grains of eikonogen. In place of the 15 grains of carbonate of potassium and the 32 grains of carbonate of sodium may be substituted, with excellent effect, 30 grains of carbonate of potassium. Bromide may also be added. This works very well on the bromised paper, and gives that crispness to negatives which is so highly prized by many artists.

The article on contretypes, communicated by M. Balagny, is of unusual length, and contains much profitable information; but the consideration of space forbids a detailed examination.

The practical demonstrations of E. de Saint Priest is another article which, owing to the same consideration, cannot be otherwise mentioned than as well worthy of an attentive perusal.

The volume of the *Bulletin*, which is concluded by the present number, contains many matters attracting the attention of the photographer. Especially may be mentioned the articles on mosaics, on colours in photography, on photo-miniature, on landscapes, on photography on wood, on the reproduction of old engravings, on the varied applications of photography, on the suppression of the red light, on impressions on clothes and other textile materials, and lastly, on the means of obtaining photographs in true colour relation by the medium of coloured crystals.

THE CHEMICAL PHENOMENA OF LIGHT.*

BY JOHN SPILLER, F.C.S., F.I.C.

As a past pupil of the late Dr. Percy, I have been permitted to read, and make extracts from, the photographic note-book of my old friend and much respected Professor, and I commence by acknowledging my obligations to the executors, who, through Mr. Hilary Bauerman, F.G.S., entrusted me with this very interesting record, and to Mr. George Shaw, of Birmingham, whose permission was freely given.

The account extends to twenty-three pages (quarto) in the note-book, and two extra pages fastened in, which are in the handwriting of our member, Mr. George Shaw; all the rest being in the clear manuscript of Dr. Percy, and illstrated by sketches of the apparatus used. The entries are arranged as a diary, commencing on the 28th October, 1844, and running on consecutively to some date beyond the 5th November. Then a break occurs, and there are occasional entries in later years—October 1850, and May 1853—with other suggestions for experiments, to which no specific date is attached. Further on the pages become a sort of general note-book, devoted to the entry of a variety of technical and metallurgical details, analytical processes, &c., with which Dr. Percy's subsequent career was so intimately associated. As showing the original intention, however, it should be stated that the cover of the book is endorsed "Light, October, 1844"—at a time when Percy was lecturer on Chemistry at the Queen's Hospital, Birmingham—and the first heading runs thus:—"Experimental Investigation concerning the Chemical Phenomena of Light. Record of Experiments, by G. S. and J. P., commenced on the evening of October 28th, 1844."

In some respects it was unfortunate that the work was begun so late in the year, for the weather on successive days was noted as "overcast and dull," "cloudy with slight rain," "dull November day," &c., and only on the 31st October and 4th November did the exposures get the full advantage of sunshine. But, on the other hand, it should be stated that the bulk of the experiments was comparative, and sometimes the slower action of the light enabled more accurate observations to be taken in the earlier stages than would have been possible under brighter meteorological conditions.

The first set of experiments was made with pure chloride of silver, precipitated from the nitrate by a slight excess of hydrochloric acid, and well washed with distilled water, by decantation, in the dark. The product was dried in a porcelain dish over a sand-bath, ground to powder, and divided out into several tubes;

* Read at the Photographic Society. The full title of this paper is "Early Experiments by Dr. Percy and Mr. George Shaw, on the Chemical Phenomena of Light."

the object being to expose them all simultaneously under various conditions, such as dry and moist air, or with dry hydrogen or ether vapour in sealed tubes; and, in one case, with potassium enclosed, so as to absorb any chlorine that might be liberated, as well as most of the oxygen contained in the air. In other words, this last tube was exposed in an atmosphere mainly of nitrogen, with an ingredient capable of taking up any evolved chloride; the potassium was not in contact with the silver chloride, but held back at one end behind a loose plug of asbestos. Details are given about the mode of drying the air, hydrogen, or other gas, and a sketch showing the disposition of the chloride of calcium and caustic potash tubes is appended. The sealed tubes prepared over night were left in a perfectly dark place until the next morning. The results (recorded by J. P.) were as follows:—

"October 29th. At half-past ten they were exposed in the open air to light; the sun was visible through the clouds, but the day continued overcast and dull. Darkening of the chloride rapidly took place in every tube, but so far as I could observe not more rapidly in one than another. They were turned round several times during their exposure to light, which continued until 4.30 the same day. From the fact of every particle of chloride not having been brought equally under the influence of light, part of the salt remained white, so that there was a mixture of black and white particles in each tube—hence the difficulty of estimating in a perfectly correct and satisfactory manner the precise degree of darkening that had been effected in each. However, that in *a* (ordinary dry AgCl, in a corked test tube) seemed to have undergone the *least* change, while that in *b*, *d*, *e* (hydrogen, nitrogen, and ether vapour) appeared to have been nearly equally affected; if anything, that in *b* (hydrogen) had been *most* altered."

There is no specific report about the final condition of tube *c* (that containing the *moist* chloride in a sealed tube), but it is evident that in this clotted state of the white chloride, the action of light at best must have been very partial. With regard to the influence of moisture, Dr. Percy goes on to say:—

"It must not be omitted that we cannot vouch for the strict correctness of the term *dry* chloride, employed in the preceding description, as we only dried it in a capsule over the sand-bath, and did not ascertain whether every trace of moisture had been expelled; so that if moisture had any influence upon the chloride exposed to light, the preceding experiments become unsatisfactory."

A second series of tubes was got ready for exposure to light on the following day; as before, five in number, but somewhat differently constituted. The chloride of silver was dried for six hours in a hot-water oven, and rubbed to fine powder for Experiment 1, or dried in the same way upon slips of glass for Experiments 2, 3, 4. Then arranged as follows:—

No. 1. Tube charged with dry AgCl in dry chlorine.

No. 2. Dry AgCl in dry nitrogen (*i.e.*, with potassium at one end of the tube, and fused chloride of calcium at the other).

No. 3. Dry AgCl in iodine vapour. (Turned yellow at once by partial formation of iodide of silver.)

No. 4. Dry AgCl in air with phosphorus. (This darkened before exposure.)

No. 5. Silver foil in dry chlorine. (The metal previously heated to redness, and dry chlorine gas passed over it for some time; the tube being full of chlorine when hermetically sealed.)

All exposed from 10 till 4 on October 30th (dull and cloudy day, with slight rain in the forenoon), and again from 10 till 5 on October 31st (a brighter day, with occasional gleams of sunshine).

Results.—No. 1 Tube. Scarcely perceptible change at the end of the first day, becoming sensibly darkened in ten minutes of bright sunshine, ultimately changing to an "ash grey."

Note.—October 31st, 1844.—"Now we learn from this experiment that, to a certain extent, the chloride of silver in chlorine affords an indication of the intensity of the chemical action of light; for that which underwent scarcely any perceptible change yesterday, became rapidly and sensibly affected to-day."

When put back again in the dark, the chlorine gas acted upon the coloured chloride, and in three hours it became perfectly white, ready to undergo a like change by repeated exposure. This observation induced Dr. Percy at a later period to propose the use of such an arrangement as an actinometer, which he described at the Photographic Society's meeting of June, 1853.—See this *Journal*, Vol. I., p. 84.

Nos. 2 and 3 tubes both changed colour to a chocolate brown, and, contrary to expectation, the iodide formed in No. 3 did not appear to retard the change, which the authors then supposed might be accounted for by assuming the existence of a chloro-iodide of silver sensitive to light, whereas pure iodide *per se* was known to be quite unaffected by exposure.

No. 4 tube also darkened considerably, and the phosphorous acid probably assisted the change, for it was bound to have had an influence even in the dark.

No. 5 tube, containing the chlorinated silver foil, acquired a beautiful iridescence by exposure to light, the film showing a play of colours, red or green, according to the direction of the reflected rays. The second day's exposure did not alter this appearance, but the *under* side of the foil began now to be attacked, and presented a dull leaden-grey colour. [Mr. Shaw repeated this experiment in a somewhat modified form, using Daguerreotype plates acted upon by the fumes arising from chlorine water. The results are described later on.]

A third series of tubes was now prepared, all charged with chloride of silver spread upon little glass plates, with the object of ascertaining whether the presence of moisture might have any influence. A pen-and-ink sketch shows the disposition of apparatus, with spirit lamp to warm the tube, and exhausting syringe to draw off every trace of watery vapour.

I. Dry AgCl in *dry* chlorine gas. Tube hermetically sealed.

II. AgCl in *moist* chlorine gas. Tube hermetically sealed.

III. Dry AgCl in dry air. Partial vacuum and tube sealed. Exposed simultaneously from 10.20 until 5 o'clock, October 31st; fine day, with gleams of sunshine.

Results.—The last rapidly changed colour (in ten minutes), and went on darkening. II. was more quickly discoloured than I., but the atmosphere of chlorine hindered the change; and the former (moist chlorine) proved most operative in bleaching the darkened chloride when the tubes were taken indoors at 5 p.m., and by nine

o'clock, as seen by gaslight, the white chloride was quite restored.

In order to set at rest this question of chlorine hindering the action of light, other experiments were arranged in which the white chloride of silver, dried upon a watch glass and covered with a flat glass plate cemented on with white wax, was exposed to light under a bell-jar, with corresponding apparatus beside it in which chlorine (and afterwards bromine) had access to the chloride of silver. The results were, as before, that only a slight darkening occurred when chlorine had access, and the bleaching at night took place as usual. The authors sum up as follows:—"We have now distinct proof that the vapour of chlorine does either retard, or otherwise modify, the chemical action of light. Is this owing to the colour of chlorine?"

Next came comparative experiments with bromine, in which a difficulty occurred from the bromine vapours attacking the wax, so the white chloride of silver was enclosed in hermetically sealed glass tubes, placed within bell-jars filled respectively with chlorine and vapour of bromine. Although the latter manifestly obstructed more light, it was found that the white chloride in the jar of bromine was *more rapidly and deeply coloured* than that contained in the jar of chlorine. "It would appear, then, (say the authors) that the modification induced in light, in its passage through an atmosphere of chlorine, does not depend upon the *colour*; because, if that were true, the degree of modification should vary directly with the intensity of colour, and should consequently be greater in the case of light passed through bromine, than in the case of light passed through chlorine."

Finally, the crucial test of exposing chloride of silver in sealed tubes, placed within a jar of *colourless* nitric oxide gas over water, and another one into a large stoppered bottle of the same gas, with occasional admission of air, so as to produce the *red* nitrous acid fumes, showed most distinctly that with the colourless gas the darkening proceeded as rapidly as in air; whilst in the deep red gas the darkening was completely prevented for some time, and only very slowly changed to a lead-grey hue as the ultimate effect of protracted exposure. Here the observed difference could only be accounted for by assuming that the highly coloured nitrous acid gases cut off the chemically active rays, and apparently did so much more thoroughly than the bromine vapour.

Experiments by Mr. George Shaw, November, 1844.—A couple of Daguerreotype plates was cleaned with dilute nitric acid and powdered tripoli, rubbed afterwards with dry cotton wool, and highly polished on a velvet buff sprinkled with charcoal powder. One of them was exposed, face downwards, for *thirty minutes*, to the fumes arising from chlorine water, and the other for *twelve hours* to the same treatment. Both were alike in appearance, coated with a deal-white film of chloride of silver, which was very compact, had considerable lustre, and reflected the images of neighbouring objects with tolerable distinctness. So prepared, half of the twenty-four hours' plate was covered up to protect it partly from light, and then both plates were exposed for several hours on a "very dull day, the sky thickly clouded."

The surfaces gradually changed to a moderately dark slate colour, neither approaching blackness or the tint assumed by precipitated chloride of silver under like circumstances. On the next day, November 4th, which was "very much brighter," the two plates were put out again, this time the half of the thirty minutes' plate being covered up, and both exposed for more than an hour to "hazy sunlight." They now suffered a very marked change; the slate-colour disappeared, and the surfaces assumed a rich brown colour, with very metallic lustre, closely resembling the appearance of old bronze medals, and those parts which had been longest exposed to light actually assumed a much *lighter* colour than the surfaces that had been partly protected.

Here the only circumstance calling for notice is the fact that Daguerreotype plates were sometimes made of rolled Sheffield plate, the upper layer of which was standard silver (containing about one-twelfth copper, and the sensitive surface was, therefore, possibly a mixture of cuprous and argentic chlorides, in which the latter largely preponderated).

Amongst other interesting suggestions given in Dr. Percy's note-book was a proposal to try, as a substitute for the amalgamation process, the extraction of silver from its ores by first attacking them with ferric chloride solution, and then dissolving out the silver chloride so formed with a solution of hyposulphite of lime. There is no record of experiments actually performed, but we know that the process was adopted later in the treatment of certain silver ores, before other improved methods came into general use.

"Indigotic acid in Calotype, Oct., 1850," is another entry, but it is not easy to guess the purport of such an experiment, unless it was an early idea of working with stained films.

"May 29, 1853. Photography. In the negative or positive impression in the Talbotype process, in what state is the silver? If it be *metal*, mercury should certainly remove it. Try the experiment. Is AgS soluble in KCy? I think not; if not, then after exposing a positive to HS it should not be obliterated by KCy. But is it not so?"

At this date I was an assistant in Dr. Percy's Laboratory at the Royal School of Mines, Jermyn Street, and I well remember some experiments being tried with hot and cold mercury to extract the silver from paper photographs, but it was found impossible to get contact with the liquid metal. I do not know whether mercury vapour was ever tried for the purpose of forming an amalgam, and then extracting this with the liquid mercury. On the second point, I also remember Dr. Percy toning some silver prints on plain paper by exposing them to sulphuretted hydrogen, and these were afterwards shown at one of the Society's exhibitions.

About this time Dr. Percy, being on the first Council of the Society, was frequently engaged in photographic experiments, and testing the permanence of silver prints, on which later he was invited to report.—See *Photo. Journal*, Vol. II. pp. 175, 190, 251.

M. Leon Vidal writes to us that he has just won the case in an action at law brought against him in Paris by Mr. B. J. Edwards, for certain criticisms on isochromatic photographs, published in the *Moniteur de la Photographie*, of which M. Vidal is the editor. The court considered that M. Vidal had not exceeded his right of criticism.

North Middlesex Photographic Club.—An outing has been arranged for Easter Monday to Welwyn, by the train leaving Finsbury Park, G.N.R., at 10.15. Any interested are invited to join. On Monday, Thomas F. Smith, F.R.M.S., delivered a lecture on "Micro-Photography," illustrating it by means of lantern slides, and showing the method of making the same. Both botanical and histological slides of interest were shown; some of them were enlarged 2,000 diameters.

EMULSIONS.*

BY WILLIAM BELL.

The accompanying formulæ for the preparation of a gelatine emulsion for photographic purposes are the result of several years of constant study and experimentation on the part of the writer, and it is believed that if the details of the process are strictly carried out with but an ordinary degree of ability, plates fully equal to the best brands in the market can be easily and uniformly prepared.

Ammonia-Nitrate Emulsion.

No. 1.—
- Boiled water ... ... 1 ounce
- Iodide of ammonium ... ... 5 grains

No. 2.—
- Chloride of ammonium ... ... 20 grains
- Water ... ... 4 drachms
- Acid, nitric, a drop or two to render the solution acid.

No. 3.—
- Nitrate of silver ... ... 60 grains
- Water ... ... 4 drachms

To the nitrate of silver dissolved in the water (No. 3) add, drop by drop, the solution of iodide of ammonium (No. 1), until the precipitate of iodide of silver formed ceases to dissolve in the solution. Then pour in the solution of chloride of ammonium (No. 2), wash the chloride of silver formed with three separate waters, draining each time; then add some pieces of broken glass to the moist mass, and then 16 grains of Nelson's No. 2 gelatine, and dissolve with gentle heat (temp. 90°—100°). Shake well, and add the following solution:—

- Water ... ... 4 drachms
- Bromide of potassium ... ... 43 grains
- Liquor ammonia ... ... ½ drachm

Pour this solution at one time into the bottle containing the melted gelatine and chloride of silver; cork the bottle to retain the ammonia. Keep at a temperature of 90° for fifteen to twenty minutes. Test the emulsion by a drop on glass, looking through by transmitted light from a match to see if all reddish colour is gone. When this has disappeared, and the emulsion viewed by transmitted light is greyish blue or green in colour, the heating has proceeded far enough; and then 120 grains of Heinrich's gelatine (previously softened in water, and melted at a temperature higher than 90°) are added to the emulsion. This is to be well shaken, and then allowed to cool by gelatinizing it slowly upon the sides of the bottle. Let it stand six hours. Re-melt at a temperature of 100°, gelatinizing again upon the bottle. Allow to stand six hours, and melt once more. It is now ready to be mixed with the boiled acid emulsion (see following formula). Or, if the ammonia nitrate formula is alone to be used, the melted emulsion, as just made, is to be poured into a dish, and allowed to cool and set: when cold, placed on a clean cloth (mesh 1-80 inch), squeezed through, the finely-divided mass well washed, drained, and pressed under weight to expel excess of water, re-melted, filtered through white silk, and then coated on glass. The final amount should not be more than three ounces: if more, then the gelatine has absorbed too much water in washing; to avoid this, press longer. In preparing this emulsion, it has been found that the presence of the bromide, with heat and free ammonia, favours the acid and alkaline emulsions. When the plates are coated, they can be immediately passed through a small opening into an adjoining room, kept at a uniform temperature of 50°, with free circulation of air, and dried either on racks or on nails on the wall, face outwards.

* Read before the Photographic Society of Philadelphia.

Glass.—This should be previously cleaned by soaking it in a mixture of equal parts of nitric acid and water, well washed, dried on racks, polished with cuttle-fish bone and water, using a piece of well-washed flannel. This should be washed with a weak solution of soda, so as to remove any traces of oil or grease. The plates, after being dried, should be edged with a thick solution of gum tragacanth, by means of a small camel's hair brush tied to a short thin stick, with the end of the stick projecting a short distance so as to act as a guide for the brush. The plates should then be stored in the hot room until wanted.

Filtering.—If this is done in the hot room, it can be accomplished by passing the melted emulsion through absorbent cotton; otherwise a hot-water jacket should be used for the filtering funnel, and the emulsion passed through well-washed white silk or cotton.

THE HAVRE PHOTOGRAPHIC CLUB.

In January, attention was invited in these pages to the circumstance that Havre, and more especially its adjacent town of Trouville, on the other side of the mouth of the Seine, offers attractions to those photographers who, when they have but three or four days' leisure, desire to spend that short time upon a foreign shore. Among London photographers, the popular landing-place for such a holiday has been Antwerp from time immemorial; Brussels, Malines, Ghent, Bruges, and Dinant being one or more of them also visited. Of late, the stream of brief holiday seekers has been slightly diverted to Rotterdam and places adjacent thereto. France alone, which is nearer to our shores than any other foreign country, seems to have its nearest seaport towns avoided by the greater throng of English photographic tourists, although Boulogne-sur-Mer is but three hours' journey from London, is exceedingly picturesquely situated, and presents to the photographer that attraction which he cannot get at watering-places near London—sunsets at sea. The reason of this disinclination of the photographer to make short photographic excursions to France is, no doubt, the uncertainty whether he will not unintentionally get into trouble on the plea that he is taking pictures too near fortifications, or in some way or other coming into adverse contact with French officialism. France is over-regulated. The troubles in which various harmless tourist photographers have found themselves in France, through not understanding local regulations and having no means of ascertaining them without losing half-a-day in the inquiry, have been from time to time published in the English newspapers, with the result that the feeling of "uncertainty" about having a spoilt holiday induces others to go as usual to Belgium, where they know that they will be well received.

We recently mentioned the existence of these deterrent influences to some of the officers of the Havre Photographic Club. They stated that, so far as they knew, anyone could take outdoor photographs of the interior of Havre, and they thought along the beach also, but would make inquiry, and send full information on the subject. The information will be welcomed, and, at the same time, they can state, perhaps, whether there are any impediments to photography in Honfleur, Trouville, and Caen. Recently we found none in photographing at various places on the lower reaches of the Loire, and found the people everywhere in that district polite and exceedingly friendly.

M. Goupil, honorary secretary to the Havre Photographic Club *(Photo-Club Havrais)*, sends us the report of its Committee of Administration about the work of the Club during the year 1889. The report sets forth that the Havre Photographic Club was founded at a meeting held on the 13th of June, 1889, and began to exercise its functions on July 1st following. The Club is composed entirely of amateur photographers, and has for its object the diffusion of the photographic art, and of all its applications. At the outset the Club had twenty-one members, and a provisional Committee of Administration, the functions of which expired at Christmas, 1889. The members of the committee were:—Mr. Emile Rougé, president; Dr. Perrichet, vice-president; Mr. David, treasurer; Mr. Acher, assistant treasurer; Mr. Albert Goupil, secretary; Mr. P. de Jonekheere, assistant secretary; and Mr. Soret, librarian. The premises of the Club were and are at 27, Rue de Normandie, and had been previously occupied by a photographer; the house has a *salon* suitable for meetings, a studio, and a laboratory: adjoining it is a large garden.

Messrs. Fleury Hermagis presented the Club at the outset with an excellent portrait lens three inches in diameter, and Mr. Mackenstein presented it a well-made camera. Mr. David, its treasurer, presented to it a picturesque background, and the Club bought a plain one. The studio is appreciated by the members, as most of them would have had difficulty in fitting up anything of the same kind at home.

The Club has three classes of members, namely, active, corresponding, and honorary. The active members pay an entrance fee of ten francs, and an annual fee of thirty-six francs. The corresponding members pay fifteen francs a year. The fee paid by each honorary member is not limited, but should not be less than ten francs a year. The honorary members have the right to a certain number of proofs, selected from among those exhibited by the Club.

The Club has developed rapidly. At the end of 1889 the number of its active members was 39, of its corresponding members 4, and of its honorary members 68—total 111. At a meeting of the Club held Dec. 20th, 1889, the following officers were appointed for the year 1890:—Dr. Perrichet, president; M. David, vice-president; M. P. de Jonckheere, treasurer; M. L. Poupel, assistant treasurer; M. Albert Goupil, secretary; M. Dorey, assistant secretary; and M. Soret, librarian. The Havre Photographic Club is prospering financially, notwithstanding the expenses of starting it. The Club had a public exhibition in Havre of the work of its members, which exhibition was open from Dec. 21st to Jan 5th last, in the Passage Bernardin de St. Pierre; the premises had been kindly lent for the purpose by M. Pellot. The exhibition was highly popular, and sometimes visited by more than 1,300 persons in a day.

At several meetings of the Club experiments have been made which have a bearing upon points in theoretical photography. M. Soret has made some experimental investigations in relation to the photographing of the electric spark. Several photographic excursions have been made by the Club, but all of them limited to the neighbourhood of Havre. During the early part of the present year a course of lectures on practical photography is being given every other Sunday, from ten o'clock until midday, in the rooms of the Club, and it is expected that these lectures will considerably augment the number of its members.

EXTRAORDINARY ASSERTIONS.

A circular has been handed to us entitled, "The New Colour Process in Photography," purporting to contain matter reprinted from *Brighton Society* of Saturday, August 31st, 1889, as follows:—

"Plain photography has made rapid advances within the last few years, and many efforts have been made by the photographic scientist, both at home and abroad, to produce a combination of the chemical action of light upon the plate and the colour vibrations that will suit the light and shade of the image. Further, the aim of experimenters has been to produce these colour effects upon the negative alone, but not with much success. Professor Ives, of Philadelphia, has laboured for years in this direction, but he has been obliged to confess that the results are evanescent. I have, therefore, much pleasure in drawing attention to the discovery of the new colour process in photography which has been made by Mr. J. E. Mayall, beautiful specimens of which may be inspected at his studio, 43, Cannon Place, Brighton.

"He has started on a new basis. Aided by spectrum analysis, he has produced a film which registers every vibration of light from the deepest red and green through the whole gamut of the spectrum to the violet and grey rays of Sir John Herschel. When this film is looked upon at an angle, the vibrations of light can actually be seen on the negative. In the process of completing the photograph these vibrations are transferred to the positive film, which registers with great accuracy the vibrations of the image. Thus he has sub-divided the subject into negative and positive photography, and by applying highly attenuated forms of colour to the delicate vibrations which the light has made—and which colours assimilate themselves to the image—he has succeeded in producing a picture in which the lights and shades of the original are brought out with an accuracy unapproachable by any other method. The colours are attenuated to the 180,000th part of a grain, and are sufficiently transparent to fill up the interstices of the portrait which the light has made. Professor Owen, who has inspected Mr. Mayall's new process, says:—'It suggests the conditions whereby the thousandfold varieties of colours are selected by flowers. I gaze upon my garden as if I had a new sense. Those conditions had never been the subject of a thought when I entered with my neighbour Chadwick your studio. But when I received evidence of the process by which not only forms, lights, shades, but also tints, in finest gradations, had been secured in the photograph before me—a second self-living and gazing at me—I began to feel that you were leading the way to a cognition of the subtle *modus operandi* to which we are indebted for the countless beauties of feathers, scales (of butterflies), and flowers that adorn our world.' Amongst the specimens I have seen at Mr. Mayall's studio, and which it should be mentioned are produced in a few minutes, are several which exhibit all the delicacy and finish of a high-class miniature by Cosway.

"Mr. Mayall possesses many high testimonials to the importance of his discovery, besides that referred to above by Professor Owen. Among them is one by Dr. Thudicum, the organic analyst to the Government. Mr. W. H. Wallen, the expert in the Patents Office, having made an elaborate and exhaustive report upon Mr. Mayall's new process, says, 'The conclusion at which I gladly arrive is that Mr. Mayall's process is the most perfect of its kind, both in regard to its perfection of optical form, its selection of the precise colour of the sitter, and its permanency.' A good deal of Mr. Mayall's success in the production of this new artistic process lies in the fact that he has discovered the way to help Nature, and that being so, there can scarcely be a doubt that the result being so beautifully effective, it will soon supersede every other method of colouring."

One would like to be informed if the writer of the foregoing knows anything about light or photography, and if so, whether he or anyone else will show the vibrations on the negative of which he speaks at a meeting of the Photographic Society; also the production of a positive image by the transference of the said vibrations, as stated.

WITH THE LUSHAI FIELD FORCE.*

BY T. D. LATOUCHE.

Leaving the Kurnafuli, with the *dolce far niente* of its dugouts, at Demagiri, and following a bridle-path made by the expedition of last year, we plunge at once into jungle as dense as any to be found in India. How the engineers managed to find their way through it is astonishing, considering they were seldom able to see more than a few yards ahead, and the hills are cut up by innumerable ravines in bewildering fashion. For the greater part of the distance to Fort Lungleh, forty-three miles, there was not a vestige of a former path. The immense trees, with hundreds of huge creepers hanging in festoons from one to the other in wild confusion, with the path winding beneath them, present one with pictures of great beauty at every turn, but it is impossible to transfer these to the camera, at any rate to a detective, as the dense canopy of leaves overhead shuts out the greater part of the light, and an instantaneous exposure results in a blank plate, or one showing the faintest possible image. Moreover, one view of such jungle is so like another, though all are beautiful, that it requires something of the human element to make such a scene interesting enough for a picture, and it is only where one can bring in a string of coolies or mules on the march, or a camp with its background of trees, or a stream crossed by a bamboo bridge, that one feels inclined to bring the camera into play. Such scenes are not wanting on a march like the present, but at ordinary times the main attribute of the jungle is its vast loneliness, and silence too, for it is surprising how few signs of animal life, even of birds, one can detect.

Fort Lungleh is built on a narrow ridge at an elevation of 3,500 feet above the sea, near the site of an old Lushai village, Saipuya's. It is surrounded by a stockade of upright timbers, within which the huts occupied by the force of the Frontier Police, who garrisoned it during the last rainy season, make a picturesque group, but its cramped position renders it difficult to get a good view of the whole work. There is a magnificent view to the north down the valley of the Dullesary or Klong river, and to the east, in which direction lies the goal of our hopes, the village of Haka, which a column from Burma is also making for. Hills piled on hills in endless confusion make up the view, all covered with a uniform expanse of dark-green jungle, amid which patches of brighter green show where the ground has been "jhúmed," or cleared for cultivation in former years, these patches being now covered with a dense growth of bamboos. A few brown patches also show where the forest is being cut down for this year's cultivation, and, with a good glass, near these a villager can generally be discerned. The large, neatly-built bamboo huts, supported on piles, like most of the hill villages of Assam, stand well out from the surrounding jungles. Most of those in sight belong to so-called friendly villagers, to whose friendship, however, it would not be well to trust in most instances without an escort at one's back. But some of those near Lungleh have shown their sincerity by assisting in cutting a road through the jungle to the north, prompted no doubt by self-interest, as the chief Lieupunga, whose village lies in that direction, is almost as much an enemy of theirs as of the British.

I accompanied a reconnaissance party sent out to inspect this path, which we found was cut along the banks of the Klong river, flowing due north towards Cachar, where it goes by the name of the Dullesary. For two marches we were able to use bamboo rafts, and numerous were the pretty views which we came across as we rounded bend after bend of the river. Some of these, when a raft or a string of coolies fording the river could be brought into the picture, were duly transferred to the camera, also a "jhúm" hut, in which we spent a night, and a group of friendly Kuki chiefs, who came down to interview their friend, Mr. Murray, our popular political officer. Altogether we were away from Lungleh for eight days, and had a very pleasant time.

After a long delay at Fort Lungleh, waiting until a sufficient length of the road ahead should be completed to make it worth while to move on, I came on as far as the camp I am writing from, which is about twenty miles from the Fort, and situated on the Mât river, a fair-sized stream which joins the Koladyne some miles below. Here there is some good fishing to be had, or rather was, for, after the first few days, when the bag included a 20 and a 17-pounder, the fish have unaccountably stopped running, and not even the most artfully thrown spoon will now induce them to leave the depths of the pools they live in. The scenery on this river is very fine, the hills being more precipitous and rocky than those on the Klong, and there is plenty of work for the camera along its banks.

Since coming up here I have seen two other forms of the detective cameras belonging to officers of the expedition. One of these is the Kodak, which is no doubt a handy little instrument, and if the paper it contains could be depended on, would be a capital sort of camera to carry with one where every extra ounce of baggage has to be considered; but, on development, none of the pictures taken with this one were entirely successful; in fact, it was difficult in some cases to make out what the picture was meant for, and the paper showed the same whitish blotches that I described in a letter written to the journal some time ago concerning paper negatives. The other camera is one of those circular "secret" affairs, which take six small pictures in succession on a round plate; I developed one or two of these for the owner of the camera, but though the image came out fairly well in some cases, the plates frilled so badly that they were of no use whatever. On the whole, I think that an ordinary detective, in which plates of an admittedly good description can be used, is the best to take on an expedition of this kind, and I am well satisfied with the performance of my "Optimus." By the way, I see that Messrs. Perken and Rayment have brought out another form of this camera, in which there is an arrangement for bringing each plate into position for exposure without opening the camera, but it seems to me from the diagram given with the advertisement that it must add considerably to the bulk of the camera. Can any reader of the journal speak from personal experience of the performance of this new form, and if so, will he, of his kindness, publish his opinion of it?

Camp Mât River, 10th February, 1890.

The Library Catalogue for 1890 of the Photographic Society of Philadelphia is to hand. The introductory notice says that "a noteworthy feature in the Library is the number of complete sets of journals, dating from the earliest days of the art down to the present time. Although separate text-books of the various branches of photographic science are not wanting in the Society's collection, the journals—which detail the progress of the art from day to day—still remain the most useful sources of information."

* From the March number of the *Journal of the Photographic Society of India*.

Notes.

Photographers who make a speciality of copying pictures have been excessively busy during the past fortnight, and will continue to be so until "sending-in day." Indeed, it is said such is the desire for artists to have their pictures photographed, that work has been turned away. No doubt the fashion of illustrated catalogues has led to this rush of business. Unquestionably artists are immensely the gainers by the publication of copies of their exhibited pictures, and they are now not contented with the sketch notes made by themselves—which were once considered sufficient—but prefer to have the originals photographed and reproduced by the Meisenbach or some analogous process. Their practice, however, of delaying the completion of their works until the very last moment rather hampers the photographer, who finds himself inundated with commissions which he is unable to execute in the limits of time allowed. Very few—if any—artists who are also photographers photograph their own pictures. As everyone knows, copying with the camera is a special study in itself, and a study which requires infinite judgment and knowledge of the relative value of tints.

Apropos of the illustrated catalogues, the majority of the artists make no charge, and make no objection to copies of their pictures appearing. One or two, on the other hand, take a keener view of the matter, and stipulate for a fee. We do not see why they should not. Though the illustration may benefit the artist from an advertising point of view, the publication of an illustrated catalogue is purely a business affair, and, we presume, is not run for the benefit of the artist, but for the benefit of the publisher. Why, then, should the latter not pay for his material? Of course, in fixing the price, the value of the picture to the artist as an advertisement would be taken into account.

"The "International Cyclorama," the title of a species of entertainment now being given in London, seems to indicate a revival of the stereoscope, which for some years has fallen into disfavour so unaccountably. To see the "Cyclorama," the visitor seats himself in a chair, and looks through a pair of lenses fixed in a large circular cabinet. A series of instantaneous views then passes before his eyes, sufficient time being given to enable him to thoroughly take in the points of the pictures. The pictures now on view illustrate the scenery of the Rhine, and the Paris Exhibition, and it is intended from time to time to replace them by other series illustrating other European countries.

Taking snap shots with an instantaneous detective camera is very much like shooting a bird on the wing. We are inclined to think that dependence on "finders" is of not much use, and that to be successful in "shooting folly as it flies," one must get accustomed to act almost by instinct. A good instantaneous photographer is more likely to be born than made. A writer in a sporting magazine, relating his experience in shooting, somewhat bears out the theory. When he commenced trap shooting he "thought it was necessary to lay my cheek down on the gun stock and screw around until I got my eye and the sight in a line with the object." The result was that he was more often at the foot than at the head of the class. Then he got reckless and fired without taking all this trouble. To his surprise he smashed the glass ball at which he fired, and having got hold of the idea, he afterwards seldom saw the sight or even the gun when he pulled the trigger, and his success was surprising. Applying the same plan to field shooting, he found it succeeded. "Of course," he remarks, "allowance must be made for birds crossing, rising, or falling, but that is instinctive, and seldom thought of by our most successful shots. Indeed, thinking has little to do with it. If it had, one's bird would be out of range before he could collect his thoughts." This puts the matter on all fours with instantaneous photography. The action of exposure must be simultaneous with the sight, or the much desired picture disappears.

The possibility of photographing a horse race at the winning post has often been talked about. The new racing club at Hurst Park, shortly to be opened, intends to try the thing practically. A new "patent camera" is spoken of, with which it is proposed to take instantaneously the "finishes," while additional instruments will be also stationed at various jumps on the course. So enthusiastic are the believers in this "patent camera," that a syndicate of well-known persons has been formed to work it commercially.

The attention which Mr. Herbert Marshall's studies of London are exciting shows how attractive and popular are pictures of life in the great metropolis. The camera has been employed times out of number, but although photographs admirable in execution and artistic in arrangement have been taken, these are very few compared with the great mass of mediocrities. To render London properly requires much patience and a good deal of luck. It is so rare that the traffic takes the exact disposition necessary for a well-balanced picture. The murky atmosphere, even on sunny days, very frequently spoils all the photographer's efforts. We believe that the proprietors of one of the illustrated papers some time ago contemplated a series of reproductions from photographs, but gave up the attempt because they did not come up to their idea of what constituted an artistic picture. London has yet to be photographed. Hitherto it has not had justice done.

Photography appears to great advantage in connection with some experiments made on the Continent with smokeless powder. To show the difference between a volley fired with the ordinary powder, and the new variety, photographs were taken at the moment the commander gave the order to "fire." In the case of the first named, a thick, black cloud is represented, through which the gunners are barely perceptible, while, in the second case, only a thin haze is noticeable.

PHOTOGRAPHY IN FLORENCE.

The *Camera Oscura* or Monthly Review of the Progress of Photography, which is published at Prato, near Florence, under the able supervision of Professor L. Borlinetto, with the calloboration of Professors L. Meil, Piccioli, A. Rossi, G. Jankovick, D. Ratti, L. Ciardelli, Sac. Sobacchi, D. Leuzi, Danesi, G. Glisante, Dr. L. Gioppi, and its energetic editor Germano Salvi, is now entering its eighth year of life. No Italian photographic journal born in Italy can boast of an equally long existence. It has not, indeed, escaped the sickness and various maladies which infest, unfortunately, adolescence. There have been times—disastrous epochs, says its editor—when this journal has seemed to be threatened with the adverse fates of the family of Saturn. It has on some evil days presented the appearance of a child desiring to devour its own progenitors, but such an accursed hunger and infuriate longing has been happily stilled without any sacrifice of artistic life; and the *Camera Oscura*, with its mystic motto taken from the pages of G. B. Porta. . . *Ex qua maxima natura si nobis illucescere possunt*, still lives, and is doing well. *Resistance at every cost* is, we are told, the motto blazoned on its ancient banner, and this motto the editor is determined to flaunt in the face of adversity, and to maintain in its full significance, undeterred by any expense and undismayed by any sacrifice. As a handsel of this heroic sentiment the readers of the *Camera Oscura* are promised a carbon photograph with the signature of the illustrious Italian statesman Quintino Sella, the work of Luigi Luzzati, a name well known in Italy and elsewhere.

The present number of the *Camera* opens with an article by Bettini on a subject of great interest to every professional photographer—the artistic property in photographic works.

A committee, it appears, was formed in Italy in the year 1855, under the able presidency of Carlo Brogi, of Florence, for the sake of obtaining from the Government some legislative disposition for the legal protection of works of photography. After much expenditure of time and labour, a letter was received by the committee from the Minister of Agriculture, Industry, and Commerce, to the effect that as the law with regard to intellectual labours included those of photography, any new legislation was inexpedient and unnecessary. Like other artistic works, such as painting and sculpture, photography deserved to be, and was, in the opinion of the Minister, under the tutelary ægis of the law. Like painters, photographers also had their exclusive rights to publish and to reproduce. The only difficulty was to distinguish counterfeit or imitations where several photographers possessed a copy of the same monument, statue, or picture.

This, however, in the opinion of the Minister, was a question rather of a juridical than of an administrative nature. A competent jury well acquainted with photographic details would, in the majority of cases, have amply sufficient data to pronounce their verdict as to whether any given photograph was or was not a counterfeit or imitation. In fine, the Minister assured the President of the Committee that he had determined to admit registration in the case of photography for the preservation of the author's rights, whether in the matter of original works, or of photographic reproductions.

Notwithstanding all this, Signor Bettini declares that arbitrary reproductions and counterfeits are as frequent as ever. He utters loud lamentations. But if it be any consolation to him to have companions in misfortune, he has many. It is not in Italy alone that proprietors, as he complains, of leading photographic establishments condescend to reproduce the work of others solely for the sake of illicit profit. And indeed it is time, as he affirms, to put a stop to such abuses and infractions of the law. Men who are capable of such dishonesty should, says Signor Bettini, not only be denounced at the bar of public opinion, but also legal proceedings should be taken against them under the statute which covers with its protecting shield all intellectual arts and labours, among which photography, as has been already shown, is to be numbered.

The next article in the *Camera* is the continuation of an instructive communication on Instantaneous Photography, giving practical rules about its expedition, rules which are at the same time exceedingly simple, and would, if borne well in mind, prevent the occurrence in the photographic laboratory of many vexatious mistakes. They all rest on mathematical considerations, by which their exactitude may be verified. The concluding article in this number treats of the Development of Latent Images.

A WRITING INK PRINTING PROCESS.

BY GENERAL JOSEPH B. BROWN.

In looking over my note-book to find some subject in order to comply with your request for an article, I came upon the appended particulars, which, you will see, were written for publication quite *ten years* ago. As I was not quite satisfied that I might not still farther perfect the process, or at least render the manipulations so exact as to ensure uniform and constant results, I deferred making it public till I had further leisure for working it. But circumstances prevented my ever taking it up again, till it was, in the pressure of other duty, absolutely forgotten. But when I found in an old portfolio some of the prints then made by the process so well preserved, and so superior to any specimens which I have ever seen resulting from the attempt to get black tones from "blue pictures," or to tone or dye the faint but beautiful prints upon plain bichromated papers, I have thought that this process deserves some attention and may be of interest, or possibly lead to a popular process. Samples of the prints then made I enclose. Remember, these prints were made ten years ago, and though "ink pictures," they were but slightly deteriorated in tone—a slight treatment with a weak gallic acid solution has brought them up to their original strength, and I see no reason why they should not, even after the lapse of fifty years, be restored in the same manner should they become faded, which is more than can be said of any silver print.

I intend, at my earliest leisure, to work at this process, according to my original idea, till I can ensure exact results, for as you will see by an examination of the prints enclosed, the effect is due to the action of light in rendering the chromated albumen insoluble the same as in pigmented gelatine in the carbon print, and of course it is liable to the same mishaps of over-exposure, rendering the whole insoluble, or of under-exposure when the carbonate of soda would remove everything, instead of producing the proper gradation to receive the required degree of staining or dyeing.

I remember that I had the best results from the use of a weak solution of gallic acid and a prolonged development in the iron bath.

Since Mr. Mungo Ponton, in 1839 or 1838, published the method of producing photographic prints by exposing papers coated with bichromate of potash under a negative to the action of the light, experimenters have never ceased their endeavours to render this agent the basis of some process by which it could be made to take the place of the salts of silver for positive prints. Its extreme solubility in plain water, by which the portions unacted upon by light can be so perfectly removed from the paper, is its immense advantage, since the silver salts require a special solvent, which itself is difficult to remove from the paper after it has done the like office for the silver, and which is unquestionably one of the chief causes of the want of permanence of silver prints. The process of Mr. Ponton gives but feeble images, and though most beautiful for their minuteness of detail and exquisite gradation, are of no practical value as pictures.

Twenty-five years ago Mr. J. Perry, an English gentleman, thought he had accomplished the business, and patented his process, which was exceedingly ingenious, and made use of some very interesting chemical reactions. His process was this, briefly:—After the original bichromate print was thoroughly washed, it was placed in a solution of protosulphate of iron, and then, after washing, was treated with gallic acid solution, which developed an "ink picture." It was found impossible in practice, however, to preserve the purity of the whites of the picture, or to prevent the paper from being irregularly stained, and the tone of the "ink picture" was also far from agreeable.

Innumerable attempts have since that time been made by French, German, and English experimenters to overcome these defects without success, till this process and its allies have been wholly abandoned.

The "Foxtype" was patented, depending upon the reaction of aniline upon oxide of chromium, but it would not give half-tones, and was only suitable for map reproductions and line work, such as the multiplication of plans. After the fact that bichromated gelatine is made insoluble by the action of light was known, and the "carbon print" was gradually brought to perfection, the use of the bichromates as printing agents was wholly given up, except in connection with some form of gelatine and pigment printing.

I find, however, in the Photographic News (British) of October 7th, 1876, a communication from the government photographer in Madras, India, describing a process for developing bichromate and gelatine prints, without pigment, by means of protosulphate of iron and pyrogallic acid, in which he claims to have succeeded in preserving the purity of the whites by glacial, acetic, and citric acids. This claim, however, proved fallacious in the hands of others.

Mr. Wharton Simpson, in an editorial, recapitulates these failures above-mentioned, as well as his own, and suggests that the only method by which the staining of the paper can be prevented would be to combine the process of dyeing, or developing, with single or double transfer, as in Mr. Swan's carbon process, suggesting logwood infusion as a promising agent for effecting the dyeing of the chromic image. No success has met this plan, it is evident, for nothing has been heard of it since that time.

In the last number of the Scovil Manufacturing Company's *Photographic Times* (January, 1890), a very pleasantly written article appears, by a gentleman who calls attention to "an unrecognized bichromate process," describing the old patented process of Mr. J. Perry, and speaks of it as "my process"! It is undoubtedly a most interesting adaptation of a well-known chemical reaction, from the cheapness of the salts used a great acquisition, and, if it could be freed from its apparently inherent defects, would be likely to supplant, for many purposes, the silver print. Its permanence is quite certain.

The platinotype process of Mr. Willis displays reactions of great beauty, and is, doubtless, all that its inventor and advocates claim, but it requires rare and expensive chemicals, and cannot be easily extemporaneously prepared by the average operator; it entails much extra trouble in preparing and using the hot developer, and for these reasons will demand much time and persuasion to supersede silver printing. The process, as originally given, called for silver salts and necessarily for hypo for their elimination, but the improved method dispenses with both, and it is therefore the most promising competitor to silver that has yet been proposed.

The new modification to Mr. Perry's process, which I have worked out, requires:—(1) Double albumenised paper; (2) saturated solution of bichromate potash; (3) protosulphate of iron; (4) carbonate of soda (washing soda); (5) gallic acid.

Float the paper on the solution of bichromate, with the albumenized side uppermost, for ten or fifteen minutes, taking care that nothing soils the upper surface. Drain and dry, preferably by radiant heat. When dry it is very sensitive, and must be carefully shielded from the light. Expose under the negative one-third of the time required for a silver print under equal conditions.

From printing frame immerse in a large quantity of pure water for ten minutes. From this time all operations can be conducted in full daylight. Change water and soak as before till every trace of unaltered bichromate is gone. Immerse in a pan containing a solution of protosulphate of iron, twenty grains to one ounce of water, for five minutes. Then place in a moderately strong solution of carb. soda (washing soda) for one-half to one minute. Wash thoroughly, and, lastly, place in the toning bath of gallic acid, three grains to one ounce water. The colour changes slowly up to full purple black, and if the soda detergent has been properly proportioned in strength to the action of light in the printing —*i.e.*, stronger for over-exposure, or weaker for under-exposure—every detail of the bichromate print will be exquisitely preserved, and in any event, the whites of the print will remain perfectly clear, and the paper be unstained. Wash in a few changes of water, and hang up to dry. Should there be any cloudiness of the whites after drying, the print may be again treated with a weak solution of soda with advantage.—*The Beacon*, Chicago.

Hackney Photographic Society.—The annual soirée of this Society is announced for the 21th inst.; this will conclude the first year of the Society's work.

The Calcutta Photographic Exhibition.—The *Journal of the Photographic Society of India* states, in relation to the late Calcutta Photographic Exhibition, that the judges have awarded a silver medal to Mr. B. G. Wilkinson, London, for his set of twelve lantern slides, and, in the Indian amateur class, a certificate of honourable mention to Mr. J. W. Wade, Cochin, for his set of fourteen lantern slides.

PHOTOGRAPHIC APPARATUS.

Mr. Eastman is now in London, and has been in this country for a few weeks. With the introduction of the Eastman Co.'s rollable celluloid film has been the advent of several new hand-cameras of the "kodak" type, which all put less tension upon the film than was the case when films supported by paper were alone used. The new kodaks take rectilinear instead of circular pictures; one camera takes a quarter-plate, and another a 4 in. by 5 in. plate. Each camera has two finders, one for use when the plate is vertical, and the other for use when it is horizontal. The camera has a focussing device, and a doublet lens with three diaphragms. The new cameras are made in four sizes, and will carry transparent film enough for either 48 or 100 exposures. For the four sizes of camera, there are but the two sizes of plates already mentioned. The new kodak for round pictures carries a film for 100 photographs, has a fixed focus lens, and one finder.

Mr. Eastman has brought with him from America a new "kodak" for 7 by 5 inch plates, which camera at some future time will appear in commerce. It carries enough film for forty-eight exposures, and has a lens of six inches focal length, with a pointer and scale to assist in adjusting the lens to focus. The side of the case containing this camera opens, and falls into a horizontal position, permitting the front and bellows to be then drawn out.

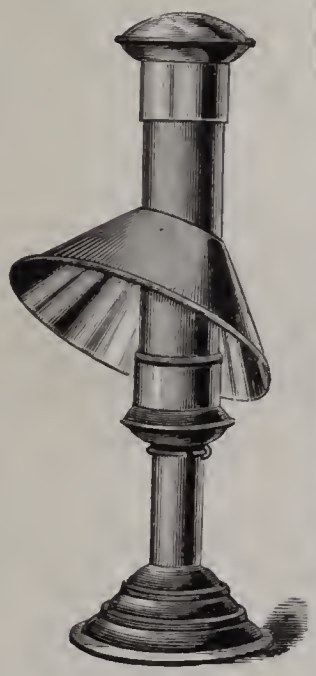

Fig. 1.

Messrs. Mawson and Swan have sent us a specimen of the developing-room lamp shown in fig. 1, the merit of which lies in its simplicity and cheapness. The lower part is a spring candlestick, which keeps a carriage-lamp candle flame always at the same level; above this is a cylindrical chimney of ruby glass, with a conical tin reflector hanging upon its exterior

Mr. J. Fallowfield's "facile" detective camera is not quite new, but has not been previously described in these pages. The instrument has been in public use for some months, and the chief merit of it is its extreme simplicity. The plate-changing arrangement consists, as represented in fig. 2, of two boxes, one above the other, and as the feeding, or upper box, is moved forwards, the lower box travels backwards; thus, when one plate has been exposed, it is drawn backwards; another sheathed plate drops into its place from above, through a slot, and is then brought to focus; and so on until the charge of plates is used up. The shutter of the "facile," which is represented in fig. 3, is also extremely simple; it consists of a light, fan-shaped piece of metal with a curved aperture near the top; this is pushed backwards or forwards to make the exposure, by either the one or the other of two light rods which project outside the box.

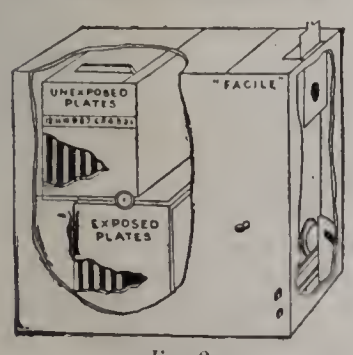

Fig. 2.

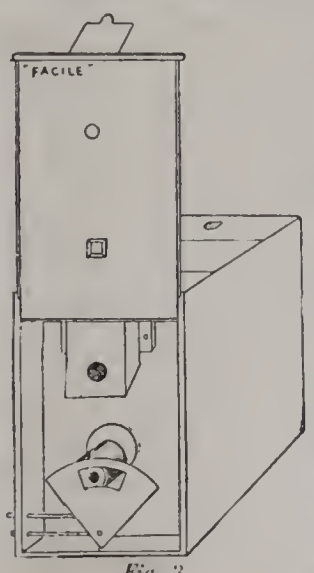

Fig. 3.

Mr. Fallowfield has introduced a light walking-stick tripod stand, represented in fig. 4. When the walking-stick has closed, it carries a long tubular top or lid. When this tubular top is drawn off, and turned bottom upwards, it will screw on the top of the tripod, and thus add to its height; by this ingenious method, which was invented by Mr. Baker, of Wallington, a fairly high stand can be closed to form a walking-stick of but moderate length. Mr. Fallowfield asks us to announce that before long he will move his establishment to new premises in Charing Cross Road, London.

Fig. 4.

Messrs. Skinner & Co. have exhibited to us a camera, fitted with an appliance, represented in fig. 5, by which the bellows can be racked out with much greater speed than usual. A toothed wheel, instead of the usual milled head, is fixed at each end of the pinion, and has a folding handle by which it can be grasped by the fingers. Several teeth of this wheel bite the rack at once, so give steadiness of motion, and the large diameter of the wheel, which is about that of the ordinary milled head, causes the bellows to be expeditiously racked out. The camera has also a fine adjustment.

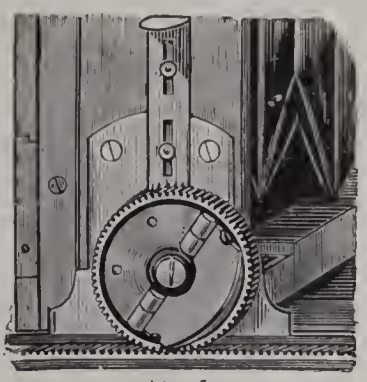

Fig. 5.

A paper in the *Bulletin de la Société Chimique de Paris*, by W. Spring and M. Lucion, says that manganese peroxide should not be represented by the formula MnO_2, but by Mn_2O_4, and it is very probably a manganous manganate MnO, MnO_3, or a manganese permanganate $Mn_2O_7 3MnO = 5(MnO_2)$.

A Detective Pencil.—"Our Celebrities" gives the following account of Mr. Harry Furniss's method of seizing points for caricatures:—"I take them how, and when, and where I can. I never let my victims know I am on their trail. Sometimes they are riding in the park, sometimes they are just getting into a train, or they are chatting to a friend in the lobby, or fast asleep in the House during some very dry debate. It doesn't matter to me; all I strive to avoid is the conventionality of a photograph. You see, a photographer may often lose all the salient points which go to make a man's individuality. I seize them all, and the result is that, in nine cases out of ten, I will produce by far the best likeness. But, mind you, it isn't always easy work, even with the same men."

THE PHOTOGRAPHER OF THE FUTURE.

While not fully sympathizing with those who write and talk about the alleged state of degradation into which photography has fallen, we are aware that it is low enough to make thoughtful photographers anxious, although it does not appear to deter the thoughtless from entering the ranks in numbers altogether out of proportion to the increase of the population, or the enhanced demand which may be expected from increased culture. In every large city, and in many of the smaller ones, too. there are men who do excellent work and get fair prices for it, but it must be confessed that they are but a few among the many; while the rank and file, or at least a large proportion thereof, can command little more than a trading profit on the material employed, which too often, alas! is really more than it is worth.

The alleged causes of this unfortunate state of matters are perhaps as varied as the men who proclaim them are numerous, but a careful consideration of the question will resolve them all into one—over supply. Photography in its trade aspects is not different in any essential feature from other trades, and is influenced as they are by the relation of supply and demand, and while, to a small extent, the former may create the latter, the effect will be small indeed compared with the influence of the latter over the former.

The cheapest of the so-called "cheap Johns" is neither the knave nor the fool that he is sometimes represented to be. He is simply a tradesman who has embraced a calling the members of which are already too numerous, and realizes the fact that wherever there are more workers than work, the work will go to the worker who offers the greatest inducement to the employer. In the case of the photographic worker the possible inducements are only, or mainly, two—better quality than the average, or lower price. Improvement in the quality or style of work is frequently, perhaps generally, beyond the reach of "John," and he knows that although it were not, the public, or a large proportion thereof, are not yet sufficiently cultured to appreciate it, and so has recourse to the other alternative, and reduces his prices to attract work that would not come to him without such reduction. In other words, the photographic labour market is overstocked, and so long as the trade aspects of photography bulk as largely as they do at present in the practice of the art, the man or body of men, by whatever high sounding title they may assume, that promises to cure or even ameliorate this unfortunate state of matters by secret methods, or methods other than those that may be legitimately applied to ordinary commercial transactions, should be disregarded as but sounding brass and tinkling cymbals.

In the good old days, when the practice of photography was profitable, and technical excellence not so easily reached, the portals by which the business was entered were either the good and time-honoured apprenticeship, by which the pupil agreed to give four or more years of labour, in return for which the master became bound to initiate him into all the mysteries of the craft; or by the payment of a tolerably large sum for the required practical instruction, followed by much patient and persevering practice, until the difficulties and uncertainties of the various processes had been overcome. Both of these methods of preparation for the life work were costly, and involved the ability to spend a considerabls portion of unprofitable, or rather unpaid for, time, and consequently the additions to the ranks were rarely in excess of the work waiting them. Then, too, the general public were less critical and more easily satisfied, looking on a photograph as simply a photograph, and considering the productions of one man just as good as those of another; so that the hands of a favoured and abler few were not, as now, crowded with all that they could do, while the visitors to the many were and far between.

All this is changed now. The introduction of the dry plate and simplification of the various processes have made the acquirement of the ability to make photographs sufficiently good to please a large portion of the community an easy matter; and the cost of apparatus that will, at least, answer the purpose has been so much reduced that any one of average ability may, and hundreds during the last year or two have, after a little reading, or a few practical lessons, started as full-fledged photographers, and thereby doubled, or perhaps trebled, the number of professional photographers actually required to do the work of the country.

But there is nothing either morally or legally wrong in this. In a free country the practice of trades and professions is open to all who care to qualify themselves, and although, in the case of professions involving the life or property of the people, the State justly steps in and demands evidence of the qualifications of the candidates for admission, the public are with equal justice left to judge for themselves of the ability of those who seek only to minister to their necessities in connection with trade, commerce, or art; and our friend "John," in trying to attract sitters to his studio by reducing his prices, is as clearly within his rights as a citizen of a free country, as are Lehmann of Chicago, or Wanamaker of Philadelphia, in advertising that they will furnish the public with crockery or clothing at prices lower than their neighbours.

It should be observed that the question is not as to the quality of the articles supplied, but as to the rights of the parties to supply such articles at such prices as will please themselves and the public. It may be that the articles supplied by the magnates of Chicago and Philadelphia and the "John" brotherhood throughout the land are not quite equal to those dealt in by higher-priced dealers, but as the magnates in question, and some at least of the "John" family, have amassed tolerably large fortunes, we may fairly presume that they are not the round men in the square holes.

The sum of the matter, then, is this:—A certain degree of proficiency in the practice of photography is easily attained, and, consequently, the ranks of professional photographers have been increased far beyond the requirements of the people.

The value of this excessive labour has, in accord with the inevitable laws of supply and demand, been so reduced in value, as to have inflicted great hardship on considerable numbers, and changed the practice of photography, in all but the hands of a favoured few, from a highly profitable to a poorly paying profession.

This being the true state of matters, is there any remedy, or possibility or probability of amendment? We think there are two movements, which, working together, may effect a cure, and restore the professional practice of photography to even a higher degree of prosperity than it has heretofore attained—the education and cultivation of the public taste and appreciation of art, and the higher education, technically and artistically—especially artistically—of

the photographers. We have already said that in many of the larger cities, and in some of the smaller ones, there are photographers whose hands are always full, but either from heredity or patient study they are artists in the true sense of the term, and find a *clientele* sufficiently cultured to appreciate their work. Through the spread of education generally, and especially the high-class illustrations in modern periodicals, and the equally powerful influence of photography itself, what is now confined to the favoured few—cultivated artistic taste, and the ability to appreciate true works of art—will become the heritage of the many; and photographs that are accepted by the thousand and paid for now, will then have no commercial value.

This movement is going on now, and will continue to go on, independent altogether of the photographer; but the other to which we alluded must be carried on by himself, or some one for him, and how is it to be done? The question is indeed a difficult one—so difficult that, like the lecturer on temperance, we almost despair of making any satisfactory impression on the old, and would fain devote our attention exclusively and hopefully to the young. The old, the men already struggling with a poorly paying business, will feel the necessary study somewhat irksome; but much may be done by first attempting to thoroughly realise the possibilities of photography, and then resolving to reach the highest, or as high as may be within their power. Careful study of engravings from the men of mark of former and present times, and analysis, line by line, of the illustrations in the leading periodicals, most, if not all, of which may be so studied with profit. Simultaneous with such study should be carried on the careful reading of works treating of art in all its phases, especially its composition and light and shade; some of Ruskin's are good, and Burnet's essays are simply invaluable. This is about all that the older men can do for themselves, and any man who asks them to pay for promises to do more, tries to induce them to lean on a broken reed.

For the rising generation we think there is a brighter prospect, or, at least, for those of them who will truly realize the importance of proper preparation for their life work. But for that preparation proper opportunities must be afforded, and that is a desideratum that can only be accomplished by the united action of those who truly wish to see photography and photographers occupy the high position to which they are, or ought to be, entitled.

It would be impracticable to restore the system of apprenticeship which, so far as ordinary trades are concerned, in spite of all that is said and written of technical schools, is the only method by which trades can be properly taught, and if it were, the masters competent to teach are too few to meet the requirements. But, properly equipped and rightly managed, schools of photography could, we think, be made to answer the purpose. Such a school should contain all the appliances of an ordinary studio, facilities for enlarging and copying of all kinds; a suitably equipped chemical laboratory and lecture room, with accommodation for both theoretical and practical instruction; and models, specimens, and all necessary appliances for the proper teaching of the principles applicable to art.

Those, in the hands of a staff of thoroughly able, conscientious teachers, selected not only for their knowledge of the subjects to be taught, but also for their ability to communicate that knowledge, would form a school from which there would periodically issue a band of young men in every way worthy of the much misused title, photographic artist.

One such school might be established in the principal city in each state, and a central examining board, or one in the East and one in the West, who would, after the passing of a proper examination, confer a diploma, which will be at once recognised by the profession, and in due time by the public, as an evidence of qualification on the part of the holder.

Of course the schools of photography and their influence could not prevent unqualified men from going into business as photographers, but qualified employers would only employ qualified assistants, and, as we said before, the general public is gradually approaching to a state of art culture and appreciation that will not tolerate work that does not come up to a certain standard of excellence. Then, however loudly the untrained and unqualified man may pipe, the trained and appreciative public will refuse to dance.—*The Beacon* of Chicago.

THE PHOTOGRAPHIC INTERNATIONAL EXHIBITION AT AMSTERDAM.

We have just received additional particulars about the photographic exhibition to be held in Amsterdam in the spring of next year. This Exhibition will be international, and for the furtherance of the photographic interest. The societies principally concerned in it are the Helios, or Dutch Union of Dilettante Photographers, and the Amateur Photographic Union of Amsterdam. The committee is under the presidency of J. G. van Gelder; and has for its treasurer D. von Bosse, and its general secretary A. Scheltema Beduin. The local secretaries are:—For France, H. v. d. Masch Spakler; for Germany, A. D. Loman; and for England, C. H. Grook.

The Exhibition, which is open to all nations, asks support from all. Its object is to make professionals and amateurs practically acquainted with the latest photographic inventions and discoveries. Medals will be awarded for the best work sent in. A programme will shortly be published, giving further and more detailed information. In the meantime, all persons interested in the Exhibition are desired to apply to Mr. A. D. Loman, Jnr., 157, Warmoerstraat, Amsterdam.

CRYSTAL PALACE EXHIBITION.

The following are the additional awards at the Crystal Palace Exhibition:—

Silver medal given by Mr. S. G. Buchanan Wollaston for the best picture, irrespective of class, in the amateur section, not having taken any other award in this Exhibition: awarded to Paul Langé for 1,431 ("A Tour in Norway").

Silver medal given by Mr. J. F. Peasgood for the best picture, irrespective of class, in the professional section, not having taken any other award in this Exhibition: awarded to F. Whaley for 1,146 ("A Tale of the World").

Special silver medal for picture not previously shown at a public exhibition: awarded to E. C. Middleton for 414 ("Gossips").

Lantern Section.

Bronze Medals.—Professional (sets of 48 slides):—Section 1, British Subjects, J. Dove; (2) Foreign, G. E. Thompson: (4) Microscopic, F. Evans; (5) Statuary, Sciopticon Co. Amateurs (sets of 6 slides):—Section 1,

British Landscape, F. Griffiths; (2) Foreign Views, A. Heywood; (3) Seascapes, F. W. Wade; (4) River and Lake, J. E. Austen; (5) Architectural (exterior), E. A. White; (6) Architectural (interior), J. A. Sinclair; (7) Still Life, J. Carpenter; (8) Animals, K. L. Reynolds; (9) Figures in Motion, H. Little; (10) Microscopic, A. A. Carnell.

The attendance at the 1890 Exhibition has beaten the record of previous years by a considerable number.

THE FOAMING OF CERTAIN LIQUIDS USED IN PHOTOGRAPHY.

Last Friday night Lord Rayleigh lectured to a full house at the Royal Institution on "Foam." He remarked that he intended the title of the lecture to be "Froth," only friends had represented to him that "foam" was more poetical. Pure liquids, he said, will not foam: those which do so are essentially dirty or contaminated with other substances, and he illustrated this point with several liquids used in photography. Pure alcohol will not foam, but water containing five per cent. of alcohol exhibits a stronger tendency to foam than would otherwise be the case. Glacial acetic acid does not foam; when made weaker it foams more, and a ten per cent. solution of it shows a much stronger tendency to foam. Some samples of ether, when mixed with water, will cause more foaming than others when similarly treated, although the proportions be the same in all cases. That was the case with two samples before them from the laboratory downstairs. Both samples were sold as absolutely pure. Why one of them should set up in water the tendency to foam more than the other he did not know; perhaps one of them contained a trace of grease. Three parts of gelatine in 100,000 of water favours the formation of foam in large bubbles, and saponine acts even more strongly. A strong solution of pure salt does not foam much. He believed the foaming of the sea to be due to something extracted from seaweeds in rough weather.

The rest of the lecture bore no relation to photographic subjects. Sir Frederick Bramwell presided.

Specifications Published.

6,264. *April 12th*, 1889.—"Cutting Screw Threads." William Wilson Hulse, Ordsal Works, Salford, Lancaster, Engineer.

Both internal and external screw threads may be cut by means of revolving radial dies moveable towards or away from the axis about which they revolve for the purposes of adjustment, and of setting them up to or withdrawing them from the work as may be required. For cutting external threads, the dies are held in a die box, and are actuated radially by a cam action such as commonly employed. The cam block is rotated by means of a worm (which is by preference made solid with its spindle) and of a worm wheel formed upon the back of the cam block of a smaller diameter than that of the block, in order that the worm and its spindle may be accommodated without increasing the diameter of the die box for the purpose. The die box is formed or secured upon a spindle, which is by preference made hollow, and is mounted in bearings in a headstock secured upon a bed. Sometimes the dies may be arranged in pairs, one of each pair cutting when the die box rotates in one direction, and the other when it rotates in the opposite direction. The work is secured in a vice which is adjustable along the bed, and which holds the work by means of gripping dies operated similarly to the cutting dies, and with a similar arrangement of worm and worm wheel. While the threads are being cut the work remains stationary, and the cutting die box and spindle have an endwise as well as a rotary movement, the endwise movement corresponding to the advance of the cutting dies along the threads they are forming.

6,963. *April 26th*, 1889.—"Securing Glass Sheets in Roofs." Alexander Drummond, 35, Montrose Street, Glasgow, Glass Merchant.

This invention relates to and is a further development of my prior invention for glazing structures No. 5,947, dated 21st April, 1888.

In securing the glass sheets in roofs of structures in accordance with this invention, I entirely dispense with the use of astragals or glazing bars.

The glass sheets are placed edge to edge, or they may overlap, and are fitted at their upper ends into grooves or recesses cut longitudinally in the purline bars. The meeting edges of the glass sheets are covered by narrow strips of glass, metal, or wood, which are, at their upper ends, either entered into recesses in the purline bars, or are held in position by forked shaped catching devices, which may be of cast or stamped metal having projections on them capable of being driven into the purlines to secure them in position, or they may be secured thereto by screwing or otherwise. The lower end of each of said narrow strips of glass is held firmly in position by a stop piece, which is secured to the purline bars by screwing or otherwise. Gutters for carrying off moisture are cut in the upper sides of the purline bars.

The stop piece, as described in my prior specification, consists of a clip or cover which is dovetailed into a rectangular or other shaped base plate secured to the purline bars. Under this invention the head of this clip or cover has two arms or projections on it, so made as to grip the glass strips and prevent lateral movement.

The stop piece, instead of being made as described in my prior specification, may be made of a base plate or piece having a thick part at one end through which a hole is bored or made; over the thickened part the clip or cover is fitted by a pin passed through a hole in each of the sides of the clip, and through the hole in the thickened part of the plate; or the clip may be hinged to the base plate, the hinged part folding over on top of the glass, and being held in position by

a pin passed through a projection on the thickened end of the base plate. In some cases the clip itself may be narrowed at one end, and may pass through, and be secured in a hole made longitudinally in the thick part of the base plate ; or the clip may be dovetailed over the thick part of the plate.

In lieu of making the base plate thicker at one end, it may be bent upwards or stepped instead, and the lower end of the clip be made to slip over or to be bent over the raised part.

Under another modification the clip may have projections at its under side which will fit easily into recesses or holes, or their equivalent, made in the clips ; or *vice versa*, the clips may fit or slide on projections made on the base plate. The base plate and the clip would each have preferably, in all cases, arms for gripping and holding the glass strips in position.

When the glass sheets overlap each over a different sort of stop piece from those hereinbefore described would preferably be used. This stop piece has only one arm on one side of both the clip and base plate, and the base plate is further provided with a raised projection or ridge to prevent the under sheets of glass from moving laterally.

Instead of being secured by stop pieces as hereinbefore described, the narrow strips of glass, metal, or wood, may have flanges or projections made on them which would fit into or catch on corresponding grooves or projections made on or in the glass sheets. In some cases the narrow strips may be T shape in cross section instead of as hereinbefore described.

Strips of tarred cotton, felt, or canvas, may, if desired, cover the meeting edges of the glass sheets, and on this the narrow locking strips may be laid.

In some cases the narrow locking strips may be underneath the glass sheets instead of above them.

My improvements, besides being used for glazing purposes, are equally applicable for securing corrugated metal roofing, tiles, slates, and sheet metal roofing in position.

Proceedings of Societies.

The Camera Club.

Thursday, March 20th.—Capt. W. de Abney in the chair.

Mr. Chapman Jones exhibited his "memorandum camera," which has already, to some extent, been described in these pages. He said that it could be used all the year round, and at any time of day, and under very different circumstances, for the lens worked at *f*/4, which enabled the user to overcome the disadvantages of bad light. The lens was a portrait one, by Swift, and had a focal length of 3½ inches, and the camera had a roller-blind shutter next the plate, giving an exposure of about one-twentieth of a second, but it could be tightened so as to give, perhaps, one-sixtieth of a second. Farther, by a modification of the conditions, it became possible to give an exposure of one-tenth the duration of that employed by Anschutz, and to obtain which he used an 800 lb. weight. The memorandum camera carried a plate of half the size of a quarter-plate, and as the latter are always in the market, there is no difficulty in getting them and cutting them in two. The camera was fitted with a finder.

Mr. Ferrero exhibited a contrivance to facilitate the taking of lantern slides from negatives.

Mr. George Davison exhibited some photographs by Mr. Corbould, showing the distortion produced in portraiture by wide angle lenses.

Mr. W. Willis then read a paper on "Platinotype Possibilities." He began by speaking of the mixed oxalate and phosphate developer for the hot bath process ; with these salts in the bath, the initial image is less rapidly dissolved from the paper, so that the developer has longer time to act, and there are extra crispness and definition in the results, with more clearness, brilliancy, and transparency. The print should be removed from the bath the moment the shadows have sufficient density, and be at once placed in the acid bath. The phosphatic salt used is the monopotassic orthophosphate. At a temperature of 120° F. this bath gives excellent results, but for hard negatives the heat should be increased. In the course of his remarks, Mr. Willis said that the object of the final washing of platinotype prints was to remove the last traces of acid, which otherwise, in course of time, might attack the paper ; therefore, the washing should be ample to clear all acid from the fibres, and it was better that a little alkali should be added to the last washing water. Few papers in the market were suitable for platinotype work. Among the prints he exhibited were some on rough paper ; they presented, he said, but slight loss of definition, and he did not know that the results were more artistic than on smooth paper. The rough paper required exceedingly careful handling in the various baths, in which also they must not be allowed to rub against each other, or the image would be taken from the tops of the minute hillocks of the paper. The prints before them, on strongly wire-marked superior writing paper, were remarkable, he stated, because of the surprisingly small way in which the wire-marks interfered with the general appearance of the pictures. Other of the prints before them presented beautiful results with certain subjects ; they had been taken upon an exceedingly strong and thin paper, namely, that used for bank notes. The image went right through the substance of this paper, and the beauty of the results did not become apparent until the prints were mounted upon pure white cardboard. Other prints before them were upon nansook, a fabric made entirely of cotton ; one of them—a snow scene—was marvellous in its intensity ; he had never seen it surpassed, and the intensity increased the stronger the light in which it was viewed. He thought that nansook gave the ideal surface, for it rendered both ends of the scale and nearly every gradation between them. The next material, sateen, was also all cotton, and such faults as were in the prints he thought to be due to that material ; the results were nearly but not quite so good as those upon nansook. Linen worked well in the matters of ease and of certainty in results, and he thought that it gave better definition than the other two substances ; the platinum pigment seemed to attach itself very strongly to linen. He knew a man in America who printed in platinum the likenesses of his lady-loves upon his shirt wristbands—he "wore his heart upon his sleeve," so to speak—

Captain Abney interposed "His sweethearts, you mean."

Mr. Willis continued that the man told him that his shirts had been washed twenty times by Wah Sing, yet the likenesses were as good as ever. He (Mr. Willis) knew the able Chinaman, Wah Sing, and the way he smashed buttons during his energetic washing of shirts was amazing. Other prints before them were upon silk ; it was a troublesome material in the platinotype process, and he could not say that his results were very successful ; the results were better when the silk was not pure, but contained a certain amount of cotton. The prints on nansook looked very bad while they were wet. The prints he had shown that evening on fabrics had all been brought out by the cold bath developer. In working the platinotype process with ferrous salts, they would find that the addition of a very little ferric oxalate had a powerful restraining effect. To mount the fabrics on card, he used a stiff cold jelly, applied thinly, and consisting of mixed starch and gelatine.

Captain Abney asked about the sizing of the fabrics.

Mr. Willis replied that those before them had all been absolutely unsized. The papers were sized with arrowroot.

Mr. Asbury Greene asked if the fabrics could be developed by applying the solution with a brush ?

Mr. Willis replied that it might be easily done without leaving marks ; he had tried the use of a spray-producer, but the results were disappointing ; the liquid then seemed to settle on the surface in fine drops which did not coalesce, so that a kind of mottled appearance was the result. A brush, to answer well, must be broad enough to cover the whole plate with one sweep, and must be charged with an amply large supply of the developer ; it must be a self-feeding brush.

Mr. F. de P. Cembrano, Jr., asked if ferric oxalate could be so used as to save an over-exposed print ?

Mr. Willis replied that it was a bad restrainer, because its action seemed to be so irregular.

Mr. Elder liked warm-toned platinotypes. Once, when using the hot bath process, he wished to prove to some pupils how damp injured the sensitive paper; he cut a print in half, and placed it over a sink for several hours. To his astonishment, the part of the print which had been made damp developed better than the other half. Once he had been engaged on some experiments in the dyeing of silks, and found that whenever a mineral dye was applied, the silk lost its lustre. The fabrics he employed were those known as "liberty silks." This destruction of lustre might help to explain the difficulties of Mr. Willis with silks.

Mr. Humphery had found maps on linen to be excellent when bicycling.

Captain Abney remarked that some years ago, when he was in charge of the Photographic School at Chatham, there was a case of preparing for war—he would not say with what country—and the War Office wanted copies of maps for use in the army. He thought that such maps must be useless for such a purpose if printed on paper, so he turned them out on linen by means of a special lithographic ink, and, on trial, it was found that they did not suffer by exposure to weather and rain in the field. He mentioned this to show that the War Office was well aware of the value of maps upon linen.

Mr. J. B. B. Wellington stated that once he had a sample of platinotype paper which gave flat images, and that when he put a little gelatine in the oxalate bath, he obtained better results; too much, however, must not be added, or it will coagulate on the surface of the paper.

Mr. Chapman Jones suggested that perhaps the gelatine filled up the texture of the paper, and made it more transparent.

Mr. Lyonel Clark had experimented mostly with silver salts; but there was an analogy between silver and platinum printing, as exemplified by the results shown that evening. The fabric which had given him the most pleasing results was satin jean, which he had sized by means of dextrine; this kept the print on the surface, just where it was wanted, and the dextrine afterwards dissolved off in the washing baths. The silk used by Mr. Willis was strongly ribbed; he thought that the French silk used in the manufacture of fans would answer better. When prints on fabrics were to be small, he mounted each piece of fabric on paper with dextrine, and kept the print on its paper support through all the solutions. As a mountant, he applied starch to the mount, and, when it was nearly dry, he placed the print in position upon it, then ran the two through the rolling press. A great advance had been made in the adoption of the platinotype process during the past few years, and he was glad to see that of the large number of prints adorning their walls that evening, only five or six were photographs by the silver process on albumenized paper.

Mr. Willis had been specially interested in what Mr. Elder had said about the action of mineral dyes upon silk, for he thought that it explained some of the phenomena which he had seen. Mr. Wellington's experiment was of interest; he had tried it himself and had failed—perhaps from using too much gelatine. Gelatine combines with platinum over the whole image, so perhaps a small proportion of it in the oxalate bath gives the developer more time to act, by preventing the ferrous salt getting away before the completion of its work. After a fabric has been sensitised by ferric oxalate, it became so brittle as to be not easily distorted in the printing frame when the size of the print is not too large; under such circumstances he had never failed to get registration after examination. Mr. Davison had just handed him some samples of Japanese paper which had been sent to the former by Mr. W. K. Burton. He (Mr. Willis) had found that it was possible to sensitise Japanese papers, but that the difficulty was great—so much so, that he had given up the attempt, although, on occasions of success, the results were very lovely.

Southsea Amateur Photographic Society.

A public lantern exhibition was given on the 26th ult. in the large Victoria Hall, Southsea. The entertainment was in every way highly satisfactory. A fine collection of pictures, representing Canadian, Scotch, and English scenery, with various genre studies, and some good cathedral scenes, were thrown on the screen by Lieut. Gladstone, R.N., and a short description of each picture was given by Lieut. Cobb, R.N. There was a large and appreciative audience. The slides were entirely the work of members of the Society, prominent among whom were Capt. Lamb, Lieut. Gladstone, Dr. Wardrope, and Messrs. Thornton and Leaventhorpe. The arrangements were under the direction of Dr. F. Lord and the committee.

Photographic Society of Philadelphia.

A meeting of the Society was held on March 5th, President Frederic Graff in the chair.

The Secretary read a communication from the President of the Welsbach Gas Light Co., announcing that the company had fitted up a room at their factory for photographing with incandescent gas light, and inviting the members to make use of the room, and to visit the factory and witness the production of the light.

Mr. Stirling, chairman of the Lantern Slide Committee, reported satisfactory progress in the preparation for the exhibition to be held subsequently, and the prospects of a fine display of representative work of the members. Mr. Stirling also announced that forty-three English slides, representing the Society's share of the hundred sent to this country by the Camera Club of London on account of the last English interchange, had been received. They had been selected by lot impartially, and after the meeting would be distributed in like manner to the ten members whose slides had been selected to send abroad. Mr. Stirling stated that hereafter the Interchange slides to be sent abroad would be simply loaned, the idea of permanent exchange having been abandoned, so that eventually each member would get back all slides lent for interchange.

Mr. Bell presented a paper on "Gelatine Emulsions." In introducing the subject, he said he thought that it was the late president of the Society, Mr. Bates, who was first in this country to bring into use the gelatine plate. In his frequent trips to Europe, Mr. Bates had had Mr. Kennett prepare some of them, and they were brought over. It was a long time before Mr. Bell had heard of anybody using them here. The next one he heard of making emulsions was Mr. George W. Hewitt. He, himself, had also been more or less engaged in investigating gelatine emulsions. The next one that was successful was Mr. Carbutt. Not having himself been successful, he did not claim anything.

Mr. Bell then proceeded to read his paper, which, he said, was the result of a good many years' experience. At the conclusion of the reading, Mr. Bell said that if any of the members were "chemically inclined" he would ask them to take the No. 1 formula, and test it to see if it was what he claimed for it.

Referring to the sensitiveness of plates, Mr. Carbutt asked "What does 10 or 80 mean?"

Mr. Coates.—I think it means the gullibility of the buyer. I have bought "10" plates, and found "20" much better.

Mr. Browne.—Mr. Bell, in the early part of his paper, alluded to Mr. George W. Hewitt's experiments. So far as I know, Mr. Hewitt was one of the earliest experimenters with gelatine plates, and certainly Mr. Hewitt's process, and the results that he succeeded in obtaining, were remarkable. There was one peculiarity about his plates that I have never seen in any purchased plates, and that was, that the appearance of the image was more beautiful than I have ever seen in a commercial plate. The appearance of the image was slow, and remarkably beautiful. I think Mr. Carbutt saw some of them. I do not know that Mr. Hewitt claims anything original in that process, but there was one difficulty in his plates which was a very serious one, and which he was never able to overcome, that was the liability to frill. I used many of his plates, but there was that uncertain character in the matter of frilling which made it to me very disagreeable. I think that in the future Mr. Hewitt will always receive credit as being one of the earliest experimenters in gelatine dry plates.

Under the head of "Verbal Communications," Mr. Carbutt referred to the subject under discussion at the previous meet-

ing—that of deposits on the cover glasses of slides, saying that he had received a number of slides from Mr. Pancoast, accompanied by a letter in which he said, "Referring again to the incrustation on lantern slides, I was looking over some old slides I made in 1883 (possibly 1882) on some of your A plates, and find them in A1 order, no discolouring, mould, or incrustation whatever. They were not varnished or protected in any way, and were subject to the same conditions as the one I showed you at the Society." In another letter of a later date to Mr. Carbutt, Mr. Pancoast wrote on the same subject; "I send you by this mail one of the lot I spoke of in a previous letter, in order that you may see how perfectly it has kept. It was in the same box as the other slides, and subjected to the same conditions as those which show such a marked incrustation. I think the glass is B. P. C., at least the plates were your regular A plates. These slides were made by contact printing, and developed with oxalate."

Mr. Bell called attention to a portion of the report of a previous meeting, in which the words occurred, referring to the use of turmeric for colour screens for orthochromatic plates, "Mr. Bell thought turmeric to be adapted to the work with orthochromatic plates, and was as good as anything." He desired to say that he distinctly stated that turmeric could not be relied upon unless freshly prepared.

Referring to orthochromatic photography, he showed a screen of brilliant yellow, prepared by Mr. Ives, and loaned by him. It was put behind the lens, holding back blue rays, and allowing the yellow to act more strongly on the plate. It was necessary to have a plate specially prepared, as the ordinary plates would not answer. It should be an orthochromatic plate. He showed two glasses in illustration of his remarks, saying that turmeric would not answer.

Continuing, Mr. Bell showed the same colour screens he had obtained in London last year. One was of pot metal, ground and polished like plate glass, and which, he said, would never fade. He had three tints, but finding one was too light, he had cemented two together with balsam of fir.

Mr. Redfield showed a screen similar to that of Mr. Bell's, made by Mr. Ives. He also showed the front board of his camera, and the slide in which the screen was placed. It was a double glass prepared by Mr. Ives. Another method was a circular piece of glass prepared by Mr. Carbutt, which was dropped in the front of the lens, and a strip of blackened leather slipped in front of it, acting as a spring, and keeping the glass in position. Probably an improvement would be the introduction of some springs bracing the plate squarely against the back of the lens, so as to prevent its being at an angle, and thus producing distortion. A still better way would be to coat the surface of the lens with some colouring matter, or have the lens made of some coloured glass, as suggested recently in one of the English journals.

Mr. Cheyney said he had found it utterly impossible to get a sharp image by focussing first and putting the screen in afterwards. If focussing were done without the screen, and then the screen put in, the focus would be altered and thrown back.

Mr. Supplee asked what would take place if placed in front of the lens.

Mr. Cheyney said the change would be very slight.

Mr. Carbutt suggested the preparation of thin films of coloured collodion attached to diaphragms of black cardboard, and used in place of the usual diaphragms.

Mr. Redfield thought that two pieces of thin black rubber could be used.

Mr. Carbutt said that he had suggested cardboard because it could be obtained so easily.

Mr. Bell said that he had already gone over that process, and found the collodion film was too brittle, and curled all up.

Mr. Carbutt said that it was not properly prepared, then. It had a natural tendency to curl, but not to such an extent as to preclude its use. If 5 per cent. of castor oil were put in, it would remain firm.

Continuing the subject of orthochromatic photography, Mr. Carbutt showed some prints illustrating the excellent keeping of the plates, and also a photogravure print made by a publishing house in Boston from a negative on one of his orthochromatic plates. The print was from an old painting, and had a remarkable brilliant quality with correct colour tone.

Liverpool Amateur Photographic Association.

The third ordinary meeting of the twenty-seventh session was held in the Association's Club Rooms, 3, Lord Street, on March 27th; the President, Mr. Paul Lange, occupied the chair. There was a large attendance.

The following were elected members:—Messrs. T. J. P. Masters, H. G. Ponting, William Mason, junior, E. M. Ratcliffe, J. A. Knowles, Oswald Harrison, J. H. Fardon, Dr. E. J. Foulston, and F. H. Dudley.

The President announced that the new Boston slides, entitled "The White Mountains," and Mr. John Hargreaves' lecture on the completed survey of the "Hundred of Wirral," would take place in the City Hall, Eberle Street, on Monday, April 14th.

Mr. Fred Evans was then called upon to explain the arrangements that were being made concerning the Convention of Photographic Societies of Great Britain at Chester in the last week of June, when, amongst other attractions, special facilities, not hitherto allowed to amateurs, would be granted by the Duke of Westminster for photographing both the exterior and the interior of Eaton Hall.

The principal business of the evening was the contemplated Photographic Exhibition of 1891. The President entered very fully into the particulars of the matter; that it should take place in the spring of 1891 for the term of one month; that the offer of the Library and Arts Committee of the Corporation of Liverpool be accepted for the use of the same splendid apartments in the Walker Art Gallery as used in 1888.

The members unanimously decided that such an exhibition should be held. The President called on Mr. T. S. Mayne, the Honorary Secretary appointed for Exhibition matters, who then explained in detail some fresh features which were in contemplation. In due time full details will appear on the prospectus.

The meeting concluded with an interesting exhibition of photographic novelties, of which there were a large collection.

Colonel Ellison explained a new hand-camera, convertible into an ordinary camera, of his own invention, working on an ingenious tripod ball-and-socket arrangement also made by himself.

Photographers' Benevolent Association.

A meeting was held on the 28th March at 4, St. James's Street, Bedford Row, Mr. Bedford in the chair.

The following were elected members:—Misses Barton and Martin; Messrs. Skillman, Gottheil, Farrington, Evans, Plummer, Hinks, and Dr. Roland Smith.

An application for assistance was considered and granted.

Mr. Hanbly was appointed hon. local secretary for Lincolnshire.

Bath Photographic Society.

March 26th. Mr. W. Pumphrey, President, in chair.

Messrs. T. Bush, W. C. Lee, H. Isaacs, and C. G. R. Wood were elected.

The Hon. Secretary (W. Middleton Ashman) read a communication from the Mayor of Sutton Coldfield, anent the Norway excursion promoted by the Vesey Club, which starts in July next.

The Chairman said the Vesey Club desired to associate with scientists of all kinds in this special tour. The arrangements were very complete, and as he should be one of the party, he hoped to report favourably upon his return.

The Secretary exhibited a dark-room candle and reading lamp known as the "perfection."

The following were appointed an excursion committee for the ensuing season: Messrs. Powell, Perren, Tabsley, Collins, and the Secretary. The first outing will take place April 24th. Train 11.25 a.m., G. W. R., to Box and neighbourhood.

The CHAIRMAN stated that the annual report having been printed in full in the *Bladud* newspaper, they had ordered 250 reprints. Copies could be obtained from the Secretary. He wished to correct an error as to date which appeared therein. The publication of Daguerre's process should read 1839, instead of 1840, and it would be more correct to say that the neighbourhood of Bath was the scene of Fox Talbot researches.

Mr. C. H. TALBOT (son of Fox Talbot) said he felt responsible for these matters mentioned by the chairman being sprung upon the meeting, he having spoken to Mr. Ashman concerning them earlier in the day. With regard to date, there certainly was an error in the committee's report. He was not then prepared to say the exact date, but it could be found in the second edition of Tissandier's work. His father made an application for a patent earlier than January, 1839; but, on the 12th of that month, he announced his method of making camera pictures to avoid being forestalled in case Daguerre's process should prove to be similar. This was followed by the paper his father read on January 31st, 1839, before the Royal Society. All these experiments were carried on at Lacock Abbey, thirteen miles from Bath.

The CHAIRMAN having read a passage from Mr. Robert Hunt's book, showing how the error referred to occurred,

Mr. TALBOT said Niepce, in all probability, produced camera pictures earlier than his father or Daguerre.

The CHAIRMAN remarked that the process must have been very slow if Niepce used bitumen for the purpose.

Mr. TALBOT: Niépce's process was very slow. Daguerre's process did not precede my father's; it must have been the other way, otherwise its publication might have been delayed. No doubt he published to protect himself. He (Mr. Talbot) was inclined to think Niépce made the earliest camera pictures. Wedgwood had tried to do so, but he failed.

A lantern exhibition of transparencies, produced by members of the Society during the past session, then took place; Messrs. Pumphrey, Bristow, Peacock, Perren, Powell, Maton, Wells, and the Rev. E. A. Purvis contributed.

Wet collodion slides, toned with potassium sulphide, were shown by the President and Mr. Bristow. The remainder were by gelatine processes, either developed with ammonia pyro, or hydroquinone. An oxy-hydrogen apparatus, lent by the President, was used.

The CHAIRMAN hoped that more members would compete next year, so that all might have an opportunity of seeing each one's work. Upon the whole he thought they had a very satisfactory display of a variety of subjects. It was interesting to note the different treatment these subjects had received at the hands of the members.

PHOTOGRAPHIC SOCIETY OF IRELAND.

ON Thursday, the 27th March, the monthly technical meeting was held, Dr. J. A. SCOTT, M.B., Vice-president, in the chair. After two new members had been balloted for, the evening was devoted to exhibiting such lantern slides as the members had brought down with them, and some pictures were put upon the screen, and elicited discussion as to the various conditions under which they were produced.

After the lantern exhibition, Dr. J. A. SCOTT showed Tylar's lanternscope, an apparatus designed for placing upon a table for the purpose of viewing lantern slides, and explained its working.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Thursday next, April 10th, will be the last lantern meeting this season. A special feature will be the exhibition of slide carriers and slide changing apparatus.

FROM Messrs. Gauthier-Villars we receive the tenth part of the second volume of Ch. Fabre's "Traité Encyclopedique de Photographie," which is being issued in parts on the 15th of each month. The number for March treats, among other matters, of phototypic negatives on flexible films, and negative retouching, not only in portraiture, but in landscape work.

F. IVES.—We will attend to your letter next week.

Answers to Correspondents.

All Communications, except advertisements, intended for publication should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Sreet, London, E.C.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

COCOA.—The details of *Obernetter's Photo-Engraving Process* will be found in the NEWS for 1884, p. 67, and for 1885, p. 159. It is there stated that a gelatino-bromide transparency may be employed, the film of which is converted into chloride of silver by a mixture of perchloride of iron and chromic acid, or your method of sulphate of copper and common salt, or any other solution capable of converting the metallic silver into chloride. This altered film is then stripped, and laid down upon the copper surface, which gradually becomes etched, especially if moistened with a solution of chloride of zinc. The process is expedited by backing up the film with any conducting surface, and attaching the positive wire of a voltaic battery with the metal to be etched, and the negative pole to the aforesaid conductor at the back. Mr. Pearson's modification (p. 159) consists in the use of zinc plates instead of copper, when no battery current is required. The transparency should be produced on a gelatino-bromide film containing a minimum of gelatine, so as to be heavily charged with silver.

W. J. W. (Hull).—*Grained Metal Plates for Photo-Engraving.* These may probably be obtained from Mr. J. J. Ayling, 12, Crane Court, Fleet Street. If not procurable from that quarter, try the method of getting a stippled surface by photographing your subject behind a wire gauze screen, or even by indenting the metal plate by powerful pressure against a bed of wire gauze.

KATIE.—*Spotting Unmounted Prints.* Indian ink will, of course, get washed off when the prints are mounted, but we are not acquainted with any medium which could safely be employed without risk of revealing itself at the time of mounting the prints.

C. T. S.—*Vegetable Parchment.* The proportions are two parts by measure of oil of vitriol to one part of water, allowed to become quite cold, and then the blotting paper immersed. As soon as saturated, remove and wash quickly in a large bulk of water. Fine cambric may be treated, but calico does not answer so well. We doubt whether you will succeed with cotton tape, or any closely woven fabric.

E. G.—*Bar of Solder Fallen into the Nitrate Bath.* Some of the silver will doubtless be reduced, and the tin partly oxidised, but only lead dissolved. Filter off and use the solution for a printing bath, either concentrating it, or strengthening by addition of more nitrate of silver.

M. P. S.—*Cyanide for Reducing Albumenized Prints and Taking out the Silver.* There is a misprint in last week's report, page 250, second column. "Half a grain to the ounce," should read half a grain to the *pint* of water. Even with this highly dilute solution the prints will suffer if left in longer than a minute or two, unless they were originally much over-printed.

L. M.—*Incandescent Gas Mantles* (Welsbach system.) Enquire for further particulars at the office, 45A, Piccadilly, W.

CAMERA.—Either your No. 1 or the "Acme." Aluminium fittings make it still lighter. We should advise you to try *b*, with the special contrivance for holding it flat, which Mr. England indicated at the last technical meeting of the Parent Society. See the NEWS, p. 251.

A. W.—*Platinotype.* Received at the moment of going to Press; we will answer your enquiries next week.

R. B., and other Correspondents, in our next.

THOMAS WEDGWOOD.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1649.—*April* 11, 1890.

CONTENTS.

ALUMINIUM IN PHOTOGRAPHIC APPARATUS.

THE dream of half a generation ago of the advent of the time in which aluminium should be used, not alone for lens mounts and the screws of cameras, but for the cameras themselves, now seems likely to be realised within a moderate period, for aluminium has been steadily falling in price, and at the present time can be bought, of good quality, at fifteen shillings a pound, and of superfine quality at twenty shillings a pound. Worse qualities can be had at eleven and thirteen shillings per pound. The lower the quality of the metal the more brittle it is, and the more likely to be attacked by various chemical reagents. There are rumours in commercial circles that aluminium before long will fall in price to about six shillings a pound, but whether there is any substantial foundation for the report we do not know. Deville, when he was making it years ago, at the cost of about forty shillings a pound, calculated on theoretical grounds that the day was likely to come when it could be sold at about seven shillings a pound. He attempted to turn it out on a large scale under the encouragement of Napoleon III., who hoped thereby to lay the foundation of a new great manufacturing industry for France. There seems to be no chance of its ever falling so low as brass in price for equal bulks, although aluminium, weight for weight, occupies about three times the space of brass. Bad brass can be bought at sixpence a pound, good at between eightpence and tenpence, and the alloy of copper and tin known as gun metal, at fourteen pence a pound.

The necessary extra cost of aluminium fittings, even at the present price of the metal, and with the difficulties incidental to its working, is not a serious question in relation to their introduction into tourists' photographic apparatus for the lightening of the weight thereof, and perhaps if aluminium milled heads were now in the market to replace those of brass, there might at once be a steady demand for them.

In addition to the two or three large London photographic apparatus firms which, as already stated in these pages, have begun to turn their attention to aluminium, Messrs. Perken, Son, and Rayment tell us that they have been experimenting with it for some months; they find it difficult to turn, and that screw-threads on it are difficult to make, and in such operations they lubricate it with soap. They find it to work well under the file, and state that one sample they have been trying has been alloyed with a slight proportion of other metal or metals.

From the Alliance Aluminium Company we have received some interesting information about aluminium, including the following table relating to the properties of various metals :—

	Specific Gravity.	Weight per Cubic foot lbs.	Melting Point Fahrenheit.
Aluminium	2·56	160	abont 1600
Antimony	6·72	420	,, 810
Zinc	7·	437	,, 736
Iron	7·23	451	,, 2786
Tin	7·29	455	,, 442
Steel	8·	499	,, ——
Copper	8·6	537	,, 1950
Bismuth	9·82	613	,, 495
Silver	10·47	654	,, 1873
Lead	11·36	709	,, 612
Mercury	13·60	849	,, ——
Gold	18·41	1150	,, 2100
Platinum	21·53	1344	,, 3080

The Company also furnishes the appended information about casting aluminium :—

The melting point of aluminium is abont 1,600° F. The melting is best performed in a plumbago crucible, but an earthenware crucible may be employed; no flux should be used, and only part of the charge be melted at a time, and added to little by little. The pieces to be melted should be dipped in benzine previous to being put into the crucible. In melting the metal the heat should be raised very gradually to the melting point, which it should not at any time much exceed. Aluminium can be cast either in metallic moulds or in sand. If in *metallic* moulds, the moulds should *first* be heated, and coated with an air-expeller, then thoroughly dried and warmed before using. If in sand, care should be taken that the mould be dry; in either case the moulds should be provided with many vents. The metal should be poured quickly, and a suitable allowance made for shrinkage.

The Allianee Co. gives the following instructions for plating aluminium :—

In order to plate aluminium with gold, silver, or other suitable metal, it is necessary first to cover it with a firm coating of copper, to obtain which the following process is recommended :—

Dissolve a certain quantity of copper-sulphate in distilled water, and add another solution made by dissolving potassium-cyanide (60 to 65 per cent.) in water. A green precipitate will appear, which dissolves by adding more of the cyanide solution ; then add a little potassium-cyanide of 90 to 95 per cent.; this may be continued until the blue colour of the liquid has completely disappeared.

The solution thus prepared will generally be too strong, and it should, therefore, be diluted with water until it indicates 20 per cent. Tw. = 11 sp. gr. This solution will only answer well if used at a temperature of 10° Celsius, care being taken that the aluminium is thoroughly cleaned immediately before immersing it. The current must be regulated in such a manner that only very small bubbles appear on the aluminium ; as soon as the bubbles get too large the coating becomes imperfect, and the current has been too strong.

After obtaining a perfect coating of copper in the manner described, it may be brushed, or polished, or simply dried ; the articles may be silvered, gilt bronzed, or brassed in the ordinary way. For obtaining a second *thick* coating of copper, use the acid solution of copper-sulphate, containing a little tartaric acid, instead of the sulphuric acid commonly employed.

For polishing aluminium the appended instructions are given :—

Equal weights of olive oil and rum are shaken in a flask till emulsified. Dip the burnisher in this mixture, and do not press heavily on the metal. To clean a soiled surface, dip the object in benzine, and dry in fine boxwood sawdust. Olive oil and pumice make a good grinding mixture for hammered or pressed objects before polishing.

Next we come to the methods of mixing aluminium with steel or cast iron, for an exceedingly small proportion of it in either of these improves its quality exceedingly.

The proportion for steel is 0·01 to 0·2 per cent.; for iron, 0·1 to 0·2 per cent.

Run the molten iron from the cupola into the ladle ; then take the right proportion of aluminium in a pair of tongs, or in a cartridge (iron) full of holes through the sides to let the gases out freely ; plunge it sharply through the molten iron to the bottom of the ladle, and stir the whole thoroughly for at least two minutes. On the introduction of the aluminium, the mixture will be found to become very lively, and to "work" considerably, almost, so to speak, to boil ; the stirring should be continued until this agitation begins to subside. If the mixture be not well stirred, the castings will be found to be spongy, and to have little air-cells in them. Both the tongs, or cartridge, and the aluminium should be heated and dried before plunging, or the metal may fly. The man who plunges the aluminium in should be well guarded against the metal flying.

Photographic Club.—The subject for discussion on April 16th will be "Printed-out Opals ;" April 23rd, "The Development of Instantaneous Exposures."

ON THE SENSITISING AND CONSERVATION OF ALBUMENISED PAPER.*

BY C. CATALDI.

It is generally allowed that a good negative ought to produce a good positive, but it must always be carefully understood that in order to have a good positive a well prepared paper is essential. The sensitising of the albumenised paper is on this account one of the most important operations of photography, and it may even be said that, next to the preparation of the sensitive emulsion for the plates, it ranks, in a descending scale of importance, the first.

A customer who pays a visit to a photographer for the purpose of having his photograph taken, is anxious to receive good pictures. He little recks that the photographer, in order to accomplish his desire, is bound to obtain a good negative, and to develop such negative with this rather than with that developer—all that the customer requires is a good portrait. This he pays for, and troubles himself no whit about aught else. It is, therefore, clearly to the photographer's interest to select a good quality of paper, to sensitise it in a proper manner, and never to entrust, through ignorance or carelessness, this most delicate of all photographic operations to any inexperienced hands.

The foregoing serves to explain why many persons well known and long experienced in the photographic art have occupied themselves in the preparation of paper with serious diligence, and why it is sought to secure, at least for some time, the preservation of the sensitive state after sensitising by seeking a remedy against the yellowing of the paper.

Signor Klary—from whose kindness I have received much information in regard to my experiments in this matter—to whom, indeed, any praise which may result from them is wholly due—has demonstrated incontestably the necessity of a strict attention to the degree of concentration of the sensitising bath, and to the duration of the floating of the paper.

The concentration of the bath determines more or less rapidly the coagulation of the albumen, and from this it follows that its density should be delicately adjusted, so as on the one hand not to hasten the coagulation necessary, because this would hinder the silver bath from penetrating the albumen ; and on the other hand, not to retard it beyond what is necessary, because then the bath would be very easily absorbed, not only by the albuminous stratum in which it ought to remain, but also by the paper itself, entailing thereby a grievous damage.

The duration of the sensitising process ought to be in exact proportion to the quantity of salts contained in the albumen, to the concentration of the bath, to its temperature, and to the temperature of the place where the process is carried on. As Signor Klary observes, in all operations having regard to the sensitising of the paper, an exact and perfect harmony is necessary, to which must be added, in my opinion, a just criterion, because it is easy to understand that the floating of the paper over the sensitising bath has no other end than to cause the transformation of the nitrate of silver into chloride and albuminate of silver, and this transformation occurs, as I have already said, relatively to the quantity of chloride of sodium which the albumen contains, and, therefore, in a

* Translated for the Photographic News from the *Bulletin* of the Italian Photographic Society, published at Florence.

determinate lapse of time. When all the chloride of sodium has been transformed, the prolonged contact of the paper with the silver bath is not only useless, but even prejudicial, because the nitrate of silver continues to filter itself into the pores of the paper, which, thus sensitised, no longer retains in the impressions that transparency of tints which would be apparent if all the salts of silver were found on the surface of albumen. In this last case the image is retained upon this surface, and the paper, preserving its whiteness unaltered, produces impressions praiseworthy alike for their transparency and their relief.

More clearly to demonstrate the truth of this assertion, I will call the reader's attention to the fact that prints taken upon aristotype paper are generally better than those upon albumenised paper in the matters of transparency and depth of tints, which the former shows in marked superiority to the latter, and this only because all the chloride of silver contained in the former paper is distributed in the gelatinous mass, and the paper itself is therefore preserved uncontaminated. An impression upon albumenised paper rendered as translucent as one upon aristotype by the method of Signor Crozat, fails to acquire the value of the latter if the sensitising has been excessive. From my own experiments, I can guarantee as fairly trustworthy the following formulæ, which I here tender with all good will to such of my honourable fellow-workers as may desire perchance to prepare in their own laboratories a paper which may be satisfactory to them.

Temperature.	Percentage of Silver Bath.	Duration of Sensitising.	Notes.
From 2° to 16° C.	10·5 Grammes	From 60 to 70 secs.	These indications are for *simply albumenized* paper. For *doubly albumenized* the duration of the sensitising must be increased by a few seconds.
„ 17° „ 29° C.	9 „	„ 35 „ 50 „	
„ 30° „ 35° C.	8 „	„ 26 „ 30 „	

The paper thus sensitised may be kept very well for a few days, if care be taken to preserve it in a dry place. If, however, it be desired to keep it for a longer period, several methods of preservation have been suggested, which I will here recapitulate for the benefit of those who may wish to avail themselves of any of them.

Dr. Van Monckhoven advises the addition to the silver bath of as much nitrate of magnesia as there is nitrate of silver contained therein. This receipt I have not found to answer very well.

Mr. William Bedford advises the sensitising of the paper in the ordinary manner, and after that allowing it to float for about a minute on the sensitised surface in a bath composed of—

Distilled water	1,000 c.c.
Nitrate of silver	62·5 gr.
Citric acid	62·5 gr.

The *Bulletin* of the Belgian Association of Photographers prescribes the use of leaves of blotting-paper impregnated with carbonate of soda, which are interposed between the sheets of dried sensitised paper. Rolled up together with these, the sensitised paper may, says the *Bulletin*, be preserved.

Doctor Stolze gives the following method:—The paper is to be sensitised upon a silver bath of 10 per cent., and while not yet completely dry, is to be floated on the side opposite to the albumen upon a bath of citrate of potassium (1:30) for about four minutes. It is to be then washed with rain water, and toned, after fixing, with a bath of sulphocyanide of gold.

M. Leon Vidal, in the *Photographie des Débutants*, suggests putting the paper, after the sensitising process, and on the side opposite to it, for the space of five minutes upon a bath composed of—

Distilled water	1,000 c.c.
Gum arabic	30 gr.
Citric acid	20 „
Tartaric acid	20 „
Hydrochloric acid	20 „

M. Leon Warnerke counsels the use of *nitrate of potassium* in the ratio of 1:4, with which the paper is to be wetted after the sensitising, and on the side opposite to it.

Mr. Debenham, of London, points out the use of the perchloric acid of commerce. He adds ten drops of this acid to every 30 c.c. of the sensitising bath.

Mr. Taylor declares that his own experiments lead him to employ tartaric acid rather than citric acid, which is the acid generally used to preserve the sensitised paper.

Captain Abney asserts that if the sensitised paper be kept in a place perfectly dry, and otherwise empty, it may be preserved for an indefinite period.

Herr Liesegang, in his treatise *Handbuch des Praktischen Photographen*, indicates two distinct methods. With the first of these he prescribes the addition of a small quantity of citric acid to the silver bath, which is composed as follows:—

1.—	Nitrate of silver	20 gr.
	Distilled water	100 c.c.
2.—	Citric acid	2 gr.
	Distilled water	100 c.c.

After the complete solution of the substances, No. 2 is poured into No. 1, and five drops are added of phenol (carbolic acid). The sensitising of the paper is effected in the ordinary manner.

For the second method we are told to sensitise the paper with the usual bath of ten per cent., then to let it float, while yet somewhat moist, on the non-albumenised side, on a bath composed of one part of citric acid to fifteen parts of water for about ten seconds.

From my own experience I have found that the best methods to adopt are those indicated by Herr Liesegang, with which I sensitised several sheets of paper upon the 21st of November in last year. These sheets I have found with pleasure to be well preserved up to the present time. Printing, toning, and fixing succeed with these methods well and easily—a result which I have not obtained after other methods of treatment.

If the advice given by M. Leon Vidal be followed, the paper will not retain its sensitiveness if it be allowed to float on the second bath for the space of five minutes, as the author prescribes, whilst, on the other hand, it will be preserved excellently well if the time be restricted to ten or twelve seconds. This inconvenience aroused in me the idea of discovering its cause, and I thought at first that some endosmose of the silver had taken place into the gummy and acidulated water, because, whilst the image appeared pale on the side of the albumen, it presented itself in the clearest manner when looked at as a transparency and from the back. But I afterwards considered that this inconvenience possibly was caused by the transformation into chloride of silver of the excess of nitrate of silver which remained in excess on the surface of the sheet—a transformation due to the action of the chlorhydric acid—and as it is known by the investigations made in this matter by MM. Davanne and Girard, that the silver reduced by the light to the metallic state releases chlorine,

which, finding itself in the presence of nitrate of silver forms successively new proportions of chloride upon which the light continues to exercise its action; so it seemed to me clear that, wanting that part of nitrate of silver in excess, the image remained somewhat faint and pale. I cannot, however, speak with any certainty, as I have not had sufficient time to study this phenomenon. Very probably one of my suppositions may be just, but I appeal to all my excellent companions and fellow students in the photographic art to endeavour to give a more exact explanation of the matter which I submit to them.

For applying the preserving bath to the paper, the method which I have hitherto found the best is that which follows:—Every sheet, as soon as it is removed from the sensitising bath, is to be suspended by two of its corners, letting it hang a little on one side, and so drained. When a certain number of sheets have been sensitised, and whilst the paper is still moist, the excess of liquid which may yet remain on the lower margin is to be removed by placing the sheet between some folds of white blotting-paper. It is then to be floated on the acidulated bath, on which it is not to be left more than ten or fifteen seconds. The object of this second bath being used whilst the sheet is still moist, is facility of the working, since the paper is then much more pliant, and in a condition most favourable for the prevention of that curling up which would certainly spoil it.

PHOTOGRAPHY IN NATURAL COLOURS.

In the *Standard* of April 2nd is the following letter on the above subject from its Vienna correspondent, who has had an interview with Dr. Eder in relation to the alleged photographs in natural colours, which attracted attention at the Camera Club Conference. From the letter it will be seen that the method of Herr Veress is a secret one, that Dr. Eder has not been made aware of its nature, and that so much of the method as has been made known is chiefly Becquerel's process, except that the chloride of silver is applied emulsified in gelatine or collodion, but that also is not new. In fact, in such details of the process as the Correspondent has been able to obtain, there is nothing new nor even comparatively recent:—

I have already mentioned, in a former telegram, that the photos of Herr Franz Veress, of Klausenburg, Transylvania, were shown to me by Professor Eder at the Photographic Institute. The interesting specimens were sent to the Institute not by Herr Veress himself, who, perhaps, does not know German, and was, therefore, not able to write to Professor Eder, but by the Hungarian landed proprietor, Herr E. von Gothard, of Herény, in Hungary, an amateur photographer, who had heard of the achievements of the unknown Transylvanian artist, and, out of scientific interest, assisted him in the pursuit of his discovery. The photos are upon glass and upon paper. The former are diapositives, and if looked through show, for the most part, a beautiful ruby-red ground colour, with a picture in bright, sometimes brilliant, colours, from the deepest hue of ruby-red—far deeper than the ground colour—to light orange, with several shades of red and yellow, and from violet to aniline blue, and the intensest, most brilliant blue that can be imagined. The same colours prevail also on the paper positives, which have all a greyish-brown ground-colour, upon which the red inclines more to purple than ruby, and the violet is especially brilliant. Green is missing on all the positives, and it is not known whether Herr Veress has succeeded in producing it, since the photos now in Vienna were obtained some four weeks ago. I looked at the photos, together with Professor Eder, through a magnifying glass, and we could not detect a single impurity in the drawing or in the pigment of the colours. The outlines of the pictures are perfectly exact, and each colour stands out from the other with marvellous distinctness. Professor Eder told me he did not dare to expose the photos to the direct sunlight, as he was afraid of their being injured; but he was astonished to find that the colours were quite unaffected, and not changed in the slightest degree, after being exposed to the ordinary daylight in Dr. Eder's office for fully three weeks, during which the photos upon glass and paper were examined by a great number of persons, were lying about uncovered at different times of the day, and were also shown during a lecture at the Society for the Propagation of Natural Science during gas-light. Such permanency of colour on photos has, Professor Eder says, never been known before, and constitutes the principal achievement of the Transylvanian discoverer. It will be necessary to expose the photos to a more severe light experiment before final judgment can be passed; but if we remember that in former cases of photographing in natural colours a coating of varnish has had to be applied to protect the colours, as otherwise they would have faded away within a few days, if not within a few hours, it must be admitted that the solution of the problem has been greatly advanced by Herr Veress, when he has succeeded in making the natural colours durable for such a long time in diffused light.

In sending the photos, Herr von Gothard gave the following details of the applied process. The sensitive preparation is a silver chloride emulsion in collodion, or in gelatine, and the solution being prepared in a peculiar way, which is the inventor's secret, it is poured upon either the glass or the paper, where it soon takes a brownish-red colour. The plate is put into a copying frame and exposed to the rays from a transparent coloured drawing, of which the negative picture is soon visible, the dark parts appearing, of course, in white. The exposure has to last in the case of glass negatives two to three hours, and in the case of paper at least three days, as the colours come out very slowly, but the picture having been fixed in an alkaline bath, the colours become brighter and more intense. The process in the camera would require an exposure lasting several weeks, but even the ordinary process will be largely reduced if some experiments on which Herr Veress is at present engaged succeed as well as he hopes, and, according to the latest information, he has already so changed his original system as greatly to lessen the time of exposure, especially for the paper negatives.

Professor Eder has not made the slightest attempt to penetrate into the secret of Herr Veress's process, in order not to deprive him of the ultimate pecuniary benefit of his arduous labours. All he would say is, that Herr Veress, who must be a very clever practical photographer, has most likely by some professional device so changed the process described by Carey Lea some two years ago, of applying the photo chlorides of silver in the form of an emulsion, as to achieve what nobody before him has succeeded in, namely, photographing in several colours which are permanent. The substance he uses is probably much the same as that experimented with by Herschel in 1840, by Becquerel in 1847, 1848, till 1855, and by Niepce de St. Victor, 1851 till 1866. But the system is a different one, and, as it has led to such great results in so short a time, it may be presumed that Herr Veress is the right man to bring the solution of the great problem within reach, if enabled to pursue his studies on the subject.

Professor Eder is not quite sure whether he must regard the colours on the Transylvanian photos as a real pigment, or as the effect of very thin layers. He is delighted with the exactness and precision of the coloured picture obtained by Herr Veress, and although he must, of course, look upon photographing in natural colours as still in its infancy, and even the results of Herr Veress as only a crude specimen of what ultimately may be achieved, the possibility of fixing colours for such a long time is, in his opinion, so great a step in advance that minor shortcomings are of small importance. I gave the professor everything to read that has appeared in the *Standard* since the first article on the subject, and after going through all the letters, he said—

"Captain Abney's results in obtaining natural colours by photography have never been seen on the Continent. I am, therefore, not able to say anything about them. The process of Mr. Ives, of Philadelphia, is printing in colours by the aid of photography, and not photographing; it can, therefore, in no way compare with the discovery of Herr Veress, which is quite a different thing. The photo-chromic pictures produced in Philadelphia are also produced in perfection by Albert, in Munich, and by Sieger and Lowy, in Vienna, and to my taste those of Sieger are the best in existence. But, as I said before, that is chromo-lithography, in which photography is only an accessory, and not sun-printing in natural colours. The other statements in the letters to the Editor of the *Standard* are completely negatived by what you have seen yourself, and what I can vouch for as really achieved—namely, the retention of the colours for several weeks. Everything else rests with the future, and the problem is, of course, not even approximately solved as yet."

The professor is quite a young man, very energetic, very cautious in scientific matters, and given heart and soul to natural science in all its branches. He is the director and leading spirit of an Institute which has not its equal in the world. It owes its existence to the energy of Baron Gautsch, the Minister of Public Instruction, who founded it as a State Institute with the assistance of the Vienna Town Council, which placed the greater part of a house in the Wertbahnstrasse at its disposal, defrayed the cost of the necessary alterations, and still provides the lighting, heating, and the service in the four glass-covered studios, nearly forty different rooms, and the large class-room, which together make up the Institute. The first expenses for fitting up, and for the purchase of a very large collection of instruments and appliances, photographic as well as physical and chemical, were defrayed out of a State grant, and the current expenses are met by a State subvention and the fees of the students. These number at present nearly two hundred, including several ladies, in addition to a great number of amateurs who do not attend all the lectures given by the six professors, but only follow special branches, and have the use of the Institute as far as they need it. The students are, to a large extent, foreigners, and I spoke to two young gentlemen, sons of photographers in the vicinity of Chicago, who have come all the way from America to attain perfection in the different arts connected with photography. The speciality of the Vienna Institute consists, mainly, in the union of every art or profession into which photography enters as an auxiliary, besides the promotion of studies in photography itself and in its application to science. The Institute has been in existence only since the 1st May, 1888, and has already such a reputation that applications are made from all parts of the world for places in the different classes, usually half a year before the courses begin, as the number of seats is limited.

Treatment of Uranium Residues.—Large quantities of uranium salts are used in the analytical laboratory for the estimation of phosphoric acid in manures and agricultural produce. M. Lacebe has proposed the following treatment for recovering the uranium in the residues of this operation:—When a sufficiently large quantity of liquid containing its precipitate of phosphate of uranium has accumulated, the supernatant liquid is decanted off, and the precipitate is boiled with soda until dissolved. After cooling, and without filtering, ammonia is added, and the phosphoric acid eliminated by means of the ordinary magnesia mixture. Twelve hours later the liquid over this precipitate of phosphate of magnesia and ammonia is syphoned off, and the residue washed with ammoniacal water. The filtrate from the phosphate of magnesia is neutralised by means of hydrochloric acid or sulphuric acid, and the carbonic acid is eliminated by boiling the liquid. The uranium which the latter contains is now precipitated by ammonia; the precipitate is washed with water, to which a little sulphate of ammonia is added. It is finally dissolved in nitric acid taken rather in excess, and the solution yields on evaporation crystals of nitrate of uranium. These are collected in a filter, and washed with a minute quantity of very cold water.—*Burgoyne's Monthly Magazine.*

THE ART OF DRAWING AND PHOTOGRAPHY.*

BY A. M. ROSSI.

In an article written by me some time ago in the *Photographic Quarterly*, I endeavoured to show the preponderating influence that photography bears on art. I went, perhaps, a little too far in mentioning certain facts and incidents, and this brought upon me an avalanche of hostile criticism from my brother artists. On this occasion I propose, notwithstanding, to follow on the same track, and try as best I can to prove that photography, instead of being the useful servant to art, has almost become its mistress.

When photography was in its infancy, a thorough academical art education was acquired by long, tedious, and assiduous study. Drawing, by which is meant not only an outline, but the inside accentuation and modelling of the form by means of the correctness of values and passages in the *chiaroscuro*, formed without exaggeration three-fourths of an art education. The rest was occupied by the student in learning, if learning it could be called, the art of painting. Students admitted in the academies began by copying from the flat, and then drawing from the cast, extremities, and heads, and busts, &c., attending at the same time classes in anatomy, geometry, ornamentation, elementary architecture, and perspective, all considered necessary for the formation of an art draughtsman, who, after a period of six or eight years, if he could distinguish himself by executing an original cartoon of a given subject, was promoted to the last and to him most fascinating school, that of painting from life, where he could nestle until he felt his wings strong enough to fly in search of name and fame. Beyond teaching a few tricks and the way of holding the pallet and the maul stick, the professors contented themselves in passing their own private opinion upon the works. Hence it was that one day Professor A. would pronounce a painting too hot, and the same would be too chalky for Professor B.; an academy from life would be lacking in transparency for Professor C., and the same a day or two later on, in too light a key for Professor D.; and so on. He who is not born a painter can never become a great one. Some of the best prodigies in the academies, in emerging into the schools of painting, have thoroughly flagged, and it is hardly necessary for me to mention many names of men of modern times who gave up the pallet, or used it to the detriment of their beautiful designs. We have an Overbeck, a Kaulbach, a Cornelius, a Tancrede, almost our contemporaries, great men who threw the brush away. We find an Ingres in France, a Maclise in England, who merely smeared their immortal compositions; the art of drawing constitutes the longest and only teachable part of an artist's education. In the days I am speaking of painters were fewer than now. Only those who distinguished themselves were recognised, or even admitted into society; wonderful transition from the days of Medicis, Charles V., of Francis I., of a Leo X., whose munificence made their courts the centres of genius, for they loved art and honoured the artist.

Nine-tenths of the art students belonged to the lower classes of the people, mostly artisans' or farmers' sons; the academies were, no doubt, well stocked, but not one in a hundred became an artist at all. Before the second or third year of their studies some would be caught by the conscription, others would become shopkeepers' apprentices, and I have known many of my chums accepting

* Abstract of a paper read before the Camera Club Conference, and published in the *Journal* of the Club.

situations as waiters at a café: thus this little illustration of which I can bear witness, is, I venture to hope, sufficient to prove that it was beyond any moral possibility in those almost pre-photographic days, for any house-painter's apprentice, or a boy cow-keeper, or a cabin lad, or an artists' colourman's son, to go to bed one night, in the fulness of his various vocations, and awake a year or two later a ready-made artist, as has been the case in this and other countries beyond any possible dispute within these last twenty years, because in those days, when artists had to depend solely on their intellectual efforts and the training they received from their masters, who admitted in their *ateliers* only men of exceptional talent, the paths of art were comparatively free from the useless and poisonous weeds that now infest it. Now, thanks to the facility that photography offers alike to the strong and the weak, the ranks of art are overcrowded with aspirants to fortune and to fame. A few push their way through the crowd and attain excellence, more wrestle with cruel mediocrity, and the majority are canvas daubers, who glut the market with rubbish, to the destruction of art, the gradual degeneration of artists, and the disgust and confusion of the patron.

With your kind permission, I will now try and put before you an illustration in support of my forthcoming assertions. We take two young men, one in good circumstances with a liking for art, although not an artist, who, not knowing what else to do, decides to become one. The other is a boy born in poor circumstances, but a painter; within him lies dormant the instincts of a designer and an artist. Whilst the first goes through his academical training, the latter goes about with the painter's can, being an apprentice to a house-decorator.

The former devotes six or eight weeks in shading the head of a Vitellius, stippling it with the point of the crayon and bread putty. The apprentice, with a piece of chalk, is smearing with forms of all kinds every available space of wall he can come across. The academy student is busy trying to win a scholarship for best drawing from the antique, and the little apprentice, getting hold of a photograph, traces it on a smooth piece of board at his master's shop, and with his master's paints he colours it. It is a portrait of his employer, who, having detected him, instead of discharging the refractory one, sends him at his own expense to Heatherly's to join the evening classes. There he learns in six months enough drawing to enable him to copy with exactness anything from the flat. After six months' education he copies from a Christmas number a picture, which he sells for £1; next he buys for 2d. the photo of a pretty lady from a hawker's wheelbarrow, makes an enlargement, paints it, and sends it to an exhibition, where it is hung and sold. Without any further instruction the boy now devotes every available minute to painting from nature, and goes to the parks, and in the country, producing landscapes. His first attempts are naturally consistent with the slow awakening of his genius, but steadily progressive, and gradually approaching that manly and rapid development characteristic to all men of genius. In that manner he devotes two years, when he has the courage of submitting one of his landscapes to the crucial test of the academical council. It is accepted, well hung, and sells. This bit of luck gives him an opportunity of visiting frequently the Royal Academy, and he uses his keen eye of observation, without, however, allowing his mind to be influenced by what he sees around him. Meanwhile the Royal Academy student sends an ambitious figure-subject, and it is rejected.

Henceforth the humbly-born young man is a regular exhibitor in the R. A.; each succeeding picture is better than its predecessor—his development is surprising to all. A pastoral subject of ambitious dimensions the following year attracts great notice, and, to cut a long story short, the young man is in the enjoyment of a great reputation, and perhaps an associate of more than one institute of arts. The R. A. student, discouraged at the repeated rejection of his works at the hands, most probably, of his teachers, throws pallet and brushes away, and turns his back on art for ever.

And yet, gentlemen, the house-painter could not draw, at this period of my narrative, from nature half so well as the Academy student, who is very well versed in anatomy, in geometry, perspective, all occult gifts to our young prodigy, who, on his part, could, however, produce a picture redolent with all the charms that only an artist can give. This little illustration, which, I venture to hope, will not flavour either of improbability or exaggeration, is a fact within my memory, which, however, could not have taken place in the days of Titian or Buonarotti under the same circumstances, unless the poor boy had a camera and all the rest of the multifarious appliances that photography offers us now.

If, therefore, we can trace the career of a brilliant artist, almost self-taught, how many more similar cases might we not have amidst us of men who attain the same results with no better means? and thus it is that I maintain that the cabin lad, and the yeoman's son, and the artists' colourman's boy, if born talented, can all reach the apex of excellence in art. It is immaterial what means are used, providing they are legitimate.

An artist must show what he can do and not how he does it. I conclude my paper by expressing my firm belief that the only teachable part of art, which is drawing, is sinking with the rising of photography, and, to my humble belief, the days are not far off when a youth, born with artistic instincts, in a few months of mechanical instruction can be his own teacher, and photography will be his academy.

PHOTOGRAPHIC GROUPS.

BY FRED HART WILSON.

The successful "group" marks the top notch in the scale of photographic achievement. It is certainly the most difficult problem, exacting and uncertain.

The painters, infinitely less trammelled than the photographers, themselves feel this; so much so, that the power of successful combination of a number of figures into the unity of a composition has always been the mark of a master. One has said that to paint one figure is simple, two very hard to manage, and the difficulty increases in geometrical ratio with every additional figure introduced. Another declares that composition is simply a special faculty, not to be acquired, but inborn; one either has it, or has it not.

This, however, is too severe, and we will proceed on the understanding that composition is not unique among human accomplishments, but, like other things, may be attained by intelligent study. The artist's assertion is simply a significant tribute to the difficulties of the subject.

In the very first place, a word on the mental side of composition may not be wasted. It does exact, for

thorough success in it, a certain mental power of calling things up, of projecting the picture on the air, of seeing with the mind's eye. One must, in fact, see the finished picture before it is begun. The way to begin the construction of a group is not to get together models and accessories that seem likely to look well, and then worry them about until an idea of some kind occurs. The idea must come first—there must be some distinct notion of what one is going to do, and the more clean-cut this idea is the better. After that, of course, there may be infinite experiment and alteration; but the thing is to get an intelligent start, and not take the subject by the tail end first.

It is the faculty the French, as a nation, possess of putting a thing visibly before one, of seizing and completely embodying the point of an idea, seeing all over and all around it at once, that makes them so supreme in art.

It may, perhaps, be well to define the group, as we begin, as a number of persons gathered in one picture, with some common interest binding them together. The last clause at once rules out the masses of people who may be seen in many so-called group pictures, each one a separate object, independent and unique. There must be some rational relation between the figures, and some reason, besides that of their being photographed, for their being there together. A pyramidal arrangement of six people, one on the floor, two seated, and three standing, all looking straight ahead, vacuous and without any visible reason for being, is not a group. It is simply six people—six units, not one.

And the photographer must realize this difference between photograph and picture. He cannot arrange people like the specimens on the shelves of a museum, and expect a picture. He cannot show the full faces of all the five people of a family, for instance, and expect anything but five separate portraits. Some of them must be sacrificed to some degree, and must be seen in profile, or three-quarter view at most. If he wants to make a picture of such a family, I think the only solution of the difficulty will often be to take two photographs, or more, if he can. In one he may show the full-face photographic portrait view of two or three, sacrificing the others to the exigencies of composition; in the other, he may make those thus lost the important heads, and subordinate the first ones. Any family which has enough artistic sense to care for a pictorial quality in their photograph, will not object to the double exposure. Yet it is by no means impossible that he could get good portraits all on one plate, which is, after all, the object of the group. He will very often find more beautiful and more characteristic aspects of the face in the quarter circle, of those from three-quarter view to full profile, than in the front face view, and by skilfully using these may safely tread in the thorn-beset path, and make both a satisfactory photograph and a picture.

A reason for the group must always exist, and be well in evidence; in other words, the composition must tell its own story. The figures composing it must not be there without a reason, and they must be doing something. It is not enough to account for their being together, the mere fact that they are being photographed—as we find so often in groups of families, associations, clubs, and societies. Of course, where three hundred men must be taken on one plate, there is usually nothing to do but put them there in rows, like figs in a box. But even this can be avoided in many cases, and with a reasonable number the devices for giving life and picturesqueness to the group are as numerous as life itself. The family may be reading, talking, looking at something, or, if accessories can be brought in, engaged in characteristic occupations. A good example of the success with which even a large group may be treated, and that within ordinary limits, is a plate I have seen of the jury for the admission of pictures into the *Salon*. All the pictures are good and sufficient, yet the whole is real and stirring with life, and does not look arranged or photographic. And this is done simply by taking a front view, facing them behind two workmen who hold up a painting for judgment. The jury is looking at it, crowded rank above rank, in various attitudes; the whole thing is a success, both as a picture and as a series of portraits. Yet though the arrangement is very subtle and practically unnoticed, it is decidedly there, and success is not an accident.

And here a word on this topic of arrangement. There are certain principles, formulæ almost, which have found great popularity and acceptance on account of easy comprehension and simplicity of application. The two such that come in particularly in grouping are the "pyramidal principle," and the principle of circular composition. The former especially has had a famous career, and I fear a good many photographers consider that they have introduced the much-desired touch of "art" into their work, and are safe and sure to make a picture, when they have adopted the "one, two, three" system of arrangement referred to above. Yet it is to be remembered that artistic quality is a delicate and evasive thing, not by any means to be secured by definite formulæ and practical receipts. These principles are simply crude and rough statements of the general experience of value up to a certain point. They are above all not to be applied too literally, remembering what "the aim of art" is said to be. They must be as well concealed as the skeleton is concealed by the flesh. They are merely the framework of a picture, and their corners must not stick out, but must be very deftly covered and hidden in the finished composition.

The truly universal principle of good composition, if there is one, seems to be a certain sinuous sway of lines and a harmonious connection of things with one another, that balances mass with mass, and gives that indescribable sense of satisfaction to the eye in passing from one to another. This is what we feel, rather than any cold and mathematical arrangement of symmetrical pyramids or complete and uniform circles. It must be much more felt than done by rule. The trouble lies in taking these abstract formulæ as rules. Any plate of the Crucifixion, for instance, by the old masters, will show how thoroughly covered up, and modified, and transgressed they have been.

A final hint on illustrative compositions, such as the Hiawatha and Evangeline. In reading over the subject, certain passages will strike one as having the graphic quality, calling up pictures. Let the photographer select a number of these, and then reading and re-reading them, try to get all the circumstances in his mind, or at least to embody his impression as vividly and really as possible, until he positively sees something. The larger part of art is mental, let him remember, and so not be in haste to get his models before him until he has something for them to do. After that let him labour, and alter, and try experiments, and re-arrange *ad infinitum* in the details, if he wish. When the jewel is secured, it may be cut and polished patiently to perfection.—*Wilson's Photographic Magazine.*

Notes.

Tho rumour is that portraits will be more numerous than ever at the next Academy. Indeed, some have gone so far as to say that it will be known as "The Portrait Year." The fact cannot be denied that the most remunerative branch of art which the painter can take up is portraiture, and it is not surprising, though it may be regretted, that men who have made their name through works of imagination and poetic feeling have turned their talents to the delineation of the features of merchants, princes, doctors of divinity, and society ladies. Towards this end, photography has contributed. Undeniably there has been a rage for portraits; the crowds round the shop windows show the direction of the public taste. The outcome of this tendency, of course, varies according to means: while those with limited purses are contented with photographs, the wealthy patronise the painter. There cannot be the slightest objection to this so long as the public who pay their shillings to the Royal Academy have not to undergo the infliction of having to gaze on perpetual portraits.

The Stereoscopic Company has had its annual meeting, and declared its annual dividend of five per cent. This is the fifth year of the Company's existence, yet it has never realised the promises held out in the prospectus. A safe five per cent. is not bad as times go, and considering that Consols yield now no more than $2\frac{3}{4}$; but the general idea is that a photographic business is an extremely lucrative one, and therefore the inability of the Stereoscopic Company to get beyond five per cent. must be a little disappointing to the shareholders. Nor does it appear that the chairman was able to give any very definite reason for the falling off. All he said was: "Five years ago, when we put this concern into a company, the price that was paid for the business was a price that would have paid seven per cent. to the shareholders taking the profits over an average of the twenty-three preceding years. Now, if these profits had been realised, that would have given you seven per cent." Quite so; but the discontented may ask how is it these profits have not been realised? Mr. Howard V. Kennard failed to explain this. Indeed, he left the statement to stand by itself, and the inference is unavoidable that the Company has not been doing so much business.

But again the question will again be asked, why? The last five years have been almost without parallel in the growth of photography, and the "turn over" in the sale of photographic materials. It is true portraiture has fallen off, but the loss here must have been nearly counterbalanced by the extension of photography in directions other than the sale of apparatus and chemicals. Under the two last heads the returns must have been very large indeed, for every amateur five years ago hundreds can now be numbered. It would have been interesting to the profession, as well as to the shareholders, if the chairman could have given his views on this point; but possibly this would have involved details of the "trading account" which few business companies like to divulge, as it gives information to their rivals. Mr. Kennard, however, has hopes of shortly being able to get back to a six or seven per cent. dividend.

Mr. Henry Blackburn, the Editor of *Academy Notes*, is advertising lectures and classes for instruction in drawing for the press. It is quite time the principles were established on some fixed basis, not the least important being the requirements of photography. We do not see this specially mentioned in Mr. Blackburn's advertisement, but it may not be overlooked. For want of the most elementary knowledge of photography, we saw the other day a reproduction of a drawing by an experienced and skilful artist totally spoilt. The artist was chiefly accustomed to draw on transfer paper, but thinking to produce a finer result, he made the drawing on card to be photographed. Unfortunately, he omitted to cut out the faint pencil lines, and then was surprised to find the reproductive print with several curious marks and blemishes, which were totally inexplicable until the original was examined. The artist then was amazed to find that lines which were quite faint to the eye, were reproduced almost as strongly as those in ink.

A curious theory as to colour-blindness and its cause under special conditions has been put forward by Mr. W. A. Sherwood, in a paper read at the Canadian Institute. He says, in regard to the effect of colour in nature upon the eye, that in Philadelphia one out of every five of the children there is found to be colour-blind or compelled to wear glasses. He alleges that this is due to the lack of colour in this somewhat prim and monotonous city. He contends that the greatest painters the world has produced flourished in lands where colour was seen on every side. From these resources of nature the artists drew their inspiration, and not from shops of fashion. Colour-blindness is almost unknown in many countries—Japan, Spain, and Italy, for example. In Philadelphia we have, unfortunately, the reverse of this. Mr. Sherwood believes this lack of appreciation accounts for the preference many persons there have for steel engravings and prints to paintings. This, he holds, is false to the principles and teachings of nature. Those who favour engravings do so honestly because of their training in black-and-white, to which from childhood they have been accustomed. The children of the Quaker City have seen the sombre attire of their parents, and even worn the same themselves; their city surroundings show the white marble residences and the black roadway, and their books and writing are all black and white. Hence their sense of colour is limited. There seems to be some force in this reasoning. A limb, if allowed to remain inactive, finally grows torpid and useless. Why not also a sense?

FERDINAND ADOLF BEYERSDORFF.

From the *Photographische Correspondenz* we translate the following account, relating to the death of the well-known Viennese photographer, Herr Beyersdorff.

With Beyersdorff disappears once more a typical figure from the familiar artistic circle of professional photographers in Vienna. Beyersdorff was essentially a self-taught photographer, skilful extremely in all the manual functions of his art, and well experienced in modern delineation. He was born on the 3rd of May, 1837, at Limeritz, in the royal district of Frankfurt-on-the-Oder, and was originally intended for a mercantile career, but apparently not liking this employment, obtained a place on board a merchant vessel as a sailor, and served afterwards in the Royal Prussian Marines. An unlucky accident, by which his breast was seriously injured, rendered him useless for military service, though he was discharged in a fairly sound condition from the hospital at Marseilles.

Beyersdorff's first acquaintance with photography was made in Berlin in the Grundner Atelier, and he afterwards obtained a place in the Studio of Reproduction of H. Hirsch, in those days a flourishing institution. Here he remained for five years, and acquired for himself knowledge of the most varied character, taking especial interest in the production of portraits on porcelain. At the age of sixty he left Berlin for Vienna, and was then employed for various intervals in the studios of Julius Leth, C. Haack, Victor Angerer, and Pokorny and Reuter. He stayed for some time at Kozmata, in Pesth. Then, for several years, he possessed a studio of his own. In the meanwhile Beyersdorff had been actively employed in reproductions by F. Bruckmann, in Munich, and Römmler and Jonas, at that time Wilhelm Hoffman, in Dresden. Beyersdorff has made himself known repeatedly to the readers of the *Photographische Correspondenz* through his communications, showing considerable practical knowledge of photography. He was nevertheless rejected when he applied for the post of Professional Instructor in the Royal Institution established for experiment and instruction in this art.

In the beginning of the current year Beyersdorff began to sicken; unlucky financial conditions affecting his private purse hastened doubtless his deathward career. As if inspired with some sad presentiment, he with much labour and difficulty reduced his varied experiences and experiments to some sort of order, intending to publish them for the use and gratification of his fellow professionals, but in the midst of his toil, in the month of March of the present year a pneumoplegea, or paralysis of the lung, brought his busy and careful life to a comparatively sudden end.

A new amateur photographic society entitled "Freie Photographische Vereinigung zu Berlin" has been established under the presidency of Herr Gustav Fritsch.

The Royal Institution.—The general monthly meeting was held on Monday, April 7th, with Sir James Crichton Browne, M.D., LL.D. F.R.S., Treasurer and Vice-President, in the chair. Mr. Arthur Edward Ash, Mr. Robert Dobbie, Mr. William S. Hall, Major Percy A. Macmahon, R.A., Miss May Pollock, Mrs. Joseph Shaw, and Major-General C. E. Webber, C.B., were elected members of the Royal Institution. The special thanks of the members were returned for the following donations to the fund for the promotion of experimental research:—Mr. Ludwig Mond, £100, and Mr. Lachlan M. Rate, £50.

PHOTOGRAPHIC EXHIBITIONS IN AMERICA.*

There are some things in connection with photography of which, as a nation, we may well be proud, and there are some in connection with which we might profitably take a leaf out of the book of our brethren across the water. Of the latter, by far the most important, in our opinion, is the holding of exhibitions of photographs as frequently as possible, and in as many centres of population as may be practicable.

Readers of the various English journals devoted to photography cannot but be struck with the many exhibitions that are noticed in almost every number as being held all over Great Britain, even in towns that a few years ago would have been considered too small to offer a chance of success, and perhaps even more striking is the fact that they are successful, not only in so far as really good displays of photographs are almost invariably got together, but that they are almost always financially so. It is true, we have annually one grand—or what ought to be a grand—exhibition, in connection with the Photographer's Association of America, but in consequence of distance, and other causes, it is seen by comparatively few, and has little or no influence in the most important phase of such institutions, the education of public taste.

Exhibitions, less pretentious, but vastly more useful, have also been occasionally held by several local societies, but before such influences can be brought to bear on the whole people, they must become much more numerous; be more systematically organized, and especially more thoroughly popularized.

We have repeatedly expressed the opinion that the only way by which photography as a profession can be raised from its present position to the platform which it ought to occupy, is the elevation of photographers themselves from photographers merely to artists in the true sense of the term. Photography will never attain to its rightful position till those who practise it cease to be content with pretty, nicely-finished photographs; and not only aim at, but succeed in making each photograph a picture.

In the present state of matters, however, so long as a certain degree of technical success in photographic practice is so easily reached, and the general public are sufficiently ignorant of art as to be satisfied with such productions, it would be unreasonable to expect much improvement; and thus we are met face to face with the fact that photographic advancement really depends on the art education and culture of the public.

We believe that properly organized and properly popularized exhibitions would be found among the most efficient, if not *the* most efficient, of all means of promoting such education, and therefore urge every photographic society and club throughout the country to get up at least one exhibition every year. How best to do that it is not for us to suggest, as the details will probably require to be different in different localities, but a few suggestions may not be out of place.

In the first place, and perhaps most important of all, there should be no question of "shop" introduced, and absolutely no distinction between professional and amateur. Although we have frequently shown the impossibility of making satisfactory awards for works of art, we know that as yet awards must be offered as inducements to photographers to send pictures for exhibi-

* From *The Beacon*, of Chicago.

tion, and so medals should be offered, but offered for the best pictures considered from an art point of view, and irrespective of process or person. Many of the societies are too weak to do much in the medal way; but we are persuaded that if the thing were fairly started and properly wrought, each exhibition would not only pay its own way, but leave a balance in its favour.

Then the Photographers' Association of America might redeem its character by lending valuable aid. It might save some of the money now worse than wasted in very much overpaying officials, and make a suitable die from which silver and bronze medals could be struck and offered for competition. The medals would cost little more than the price of the metal, and be infinitely better than the fancy, but generally little to be fancied designs that are selected from year to year. One or more of each of such medals given to each society, and offered as the "Association medal," would be, we believe, eagerly competed for, and an excellent means of securing large numbers of exhibits.

Another cardinal point should be the abolition of the foolish system of charging for wall or exhibition space. Not only should the exhibits be admitted free, but, whenever the society can see its way to it, the carriage should be paid one or both ways, and the hanging committee should have full power, and exercise it rigorously, to exclude every frame that does not come up to a certain standard. By frame we of course mean picture, and no picture should be admitted without a frame.

The most difficult question is undoubtedly that of the judges. In selecting them it should be kept in mind that the object of the exhibition is to promote the advancement of art, and that fine finish, "chemical effect," and all that sort of thing, should be utterly disregarded. At the present time that would almost imply that the jury should not include a photographer; or, if it does, he should be one who would rather give the prize to a production of Mrs. Cameron or Rejlander, stained and blotched, and technically imperfect, as they too often were, than to some pictures to which were awarded a gold medal at the Boston convention for nothing but nice finish and technical qualities. But it is difficult for a photographer to altogether ignore "beautiful sharpness" "delicate detail," &c., &c., and, therefore, we would put our trust in a jury of acknowledged artists.

But all this, even if done in the very best way, will be but labour in vain, so far as the main object is concerned, unless the public can be induced to come and see. How this is to be achieved each society must decide for itself. We were once prominently connected with an exhibition in a city of 250,000 inhabitants, for which we had gathered together from all quarters of the globe 1,149 frames, sent by 208 exhibitors, and displayed them to excellent advantage in a suite of six great halls, the use of which was liberally granted by the government of the time. The galleries were occupied till 10 o'clock on the night before the advertised day of opening, but the pictures were unpacked and standing in corridors and ante-rooms, and a few minutes after that hour a number of willing hands carried them in. They were examined by the committee of selection, passed to the hanging committee, and hence to the walls so rapidly that by 10 o'clock next day the exhibition was opened and the catalogue in the hands of the printer, who handed us the proof-sheets a little after 12 o'clock.

We doubt whether ever so much work was done and done so well in such a short time, but it should be remembered that it was not done by paid officers. It was all a labour of love and could not have been done for filthy lucre.

But although we had arranged certainly the best photographic exhibition that had as yet been seen, and had ticket seller, check taker, and doorkeeper—the latter a government official in uniform and cocked hat—all ready to welcome the dear public, that public did not come. The second day seemed about to pass as unsuccessfully, and some of us were looking, or at least feeling, very blue. A meeting of the committee of management was held, and one of the members said it was quite evident that the public had no idea of the treat that awaited them, and, consequently, must be brought in to see it. The only way to do that was to make the exhibition fashionable by getting the military band to play during the afternoons. On its being pointed out that it would cost 35 dols. a day, or some 875 dols. for the month, and that we had not the wherewithal to pay it, he offered to guarantee the payment, and the offer was accepted on the spot.

Next day the band marched from the castle through some of the principal streets and into the galleries, bringing in its train an influx that almost filled the rooms. In the meantime some of the newspapers were induced to send art critics, and for others art critisms were written, so that for a few days every morning paper contained a glowing account of the treasures to be seen, and thousands that were crowding to see them. In short, the exhibition was a great success, and yielded a revenue of nearly 4,000 dols., which not only enabled the committee to pay all the expenses and give a handsome, but unexpected, honorarium to each of a few of the most active workers, but also to place in the bank a good round sum to be available on a future occasion.

Somewhat Dismal News.—"We have been favoured," says *Burgoyne's Monthly Magazine*, "with a copy of the weather chart of London, compiled by Mr. B. G. Jenkins, F.R.A.S., from which we abstract the following particulars concerning our disgraceful climate for the year of grace we are now in:—April—Rather wet, especially for ten days round middle. May—Rather dry; wet for about a week round the 25th. June—Rather wet. July—Wet; thunderstorms about 3rd, 8th, 15th. August—Wet; stormy about 9th and 22nd. September—Rather wet. October—Dry; but gales about 5th, 15th, 22nd. November—Dry; fog about 12th, 17th, 19th. December—Rather dry; but gales about 8th, 20th, 27th.

The Liverpool Amateur Photographic Association.—This Association will have an Optical Lantern Evening on Monday, 14th April, when an entertainment will be given at the City Hall, Eberle Street, Liverpool.—Part I., at 7·30 promptly, "The Hundred of Wirral," the Completed Survey, with Descriptive Lecture by Mr. John Hargraves, when about one hundred and fifty lantern slides will be shown, from negatives taken by the members of the Liverpool and Birkenhead Societies. Part II., at 9·15 promptly, the New Boston (U.S.A.) Set entitled the "White Mountains," with full descriptive matter supplied by the Boston (U.S.A.) Photographic Society. An excursion will be made to Raby Mere, on Saturday, 12th April. Members can meet at Club Rooms, at 1·30, or on the Stage at 2 p.m. The train leaves Birkenhead at 2·20, and is due at Bromborough at 2·39; taking the lanes and cross country route, finishing up at Raby Mere. The train leaves in return at 6·40, due at Landing Stage 7·15, or a later train is timed from Bromborough 7·45; due at the Landing Stage at 8·25. Conductor: Mr. William Tomkinson. The pictures of Mr. Harry Tolley are now on view. Members can obtain tickets for the admission of friends on application at the Rooms.

THE LATENT PHOTOGRAPHIC IMAGE.*

BY C. H. BOTHAMLEY, F.I.C., F.C.S.

Few questions are of greater interest to the scientific photographer than the nature and properties of the latent image, *i.e.*, the result of impact of light on a photographic plate, invisible to the eye, but quickly revealing its presence when the plate is treated with a reducing agent in the form of a developer. It has been the subject of a considerable number of experiments, and a very large amount of speculation, and a paper which aims at giving a complete summary of what is known about the matter, as distinguished from what is merely guessed or surmised, may not be without some value. It is often very useful to realise exactly what point we have reached, and what problems still remain to be attacked.

We are concerned with the action of light on the haloid compounds of silver embedded in gelatine or collodion and surrounded by the aqueous vapour and other gases of the atmosphere, and are only indirectly interested in the effect of light on these salts when pure or merely in contact with water. The changes which take place under the latter conditions have, however, an important bearing on the probable nature of the latent image. Briefly, it may be said that the published experimental evidence shows that perfectly pure silver haloids in a vacuum are not decomposed by light at all, but in the presence of moisture silver bromide or chloride is altered with formation of a dark-coloured compound containing a lower percentage of the halogen than the original salt. At the same time a substance is formed which has the power of liberating iodine from potassium iodide, and if the action of light takes place in presence of liquid water, the solution gives a precipitate of silver bromide or chloride on addition of silver nitrate. The nature of the substance which acts on potassium iodide has never been satisfactorily investigated. The dark, solid product is in all probability not metallic silver, because the action of light readily takes place even in the presence of nitric acid so strong that it readily dissolves the metal. For a long time it has been supposed that the dark substance is silver-sub-bromide or sub-chloride, but this point will be discussed later on.

When light acts on the silver haloids in a collodion film, the halogen which they lose may interact partly with the moisture which is always present, partly with the pyroxiline. It is, however, well known that pyroxiline shows comparatively little tendency to yield chlorine or bromine derivatives, and hence it is probable that the part which it plays in the alteration of the silver salts is of secondary importance.

Gelatine, however, behaves quite differently. It readily takes up chlorine and bromine, and if bromine water is added to a solution of gelatine, a yellowish, curdy precipitate of a bromo-gelatine is formed. Knop found † that gelatine will take up as much as 30 per cent. of bromine, forming a yellowish, insoluble compound. There can be little doubt, therefore, that when light acts on the silver haloids in presence of gelatine, the bromine or chlorine which they lose combines with the gelatine. We have, indeed, direct evidence in the fact that where the light has acted the gelatine becomes less soluble. The readiness with which the gelatine takes up the halogen explains its great efficiency as a sensitiser, and the consequent high sensitiveness of gelatine plates.

* Read at the Camera Club Conference, and published in the Journal of the Club.

† *Chem. Centralblatt*, 1879.

Three views as to the nature and mode of formation of the latent image seem to me to deserve attention. Many hypotheses, and guesses unworthy even of the name of hypothesis, have been put forward, but have served only to prove that their promulgators were incompetent to deal with the question by reason of their want of acquaintance with the established facts of chemistry and physics. The problem is, in fact, of a high degree of difficulty and complexity, and its solution will require experimental work of the same order of accuracy as the work involved in the determination of the atomic weights of the elements. It seems almost necessary to point out that work of this kind involves a certain amount of preliminary training.

The physical theory of the latent image assumes that the energy of the light rays is transferred to the molecules of the silver haloid, which are thereby thrown into a state of unstable equilibrium such that the compound is reduced to the metallic state by re-agents which, under normal conditions, would have no action on it. The chief evidence in support of this view was the observation that the latent image spontaneously disappeared. There is, however, a considerable amount of evidence to show that the latent image does not fade spontaneously, but in all cases where its disappearance is observed it is destroyed by the action of atmospheric impurities, or by secondary reactions with substances retained in the film. Carey Lea, who was at one time one of the firmest supporters of the physical theory, showed* that silver iodide will absorb free iodine, and hence the gradual disappearance of the latent image on Daguerreotype plates or any other films obtained by treating silver with an iodising agent may be traced to the fact that the silver iodide has absorbed an excess of iodine during its preparation, and this iodine gradually acts upon the product of the action of light and re-converts it into normal silver iodide.†

Analogy would lead us to expect that if the silver haloid were thrown into an unstable condition by the action of light waves, it would gradually and somewhat rapidly return to its normal condition when the disturbing cause ceased to act. I have myself kept gelatino-bromide plates for fourteen months after exposure without observing any reduction in the character of the image on development. Other workers have kept exposed plates for two‡ and even three§ years. It is in the highest degree improbable that a mere *condition* of unstable equilibrium would persist for so long a time, and these facts, combined with the fact that the latent image is destroyed by re-agents of a particular kind, but not by others, seem to me to be conclusive against the physical theory.

(To be continued.)
