A Japanese Photographer.—In its issue of March 22nd, *Anthony's Photographic Bulletin* gives a photogravure reproduction of the portrait of K. Ogawa, founder of the *Shashin Shimpo*, the only photographic periodical published in Japan. Prof. W. K. Burton gives a very interesting personal history of the Japanese photographer, and recounts the difficulties that had to be overcome by him in acquiring a knowledge of photography. The picture referred to was reproduced from a print furnished by Mr. Burton.

* *Amer. J. Science*, xxx ii.; Photographic News, xxxi., p. 386.

† Carey Lea himself *(loc. cit.)* supposes that the iodine which the silver iodide loses when exposed to light is absorbed by the adjacent unaltered silver iodide, and in course of time re-converts the photo-iodide into the normal iodide. It is doubtful whether silver iodide can act as its own sensitiser, and it seems to me that the other explanation here given is the more probable.

SUPPLEMENT TO THE "PHOTOGRAPHIC NEWS."

With the present number of this journal is issued a portrait of Thomas Wedgwood, who produced in 1802 the first English photographs. The original is a crayon drawing in the possession of Miss K. Wedgwood, of which a negative was taken for us by Mr. Ralph W. Robinson, and the photogravure work has been done by Messrs. Waterlow and Sons.

Correspondence.

THE PHOTOGRAPHIC SOCIETIES' NATIONAL CHALLENGE CUP.

Sir,—In reply to the letter in your last number, signed by Mr. Edgar G. Lee, we append the following copy of a letter addressed to that gentleman some days before the opening of the Exhibition. We venture to think that your readers will conclude that in offering to allow the Newcastle Society to substitute other pictures for those which had been previously shown and medalled at the Crystal Palace Exhibitions, we did even more than they had a right to expect.—Yours faithfully,

S. G. Buchanan Wollaston.
J. F. Peasgood.

Crystal Palace, March 28, 1890.

Edgar G. Lee, Esq.

Dear Sir,—Your papers duly to hand, and we are much obliged for the great care you have taken. We must just point out that Mr. Gibson has included two pictures with the same titles as previously sent; also Mr. Lyd. Sawyer has sent again "The Boat Builder," though shown here in 1888, and "The Castle Garth," shown here last year. As we cannot admit pictures more than once, perhaps they would like to substitute others.—Yours truly, J. F. Peasoood,

Crystal Palace, Feb. 26, 1890.

THE CRYSTAL PALACE CHALLENGE CUP COMPETITION.

Sir,—We approach this subject fully aware how unpleasant the task usually is of championizing our own works, and this alone would have induced us, under any other circumstances, to leave matters as they stand in the Crystal Palace Club Cup Competition, but for the glaring injustice of this extraordinary award, and the duty it involves of warning the photographic world against encouraging its repetition.

We have so much proof of the Cup having been misdealt with in this present case as to amount to a positive *embarras de richesse* when it is necessary to reduce it to a sufficiently compressed space for presentation before your readers.

Previous to determining on entering for this Challenge Cup Competition, we carefully perused the entire rules appertaining to it, as forwarded to us for that purpose, and found it to be thoroughly open, with absolutely no restriction as to amateurs or professionals only competing, no limitation as to size or class of photograph, and no mention even that pictures which had been previously exhibited in individual classes at the Crystal Palace were not eligible. Carefully abiding by these rules, we selected and sent 75 pictures, more than 45 of which had already received awards; 24 lantern slides and 6 stereoscopic slides, most of which had also previously been medalled.

We received the following acknowledgment and acceptance of our exhibit, under date of February 26th. [See letter quoted above.]

This was, of course, tacitly accepting all our exhibits with the exception of the four pictures mentioned. These latter were sent because we found that *there was no rule debarring them*, and because it was as reasonable to accept pictures for the Challenge Cup class which had been shown in individual classes last year as to accept pictures shown in individual classes this year. However, on receipt of this letter, Mr. Gibson and Mr. Sawyer each wrote to the executive separately, requesting that the four pictures alluded to should be placed aside until the end of the exhibition, and Mr. Sawyer forwarded two others in place of those of his objected to.

Subsequently, we received another letter from the same source, of which the following is a sufficient extract, dated March 8th:—

Your Club exhibit has arrived safely, and all pictures are hung. I think you will be very pleased with the show.

If all our pictures were hung, in face of two separate requests from us for four of them to be withdrawn, it suggests that either they were, after all, accepted as admissible by the executive, or else that they were still hung as a weak plea for afterwards disqualifying us. Which was it?

We next hear of our pictures through *Photography* of March 20th, which states:—

At the time of writing this we do not know the awards, but, to our minds, Newcastle—by reason of having at least five noted professionals represented—stands far away ahead. Next must come the Liverpool Amateur, which is represented by an excellent lot of pictures.

Writing later, in the same number, *Photography* again says:—

It will be seen by our report that the Society Challenge Cup Competition at the Crystal Palace has fallen to Birmingham. It is rather a significant fact (*vide* report) that when the award was announced on the sheet, it appeared as "Three Cheers for Birmingham." Before expressing any further opinion on the matter, we should like to know *if any Societies were disqualified, and why?*

The *Amateur Photographer* for March 21st contains the following anent the Cup Competition:—

Next year probably some conditions will be laid down by the management, for surely it cannot be an equal competition when one of two alcoves occupied by the Newcastle Society is filled by the work of two such men as Gibson of Hexham, and Lyd. Sawyer.

Now, one of the extraordinary parts of this quotation is that we have reason to believe it was written by one of the judges of the Cup Competition, and, although it says plainly that our exhibit was too good for the rest, yet the Cup has not been awarded us! We know that we *cannot* be *honestly** disqualified, and, as stated in our previous letter which appeared in your columns, we challenged an explanation, and stated that we had good authority for knowing that only a portion of our pictures was judged.

The following reply from the Executive, dated March 24th, was duly received:—

In reply to your letter of 21st inst., I have the honour to refer you to our letter of 26th February ult., and to Rules 6 (note to rule) and 16, marked and enclosed. You can have no *authoritative* information except through the hands of the Executive, consisting of Mr. Peasgood and yours faithfully, S. G. Buchanan Wollaston.

This is very nice and decisive, if we were prepared to accept it, and if there was no higher tribunal than these same Messrs. Peasgood and Wollaston to appeal to. But we did not take the trouble to make and send our exhibit only to be dealt with as *their* whims or interest dictated. There *is* a higher tribunal, in the shape of our photographic *confrères*, to lay the matter before.

Here, then, let us analyse their lame attempt at justification. "Our letter of 26th February" refers to the one above quoted, in which they objected to two pictures sent by Mr. Gibson and two sent by Mr. Sawyer. As Messrs. Gibson and Sawyer each individually wrote asking for these four pictures to be withdrawn, this fact ceases to have any bearing upon the case. The "Note to Rule 6" referred to says:—

N.B.—The Executive reserve all rights as regards the hanging of pictures, and may refuse to display any picture without assigning reasons for so doing.

This rule *in no manner* applies to us, as, according to their own statement of March 8th, *all our pictures were accepted and hung:* but whether or not this includes the four pictures objected to we cannot say, and as it was a matter entirely resting in their own hands, we are not legitimately affected by it.

Rule 16, as underlined by them, says:—

From the decision of the Judges there can be no appeal.

Very proper, so far as it goes; but more remains behind. They continue:—

You can have no *authoritative* information except through the hands of the Executive, &c.

* There is no question as to the absolute honesty of intention of the Crystal Palace authorities, and of Messrs. Wollaston and Peasgood.—Ed.

That is official-like, but, unfortunately, it is not, or *should not*, be true. The *judges* are—or, shall we in this case say, *should be?*—the first authorities in these matters, and it is from *one of the judges* we learn that Messrs. Gibson and Sawyer's pictures (not the four of them in question, but all, or nearly all) were left unjudged; hence, as the judges did not decide on all our exhibits, it is not a complete decision, and need not be final. Now what can your readers infer from this array of facts? The letter of the judge—a man of known integrity and eminence—was not sent us for publication, so we refrain from any possible breach of confidence by further locating it, and we have an amount of other confidential correspondence touching on the subject, couched in terms which would make Messrs. P. and W.'s ears tingle if they heard it.

We hope your readers will not think that we are still sighing for "the Cup that cheers" (!) We did at first intend to obtain it by legal means, but now feel it to be made of a too "base metal" to touch on any consideration; and if our Birmingham *confrères*—against whom we have no single word to say—feel that they can hold with honour what they must now know is not fairly their own, then they are very welcome to keep it.

It remains for us to apologise to you for the unavoidable length of our communication, which we trust may come, at all events, with some nogative appropriateness to the present discussion on rules and regulations at exhibitions. We, at least, have arrived at a very unanimous decision from this experience, which is, that we will individually and collectively carefully avoid any future exhibition associated with the names of Messrs. Wollaston and Peasgood, in the event of such a contingency ever again arising.

THE CRYSTAL PALACE EXHIBITION.

Sir,—Will you please announce in next issue that the award in Section 4, Lantern Division, was made to Fred H. Evans, and that Mr. Wade's initials should have been "J. W."

J. F. Peasgood.

Photographic Society of Great Britain.—At this Society on Tuesday, April 15th, at 8 p.m., at 5a, Pall Mall East, London, a paper will be read by Mr. C. H. Bothamley, F.C.S., F.I.C., on "A Standard Method of Development."

Salted Paper for Enlargements.—The *Bulletin* of the Photographic Society of Italy, published at Florence, gives in its last number a special formula for salted paper for enlargements, communicated to it by Signor G. Moretti, a member of the Society and Director of the Studio for the Dilettanti Photographers in Florence. The formula is this:—

Water	1,000 gr.
Gelatine	2 ,,
Chloride of sodium	4 to 6 ,,
Citrate of soda	21 ,,
Ammonia chlorhydrate	13 to 16 ,,

The gelatine, cut up into very small slices, is first dissolved in the tepid water; afterwards the other substances are added: when all are dissolved the solution is filtered, and placed in bottles for use. To prepare the paper, the mixture is poured into a basin, and the sheets are allowed to float for three minutes, using the same precautions as in the preparation of albumenised paper. After the moisture has been removed from the sheets prepared with this solution, they are sensitised on an ordinary 12 per cent. silver bath, and when dry they may at once be used, and a beautiful tint, imitating perfectly that of hematite, will be obtained. When the bath above described is employed, especially if it be fresh and uncontaminated by any noxious vapours, the sensitised paper may be kept in excellent condition for three days during the summer, and for a week in the winter season.

Patent Intelligence.

Specifications Published.

5,337. *March 28th*, 1889.—"Photographic Cameras, and Apparatus in connection therewith." William Henry Smith, Upton Villa, Beckenham Road, Kent, Engineer, and William Willis, Bromley, Kent, Manufacturer.

Our invention relates to photographic apparatus, and one of its objects is to provide improved means whereby sensitised plates or films may be conveniently transported, and may at any time be inserted in and removed from the camera without liability to exposure of the said plates or films to light. Our said invention, moreover, comprises an improved shutter, hereinafter described, for facilitating exposures of short duration.

For holding the sensitised plates and transferring them, as required, to and from the camera, we employ a holder or dark-slide, which comprises a metal sheath or case, one end of which is open, and is firmly attached to one side of a tube having slots therein through which the plates may be inserted in and removed from the said sheath. In the said tube is fitted a plug of shutter of any suitable material. This plug is so formed that the portion thereof which corresponds with the slots in the tube is semicircular or of other convenient shape in tranverse section so that it will, in one position, close the opening or mouth of the sheath, or case, and thus exclude light, but, by turning the said plug about its axis through a greater or less angle, a clear way through the slots and the open end of the sheath may be made, through which the photographic plate can be inserted or removed.

Our improved dark-slide is very compact and can be cheaply manufactured. Moreover, the said dark-slides can be very closely packed, so that a large number of them may be contained in a comparatively small space.

To provide for the use of our improved dark-slide on a camera, we attach to the said camera a tube or portion of a tube with a slot in it through which a plate may pass into or from the camera; this tube is of such internal diameter that the tube on the aforesaid sheath or case will accurately fit and slide in it. The tube or socket on the camera is, moreover, provided with a slot throughout or nearly throughout its length to admit the sheath or case, so that the dark-slide can be readily applied to or removed from the camera. When the dark-slide containing the plate is slid into position in the aforesaid tube or socket, and the plug is turned by a key or otherwise through the required angle, the plate will fall through the slot in the said tube or socket into the camera; grooves or other suitable means are provided in the camera to hold the plate in a proper position therein. To remove the plate from the camera, the latter is inverted, and the operations above described are performed in the reverse order.

In some instances, we provide a key or other device in one end of the tube or socket on the camera, so that, by turning the dark slide through the required angle after it has been inserted in the said tube or socket, the said dark-slide may be opened and closed.

In other instances, we arrange within the tube or socket on the camera another slotted tube capable of revolving therein, and adapted to receive the tube on the sheath. Then, by arranging in a proper position the key or other device for opening and closing the dark-slide, we are enabled to insert the sheath in the tubes on the top or side of the camera in a plane parallel thereto, and then, by turning the said sheath about the axis of its tube, the opening of the sheath will be effected, and the slots in the tubes brought into line with each other, thus permitting the plate to fall into the camera. When the plate has been thus transferred to the camera, the sheath may be turned back so as to lie parallel with the top, and therefore out of the way, or, when in this position, it may be altogether withdrawn, the slot in the camera, when the inner tube is in this position, being closed by the said inner tube.

We sometimes provide the camera with means for attaching a dark-slide to the top thereof, and another dark-slide to the bottom thereof, one for the insertion of the unexposed plates

into the camera, and the other for the reception of the exposed plates from the camera. We can employ with a camera any desired number of interchangeable dark-slides constructed as above described.

If desired, we provide means whereby the sliding of the tube on the sheath into the tube or socket on the camera will effect the opening of the dark-slide.

We sometimes employ a slotted tube, or socket, similar to that above described, in combination with a dark-slide of ordinary construction (or with a receptacle similarly used), so that plates or films may be inserted therein and removed therefrom by means of our improved dark-slide without risk of exposure of the said plates to light.

Our improved dark-slide is constructed to contain a single plate, or is adapted to contain and successively deliver more than one plate. In the latter case, the dark-slide is provided with grooves, or other devices, for keeping the plates apart, and is made reversible in the tube, or socket, on the camera.

We sometimes provide for facilitating the removal of the camera from a tripod for the purpose of inverting the camera to change plates by means of our improved dark slide, and for permitting the removal and replacement of the camera without risk of altering a position already secured by the tripod. For this purpose we provide on the underside of the camera a projection, or block of wood or metal, having parallel sides. This projection fits into a suitable groove, or opening, in the tripod-head, or, preferably, in a turntable which is attached to the tripod-head, capable of being partially closed, so as to tightly clamp the said projection. The closing of the sides of the groove against the said projection may be accomplished by means of a spring, screw, cam, or eccentric, or otherwise.

Our improved shutter for effecting exposures of short duration comprises two plates, or pieces of metal, or other suitable material, each having its inner end V-shaped, and its outer end provided with a projecting pin or stud. These pins or studs slide in cam-grooves formed in a disc of ebonite, or other suitable material, acted upon by a spring whereby it is partially rotated to open and close the shutter.

If the shutter is applied to a lens of the doublet or rectilinear type, the slides are preferably arranged to operate between the lenses, the mount of the lens being cut or divided for the purpose of admitting them. When the shutter is closed the V-shaped ends overlap each other, and when the shutter is opened so far as just to admit light through the lens, the aperture thus formed should be central in respect to the lens. These V-shaped shutters slide easily over one another in grooves, and, on being operated, they first of all recede from one another until the maximum aperture is given to the lens, and afterwards approach each other until the aperture is closed. The aforesaid grooved disc is preferably fitted to turn on the mount of the lens. A catch with a trigger forms a convenient means for releasing the spring for operating the shutter. A suitable device is provided for winding up the said spring. We prefer to use, for this purpose, a ring or annular piece fitted to turn in a box or case enclosing the said disc. The duration of the exposure may be regulated by winding up the spring more or less as may be required.

Twelve claims are appended to the complete specification, which specification is accompanied with drawings.

8,085. *May 15th*, 1889.—"The Production of Developers." Henry William Jones, 17, White Street, Coventry (formerly, and at date of application, residing at 3, Grosvenor Street, Coventry), Chemist.

The nature of the said invention described as "Improvements in the Production of Developers for Photographic Use," is to produce a portable and permanent photographic developer, consisting of a specially prepared compound of hydrokinone in a compressed state. To accomplish this I take crystallised sulphite of sodium, or similar alkaline sulphite, but I prefer to use the ordinary sulphite, and I heat this until it fuses, and until all water of crystallization has been driven off. The dry mass is then ground with an equal weight of hydrokinone or other similar proportion, but I prefer an equal weight, and one-tenth part of the whole of bromide of sodium added. The mixture, after being thus made, is wetted with aqueous sulphurous acid, and then partially dried; and whilst still damp forced through a sieve of forty meshes to the inch, and dried at a gentle heat, by which means the compound is obtained in small dry granules. The compound thus formed is made into tablets, or circular discs, or pellets, by a powerful press.

What I claim is:—

1. The production of a compound, formed from alkaline sulphite, as sodium sulphite which I employ, hydrokinone and alkaline bromide, as sodium bromide which I use; the same compound being produced in the dry granular form, as and after the manner described.

2. The formation of the compound hydrokinone, produced after the manner described, into pellets, or tablets, or discs by pressure, exerted by a steam or other form of press.

7,939. *May 13th*, 1889.—"Shutters for Cameras." John Thomas Daniels, 14, Smith Street, Northampton Square, London, E.C., Mathematical Instrument Maker.

This invention relates to improvements in shutters for photographic cameras, the object being to combine simple instantaneous shutting mechanism with equally simple devices whereby the shutter can be kept open and the lens exposed for any desired length of time.

The shutter which I propose to use consists of a rectangular piece of sheet metal, mounted in vertical guides fixed in front of the lens or object glass. On the outer face of the shutter is a stud or button, and on each of the vertical guides is a similar stud or button, these latter being placed horizontally opposite each other and vertically above the stud in the shutter so that the three studs represent the three corners of a triangle of which the apex, represented by the stud in the shutter, is the lowest. For a reason which will be afterwards explained, the upper studs project further from the guide pieces than the lower one in the shutter. Around the three studs is stretched an india-rubber ring which, when free to act, raises the shutter and exposes the object glass. The shutter is, however, controlled by a notched lever pivotted below the lens tube, the notch spanning a pin on the bottom of the shutter, in which position it is retained by a flat spring. The releasing motion can be effected by pneumatic pressure or other device, and the contraction of the india-rubber ring jerks the shutter quickly upwards and retains no further hold on the stud in the shutter, as the latter falls in consequence of the lower stud lying in a different plane from the two upper ones, and the tendency of the ring to hang vertically when free to do so. Thus released, the shutter would fall under the influence of gravitation, but its downward motion is accelerated by a second india-rubber spring which is stretched across its upward path, and with which the stud in the shutter comes in contact, whereby its upward course is checked, and a rebounding motion imparted to it. For "time" exposures a vertical lever is pivotted to the shutter slides or other convenient part, the upper end of which is turned inwards towards the shutter. To the lower end of this lever is hinged an arm, which can be connected to the catch lever which retains the shutter in its closed position. As soon as the latter is disengaged by the pneumatic or other appliance, the shutter flies upwards, but before it can descend, the turned-in end of the side lever has advanced sufficiently to intercept its downward motion, and the operator can thus obtain any desired period of exposure.

It must be understood that the details above mentioned may be modified without departing from the main features of the invention.

7,007. *April 26th*, 1889.—"Producing Negatives for Mechanical Printing Processes." Charles Studders and Georg Kohl, of the firm of Studders and Kohl, of Leipzig Reudnitz, Germany.

This invention relates to the production in a camera of photographic negatives suitable for mechanical printing processes, and especially to the process in which the said negatives are produced by arranging before the sensitive plate a transparent screen having a number of opaque parallel lines or cross hatchings. Heretofore it has been usual to place the screen and plate in the dark back, and to expose the same in the camera for a certain period, and then to remove the dark back

and replace the screen by another screen, the lines of which stand generally at an angle of 90° to those of the first screen, and again expose the plate in the camera for the remainder of the necessary period of exposure. This twofold insertion of screens occupies more time and trouble, and the sensitive plate is liable to be shifted in the process so that the negative is doubled and therefore useless.

The object of this invention is to enable one screen to be used, and to be moved into the second position without removal from the camera.

To this end they support the said screen in a circular frame, providing the latter with a fixed bead and with a movable bead adjusted by set screws for holding the screen. This circular frame is supported in a circular hole in a suitable carrier, adapted to be placed in the camera so that the frame may be moved to an angle of 90° (or for a greater or less angle if desired) in its plane. Suitable stops are provided for accurately limiting this movement, which may be effected by hand by means of a cord connected to the frame and led out through a suitable hole in the camera. The screen being set in one position and the sensitive plate inserted, the lens is uncovered, a half time exposure given, and the lens is again covered. The screen is then revolved by the cord into the second position, and the remainder of the exposure given.

4,082. *March 8th*, 1889.—"Head for Camera Stands." Fox Shew, 88, Newman Street, Oxford Street, London, W., Maker of Specialities in Photographic Instruments.

The invention relates to an improved head for portable folding or non-folding camera or other stands: to this end the inventor so constructs the head that the supports may be removed, and when closed by inserting two of them within the third, and capping the third with a top, the stand may be used as an ordinary walking stick, preferably bamboo.

In practice he makes the head circular smaller at top than at base, for the purpose of obtaining an angle inside, so that when the sticks are inserted in their respective positions they form an extended triangle at base, making a firm support for the whole apparatus.

The inventor claims:—

The use of one complete circle and two half sections or half squares, preferably half circles, contained in one large conical ring, to attain the object shown in the drawings accompanying the provisional specification.

Photography and Wood Engraving.—Mr. H. Trueman Wood, in the course of discussion on a paper read at the Society of Arts by Mr. W. J. Linton, said that he thought the recent school of wood-engraving, in great measure, owed its faults and merits alike to photography and the public taste as influenced by photography. He had heard a lecturer on photography, holding up an excellent old woodcut and a modern one by the side of it, point out that by means of photography the public taste had been educated to look for something better than they were satisfied with twenty years ago. The public had got to look for minute detail, and the exquisite rendering of tone and colour effect which they found in photography, and hence were not satisfied with the semi-conventionalised older forms of wood-engraving; but this public taste for photography had somewhat avenged itself, for the recent school had succeeded mainly in copying the faults of photography, so that many of their engravings looked like badly exposed photographs. It seemed to be much easier to copy photographic faults, flatness, and absence of vigour, than to render that microscopic minuteness of detail which was in part one of the beauties and in part one of the greatest defects of photography. On the other hand, some of the more recent school of photographers—the impressionist or naturalistic school, as they were called—tended to imitate inferior wood-engraving, to strive after effects which photography was not capable of rendering, whilst dispensing with those which it would render most satisfactorily. Possibly by means of photographic methods they might get back again to a more vigorous style of work. The modern periodical press, which now depended for its illustrations to a large extent on photographic methods, demanded a rapidity which was incompatible with the finer quality of work.

THE LANTERN SOCIETY.

The new Lantern Society, under the chairmanship of the Hon. Slingsby Bethell, C.B., has issued a notice drawn up by its Council, suggesting that the objects of the Society may be fittingly attained in the following manner:—

1.—By the engaging of premises in some central position in London, at which the meetings of the council and of the Society may be held.

2.—By acquiring suitable apparatus for the purpose of giving exhibitions of general and scientific interest, to both members and their friends.

3.—By obtaining the services of specialists in every branch of art or science suited to optical demonstration.

4.—By offering, as far as the funds of the Society will permit, remuneration or awards for the development of the optical lantern, and of all apparatus pertaining thereto.

5.—By imparting instruction to those who are desirous of learning how to effectively manipulate the optical lantern, to produce slides and apparatus, and to efficiently employ the same both in private and public.

6.—By securing for the members of the Society special and advantageous terms from manufacturers and others for the purchase or loan of apparatus and slides.

7.—By forming a large and comprehensive loan collection of lantern transparencies pertaining to art, science, and kindred subjects; such loan collection to be placed at the disposal of every member upon conditions to be laid down by the council.

8.—By providing a means of inter-communication between the members of the Society, whereby each member may be made acquainted with the private collections of his fellow-members, and may be able to negotiate a mutual loan if so desired.

9.—By arranging an interchange of demonstrations between photographic, microscopical, and other societies interested in optical lantern work.

Proceedings of Societies.

Sheffield Photographic Society.

The monthly meeting was held at the Masonic Hall on Tuesday evening, when it was unanimously agreed that the first excursion be to Bolton Abbey and Woods, June 11th, or as near that date as can be arranged.

In reference to the late exhibition for the benefit of the Sheffield General Hospital Building Fund, it was announced that the nett amount to be given to the same was £10 10s., along with £1 2s. 9d., given by Miss Dorris Taylor.

Mr. T. Hibbert laid on the table some prints produced by the new "kallitype" process, which gave satisfactory results; after which Mr. R. J. Shields, of Mexbro', gave a paper, subject "Notes on a Tour in Norway."

London and Provincial Photographic Association.

At the meeting on the third inst., Mr. W. Bedford occupied the chair.

Mr. H. M. Hastings exhibited a print from a negative taken on an isochromatic plate, and also a print from a negative taken on an ordinary plate. From a comparison of the prints, it was generally conceded that the ordinary plate had proved the more rapid of the two.

Mr. J. J. Briginshaw showed a lantern slide of a microscopic object, from which the cover glass had been removed; the part of the film which had been in contact with the mask was covered with brown markings.

Mr. A. Haddon thought that the effect might be due to moisture from the binding strip getting between the glasses, or to insufficient washing.

Mr. Briginshaw exhibited a "facile" camera fitted with the new patent sheaths for holding the plates, by which any thickness of plate could be used.

Mr. A. Haddon, referring to a published article on "Celluloid and Electricity," in which a possible danger of electricity being generated in a celludoid film was suggested, said that he had made several experiments in coating celluloid films with emulsion, and he showed a negative in which the ramifications

of what was believed to be an electrical discharge could be clearly traced. Celluloid, he said, is composed of gun-cotton and camphor, and is known to be highly electrical, therefore as a support for sensitive emulsion is liable to give off a discharge with the least friction. Mr. Haddon mentioned an instance of simply drawing the film through the fingers in the act of unwinding it from the roller being sufficient to set up an electrical discharge to the detriment of the film.

Mr. W. COLES, in comparing the results of his experience with the eikonogen and ordinary pyro developers, said he should give preference to the latter developer for density of image.

Mr. W. E. DEBENHAM suggested that when reference is made to density, it should be borne in mind that it is of two kinds, ocular and printing.

The CHAIRMAN said that some makes of plates gave out during development a greater amount of free bromine than others, and this would influence the action of the developer, causing it to be more or less restrained.

Mr. A. COWAN had made many experiments with eikonogen by itself and also mixed with pyro, and had found no decided difference.

LEWES PHOTOGRAPHIC SOCIETY.

AT the ordinary meeting April 1st, with the President in the chair, Mr. G. J. Wightman opened a discussion on "Pinhole Photography," and specimen negatives and prints were passed round for inspection.

The Society is about to commence a photographic survey of Lewes and environs, to be carried out as far as possible during the coming summer; and it is intended to produce a set of lantern slides which can be sent to any other Society in exchange for a similar set.

The first excursion of the season will be to Newhaven, on April 24th.

At the next meeting, on May 6th, Mr. J. J. Holloway will read a paper on "Cloud Photography."

BOLTON PHOTOGRAPHIC SOCIETY.

THE monthly meeting was held at the Baths, Bridgeman Street, on Thursday, April 3rd, Mr. EDMUND NAISH ASHWORTH in the chair.

Mr. R. HARWOOD gave a lecture on his journey round the world. Many of the places described by Mr. Harwood were, by the aid of the optical lantern, worked by Mr. James Leach, disclosed to view.

Mr. WALTER KNOWLES exhibited an apparatus, actuated by clockwork, for mechanically rocking the plate during development.

ERRATA.—In our last, the statement that Messrs. Skinner and Co.'s camera therein described was provided in addition with a fine adjustment, should have been, was "not" so provided. Mr. Fred. Ives, of Philadelphia, writes that the sense of the four last lines of the first paragraph of his communication (page 153) was destroyed by the transposition of punctuation marks: "The first semicolon should be a comma, and the next comma a semicolon; the last semicolon should be a comma."

FILTERING-PAPER FROM GRYCKSBO, SWEDEN.—In his "Treatise on Chemistry," vol. viii., p. 222, Berzelius expresses himself regarding the valuable qualities of this paper as follows:—"The best filtering-paper I know of comes from Grycksbo, in Dalecarlia; the water with which it is made is so pure that it does not give any reaction indicating the presence of foreign substances, nor does it retain any of the earths in solution. The acid and the water extract from this paper, and the ash which it leaves when burnt, are not more abundant nor of any other nature than those which come from the most unadulterated linen; that is to say, they do not amount to more than 0·006 of its weight. Latterly they have begun to make this paper an article of export, and assuredly there are few localities where nature has combined with so many favourable circumstances as at Gryeksbo for the fabrication of an excellent filtering-paper." Fresenius's "Guide to Quantitative Chemical Analysis" (1862, Fifth Edition, p. 81), on the subject of filtering-paper, says:—"The best is that known by the name of 'The Swedish Filtering-Paper," and which bears the water-mark of J. H. Munktell."—*Chemical News.*

Answers to Correspondents.

All Communications, except advertisements, intended for publication should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Sreet, London, E.C.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

H. G. P. (Ireland).—*Kiewning's Gold Toning Bath.* Our correspondent is thanked for calling attention to some errors that have crept into the formula extracted from *Lux*, and printed at the bottom of page 196 of the NEWS for March 7th. First, that grains and grammes are mixed up together, and that "chlor. potass." is ambiguous, for it may mean either chlorate or chloride of potassium; it ought to be the latter, KCl. Furthermore, it should be stated that the proportions given furnish a concentrated solution, which requires to be diluted with from fifteen to twenty times its bulk of water before use. Employed in this way, our friend says that the bath produces remarkably fine tones, and that he has used it also with aristotype paper, getting shades of colour which he has not seen excelled.

UBIQUE.—*Photographic Triplicates.* The difficulty is to get rid of the lines of junction, and instead of printing the negative piecemeal, you should try and separate the exposures by moveable screens within the camera, but out of focus, as is always done in the case of photographic doubles. It may not be easy to accomplish this at once, but a few preliminary experiments may give you the requisite technical skill, and you should aim at producing a negative with uniform density throughout. We understand the problem by the help of your sketch. It is, as we supposed, two men playing at chess, and one (full face) looking on, all three being portraits of the same individual.

R. B.—*Portraiture Prices.* We are sending you two cards of terms for London: remember it is easier to make a reduction than to advance your scale of prices afterwards.

HISTORICUS.—*Some Dates.* Your list requires rather an extended search, but we can give you at once the following dates:—"Two Ways of Life," O. G. Rejlander, 1857; "Fading Away," H. P. Robinson, 1858; "Bringing Home the May," ditto, 1863; "Stolen Moments," John Hubbard, 1869; "A Wee Customer," Adam Diston, 1871; "Rebecca at the Fountain," Valentine Blanchard, 1873; "Tired Companions," George Nesbit, 1877.

K. SCHWIER is thanked for sending us the programme of the German Photographic Convention to be held from 26th to 29th August, at Eisenach, Saxe-Weimar. To those who can spare the time to visit this attractive region, seldom seen by Englishmen, a rich treat is provided, including the usual business meetings, an evening concert at the Wartburg, and excursions to Wilhelmsthal, Ruhla, and other places in the Thuringian Forest. There is likewise to be an exhibition of photographs, mechanical prints, apparatus and materials, for which gold, silver, and bronze medals, diplomas, and money prizes are offered. Full particulars will be duly announced in our columns.

PHOTARGUS.—*Small Pictures taken with Large Lenses.* Your questions 1 to 3 may all be answered in the negative; there would be no advantage in employing a whole-plate lens for carte-de-visite work. The *f* 4 lens would be most suitable for photographing animals and children. Other points in your letter demand a fuller answer, but this Easter week is a bad time for making enquiries.

A. W.—*Platinotype Patents.* 1. All the patents are protected in France and the United States, and some of them likewise in the more important countries of Europe, including those you named. 2. The Pizzighelli process could not be worked here without infringing the Company's patent. 3. But it is open both in Germany and Belgium. 4. There are two patents, bearing date 1887, the latest.

CINCINNATI and J. H. AINLEY.—Received with thanks.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1650.—*April* 18, 1890.

CONTENTS.

A PHOTOGRAPHIC EXHIBITION IN THE CITY OF LONDON.

THE Photographic Section of the London Chamber of Commerce, which includes among its members several of the chief merchants connected with the art-science in the Metropolis, has resolved to hold a trade Photographic Exhibition in the heart of the city of London. This Exhibition will open on Friday, May 30th next, and remain open till June 10th. No charge will be made to the public for admission. The committee of management of the Exhibition consists of Mr. W. S. Bird (Autotype Co.), chairman; Mr. Frank Bishop (Messrs. Marion & Co.); Mr. T. Watson (Messrs. W. Watson & Sons); Mr. Payne Jennings, and Mr. Conrad Beck (Messrs. R. & J. Beck). The Drapers' Company, which is one of the great livery companies of London, has generously lent its hall for the purposes of the Exhibition, and the Lord Mayor has expressed his interest in the undertaking.

The Drapers' Hall, in Throgmorton Street, in which the Exhibition will be held, is a more luxurious building than has ever before been used for public photographic purposes in this country. It is a palatial establishment, more of the type of the chief *salons* of Paris, than of the cold, repellent structures commonly used for public purposes in London. A range of gilded chambers will be used for the Exhibition, and the apparatus will be chiefly displayed in the Banquetting Hall. The Drapers' Hall is a quadrangular building, with a fountain in the centre; it is rich in statues and paintings, and belongs to a powerful and wealthy organisation of high antiquity. The first Drapers' Hall upon the Throgmorton Street site was bought of Henry VIII. in 1541, and had formerly been the house of Cromwell, Earl of Essex. The present magnificent hall, on the same site, was built in 1869.

The Drapers' Company was founded before 1252, and was incorporated in 1439, "the seventeenth year of the thrice Christian king, Henry VI.," whose letters patent gave it the name of "Masters, Wardens, Brethren, and Sisters of the Guild or Fraternity of the Blessed Mary the Virgin, of the Mystery of Drapers of the City of London." Immediately after its foundation, the livery began to expend for charitable purposes about £4,000 a year. Photographers will be deeply moved upon learning that the armorial ensigns of their new friends, the drapers, are three clouds radiated proper, each adorned with a treble crown or, the crest on a helmet and torse; a ram lodged at the second, attired as the third. Supporters, two lions, as the last, peletee. Motto: "Unto God only be honour and glory." The patroness of the Company is, or was, the Virgin Mary. Those photographers who, on bended knees, have, during the past two or three years, begged to be patronised, are thus, it will be seen, supported by an ancient precedent, and those other photographers who wish to spend much money for a peacock's feather—in shape of a royal charter—to stick in their hats, before getting their work done in establishing a library, laboratories, and so on, might persevere in their present principles by going to the Herald Office for a helmet and torse, as well as for other necessaries for the promotion of photography as an art and a science.

The coming Exhibition will no doubt be one of a first-class nature; it is under the control of good practical men, and will take place in the greatest centre of commercial activity in this country.

THE CAMERA CLUB CONFERENCE.

LONG reports of the proceedings of the Camera Club Conference have been published in these pages, and now, by the courtesy of the Camera Club, which has lent us the wood-blocks, and permission so to do, we are enabled to print more or less in full the papers read at the Conference.

PHOTOGRAPHIC COMPOSITION.

BY JAMES MEW.

Pope, in his Epistle to the Earl of Burlington, which constitutes the fourth of his so-called Moral Essays, after speaking of the use of riches and the abuse of the word "taste," gives some examples of the latter in horticultural construction in the following sentence:—

"No pleasing intricacies intervene,
No artful wildness to perplex the scene;
Grove nods at grove, each alley has a brother,
And half the platform just reflects the other."

The poet here finds fault in the matter of gardening with repetition, or that orderly and exact arrangement which Nature so seldom shows, and is therefore one of the evils to be guarded against by the artist, whether painter or photographer. Though, however, the sides of a picture, like those of a garden, should be different from each other, and though the character of the distance should not be reproduced in the foreground, or of the foreground in the distance: in a word, though repetition is offensive, yet balance is necessary. It would be clearly a mistake to photograph all the tall people of a group on one side, and all the short on the other. This would not, indeed, be repetition; but in running from one vice, we should be making our escape into its contrary. If in a picture there be a large tree on one side, and a vacuity—or, as Dr. Johnson might have said, a copious negative catalogue—on the other, the effect will be unpleasing.

This absence of balance—speaking with all possible deference to a distinguished Dutch artist—seems to be a defect in a well-known picture by Cuyp in the National Gallery, catalogued as a landscape with cattle and figures. Here the left-hand side contains little of importance, while the principal elements of the picture are grouped on the right, the figure on horseback, dressed in a coat of glaring vermilion, throwing additional weight into a portion of the painting which had already too much. On the contrary, Claude de Lorraine—who is now called Gellée in the catalogue of the National Gallery, which, indeed, was his proper name—has given, in a landscape known as "The Ford," a very admirable example of balance; and indeed of all the best general qualities of composition. The trees on each side of this picture are different, and answer well the purpose of their introduction. The right side is bold, but light; the left strong, but delicate. The whole presents that "artful wildness" which seems to have been as much desired by the painter as by the poet.

Composition in art has been well defined to be an arrangement of the separate objects represented, which leads the spectator to conceive that such objects are connected or interested in a subject common to them all. There must be in a well-composed photograph, whether of landscapes or figures, some central thought or fact animating the whole picture. What that central matter may be is of comparatively small importance, but it must exist. It is the pictorial *raison d'être* of the work. It is the focus of interest to which all the forms in the picture converge. It is the string which binds the scattered sticks together, giving them a force and meaning which, isolated, they cannot possess. It is the primary law of what is known as grouping. Digressions from this rule may be licensed in poetry, but in painting, photography, and sculpture, they can never be permitted. The picture of the photographer who has to represent a number of persons together must tell some story. It must not be in the condition of Canning's needy knife-grinder. The wheel out of order, the hat with the hole in it, and the breeches in a like condition, the knife or scissors in the act of being ground—these are all good in themselves, but they are not enough. The photographer who takes a group, say, of a dozen persons, every one of the twelve having none other connection with his neighbour than this, that he conceals more or less of that neighbour's figure by his own, or is himself concealed by more or less of his neighbour—every one of the twelve with a fatuous gaze on a previously indicated spot, a gaze which reveals only every one of the twelve's consciousness of having his portrait taken—every one of the twelve with a full-face aspect of melancholy resignation, or of smirking conceit—every one of the twelve so wholly isolated, in conception, from his fellow as to form no part, save numerically, of the picture—such a photographer clearly says, with the knife-grinder,

"Story! God bless you! I have none to tell, sir."

And, though he meets with no such sad fate as that outcast met with at the hands of the Friend of Humanity, yet he seems to merit some shadow thereof, if he calls himself an artist.

There is no surer proof of failure in any æsthetic composition than the fact that it is unable to tell its own story to the intelligent spectator. A photograph which needs the help of a commentary, a picture of which the meaning can be alone explained by a reference to its number in a printed catalogue—and not always by that—is clearly of less value than something which he that runs may read. The essential and fundamental notion of an æsthetic composition is an appeal to the senses. Intellectual difficulties would transfer it into another region, of which it is not an indigenous growth.

Though the subject of composition is extremely important to the photographer, it is, unfortunately, very difficult to give other than general rules concerning it. Like so many matters of importance, it cannot be taught by rule and square. There are audacious folk who have not hesitated to publish Rules of Politeness, Rules of Letter-writing, Rules of Etiquette, and many other rules, which are, doubtless, good enough of their kind so long as they remain in the region of the abstract and the general, but whosoever seeks in them a rule of conduct for a particular occasion will probably never find it, or, having found it and followed it, will not look back upon his conduct altogether with satisfaction. Some general hints may, however, be given, of which the first is of universal application. Let the photographer who is about to take a group form some clearly defined idea what his work is intended to express before he attempts to arrange its elements. This is such a plain, matter-of-fact piece of advice that its insertion would seem to be unnecessary, and so unjustifiable, were it not for the notorious fact that so many photographers sin against this, the first of the laws of composition. It were, indeed, all one for a man to attempt to paint something which he has not previously drawn, or to build a house without a scaffold. The artist must, in the first place, make his work clear to his own mind, and then it may afford intelligible interest to the minds of others. Having conceived his idea, he will arrange his characters to correspond with it. The usual plan is the reverse. He shuffles together his personages at haphazard, and if the group should turn out to be something in the nature of a circle or pyramid,

the two figures chiefly affected by the ordinary photographer, he will therewith rest content.

The absence of sameness, or the presence of variety, is another leading principle of composition. It is probably for this reason that an old cottage, however inferior to inhabit, pleases more in a photograph—owing to the many alterations in it sketched by the hand of time—than a brand new building, smooth and well adjusted by the builder's adze. So, again, a winding road or river delights the eye more than one which is straight.

Another rule for photographic composition is that the principal object should never be placed in the centre of the photograph; nor again, should several figures be in a direct line with one another.

Such rules, and others like them, are commonly understood by the experienced photographer, but they are not always followed. The unhappy man is only too often not allowed to follow them even when he will. He has to consider his customers. The Cheap Jack and the Beach-man, with whom public favour is as the very breath of their nostrils, though they may clearly understand such principles, experience constant difficulties in carrying them out. Their position is very much that of the poor playwright, who has too frequently to spoil his play for the sake of his players. Thoroughly acquainted with the principles of dramatic proportion, he must nevertheless make his drama lopsided to suit their notions of their own importance.

As every actor desires what is called in theatrical slang "fat," so every person of a group to be photographed commonly desires to occupy a prominent position. The idea of sacrificing herself or himself to the interest of the whole seldom enters the head of any individual member of a group. For such interest it is, of course, usually necessary that some faces should be taken in profile, and some in three-quarter face, but to bring about such a simple arrangement involves no ordinary toil. The pride, envy, jealousy, vanity, and general ill-feeling evoked on such an occasion is too well-known to the conscientious artist, and he must succumb in nine cases out of ten to the wishes of his clients, and the ordinary photograph of a dozen full-faces looking at nothing is the melancholy result. Were he to kick against the pricks his party would go elsewhere, and, after a preliminary fight among themselves, be photographed at last more or less to their own satisfaction, but with an utter disregard to the elementary principles of composition, and in a manner which would seriously shock any photographer who has received a proper education, or possesses an innate particle of artistic taste.

The Welsbach Gas Light Company, Gloucester, New Jersey, have fitted up a room in connection with their factory, for the purpose of showing the suitability of the light given by their burners for photography, and invite photographers to visit it, and satisfy themselves by experiment or otherwise.

Water-developing Plates.—The following is the formula used by Dr. Backelandt for coating the backs of his water-developing plates:—

Pyrogallic acid	...	154 grains
Salicylic acid	...	15 ,,
Gum or dextrine	...	154 ,,
Alcohol	...	1 fl. dr. 21 minims
Water	...	5 fl. drs. 25

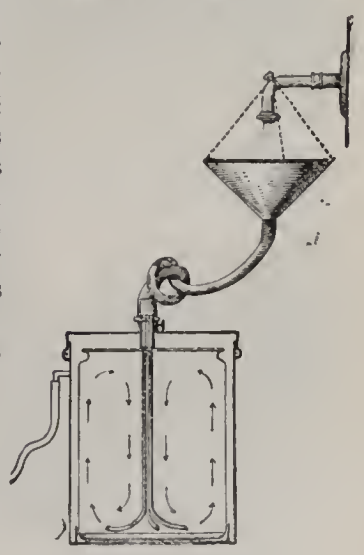
This is allowed to dry at the ordinary temperature. Development takes place by immersion in water with the addition of a very small quantity of ammonia.

PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Washing Apparatus for Emulsions—Acid Eikonogen Developer — Cheap and Effective Flash-Lamp — Chloride of Iron as a Restrainer — Eliminating Hyposulphite of Soda—Print-Washing Apparatus.

Improved Washing Apparatus for Emulsions.—In most of the existing pieces of washing apparatus for gelatine emulsions the threads of gelatine are, by the pressure of the water entering from above or from below, pressed tightly against the outlet tubes, where they stick, pap-like, and allow only a comparatively small quantity of water to pass. The washing therein is therefore imperfect, and must be continued for a comparatively long time. To prevent this, Herr Alois Brunner has constructed the following arrangement, in which by the inflow of water a constant circular motion of the threads from below upwards, and *vice versa*, is produced; the flow off of the water is not at all disturbed, and no loss is caused by the finer particles of emulsion being washed away. The arrangement consists of a sufficiently large, wide-mouthed glass vessel, in which a system of three or more small glass tubes reaches to the bottom. The glass tubes are at the lower end curved in the direction of the sides of the glass vessel, and at the other end, before they pass through the top of the vessel, they are cemented in a stout metal tube. The glass vessel is placed in a somewhat larger vessel of sheet zinc, which can be covered light-tight by means of an overlapping cover sliding in a groove. The cover in its centre has an aperture provided with a short tube, through which the metal tube bearing the glass tubes projects so far that india-rubber tubing for the introduction of the water can be attached to it. In order to prevent the glass tubes from being broken by pressure in attaching the india-rubber tubing, they are fixed by an adjusting-screw affixed to the short tube in the aperture of the cover. At the upper end of the india-rubber tubing a sufficiently large funnel is placed, which is suspended by means of cords to the water-tap. The number and diameter of the glass tubes depend on the size of the washing bottle, and on the quantity of emulsion to be regularly worked.



The Acid Eikonogen Developer.—It has been found by some experimentalists that the keeping qualities of the eikonogen developer are much improved if it is made acid, or nearly so. With regard to this, the following formula is recommended by Mr. T. H. Voigt, chairman of the Photographic Society of Frankfort-on-Maine:—

Solution No. 1.

Water	...	500 c.c.
Sodium sulphite	...	25 grammes
Eikonogen (previously pulverized)	...	5 to 6 ,,

As soon as the eikonogen has completely dissolved, 20 c.c. of a mixture of 500 c.c. of a saturated solution of sodium

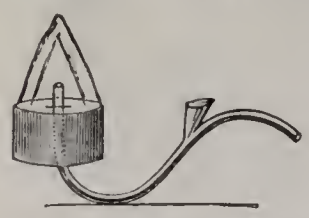
sulphite, and 40 c.c. of hydrochloric acid, are added to the above (Solution No. 1).

Solution No. 2.

Water...	500 c.c.
Carbonate of soda	20 grammes
Carbonate of potash	5 ,,

To develop a cabinet plate, 30 c.c. of solution No. 1 are poured over the plate in the dish, and the latter is well rocked, so that the plate is entirely covered by the solution. Previously 10 c.c. of solution No. 2 have been poured into a measure; if it is probable that the plate has been over-exposed, at first 5 c.c. of solution No. 2 are added to the developer in the dish; if, however, it is found that the plate has been correctly exposed, the remaining 5 c.c. of the alkali solution are also added. It will be noticed that with this method of development only about one-third the quantity of the alkali which is usually taken is used. It seems that the minute quantities of the chloride of soda and chloride of potash, which are formed by the addition of the hydrochloric acid, increase the energy of the developer.

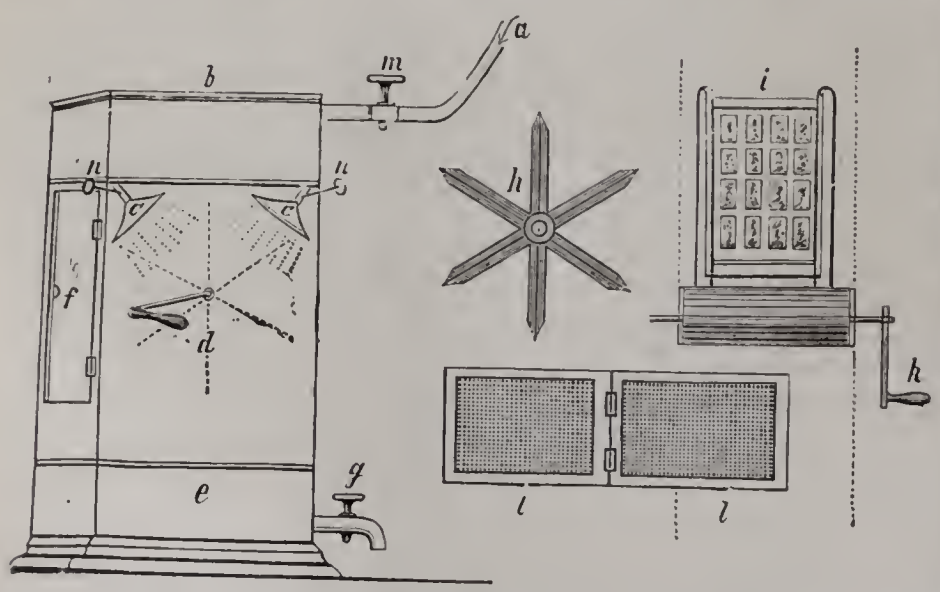
Cheap and Effective Flash-Lamp.—The following instrument, of which I give a sketch, is said by Herr Sasse to give as good results as the more elaborate and expensive lamps which are in the market. It consists simply of a curved tube provided with a small spirit reservoir, which is filled with cotton-wool, and of a small funnel for dropping down into the curved tube dry magnesium powder. To the end of this tube an india-rubber tube, with ball attached, should be fitted. The size of the spirit flame can be regulated by pulling out the cotton-wool more or less.



Chloride of Iron as a Restrainer.—A. Einsle has found that chloride of iron forms an excellent means of saving over-exposed plates. If a plate which has been exposed five times too long is placed before development for two minutes in a ten per cent. solution of chloride of iron, then rinsed under the tap, and then developed, a vigorous negative, full of contrast, is obtained. Dr. Miethe suggests in the case of hydroquinone and eikonogen development the washing of the plate thoroughly, in order to prevent the staining of the negative.

Eliminating Hyposulphite of Soda.—Dr. A. Bannow publishes in Prof. Eder's year-book a series of most careful and interesting experiments which he has made in order to ascertain the method by which hyposulphite of soda is eliminated most efficiently and thoroughly from negatives and prints. The results of these experiments, which are too extensive to be reproduced in full, are the following:—Washing in a current of water is more efficient than the washing in several changes of water; the bulk of the hypo is soon removed, but the last traces stick very obstinately. After the pictures have been washed in five to six changes of water after they have been washed for one to two hours in running water, they may practically be taken as freed from hypo. Paper prints are freed from hypo a little sooner than gelatine plates: they are, however, more sensitive to its action on account of the smaller quantity of silver they contain. The various substances which are from time to time recommended to accelerate the washing process—as, for instance, alum, common salt, and chloride of lime—are unnecessary, and even doubtful, inasmuch as it has not yet been proved that their action upon the small quantity of silver contained in the pictures is not an injurious one.

Washing Apparatus for Prints.—A skilled photographer of Braunau, Mr. J. F. Klinger, has for his own purposes constructed the following washing apparatus for paper prints. It consists of a wooden box *d*, about 6 feet high, 34 inches broad, 16 inches deep, lined inside with thick sheet zinc. The box consists of a small water-reservoir *b*, with roses *cc* attached, and at the bottom it has another reservoir *e*, in which the waste water is collected, and which is provided with a delivery-cock *g*. The centres of the side of box support the winch handle of the rotating paddle-wheel *h*. To the shaft of the handle, at each of its two ends, are fitted six wooden carriers provided with a groove: these serve as carriers of the horse-hair slides *ll*. One of the horse-hair slides, after it has been inserted in the apparatus and covered with prints, is shown in the sketch by *i k*. As soon as all of the six slides have been covered with prints, they are inserted in the grooves of the carriers at the small door *f*; the latter is then shut, and the apparatus is ready for use. At first the water is turned on by means of the tap *m*; then the valves *n* of the roses *cc* are adjusted, and the handle is turned. Mr. Klinger asserts that, by means of this washing arrangement, the prints are soon entirely freed from all traces of hypo, and that they are never injured.



Fotografi-Foreningen i Upsala.—This Society, founded at the beginning of the year, now numbers thirty-eight members. Its president is Dr. E. Duner, who informs us that he has just learned that the Swedish Parliament has afforded the means for fitting the observatory under his charge with a photographic refractor of thirteen inches aperture, so that in 1892 he expects to be able to do good astro-photographic work.

A PHOTOGRAPHIC UNTRUTH.*

BY CAPT. W. DE W. ABNEY, C.B.

When pressed by the Secretary of the Camera Club for the title of my paper, I was at a loss to know what to give. I felt that as your President you would have quite enough of my voice, and thought it hardly fair that I should read a paper at all. However, on the spur of the moment, I put down "A Photographic Untruth" as the heading—not for any sensational purpose, but because I knew that there were many untruths perpetrated by photography, any one of which might well be treated of. The particular untruth I am going to touch upon to-day is the untruth of form which a photograph gives when judged by depths of light and shade. A dead white cylinder standing vertically and illuminated by horizontal parallel rays of light, or by what is equivalent, by light projected from a point at a long distance from it, in a dark room, is a good example of what I mean. The part of the surface which will be most strongly illuminated is the line where a plane passing through the axis of cylinder and parallel to the rays of light cuts that surface. If the illumination of the vertical line be expressed by I, then the illumination falling on any other vertical line can be theoretically expressed by the formula $I' = I\cos\theta$, where I' is the illumination required to be found, θ is the angle between the plane passing through the axis and parallel to the direction of the light and a plane passing through the axis with the part of the cylinder whose illumination is

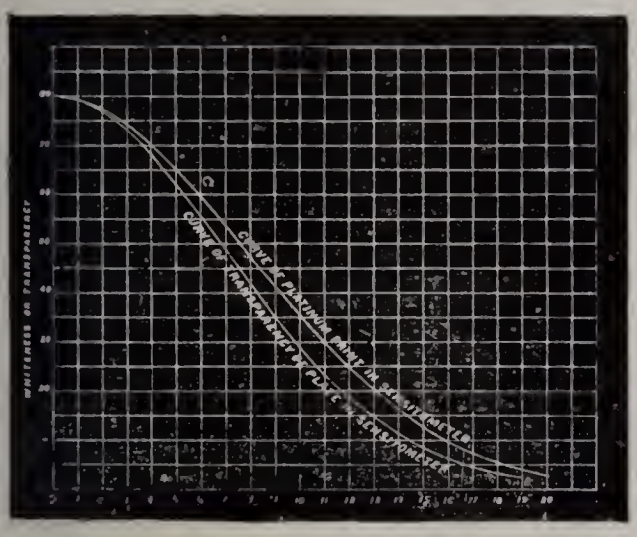


Fig. 1.

required. This is evident: let AB be a section of one plane of a length unity, BC be the section of another plane of the same length, but inclined at an angle θ. The light falling on AB in a perpendicular direction is evidently more than the light falling on BC, though it is the same length. Simple mathematics show that the light thus falling on the surface is BC $\cos\theta$, and the illumination of BC is therefore to that on AB as $\cos\theta : 1$. A little more simple elementary geometry will show that the inclination of the surface of any cylinder to a fixed part is the angle made by the two radii, and therefore this law applies in this case.

Instead of a cylinder, I have taken a polygonal prism of twenty-four sides illuminated as described, and calculated the illumination which is given to each side, and I have supposed that one side is exactly perpendicular to the path of the rays of light illuminating it, the other sides lying symmetrically around it. From the curves of gradation in a negative, as given in the *Photo. Journal* of last November, of which one of the curves in fig. 2 is a transcript, the transpareney of the images of the different sides, as shown in a negative which could be taken from it, have been calculated, and then from these transparencies the amount of white in a resulting platinum print, for every side exposed to the light, or the amount of white has been deduced from a curve of the gradation from a platinum sensitometic print (fig. 1). Taking the amount of whiteness of the lightest side as unity or 1, I have calculated the angle that the side should make with this side (which is perpendicular to the direction of the light), and constructed the polygon in fig. 2, remembering that the projections of the angles of the polygon must always be the same.

The following table gives the theoretical illumination. The side No. 1 is that on the left or right, and is parallel to the beam:—

THEORETICAL ILLUMINATION OF THE DIFFERENT SIDES OF THE POLYGONAL PRISM.

	Inclination.		Numerical Value.
No. 1 and 13 ...	cos 90 ...	=	0
„ 2 and 12 ...	cos 75 ...	=	259
„ 3 and 11 ...	cos 60 ...	=	500
„ 4 and 10 ...	cos 45 ...	=	707
„ 5 and 9 ...	cos 30 ...	=	866
„ 6 and 8 ...	cos 15 ...	=	966
„ 7 — ...	cos 0 ...	=	1,000

If in fig. 1, 1,000 be taken as 15 on the scale, that is, the intensity is $\sqrt[3]{2^{15}}$, the following table is arrived at for the transparency of the negative for different sides of the polygon. This number on the scale is chosen as giving a negative fairly dense for the whitest side.

No. of sides.	Illumination.	Value on scale of fig. 1. $\sqrt[3]{2^{x}}$	Relative transpareney of negative.
1 and 13	0	0	80·0
2 and 12	·259	9·1	34·0
3 and 11	·500	12·0	18·0
4 and 10	·707	13·54	12·5
5 and 9	·866	14·4	9·6
6 and 8	·966	14·9	8·4
7 —	1,000	15·0	8·2

It must be remembered that sides No. 1 and 13 are not visible, so cannot be taken into account.

From such a negative we can take platinum prints, and knowing the value of the transpareney, we can calculate the whiteness of each side as it would be rendered.

Supposing 80 to be the greatest transpareney of the negative we have produced theoretically, and that we take the whiteness of the print produced with this transparency to be 5·6 (white being 80), then 80 corresponds to No. 18 hole of the sensitometer, or $\sqrt[3]{2^{18}}$. We then get the following table:—

No. of Sides.	Transparency.	Value on scale of platinotype curve.	Amount of white, 80 being maximum.	Taking 46·5 as white, or 1·000	Angles whose cosines are those in Col. V.	Original angles, corresponding to these.
1 and 13	80·	18·	5·6	·120	83°	90°
2 and 12	34·0	14·5	14·0	·301	72°30′	75°
3 and 11	18·0	11·6	26·0	·559	56° 0′	60°
4 and 10	12·5	10 0	35 0	·752	41°46′	45°
5 and 9	9·6	8·8	42·5	·913	24°30′	30°
6 and 8	8 4	8·3	45·5	·978	12°25′	15°
7 —	8·2	8·1	46·5	1·000	0	0°

* Abstract of a paper read before the Camera Club Conference, and published in the *Journal* of the Club.

Nos. 1 and 13 are not seen, so in constructing the polygon in the diagram these sides have been shown as the original lengths. It must be noticed here that the photograph shows the side No. 7 as a mixture of more than half white with rather less than half black, so the print would look very grey.

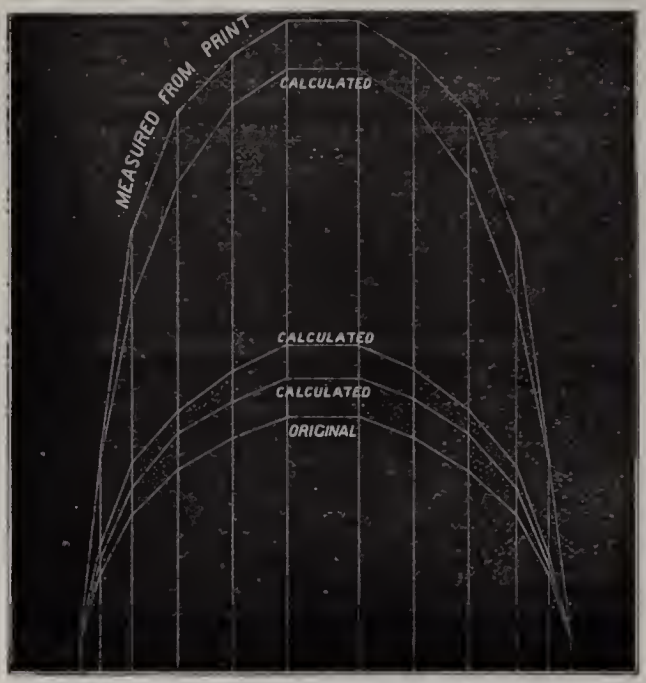

Fig. 2.—Sections of Polygons.

In the two outside polygons the lightest side is nearly pure white.
In the two inside calculated curves the lightest sides are dark grey.

We can, however, take a lighter print. If we take 80 transparency as represented by 12 on the scale of the platinotype curve, we get the following table:—

No. of sides.	Transparency.	Value of scale of Platinotype curve.	Amount of white, 80 being maximum.	Taking 77 as white, or 1·000.	Angles whose cosines are those in Col. V.	Original angles corresponding to these.
1 and 13	80·	12·	24·	·322	71°12′	90°
2 and 12	34·0	8·2	46·5	·598	53°50′	75°
3 and 11	18·0	5·5	62 5	·812	35°40′	60°
4 and 10	12·5	4·0	70·5	·916	23°30′	45°
5 and 9	9·6	2·8	75·5	·981	10° 0′	30°
6 and 8	8·4	2·25	76·5	·994	6° 0′	15°
7 —	8 2	2·15	77·0	1·000	0°	0°

As before, 1 and 13 are hidden, so are shown of original length in the diagram.

Here the print is nearly white as regards side No. 7, but the shading is incorrect as before.

The nearest approach to correctness tried is when 80 is made to be of the value of 21 on the scale of the platinotype prints, when we get the following results:—

Sides.		Calculated angles.		Corresponding angles in original.
1 and 13	...	84	...	= 90
2 and 12	...	76·50	...	= 75
3 and 11	...	60·30	...	= 60
4 and 10	...	45·34	...	= 45
5 and 9	...	28·55	...	= 30
6 and 8	...	11·20	...	= 15
7 —	...	0	...	= 0

But in this case the whiteness of the whitish side No. 7 is only $\frac{2}{8}\frac{1}{0}$ of pure white, and is, consequently, a very grey dull print, which no one could accept. A model of the polygon was illuminated as described and photographed in a dark room, and a print taken from the negative, which experts judged satisfactory. The blackness of the different sides was measured, and the results are given in the following table, and is also shown in fig. 2.

Three different depths of printing are here given:

No. of sides.	Whiteness measured.	Whiteness with maximum 1	Angle whose cosines are those of Col. III.
1 and 13	0	0	0
2 and 12	6·5	·08	4° 30′
3 and 11	10·6	·14	8° 10′
4 and 10	24 0	·32	19° 0
5 and 9	50·0	·67	47° 30′
6 and 8	69 0	·92	67° 0
7 —	75 0	1·00	90° 0

Pure white in this case was 80.

The following table gives the values of the curves for the negative and for the platinum print; see fig. 1:—

No. of hole of Sensitometer.	Transparency of Platinotype.	White in Platinotype.	Remarks.
0	80	80	
1	79·2	79 3	Each hole of the sensitometer diminishes $^3\sqrt{2}$.
2	76 8	77·0	
3	74 0	74·3	
4	68	70·2	
5	62·1	65·2	The curves of the negative and platinotype print each follow the curve given by $I' = Ie^{-\mu x^2}$, I being the intensity of the No. 0 hole, I′ that to be found, μ a constant, and x the number of the hole.
6	55·5	59·6	
7	48·7	53·5	
8	41·8	47·3	
9	35·1	41·2	
10	29·0	35·2	
11	23·4	29·7	
12	18·5	24·6	
13	14·4	20·1	
14	10·9	16·0	
15	8·2	12·6	
16	5·9	9·8	For the negative, $I=80, \mu=·01015$.
17	4·25	7 5	
18	3·0	5·6	
19	2·0	4·0	For the platinotype print, $I=80, \mu=·0082$.
20	...	3·0	
21	...	2·5	

It will thus be seen that, judging by shades, photographs give no correct rendering of slopes, and no matter how the light is altered by reflectors and so on, untruth must always be present. A painter can afford to do with one light to illuminate his sitter, a photographer uses reflectors to lighten the shadows. If not lightened, the tendency is to make the head look deeper than it really is.

A very good plan of demonstrating this untruth in photography is by photographing discs, some rotating and some still. The accompanying figure shows what is meant (Fig. 3). The two outside rings contain each one part of black and two of white, whilst the two inside ones contain two parts of black and one of white. It is easy to arrange cards so that the two centre ones shall rapidly rotate, and the innermost and outermost remain fixed. In the negative representing these and in subsequent prints, we shall have two grey rings, bounded by rings made up of black and white segments. If photographic representation were true, then on rotating the print obtained round its centre the innermost and outermost rings should give the same greys as the rings next to them. No variation in the intensity of the negative nor in the depth of print will give this result. One ring will always be darker or lighter than that which it should match, even when the printing is carried on so far that a match is made in the other. A

further development of the plan is to rotate the original sectors with the different proportions of black to white, that containing the two-thirds white outside the photographed discs, and the other within them. We then have three rings containing what should be the same proportion of black to white in both cases, and which should give the same grey. It is found that none of them will probably match, or that if two rings of grey of one set

Fig. 3.

match, the other one differs from them, and in the other set of three rings they will all differ.

One word in conclusion: let it not be imagined that the untruth appears only when one direct light is employed. The same differences will exist however an object is lighted, but the lighting may be so modified to the eye that it may appear fairly correct in the photograph, but for totally different lightning.

SELECTING A LENS.*

BY J. K. TULLOCH, M.B.

In order to come at the optical aids which the average amateur requires, let us consider what will be the probable work he will undertake. First, then, landscape pure and simple will probably be the chief item; secondly, he will ere long want to do a little instantaneous photography; thirdly, architecture, including interior work; fourthly, portraiture, either in a common sitting-room, or perhaps out of doors. Now, the problem to be solved is this: How to provide one's self with the necessary lenses at the least cost, and at the same time with no sacrifice of efficiency. Let it be understood that the arguments to be advanced hold equally well whatever the size of plate.

In order, however, that it may be easily followed, let us say that a half-plate kit is in view. For a half-plate, opticians generally advise a rapid rectilinear of about nine inches focus, that is if only one lens is to be supplied. This, to my mind, is a very absurd proceeding, and for the following four reasons:—First, while, of course, it is rectilinear for a half-plate, or any other plate it can cover, a cheap single lens is also rectilinear on a half-plate, that is if it is about nine inches focus—the same focus as the rectilinear. Second, a rectilinear is much more expensive than a single lens. Third, a rectilinear of nine inches focus is made up of two achromatic combinations, each of them so long in the focus that they cannot be used singly in any ordinary camera; add to this that they are generally symmetrical, that is, of the same focus, and even if you can use one the other is never of any service. And the fourth reason is that the focus is too long for wide-angle subjects, and you need another lens to take them.

A much better bargain—so to speak—can be made than this; but before propounding my own ideas on this matter, it might be as well to explain to the uninitiated why lenses have to be of different lengths of focus.

Since light travels in straight lines, a certain size of plate being given, the focus of the lens directly determines the amount of subject included; or, to use the proper expression, the focus of the lens and size of plate together give the angle included by the lens. A short-focus lens includes a wide angle, and a long focus lens a narrow one. A lens which would give a wide angle for interior work would be of little use in the great bulk of landscape work, for it would include too many objects at the expense of the *size* of these objects. A lens of long focus, first class for sea or hill subjects, would be useless for interiors, for a long-focus lens renders the various objects of such a size that but few of them can be represented, and in place of getting a representation of a whole room, one would barely get in the whole of the end wall. One could do with a great many lenses of different foci, but practically in landscape work generally, including exterior and interior architecture, a choice of three lenses of different foci is sufficient.

Granted, then, that the necessity for different lenses is allowed, what does experience suggest as to the focus for each of the three lenses, and is it possible to get one combination to give the whole three? We have seen that to have a nine-inch rectilinear as an *only* lens for a half-plate ties you down to having only one focus, for the two halves of the lens cannot be used singly on account of their extreme length of focus; therefore this does not fulfil the required conditions. If, however, we substitute a wide-angle rectilinear in place of a rapid rectilinear, we will have attained our object almost at a single step. Let a wide-angle rectilinear of, say, four and a half inches focus be chosen for a half-plate, and the following advantages immediately accrue.

First: Used just as it is—that is, both combinations together—it makes a first-class short-focus lens for a half-plate, including a wide angle, with great depth of focus and perfection of detail all over. In this shape it is the very thing for interiors and cramped exteriors, such as buildings in closes or narrow streets, and, of course, it is strictly rectilinear. The two halves used separately (and the mount is always arranged so that they may be) give other two foci of about eight and ten inches. Now, on a half-plate an eight-inch and a ten-inch single lens are to all intents and purposes rectilinear, so that we have in this one combination a choice of three different foci, all of them rectilinear on a half-plate.

But, it may be said, what are the disadvantages of this system, for surely everybody would adopt this were there no equally powerful drawbacks? It has only one drawback, and that is its want of rapidity. I have two answers to this: first, the double combination is rapid enough for all ordinary instantaneous work; and secondly, even if

* Abstract of a communication to the Dundee Photographic Association.

it were not, a single lens can be purchased for a mere trifle capable of taking up the instantaneous and portrait branch of the subject. All the finest professional instantaneous work has been done with lenses working no quicker than this, and I myself find that for street views, including moving figures, the lens is amply quick enough. For certain optical reasons a small stop, that is, a comparatively small stop, has to be used with wide-angle lenses, and this prevents them being the most rapid form of lens, but their other good qualities far more than make up for any loss of rapidity, that is, always supposing the very highest degree of rapidity is required.

Assuming, however, that it be allowed that this wide-angle combination is the best for landscape and architectural work, but that a quicker lens is necessary for portraits and instantaneous views, what lens should be recommended? During the winter that is past I have been much pleased with the working of plano-convex lenses. Those who have not experimented somewhat have no idea how interesting a field this is. Compared with the meniscus form, which is the usual form of single lens, I find that the plano-convex works with a much larger aperture, giving excellent definition, but this through a somewhat restricted field. Given a meniscus and a plano-convex, I find that if they are of the same focus the plano-convex will give crisp definition for a certain space, while the meniscus will give a far blunter image, but not falling off in defining power so rapidly towards the edges.

But in these days of enlarging from small negatives, the plano-convex is just what is wanted, for it matters little what size the negative is if it is very good, what there is of it. The moving object in instantaneous work generally occupies only a very small part of the field, and the plano-convex is the very thing for this. Again, in portraiture, what though the shoulders and draperies be a little blunt, if the head, the centre of attraction, be faultlessly rendered.

A good plano-convex lens will work as rapidly as ninety-nine per cent. of the rapid rectilinears, while the cost is not a fourth part.

It is perfectly astonishing to me why this most excellent form of lens has been in abeyance so long, unless on the assumption that its narrow angle has prejudiced workers against it. Of course, it must be understood that I only strongly uphold it in such cases as are of narrow angle naturally, such as portraiture and instantaneous work.

But it might be argued that by this system the wide-angle lens in its double form would be but rarely used, while one would constantly be working with a single lens. This, of course, is quite true, but there is no determent in this. Lantern work, which, of course, requires negatives of the highest degree of sharpness, is a good test for any lens, and the whole of my very finest slides are from negatives taken by a single lens, and leave absolutely nothing to be desired in fineness of detail.

To recapitulate, then, I think that an amateur who would have a thoroughly reliable battery of lenses requires nothing more than, first, a wide-angle rectilinear with a focus of about two-thirds the long diameter of the plate, and secondly, a simple achromatic plano-convex lens with a focus about one and one half times the long diameter of plate. The wide-angle lens will give him three different foci, all practically rectilinear, and as good as can be made for all kinds of photographic work, except the fastest instantaneous and portraiture. The plano-convex lens will give him a fourth focus for landscape, and at the same time be an instrument second to none for the quickest instantaneous work and portraiture.

I am not advising a system which has been imagined but never tried. The arrangement described is precisely the one which I have used myself for years, with the exception of the plano-convex lens, the splendid properties of which I have only been acquainted with for the last six months past. With regard to everything else proposed, I may say that with a photographic experience ranging through every branch of the subject, I have never once failed through not having a proper lens. I have since got a plano-convex suitably mounted, and feel now quite at ease whatever kind of work I determine to undertake, although I must say I never had any difficulty in instantaneous work, using my wide angle lens at full aperture, which is about *f*-16.

It must not be understood that I advise cheap lenses from second-class makers—nothing is further from my purpose. I wish rather to point out that a suitable choice of *one* first-class lens will do all the work of three equally expensive instruments; that the economy comes in in carefully choosing one good lens that is capable of overtaking all the work, rather than being at the expense of three separate instruments that can do no more than the one, provided it be intelligently chosen.

A few words may be said as to the more material side—I mean the actual workmanship of a lens. The brass work should be first-class. In second-class lenses this is frequently defective. Threads of screws should be clean cut and not too fine. The diaphragm or diaphragms should fit the slot accurately, neither too tight nor too easy. If the diaphragms be the ordinary Waterhouse ones, there should be guides to the very bottom of the slot, so that the diaphragm when pushed home may be properly centred.

The Iris diaphragm is better than Waterhouse, but inferior to rotating, where this form can be used, which is not always. I have no special objection to Iris diaphragms when dealing with larger apertures, but when the light is shut off from *f*-32 to *f*-60, a very trifling error in the adjustment may seriously increase or diminish your exposure.

A wide-angle rectilinear, such as I have recommended, is invariably fitted with rotating diaphragms, and in having it screwed to the camera, care should be taken to have the diaphragm slot on the *under* side (not the *upper*), so as to prevent or lessen the chance of light getting in where it is not wanted. When the lens is not in its place in the camera, it should be kept covered at both ends—a screw cap being generally provided for the one end, and the ordinary exposing cap for the other.

Photographic Convention of the United Kingdom (Lens Standard Committee). — Opticians and all interested are invited to a meeting to be held at the Mona Hotel, Henrietta Street, Covent Garden, on April 25th, 1890, at 7·0 p.m., to discuss the desirability of adopting and further defining "The Lens Standards of the Photographic Society of Great Britain." —April 14th, 1890, by order of the Committee, A. Haddon.

At a lecture, by Mr. Henry Blackburn, Editor of *Academy Notes*, to be delivered at the Kensington Town Hall, on Friday, April 18th, at 8 p.m.; and at the Eyre Arms Assembly Rooms, St. John's Wood, London, on Friday, April 25th, at 8 p.m., a series of instantaneous photographs, taken lately in Algeria and Morocco, will be shown by the oxy-hydrogen light.

ON PHOTOGRAPHY BY THE LIGHT OF THE ELECTRIC SPARK.*

BY LORD RAYLEIGH, SEC., R.S.

I HAVE long wished to illustrate by instantaneous photography the many curious phenomena attending the resolution of liquid jets into drops, and the subsequent behaviour of the drops during collision; but it is only recently that I have carried the desire into effect. In order to secure good definition, the exposure needs to be

Fig. 1.

less than 1-1000th second, and in some cases 1-10000th second. For this purpose the light attending the discharge of Leyden jars seemed to be the most promising.

There is no difficulty, of course, in getting a photographic image of the spark itself, for in this case the light is concentrated upon a very small area of the films. But in order to photograph upon a satisfactory scale other objects by the light of the spark, the whole illumination has to be diffused over an area of several square inches of sensitive surface. Under these circumstances it requires special arrangements to secure a sufficient chemical action.

The spark is taken between brass balls enclosed in a magic lantern. The light issuing from the condenser, still slightly divergent, falls at a distance of sixteen feet

Fig. 2A.

upon a large single lens of about ten inches diameter, which plays the part of a field-glass. The photographic lens, a large portrait combination by Dallmeyer, is situated about seven feet behind in the image of the lantern condenser as formed by the field-glass, and is just large enough to include it. The jet to be photographed is placed parallel to the field-lens, and as near as conveniently may be upon the side next the photographic camera. The preliminary focussing of the image upon the ground glass cannot well be effected by the light of the sparks. For this purpose a candle, which may stand before the lantern condenser, is substituted.

In the earlier experiments, where jars of small capacity only were available, the images were found, on development, to be under-exposed, although the impression made upon the eye by the image upon the ground glass was sufficiently startling. In later work at the Royal Institu-

Fig. 2B.

tion, I have had the use of a large Leyden battery charged by a Wimshurst machine, and there has been no difficulty in securing sufficient exposure.

The photographs illustrate the behaviour of fine, nearly vertical fountains, and the modifications which they undergo under feeble electrical influence. In the normal condition (Fig. 1) the drops on collision rebound, and are thus scattered about over a considerable space. Under the action of electricity the drops coalesce upon collision, and thus in place of a large number of small drops the photograph shows (Fig. 2A) a smaller number of widely-separated conglomerates. It is evident that the electrification has no effect upon the original separation of the liquid column into drops.

Another set of photographs shows the details of the resolution of a larger jet (Fig. 2B). In this regularity is promoted by the operation of a tuning-fork.

* Abstract of a paper read before the Camera Club Conference, and published in the *Journal* of the Club.

THE annual dinner of the employées of Messrs. Wm. Watson and Sons, of 313, High Holborn, took place at the Holborn Town Hall on Saturday evening, March 12th. Mr. T. P. Watson occupied the chair, and in the course of his remarks mentioned that it was was usual for that dinner to be held at the beginning of the year, but owing to the prevalence of influenza, which rendered it impossible for many to attend whom they would not like to be absent, it had been deferred till the present. In proposing the toast of the cabinet workshop, the chairman spoke in warm praise of the work it turned out, although he felt that the microscope shop this year took the palm. The toast of the visitors was responded to by Mr. Traill Taylor, who endorsed the chairman's remarks. During the evening a capital programme of songs and recitations was gone hrough.

Notes.

A picture by Mr. Carl Haag, in the forthcoming exhibition of the Royal Society of Painters in Water Colours, will excite the attention of the photographers who gather there at the meetings of the Photographic Society of Great Britain. It represents the portrait of the chairman of one of the city companies in his official robes, painted in the full blaze of sunlight—an effect, it is said, which, as far as the artist knows, has never been attempted. This assertion is probably correct so far as portraiture is concerned, but surely artists have attempted the effect of sunlight on faces before now. Photographers have gone beyond this, for experiments with the face in full sunshine have been made many times with more or less success. Anyway, Mr. Haag's picture will be regarded with some curiosity by those who know the difficulty of the task.

It is strange to find the naval authorities moving with the times. They have certainly done so in a new and unexpected use which they have found for photography. The important question of the salute has been occupying their minds, and they have decided that for the future there is to be no doffing of hats, but, from the second-class boy to the post-captain, the salutation is to be performed by raising the hand to the cap, somewhat in the military fashion, but with a slight difference. So that there shall be no mistake about the matter, they have had a man photographed in the correct attitude, and a copy has been sent to all the harbour ships. This is an excellent idea, and one that we should not have thought "my Lords" would have adopted, as it is a total departure from the old form of issuing instructions. But photography now-a-days finds its way everywhere.

The latest royal devotee to the art of photography is the Duke of Aosta. Instantaneous photography is one of his hobbies, and we read that his small pocket camera is held in horror by the ladies of the household, who know that they might be taken at any moment without time to arrange themselves in a graceful pose. We trust this is an exaggeration; but there is this comfort, that the ladies who are thus tormented have the means of revenge within their power. The domestic gimlet or bradawl skilfully applied will at once render the efforts of the amateur abortive, and send him distracted.

The Chinese have a knack of anticipating every European discovery. It might be supposed that thought-reading was exclusively our property, or, at least, the property of America; but, according to a recent traveller, the Chinese have gone a long way beyond the reading of thoughts, as they have succeeded in photographing them! A Mr. Horace Jones tells how he was taken to a joss house, where prepared papers were applied to his head. The result was that his thoughts appeared in pictorial fashion, but unhappily faded in about half-an-hour. Thus, we are told, though the art has been known to the Chinese priests for some 3,000 years, yet they have never succeeded in fixing these thought pictures. Travellers are credited with telling very wonderful stories, and this certainly is one of the most wonderful.

Complaints are being made in New York that not only are prints from portrait negatives of attractive ladies being sold to the general public, but that the detective camera is freely used to obtain portraits surreptitiously. These photographs are afterwards used for the adornment of advertisements or for the decoration of packets of cigarettes. A correspondent of the *New York Nation* wrote recently in great indignation complaining of the practice, and proposing that a short statute should be passed prohibiting the publication of a photograph without the consent of the subject. We do not know how the law may be in America, but we should fancy that if such a practice were at all in vogue in England, some means would be found to reach the offenders. An injunction to restrain the publication would certainly be at once granted by the Court of Chancery.

A Mr. A. P. Laurie claims that he has solved the difficulty of preventing paints used by artists from fading. His experiments have been in the direction of obtaining a medium which is unaffected by moisture, and he has made a varnish out of sulphate of copper which, after drying, remains perfectly colourless. No doubt damp is a great factor in the fading of paintings, as it is in the fading of photographs, but it is not the only factor. Unquestionably the action of light causes a reaction between the chemical constituents of the various pigments, which a colourless, damp-proof varnish cannot arrest. What would seem to require study is the chemistry of pigments, so as to know the effect of light on two or more pigmentary compounds when mingled together. In this direction much has to be done.

M. Léon Brin, whose oxygen-making process is so well known, and which has proved of such great use to photographers, has for a few years past been residing in London, and has been largely engaged in experiments relating to the cheapening of the manufacture of alloys of aluminium direct from the ore of that metal. In early times he gave some attention to photography, and he made some photographic lenses by specially devised machinery; in those times, also, he was acquainted with Niepce de St. Victor. He informs us that he was the inventor of butterine, and considers that compound to be a boon to mankind, because in it the poor man gets something as good as butter at a cheap rate, and the rich man obtains genuine butter at a reduced price.

COLOUR SENSATION.*

BY CAPT. W. DE W. ABNEY, C.B.

Though we know not the "reason why" of colour sensation, we yet know that there are three distinct colour sensations, the existence of which I have heard so eminent a physicist as Lord Rayleigh say is as well proved as the law of gravitation. I may add that I am one who boldly accepts the theory of trichromatic vision in a normal eye, and hold it as being sound physiological physics. But what has this to do with photography? Just this, that the same theory that applies to the sensitive retina may equally well apply to the sensitive plate. The eye, *i.e.*, its retina, is sensitive to three primary colours, red, green, and violet, and if we take the spectrum we find that any

Fig. 1.

intermediate colours can be compounded of two or more of these three colours. Thus the orange sensation is caused by a combination of the red sensation with green sensation, and the blue of violet and green. Further, when we come to show graphically on paper the curves of luminosity of the three different sensations to the spectrum, we cannot but be struck with the similarity that they bear to the curves of sensitiveness of the different salts used to register the photographic image

Fig. 2.

There is no difficulty in taking in the fact that some one particular wave-length can cause one sensation in the eye, but it is harder to understand that another wave-length not differing much from it can give rise not only to the same sensation, but to one or two others. The theory of sound, however, helps us in the first case. When one tuning-fork is not quite in tune with another, the one sound from one will reinforce the other to a certain extent, but as the discordance increases the reinforcement becomes less and less, and finally vanishes altogether. So with waves of light; the waves which are in exact accord with one part of the machinery (whatever it may be) in the eye will produce a maximum effect, producing eventually a motion which gives rise to the impression of a primary colour. The waves which are slightly longer or shorter than this will be only capable of giving a smaller amplitude of vibration to the same part of the apparatus existing in the eye, and consequently less intensity of that particular colour sensation, till finally, as the wave-lengths become shorter and longer, the amplitude of vibration in that machinery becomes nil or imperceptible. But at the same time that part of the machinery which is exactly in accord with another wave-length, and is, consequently, another colour-sensation, may also respond to the same wave-lengths as those which partially affect the machinery answering to the first colour sensation, and for the very same cause, though it may be to a greater or less degree. Thus the same wave-length, which is not in true accord with either, may cause both colour-perceptions to respond.

The same argument applies to three colour-perceptions, and would do so to more if they existed. Now a sensitive plate may be said to take the place of the retina, and the sensitive salts used to a colour-perceiving tissue. The simple salts have but one colour-perception, but where two salts are mixed, we may have two perceptions, and when dyed plates are used, we may have two or three colour-perceptions. Even where one sensitive salt, the silver bromide, has been used, I have traced three distinct colour-perceptions, or, to speak more accurately, radiation-perceptions, one situated in the violet, near G, another in the green, between F and E, and the third in the red, and extending into the infra-red. The places of maximum sensitiveness in the three correspond to three simple colour-perceptions, but not situated in the same place in the spectrum as those of the eye. These curves, however, differ from those of the eye colour-perceptions, in that whilst the curve of luminosity of the spectrum arrived at by compounding the latter is a smooth curve, the former is not; but the curve of photographic sensitiveness is in a series of hummocks or ridges. We can find something similar in some eyes; for instance, where there is a slight deficiency in the perception of green. Again, there is this difference, that whilst in the eye the luminosity curves of the red and green are the greatest, and the violet the smallest, in the silver bromide, the violet is the largest, and the green and red the smallest. In fact, when the colour-perceptions of the eye are altered in their proportions, by looking through a pale blue solution they are very much the same as those of the photographic film already alluded to. It may be asked how and what am I driving at, and my reply is that I think that the photographic spectrum curves of sensitiveness are analogous to the spectrum curves of colour-perception in the eye, or, in other words, that a photographic plate has, in reality, only one, two, or three colour-perceptions, and that all sensitiveness to other colours is due to only partial response of the vibrating atoms in the molecule to wave-lengths which differ slightly from those with which one or more perception is in accord. A study of the simple mixture of the haloid salts favours this view, and I believe that by using it as a working hypothesis, a better understanding of the apparent vagaries in the extent of sensitiveness will be attained.

I would here add that the generally adopted physiological interpretation of colour perception is one which is very open to discussion. It can scarcely be conceived that even the delicate rods and cones of the retina are not much too coarse to be primarily affected by waves of light.

* Abstract of a paper read before the Camera Club Conference, and published in the *Journal* of the Club.

In the ear there is an equally delicate mechanism which is affected by vibration in the air; and we can scarcely expect the mechanism in the eye to be responsive to vibrations infinitely more rapid, and in a medium infinitely more subtle. Probably it will eventually be found that light acts on matter to produce a chemical change in it, and that the change so produced is capable by electrical currents to set in motion the mechanism required to give the sense of colour. This, however, is travelling beyond the limits I have set myself to keep, and I leave it there.

I have to ask those of you who are interested in theory to take this hypothesis into your consideration. My late researches into the sensitiveness of various compounds recently published by the Royal Society have made me offer it to this Conference.

Quite recently we have had an announcement that a Herr Veresez has achieved photography in natural colours, and that it is a printing process. In the paragraph which appeared in the *Standard* the name of Dr. Eder appears as supporting the discovery. Were it not that the statement in some degree has received an *imprimatur* by such a name being connected with it, one would at once have discarded it as one of those periodical outbursts of journalistic credulity which are so often rife at certain seasons of the year. There is one thing which is admitted, viz., that although red and orange have been secured, they fade in the light.

Now, as I pointed out in my address to section A of the British Association, photography in natural colours is a *fait accompli* of many years' standing, but the process is so long, and the results so evanescent in light, that there has been no practical use of the discovery so long ago made. Before we can hope to attain the goal which so many have tried to reach, at least two things have to be accomplished—the first, diminution in exposure of the sensitive surface, and the second, a means of preventing the print fading in white light, which is commonly called fixing the print.

That the first may be done I will not deny, but I think a glance into the physics of the matter will at once demonstrate that the second desideratum is chimerical, for the following reasons:—

There is no known element which is capable of taking on itself three colours, owing to molecular change, and this would be the least number of states in which it must exist to reproduce all the spectrum colours. We may, therefore, at once dismiss from the possibilities that a printed image in colours can be composed of elemental matter. This makes the possible image a compound which has to be acted upon by light. The action that must take place on such a compound must be either a reducing action or an oxidizing action (probably both), or else a molecular re-arrangement. In the case of chloride of silver, which, after a preliminary exposure to the light, can be impressed by the spectrum colours, I have found that the blue end of the spectrum is reproduced by reduction, and the red end by oxidation, there being a position where there is a combination of both. We can conceive matter to be so composed molecularly, that coloured light may sift out certain molecules, which shall in the aggregate reflect red light when the rays acting on them are red, or when green light acts on them, reflect the green rays, and so on. Let us fix our attention on the molecular aggregations which reflect red light. Since red light is reflected, it follows that all the rays existing in white light are absorbed except the red rays, and we know that when absorption takes place then internal work of some kind must be performed. In the spectrum, where these colours are produced on the sensitive surface, it must be recollected that no blue light acts on the part exposed to the red rays, and is, therefore, during that exposure incapable of doing any work in the molecules. Now, the very fact that the molecules are ready to arrange themselves into aggregations reflecting different colours, show that they are very susceptible of taking a new form of aggregation, and those which had aggregated into red reflecting masses by the action of the spectrum would be the first to re-arrange themselves into blue reflecting aggregations when acted upon by the blue rays which they absorb. The blue reflecting aggregations would also be the first to re-arrange themselves as red reflecting aggregations under the action of red light, and so on. Red, green, and blue reflecting aggregations—arrived at by exposure of the matter to the spectrum colours on subsequent exposure to white light, which is a combination of the three colours—must, therefore, rapidly change to a neutral tint, following out the above reasoning; and this is found to be the case in the photographs in natural colour taken up to the present time. We may take it, then, that no mere re-arrangement of molecular groupings by coloured light can remain stable in white light. Let us see if there is a probability of fixing the colour by chemical means. Fixing would mean removal of some matter still sensitive to light. As from the nature of things such matter is part of the molecular aggregation which causes the colour to be reflected, it is evident that the removal of a part of such aggregation must at once change the colour. If fixing be attempted by adding to the molecular aggregation, the same reasoning applies. We therefore are in this quandary as to a printing-out process in natural colours: If the colour be produced by change in composition of the matter acted on, it must be fixed by chemical agencies, which means destruction of colour. If it be formed by altered molecular arrangement, white light must of necessity alter its colour.

A process in natural colours which depends on development is out of the range of probability, as I have already stated in my British Association address. An embryo photographic image in natural colours might be possible, but to imagine that a coloured image can be built up by chemical means, such as by the deposition of silver on such image, is to endow the depositing atoms with a discriminative judgment, which, so far as is known, not one has the slightest symptom of possessing.

It will be seen from this that I am no believer in the discovery of a really practicable process for producing photographs in natural colours. We may wish every success to the gentleman who is making these researches, but the telegraphic description in the *Standard*, to my mind, does not require to be read between the lines to see that there is a great deal more of hoped for than of accomplished success in what has been done.

Crystal Palace Exhibition.—Mr. J. Dore writes that in the notice of the above, in our issue of the 4th inst., he was erroneously described as J. Dove as the winner of the bronze medal, Section 1 (professional), British subjects, in the lantern section of the Exhibition.

Croydon Camera Club. — Excursions will take place on April 19th and on Whit Monday; and on April 23rd there will be an exhibition of bromide enlargements. Information may be had from Mr L. De Clercq, 38, Lansdown Road; or Mr. Alfred Underhill, 23a, Clarendon Road, Croydon.

PHOTOGRAPHIC APPARATUS.

The following cuts represent pieces of photographic apparatus which Messrs. Marion and Co. have just introduced into the English market. Fig. 1 represents a new shutter by Voigtlander and Son, which is one of that class which opens and closes from the centre. Its peculiarity is that, after opening uniformly a small way, the aperture suddenly assumes somewhat a star-fish form, so in opening and closing allows more light to reach the plate than would be the case had it still an approximately circular form. This shutter works between the lenses. Messrs. Marion and Co. also have just introduced a stereoscope and stereoscopic camera combined. The ground glass screen is contained in a rectangular chamber, and when placed on the side nearest to the lenses, serves for focussing purposes, and the chamber keeps it sufficiently in shadow to render a focussing cloth unnecessary under ordinary circumstances. When placed on the farther side of the chamber it serves as a diffuser of light when the camera is used as a stereoscope. In whichever character the instrument is used, the same lenses are employed, but eye-cups are fitted into their hoods when the camera is employed for viewing stereoscopic pictures.

Fig. 2 is the camera invented by Mr. Samuels, and the cut shows one side of its lever arrangement for focussing; by the lever motion the lens is brought to focus expeditiously. The construction of this camera is extremely simple, and when it is closed it forms a cubical box, which looks as if it would bear a kick anywhere

Fig. 1.

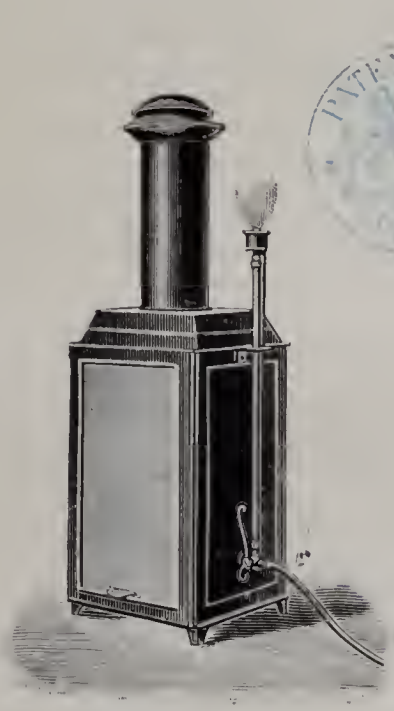

Fig. 4.

Fig. 3.

without injury to its contents. Fig. 3 might be called a "bipod" head-rest; the additional leg gives great firmness; the whole arrangement rests upon castors, which will roll in a forward, but not in a backward direction.

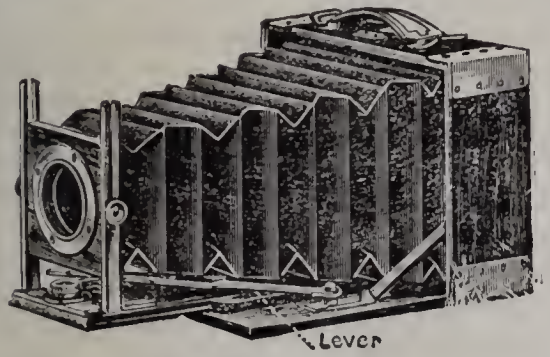

Fig. 2.

Fig. 4 is a developing-room lamp; when the tap is turned in one direction, the gas-flame rises inside the lamp, and there is no light in the room: when it is turned in the opposite direction the aforesaid flame is, practically speaking, extinguished, and the room becomes illuminated by the exterior gas jet.

Messrs. Marion and Co. have also exhibited to us a modified Kershaw shutter, with a "time" arrangement affixed thereto. The same firm is introducing a new reflector of light for studio use. It gives the power of universal adjustment, and consists of an upright iron rod fixed to a circular base: this rod is 4 feet 6 inches high, and on it run two junctions, each carrying a reflecting screen measuring 4 feet by 2 feet, the one covered with white calico, and the other with a brownish colour. These can be turned at any angle, thus allowing of reflection of light as desired. Another piece of apparatus Messrs. Marion and Co. have on view, is a portable stand for four or six or more pieces of flash light apparatus: the stand will pack away so compactly as to be easily transported to private houses for purposes of portraiture.

The California Camera Club.—Another photographic society is proposed for San Francisco, to be entitled the California Camera Club. The objects of the promoters are said to be the formation of a social, scientific, and art centre for photographers, and the establishment, in a convenient locality, of rooms for the use of the Club.

PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

Halation—Magnesium Flash-Lamp—Developing Capsules—Sulphite of Soda—Use of Flexible Films in Egypt—Photographic Societies and Clubs in London—Negatives on Celluloid Pellicle—Lantern Projections.

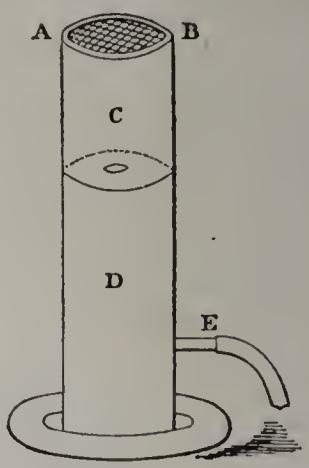
The French Photographic Society held its usual monthly sitting on the 11th inst.; the following were the principal questions discussed.

The Commandant Möessard has occupied himself with the question of halation; as for the causes of it, he has said nothing further than was told us by MM. Cornu and Lumière, but he has been seeking for a way to provide a remedy. He has not arrived at any practical solution, but he thinks suggestions ought to be made to the manufacturers of plates. In the first place, he remarked that if the sensitive film is very transparent, there is no diffusion of the luminous rays; they pass in a straight line, and consequently there are no reflections produced in the nature of halation. On the other hand, if the film is absolutely opaque, halation cannot exist. There is, then, a point of relative translucence or opacity at which halation is at its maximum. We must, says the Commandant, endeavour to arrest the transmission of reflected rays, or use thin pellicles.

It has been already shown, he says, that halation exists to a much less extent with pellicles. As for glass plates, the remedy proposed by M. Cornu appears to be good; but, further, could not the sensitive film be stained with some inert colouring material which would give sufficient opacity to arrest the light in the film itself? It would appear that in orthochromatic plates halation is much less pronounced. In short, these are simply suggestions of principles, and it is left to experimenters to try them, and choose that which succeeds the best.

M. Vidal pointed out an objection to staining the film, as if the film is so coloured as to retain the whole of the rays of light, it would be insensitive. He thought that the use of a coloured screen which should greatly diminish the power of the blues, the violets, and the high-lights, would contribute to diminish halation. In his opinion, the introduction of anything into the sensitive compound except substances capable of bestowing orthochromatic properties upon it, should be avoided. In this connection, he mentioned that, if a little too much of the colouring matter intended to orthochromatise the sensitive product is added, a general insensitiveness occurs, which must be avoided. Good orthochromatic plates, whilst containing a sufficient amount of the colouring principle, are, or ought to be, almost colourless. In his humble opinion, the best thing was to follow the path indicated by M. Cornu, and to seek for an easy means both of covering the back of the plates with a medium possessing the same refractive index as glass, and to be able, without trouble, to remove this coating from the plate at the moment of development. As pellicle suppresses halation almost completely, we have again this resource, and it is a question of great interest to be able to produce images free from this annoyance, this defect.

A new magnesium flash-lamp was shown in the name of M. Vergeot by the Commandant Fribourg. It consists simply of a metallic tube of the height of about ten centimetres, and of the diameter of an ordinary candle. It may be placed in a candlestick or chandelier. It consists of two distinct parts, C a spirit lamp, D a reservoir of pure magnesium powder. At E is seen a tube to which to attach the flexible pipe from a pneumatic ball. At the top of the lamp AB is a wire grating, and below at C is cotton impregnated with spirit. The combustion lasts about a quarter of an hour. The reservoir D being filled with magnesium and the spirit lighted, if a pressure is given to the ball the powder is blown through C; it is inflamed and the flash projected. In this manner a series of very luminous flashes may be produced successively and without danger. This lamp is one of the simplest and the best which I have seen.



A chemist of Niort, M. Michelin, has devised capsules containing each a dose of developer, which are easy of carriage, and which at the desired moment permit a developing solution to be rapidly made up. These capsules contain, the small one pyrogallic acid, and the large one the desired mixture of alkaline salts, carbonate and sulphite of soda. The contents of these two capsules are placed in from forty to fifty centilitres of water. M. Michelin proposes to prepare other portable capsules for different developers—hydrokinone, pyrocatechin, eikonogen, and others. We have already in this direction had the developing pastilles of Ener.

Another chemist—M. Chicandard, of Lyons—has communicated the results of his interesting study of sulphite of soda. This product, he tells us, is very rarely pure; it most frequently contains sulphate of soda in larger or smaller quantities, and free carbonate of soda. To assure oneself whether there is any sulphate of soda, it suffices to produce with excess of chloride of barium a precipitate in a solution of sulphite of soda. If this precipitate is not entirely dissolved by hydrochloric acid the sulphite is impure. To demonstrate the presence of free carbonate, we have recourse to phenol-phthalein. A drop of an alcoholic solution of this product becomes red if the sulphite contains free alkali; if on contact with the sulphite no colouration takes place, it shows that no free carbonate is present.

To ascertain the quantity of sulphate which impoverishes the sulphite, M. Chicandard advises the employment of the following process. In the first place, a solution of 2·45 grammes of the sulphite to be tested is made in 100 grammes of distilled water; secondly, a mixture of

Iodine (in crystals)	... ...	2·53 grammes
Iodide of potassium	... ...	3·60 ,,
Distilled water ...	... ...	100 ,,

Ten c.c. of the first solution are taken, and drop by drop the second is added from a burette graduated in tenths of a cubic centimetre until the liquid takes a permanent yellow colouration. A few drops of thin starch paste may be added, and in this case it is an intense blue colouration which indicates the end of the reaction. The number of tenths of cubic centimetres of the iodine solution employed indicates the percentage of sulphate contained.

M. Chicandard recommends keeping bottles of sulphite

and of pyrogallic acid in the light, contrary to the prejudice which insists that light is injurious to pyrogallic acid.

M. Balagny showed a series of negatives, 21 by 27 centimetres, on flexible films, obtained in Egypt during a scientific mission. They number 120, and are very remarkable. They have undergone for more than three months a temperature of about 40° Centigrade. He considers this as a new proof of the resistance of these pellicles to very high temperature, and he adds that, thanks to this light and unbreakable support, the tourist is always sure of obtaining negatives, and is exempt from the considerable expense of carriage occasioned by the use of glass plates.

Mr. Stebbing, on returning from a journey to London, greatly interested the Society by a description of the photographic clubs and societies in London; he also mentioned numerous hotels in which amateur photographers will find a dark-room for their travelling work.

M. David claims to have been among the first to recommend celluloid pellicles for photographic negatives; he showed some thus obtained by him from 1883 downwards.

Some interesting slides were shown in the lantern, amongst them reductions from the negatives on flexible films shown by M. Balagny, and some experiments in coloured work by M. Maurice Buguet. The latter, although as yet incomplete, promise good results with perseverance. A lantern slide gains much by being coloured, provided that this supplementary work is done with art and sobriety.

A French Exhibition in London is in course of preparation for the month of May. There is room for doubt whether photography will be largely represented in it. A committee is occupied in organizing this special class.

THE LATENT PHOTOGRAPHIC IMAGE.*

BY C. H. BOTHAMLEY, F.I.C., F.C.S.

A second hypothesis, also physical in its character, was propounded by Mr H. S. Starnes,† and was based mainly on the facts that an unexposed gelatino-bromide plate is not affected by solutions which will reduce ordinary precipitated silver bromide, and that if a quantity of emulsion which has been exposed to light is melted up with a fresh quantity of emulsion or gelatine, or is simply re-melted without any addition, the resulting emulsion shows only a trace of fog on development. It was suggested that each particle of silver bromide is enclosed in a protective envelope of gelatine, and that the impact of light waves ruptures this envelope and exposes the contained silver bromide to the action of the developer. The destruction of the latent image by potassium bichromate was supposed to be due to the hardening effect of the bichromate on the gelatine. It is not easy to see, however, how bichromate could heal up, so to speak, the ruptured envelopes; nor why the image should be destroyed by bromine, which tends to destroy or alter the gelatine; nor why silver bromide in gelatine should be more sensitive than silver bromide in collodion, the latter being by far the more porous medium of the two.

All the evidence indicates that the formation of the latent image is a photo-chemical operation, the composition of the material forming the image being different from that of silver bromide. The difference between the formation of a visible image and a latent image is, in fact, as our President, Capt. Abney, has always insisted, a difference in degree and not in kind.

It is well known that bromine, chlorine, and any substance which will readily give up bromine or chlorine, will destroy the latent image, the result being independent of the mode of manufacture of the emulsion. (Examples shown.)

Potassium dichromate in neutral or acid solution has the same effect. I observed that a mixture of the dichromate and potassium bromide produced this result more rapidly than the dichromate alone, and, therefore, it seemed not improbable that the effect is not simply an oxidising action of the dichromate, but is due to a simultaneous action of the dichromate and the small quantities of soluble bromide which are almost invariably present in gelatine plates.* This point does not seem to have been investigated before.

It is practically impossible to wash out the last traces of the bromide, and hence the only course open is to convert all the soluble bromide into silver bromide, and this was done by immersing the plates for an hour in a 2 per cent. solution of silver nitrate, slightly acidified with nitric acid. They were then washed, first with distilled water containing a little nitric acid, perfectly free from chlorides, &c., and finally with water alone. I think it may be taken that they contained no soluble haloid salt.

Potassium dichromate solution (5 per cent.) was purified from haloids by adding a small quantity of silver nitrate solution and filtering through glass wool previously well washed.

The plates were exposed to light, and one half was immersed for five minutes in the dichromate solution, very thoroughly washed, and developed with ferrous oxalate containing no bromide. Although there could not have been any simultaneous action of the dichromate and a soluble haloid, the latent image was destroyed (example shown); and therefore we may take it, I think, as established that the destruction of the latent image is due solely to the action of the dichromate, which probably exerts an oxidising action, but may also be effective because it converts the material of the latent image into silver chromate.

Nitric acid is also commonly said to destroy the image, but I found that the strongest acid that the gelatine would stand after previous treatment with chrome alum certainly did not destroy it. (Examples shown.) A washed collodion emulsion made with excess of silver nitrate and washed with distilled water in order to avoid introduction of soluble haloids, was exposed to light and then treated for twenty minutes with nitric acid containing 25 per cent. of real acid. After washing and development it was evident that the latent image had not been destroyed. (Example shown.) Other similar experiments gave similar results, but in all cases the action of the acid on the gelatine or pyroxiline made it impossible to obtain density. I am making further experiments, but the results so far obtained seem to indicate that the nitric acid does not destroy the latent image, although it may prevent its development. In this connection we may recall the fact that even the strongest nitric acid does not prevent the darkening of silver chloride or bromide when exposed to light.

It seems to me that it has not been clearly recognised that the formation of a developed photographic image

* Continued from page 283. † *Brit. J. Phot.*, 1883, p. 643, 656, &c.

* See for example, Zettnow. *Phot. Correspondenz*, 1889, p. 56 *et seq.*

takes place in three distinct stages, which may and probably do differ considerably in the nature of the changes which occur. First we have the *latent photo-image* formed solely by the action of light, and therefore of photo-chemical origin; secondly, we have what I propose to call the *primary* or *fundamental image* formed from the latent image by the action of the developer, and therefore partly of photo-chemical and partly of chemical original; and thirdly, the *developed image* formed by the action of the developer from the primary image and the unaltered silver bromide in the film. This last process is probably mainly electro-chemical.

Potassium iodide is also said to destroy the latent image, but I find that after immersion in a 5 or 10 per cent. solution of the iodide for a time sufficient to convert all the silver salts in the film into silver iodide, there is still left an image which can be seen during development, and can still be seen after fixing, although it is then very faint. (Examples shown.) The same result is obtained with pure bromide or brom-iodide emulsion. It might be argued that the action of the iodide had not been continued sufficiently long. Twenty minutes' immersion in a 10 per cent. solution of the iodide was the maximum given, but the conversion of the silver bromide into silver iodide was certainly complete, and it may be assumed that any action on the latent image had reached its limit. It seems, then, that potassium iodide does not destroy the latent image, nor prevent its conversion into a primary image by the developer, but does prevent the formation of a developed image, doubtless because the silver salts in the film are converted into silver iodide.

Hydrobromic acid and hydrochloric acid are also said to destroy the latent image. The action of the first acid I am investigating. Hydrochloric acid containing 12 per cent. of real acid does not destroy the image on a gelatino-chloride plate after twenty minutes' immersion. (Example shown.)

(To be continued.)

LIMITATIONS IN THE TREATMENT OF SUBJECTS BY FOCUS.*

BY T. R. DALLMEYER.

That the combined chemical and mechanical process known as "Photography" be admissible in the sciences must be determined by its exactness. So far as a photographic lens can be made perfect (speaking technically, this means that the instrument be aplanatic), the applications to science are eminently satisfactory in records and investigations, in that but one plane of the object has to be represented by one plane in the image, or that the conjugate points in the object are so situated that they are simultaneously received to an accurate focus on the plane of the photographic plate. These conditions are practically maintained in stellar photography, micro-photography, &c. Photography in many such applications is not only sufficiently truthful, but records on the sensitive plate more than the most practised eye can ever see, for physiological reasons. Immediately photography is employed to depict objects in different planes, where the corresponding points in the image are formed on sensibly different planes, the representation by receiving them on one plane is no longer truthful nor exact. A photographic instrument to accomplish this theoretically is simple enough, but nevertheless is a practical impossibility. It would only necessitate the employment of an imaginary "pinhole," the aperture of which shall be the section of a mathematical straight line. In such a case, every plane in the object would be equally and perfectly rendered, mathematically true and exact in position on the plane upon which the image was received, the size of the image itself being dependent on the distance of this plane (of the plate) receiving the image from the imaginary "pinhole."

From the fact that in pictorial photography it is necessary to depict different planes at once, it follows that, strictly speaking, the results are untrue in drawing, although relatively they can be made in so-called sharp photographs far truer than any artist could ever expect or would attempt to render them in detailed drawing. Such approximate precision capable of being produced by a photographic instrument might be the envy of the mere still-life painter, and is certainly acknowledged by all painter artists as a useful elementary means to an end.

I understand the attitude of a painter artist in depicting a scene to be that of a workman with an artistically educated sight (with binocular vision), anxious to portray or reproduce the individual feelings and emotions produced in *his* mind by the scene before him, and with working tools at his command that he relies upon to help him in giving a truthful impression of what he sees. This individuality is not capable of any exact definition, although he may succeed in impressing others with the very same feelings that his transcript was intended to convey. Impressed by this individuality he will emphasise or subdue, according partly to his own taste, and partly according to the principles of composition (the latter being mostly negative principles), which are the result of long study and practice.

With the photographer the attitude is very different. Grant that he is perfect in his technique; the tools at his disposal are self-acting, recording the image from one point of sight only, and the individuality of the instrument is limited and capable of exact definition, but here his own individuality is restrained by the latter's artistic capabilities. The question of the production of effects is *now* one dependent entirely on scientific laws, and is defined by the optical construction of the lens itself and the law of conjugate foci.

As the camera can only depict what is placed in front of it, the photographer, to produce work that can be called artistic, has, or must cultivate, that artistic appreciation of nature in all her moods which the true artist observer and admirer of her finds so much pleasure in. The choice of the subject, its charm or interest, and its more or less good composition as seen from different points of view, will indicate the operator's greater or less artistic appreciation and individuality; but having only an inanimate and unthinking machine, he is bound to look for such phases of nature as can give that machine the greatest opportunity of utilising its limited powers. The limited treatment in point of definition lies in the adjustment of "focus"; the controversies that have arisen on this point, on the art side, have certainly done much to raise photography from a copying process to that of a fine art.

You have before you a series of photographs that show the *tendencies* by various treatments of the focus towards the destruction of the best possible image as given by a perfectly corrected lens. They are the result of a series of accurately performed experiments, and as a record may

* Abstract of a paper read before the Camera Club Conference, and published in the *Journal* of the Club.

prove of value and impress the memory with the *tendencies*, without resort to the theoretical study of the principles that guarantee the results.

It is probable that you are all well aware that the test for a perfectly aplanatic lens is that when a point of light is focussed for the image it is seen sharp, and that on wheeling the plane of the best focus in or out the image vanishes equally on either side; if positive spherical aberration is present on the inside of the focus, the image vanishes or loses structure very rapidly, but on the outside lingers for a considerable distance, and its structure is maintained; this becomes more and more remarkable the more positive spherical aberration is present. The converse of this occurs when negative spherical aberration is present.

The reason—and it is easily shown mathematically—is, that in the former case there is an outward concentration of the image-forming rays inside the focus, and an inward concentration of the image-forming rays outside the best focus; and the converse of this occurs in the latter case. Again, it must be borne in mind that the least circle of aberration in a non-aplanatic lens is *not* the best focus visually, but at the plane where there is the strongest inward concentration of the image-forming rays. I have intentionally laid some stress on this point now, as objection has been taken to the fact that spherical aberration improves the out-of-focus planes, simply from ignoring the fact that the important element, viz., the measurement of the longitudinal aberration, has been lost sight of in comparisons made of the transversal measurements of the circles of confusion as compared to those of an aplanatic lens.

With regard to the illustration, you will note various regular steps in the alteration of the plane receiving the image; if the focus be shortened, or a movement *in* be made, you know it corresponds to a more distant object, and hence the plates in which there has been an inward movement correspond to *foreground* tendencies when some more distant object is focussed for; and, on the other hand, if the focus be lengthened, or a movement *out* be made, the focus is made for some nearer object, and hence the plates correspond in these cases to background.

It would be an easy matter with any lens to construct a table showing the limits of movement of the camera back permissible, not to exceed a certain definite out-of-focus circle (deemed consistent with sufficient maintenance of structure), for planes on either side of the one chosen that should include such treatment for the extreme distance and nearest foreground required. If these were exceeded by a given lens with full aperture, the requisite limit could be arrived at by reducing the aperture exactly in the proportion you wish to reduce the out-of-focus circle produced to that required.

(*To be continued*).

Correspondence.

THE CRYSTAL PALACE EXHIBITION AWARDS.

Sir,—I am requested by the Manager, on behalf of the Company, the Committee of Judges, and the Executive, to deny unequivocally the allegations contained in a letter signed by Mr Edgar G. Lee and others, and published in your last issue, respecting the award of the National Photo. Club Challenge Cup, and to add that the company is in a position to prove that such allegations have absolutely no foundation in fact.

I am further desired to thank you for your editorial note at foot of letter, which is as courteous as it is strictly true.

S. G. Buchanan Wollaston.

Specifications Published.

7,659. *7th May*, 1889. "The Preparation of Crude Glass.' Julius Quaglio, 25, Louisenstrasse, Berlin, N.W. Germany, Engineer.

In the glass industry, the glass used for treatment proceeds from compounds which are melted in the pots or hearths of furnaces, serving likewise for working the same throughout. Separate experiments have been undertaken by various experimenters with a view to carry out the melting process in peculiar furnaces, and to feed the melted mass in a liquid or cooled state to the working furnaces while endeavouring to free the mode of proceeding hitherto resorted to from a number of the defects attending the same.

A series of practical experiments has led to a new process for the manufacture from a vitreous mass of a middle or intermediate compound: to this intermediate compound the inventor has given the name of calcin (crude glass), which calcin can be fed to the working furnace without any admixture of alkalies, and in a cold state, in order to be heated therein, and used for the manufacture of the glass wares of commerce. By these means, he says, an extraordinary yielding manufacturing mass can be continuously supplied as well in pot furnaces as in furnaces provided with tanks or cisterns (hearths). Owing to the use of calcin, the rapid destruction of the material constituting the furnaces, whether furnished with pots or cisterns, which is brought about by the decomposing action of the alkalies when the mass is directly melted, is, he says, prevented, and a better product free from threads or streaks, striae, or wreaths is thus obtained.

8,054. *May 14th*, 1889.—"Photographic Cameras." John Henry Skinner and Edwin Jackson Lyth, trading as J. H. Skinner and Co., East Dereham, Norfolk, Photographic Apparatus Manufacturers.

The object of this invention is to provide photographic cameras with means whereby they can be quickly extended or closed as desired.

The extension apparatus of photographic cameras at present in use consists of a pinion gearing into a rack, the said pinion being actuated by a milled headed screw.

According to this invention we dispense with the pinion, and provide a cog wheel of suitable size gearing into the rack on the frame. This cog wheel is provided with a handle or turn for actuating the same.

Photographic Club.—The subject for discussion on April 23rd will be "Development of Instantaneous Exposures;" on the 30th, "Development of Unknown Exposures."

The *Journal of the Society of Arts* announces that the lectures on "Colour and Colouring," the last of which was given by Professor A. H. Church, M.A., F.R.S., on March 31st, will be printed in the *Journal* during the summer recess. On April 30, Mr. T. R. Dallmeyer is to read a paper on "Photographic Lenses," at the Society of Arts.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

AT the ordinary meeting of this Society held on the 15th inst., the chair was taken by Mr. J. GLAISHER, F.R.S., President.

A paper on "A Standard Method of Development" was read by Mr. C. H. Bothamley, F.C.S., and illustrated by a table showing the sensitometer numbers procurable by various developers and times of development. In the course of his observations, Mr. Bothamley said that it would not be proposed to fix one uniform system of development for all subjects. Generally speaking, the nature of the subject and the intention of the photographer as well as other circumstances must be taken into account. If all subjects were to be developed in the same way photography would be lowered from the position of a fine art to that of a merely mechanical one. There was, however, an advantage in adopting some definite standard for the purpose of comparing results in a scientific way. In considering what it was desirable to compare, they might take either the least amount of exposure that would suffice to bring out a visible image, or they might take the amount of gradation obtainable. For the latter purpose he thought no standard developer could be found, as a different constitution of it would be required for different makes of plates, and to suit the tastes of different photographers. The same developer would not suit the photographer who delighted in softness and the one who desired chiefly to get what was called pluck. We might then look upon the problem as narrowed to the question of obtaining detail, but such detail must be got without fogging. What was wanted was to utilise to the utmost the selective power of the developer in reducing silver where light had acted on the film, and in not causing reduction independent of the action of light. One of the things to be considered was that photographers were dependent upon dealers for the purity of the chemicals they employed. Several conditions were required to be fulfilled in a standard developing solution. It should be simple in composition, and, if possible, should be like what was in general use. Then only such chemicals should be required as can be obtained in a fairly pure state. Of the various developers available, ferrous oxalate was noticeable as failing to fulfil several of the conditions that had been laid down. Although potassium oxalate could be obtained tolerably pure, this was not always the case with ferrous sulphate, and even when pure to start with, it rapidly changed. The developing solution, too, soon oxidised, and ferric oxalate, the product of oxidation, was not only a retarder, but actually a reducing agent. Finally, it was now but little in use for developing negatives, although for positive work it was still largely employed. He did not think that at present eikonogen could be relied upon for purity, and, therefore, we were reduced to select either pyrogallic or quinol. Of these, the first-named is to be preferred. It is the developer most largely used ; in the dry state it keeps well, and its great solubility makes the preparation of solutions very easy. With pyro, however, we must not use caustic soda, or caustic potash, but must select either liquid ammonia or an alkaline carbonate. With liquid ammonia a restrainer is generally used, and this may take the form of bromide either of ammonium or potassium, or of a salt containing an organic acid. Bromide of ammonium, on the whole, he had found to be the best restrainer. With potassium bromide there was commonly present some bromate, and not unfrequently a little caustic potash. Carbonate of potash is not so readily obtained pure as carbonate of sodium, and is, moreover, objectionable from its hygroscopic character. Carbonate of sodium exists in various forms as regards the amount of water and consequent value of the salt and proportion of it required to produce a given effect. The anhydrous variety is that most likely to be pure and definite, and may be prepared by heating the ordinary carbonate. When obtained it should be kept in a glass bottle fitted with an india-rubber stopper ; a glass stopper is very bad both for keeping air out, and, in the case of volatile substances—like ammonia—for confining the vapour. When ammonia is used for the standard developer its strength should be determined by titration. There is no large amount of apparatus and no great deal of skill required for this process. A standard acid is required, and oxalic acid is found to fulfil the necessary conditions. A little of a solution of aurine, one in 500 of diluted alcohol, should be used with it as an indicator of the neutral point. 37·06 grammes of oxalic acid is dissolved in a litre of distilled water, and 1 c.c. of this solution is sufficient to neutralise a centigramme of real ammonia, NH_3. The pyro for a standard developer should be dissolved in distilled water just before required. No acid should be added. It is not admissible to use sulphites in standard solutions. Not only is it rare to obtain sulphites pure—samples professing to be sulphite have, indeed, been found to contain no sulphurous acid at all—but the action of sulphite upon development is not determined. An approximation only to purity can be obtained when using the neutral or anhydrous sulphites. The standard developer will consist, then, of pyro, with liquid ammonia, and bromide of ammonium, or of pyro with carbonate of sodium. The preparation that he had used as a standard for a long time was composed of—

Pyro	2 grains
Ammonium bromide	1 grain
Liquid ammonia	3 grains

As this proportion of liquid ammonia contains about one-third of its weight of real ammonia, NH_3, the formula may be put into parts of 1,000, thus—

Water	1,000
Pyrogallol	5
Ammonia bromide	2·5
Real ammonia	2·5

It occurred to the reader of the paper to try various forms of developers to see whether anything better could be got at as a standard. To try them he had used a sensitometer exposed to the light coming through an opening one centimeter square, placed close in front of the brightest part of the flame of a Sugg's Argand burner. He had found that all the detail that was obtainable would come up in five minutes, but that the action might be continued up to an hour without much fogging, and with considerable accession of density. The proportion of bromide might be doubled without keeping back detail, and with improved clearness during long development. With carbonate of sodium as the alkali, development was lengthened ; it required ten minutes to get out the detail, and if the plate was left for an hour in the solution, it was much degraded by a general deposit or chemical fog. Whenever development was continued for a period of more than ten minutes, he advised that it should take place with the air excluded as far as possible, and this he accomplished by using an upright vessel and covering it with a fitted top of india-rubber. The temperature at which the experiments had been carried on was 60° Fahrenheit.

Captain ABNEY said that the method of reckoning sensitometer numbers by the last one that was just discernible was very misleading ; it was far better to measure the density of deposit of some of the numbers.

Mr. W. E. DEBENHAM thought that although the question of temperature had been touched upon, the difference of result due to differences in that respect were not sufficiently appreciated. In cold weather a much longer time was occupied with developer of a given strength, and in hot weather the amount of alkali or time of development might again be considerably reduced. He had known even experienced photographers to be misled by this effect at the first coming of cold in winter.

Mr. JOHN SPILLER welcomed a paper in which scientific bases were established for experiment. As for what Mr. Debenham had said about the effect of temperature, he could quite corroborate that. During the cold weather a few weeks since, he was quite surprised to find the immense difference that variations of temperature caused in the action of the developer.

Mr T. SEBASTIAN DAVIS congratulated the reader of the paper upon its scientific character. He was pleased to find the system adopted of measuring by 1,000 parts, which he thought

better either than the proportions by ounces or grammes, or than the per centage method.

The Chairman referred to his own experience some years since, when more actively engaged in photography, and said that he had noted the remarkable difference of behaviour of the developer due to variations of temperature.

Mr. Friese Green exhibited the camera already described in these pages, fitted with mechanism for producing a series of photographs of moving objects taken in rapid succession. By turning a handle, successive portions of a roll of sensitive film were placed in position behind the lens, and exposed. It was stated that the camera could be worked at the rate of 600 photographs per minute, or even faster.

Messrs. E. G. Amplett and W. Symon were elected members of the Society.

Camera Club.

On Thursday, April 10th, there was an exhibition of lantern slides, eight or nine members contributing towards the show. Mr. Gambier Bolton exhibited a new set of animal slides; Mr. Elder some Dutch scenery; Mr. Ferrero, landscape work; and Messrs. Grimshaw, Howson, Robertson, and Noel-Cox, pictures of various kinds. An interesting set of Arctic subjects lent by Messrs. Fry was also shown and described, and a variety of slides by the Woodbury process.

During the evening, proofs of his recent pictures, "The Haysel" and "Breezy Marshland," presented by Dr. Emerson to the Club, were exhibited.

On Thursday, April 24th, there will be a discussion upon Mr. Dallmeyer's paper read at the Conference; the subject was "The Treatment of Subjects by Focus."

Hackney Photographic Society.

On Thursday last the ordinary meeting was held at Morley Hall; Mr. A. Dean presided.

After confirmation of the minutes, the Secretary drew the members' attention to the annual soiree to be held on the 24th, and announced that the Society's orchestra would play on that occasion. Messrs. Cocks and Beurle were elected members, and Mr E. H. Jones was nominated.

The Secretary handed round the Eclipse lantern carrier, which Mr. Pringle had so highly spoken of.

Mr. Gosling wanted to know what were the disadvantages of a shutter going from side to side.

Mr. Spratt thought it would probably cause vibration, and he showed Crouch's detective camera, the spring of which was taken from a clock. There was, however, no vibration in this.

Mr. J. Carpenter then read his paper on "Lantern Slide Making," and finally concluded by a demonstration. He generally masked the margin of the plate, so that if there was any fog it would show. His favourite lantern plate formula was the following:— Eikonogen, ¼oz.; sulphite soda, ½oz.; bromide potassium, 3 grains; carbonate of potash, ¼oz.; making the whole up to 10 ounces of boiling water. For use he diluted 1 part with 2 to 4 of water, fixing in two baths. Mr. Carpenter secured a medal at the recent exhibition for this work.

London and Provincial Photographic Association.

At the meeting on the 10th inst., Mr. A. L. Henderson occupied the chair.

Mr. F. York exhibited a cover glass from a lantern slide very much clouded, and read a letter he had received in reference to some from Mr. Pancoast, of Waterbury, Conn. At a recent meeting of the Photographic Society of Philadelphia, the subject of erosion on lantern slide cover glasses was discussed at some length, and reported in the *American Journal of Photography*, a copy of which Mr. York passed round.

Mr. A. Edwards showed prints from negatives of the Oxford and Cambridge boat race taken on isochromatic plates.

Mr. J. B. B. Wellington used this kind of plate on the same occasion, and found them very quick.

A question was asked how to varnish celluloid film negatives.

The Chairman advised rubbing them over with bees-wax dissolved in turpentine.

The Hon. Secretary recommended gold size and turps, and the films hung up by one corner to dry.

Mr. F. P. Cembrano exhibited a lantern slide of a "pellicule," showing sixteen pages of printed matter. During the siege of Paris, attached to a pigeon's wing so as not to interfere with its flight, these "pellicules" were used for the transit of information from one place to another.

Mr. Davenport showed a lantern carrier, fitted in a perpendicular position to the lantern; the slides are pushed upwards, the same action covering the lens during the changing of the slides.

Mr. Edwards exhibited a lantern carrier he had constructed. It consisted of a frame for holding two slides, which were set at an obtuse angle. The frame worked backwards and forwards on a pivot fixed to the front of the lantern.

A collection of members' slides was then projected on the screen, the work of Messrs. H. M. Hastings, A. C. Pemberton, J. Atkinson, R. P. Drage, P. Everitt, Teape, Edwards, T. E. Freshwater, and F. P. Cembrano.

Leicester and Leicestershire Photographic Society.

The monthly meeting was held on April 15th, when two propositions were received for ballot at next meeting.

The prints sent in for competition were placed on view, and were considered the best the members have yet sent in. The members who sent prints were Messrs. Bankart, Pierpoint, Woodland, Leeder, Wilson, Joliffe, Porritt, Partridge, Cook, and Squire.

A number of photo-litho prints, sent by the Graphotone Company, Enfield, was placed at the disposal of the members.

Newcastle-on-Tyne and Northern Counties Photographic Association.

An exhibition of photographs, apparatus, and photo-mechanical reproductive processes will be opened in the Central Exchange Art Gallery in Newcastle. The Mayor of Newcastle will open the Exhibition on Friday evening, after which a lecture, entitled "A Tour in Norway," illustrated by means of the oxyhydrogen lantern from slides taken by the lecturer, will be given by Mr. Paul Lange, the President of the Liverpool Amateur Photographic Association. Over 1,200 pictures will be on exhibition, apart from the section devoted to apparatus. The number of exhibitors exceeds 100. To add to the attractive character of the Exhibition, special vocal and instrumental concerts will be held each Saturday, and on the other evenings illustrated lectures by Messrs. W. Lang, of Glasgow, W. D. Welford, of Birmingham, J. P. Gibson, of Hexham, and other persons, besides interesting evenings with the oxyhydrogen lantern.

Dundee and East of Scotland Photographic Association.

April 8th.—General meeting; Mr. J. D. Cox in the chair.

Excursions were arranged to take place on May 21st, The Trossachs; June 28th, Lochearnhead; and the date of a third was left open.

The President (Dr. J. K. Tulloch) read a paper entitled, "Selecting a Lens" (see page 295).

Specimens of "Kallitype," a new printing process, were on exhibition, and a demonstration of the process was promised to be given at the May meeting.

Croydon Camera Club.

A meeting was held at the head-quarters, Public Hall, on April 11th, The President (Mr. H. Maclean, F.G.S.) in the chair.

The subject for the evening was a demonstration of "Platinotype Printing" by the Platinotype Company's representative, Mr. Smith, who gave the history of the platinotype process of photographic printing, describing the action of the various chemical substances used. He then developed a number of prints which had been taken from members' negatives by the Platinotype Company, these being distributed among the members. An interesting discussion followed.

Four new members were elected during the evening.

PHOTOGRAPHIC SOCIETY OF IRELAND.

An ordinary meeting was held in the Rooms, 15, Dawson Street, Dublin, on Friday the 11th inst., Mr. GEORGE MANSFIELD, J.P., in the chair. After two new members had been elected,

Prof. STEWART gave a lecture on "The Stop and the Optical Centre," and illustrated his remarks by numerous diagrams drawn upon the blackboard. In the course of his lecture he said the optical centre of a lens had important properties, and these properties, and how to find the position of the optical centre, should be understood by every photographer. In many cases the optical centre was outside the lens, and this was an important item to remember. In referring to spherical aberration, he said that all attempts to grind lenses so as to get rid of spherical aberration had been failures, but the use of a stop not only got rid of spherical aberration, but it also cured the curvature of the field of view. The stop also produced what was known as "depth of focus." Depth of focus was not so much a property of the lens as a property of the stop; by using a small stop depth of focus was obtained. Get the nearest object in a picture well focussed, put in a small stop, and everything else must be in focus. Another advantage of the stop was that it produced an approximately uniform illumination all over the plate. An ordinary lens was such that if it were used without a stop it would give unequal illumination over the different parts of the plate.

A discussion ensued in which the following members took part, namely: the President, Messrs. L. Meldon, J. H. Hargrave, J. H. Woodworth, and J. V. Robinson. A vote of thanks was passed to Prof. Stuart for his interesting and practical paper, after which Dr. J. Alfred Scott described what he termed an instantaneous work formula, and explained how it was possible for a photographer, by making a calculation, taking the different factors governing instantaneous work into account, to ascertain beforehand whether it would be possible to get satisfactory results on any given day.

The meeting then became conversational, and praise of the Society's new dark room was freely expressed.

WEST LONDON PHOTOGRAPHIC SOCIETY.

A TECHNICAL meeting of this Society was held at the Addison Hall on the 17th inst.; the President, Mr. CHARLES BILTON, occupied the chair for the first time since his recovery from serious illness. There was a goodly attendance of members, some of whom had brought with them various objects of interest.

Mr. SELBY showed Rouch's detective, which led to a discussion upon hand-cameras in general. One member, who worked with a Rouch, had found the lever would not always raise the plate; this defect, however, he had managed to set right. Other speakers testified to the capabilities of the camera.

Mr. WINTER kindly offered to allow members to test his Giah camera. He considered that all instruments should be practically tested before being issued to the public.

A discussion took place as to the comparative effect of printing in platinum in the sun and in the shade, in which several members took part.

Mr. WHITING showed a home-made view-finder, and advocated the more general use of that instrument. Whenever he went for a walk he put it in his pocket, so that if he came across a pretty bit he looked through the finder and ascertained how it would look as a picture, and if he thought it worth taking, he visited the spot subsequently with a camera.

Dr. F. H. LOW passed round some blue prints, some of which had been toned by a process described in a recent almanack, and the SECRETARY showed aristotype prints from negatives taken by flash-light of wine vaults in the Minories.

Mr. RICKFORD exhibited negatives, some of which had been intensified, and showed a number of prints from the same by a variety of processes, illustratiug the comparative results which might be obtained.

The PRESIDENT then announced that the Secretary would read a paper upon "Lenses" on the 25th April, and that the Annual Smoking Concert would be held at the Richmond Hotel on May 9th.

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Sreet, London, E.C.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs Piper & Carter, 5, Furnival Street, London.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

A. W. (Brighton).—*Axel Lagrelius's Phototype Process.* For fuller particulars you should write to Herr Albin Roosval, Editor of the *Fotografisk Tidskrift*, Stockholm, who might also be able to furnish specimens, by small payment, in addition to the one issued with the Journal.

A. M. M.—*Specification of Copying Apparatus* has been sent on to you. We are always willing to undertake this small service, the Patent Office being so near our head-quarters.

J. H. AINLEY.—*Zinc Photo-Block and Prints.* We are sending you a small block which has done duty in the NEWS; from this you will see that yours is not etched deeply enough, but we think you have scarcely done justice to your own work, as the prints forwarded will show.

MRS. CHERRY.—*Old Plates Illustrating Styles of Engraving.* After consulting several old works in the Patent Office Library, "The History and Art of Engraving," date 1747, Senefelder, the Vicomte Henri Delaborde, Thomas Hodgson, 1820, and others, we found nothing answering the description of the two plates referred to in your letter. They may be valuable, and we will take an early opportunity of making further search in the Art Library, South Kensington.

ARGENT.—*The Eikonogen Patent* covers both the alpha and beta naphthol compounds. See top of page 3 of the Specification, where it is stated that the alpha naphthol developers require more "sulphide," misprint for *sulphite* of soda, to keep them in solution.

R. S.—*Plain Paper Prints.* An excellent suggestion was made by Mr. Valentine Blanchard, in 1868, to sensitize and print on the *wrong* side of albumenised paper. By this scheme one finds already in commerce a paper which has undergone the salting process, and the action of light is aided by the presence of a small quantity of albumen which soaks through, but not enough to glaze the prints.

L. E. N.—*Lime-Light Apparatus.* Use coal-gas in place of hydrogen, and rely upon getting your supply of oxygen from one of Brin's cylinders, to save the trouble of making it for yourself. The lime balls or cylinders are best preserved in closely fitting tin cases; they shrink rather than expand by use, in consequence of the fritting and crystallization of the lime.

COLLODION.—*The Preparation of Enamel Collodion.* Methylated ether and alcohol will answer sufficiently well. Details are given in Captain Abney's "Instruction in Photography," pp. 255 and 256, together with the following formula:—

Soluble guncotton	48 grains
Alcohol	4 ounces
Ether	4 ,,

M. E. T.—*Celluloid Films.* Although these undoubtedly contain camphor as one of the ingredients of their composition, there is no evidence of any prejudicial action being exerted upon the sensitive emulsion with which they are coated.

R. E.—*Blue-Black Ink for Transfers.* If you find any difficulty in procuring the Victoria green for mixing with magenta to produce the blue-black ink, it is equally possible to employ the common malachite green, which is cheaper and answers quite as well. For violet ink, use 3 B. Hofmann or extra methyl violet.

W. MORGAN.—Mr. W. T. Wilkinson's "Manual of Photo-Engraving and Photo-Lithography" is not yet reprinted. Apply to Messrs. England Brothers, 25, Charles Street, Notting Hill, W.

TYRO.—*Varnish for Gelatine Negatives.* Messrs. Burton and Pringle recommend orange shellac 1½ ounce; methylated spirit 1 pint. When dissolved add a tea-spoonful of powdered chalk (whiting); shake up well, allow to subside, and filter.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1651.—*April* 25, 1890.

CONTENTS.

THE NEWCASTLE INTERNATIONAL PHOTOGRAPHIC EXHIBITION.

LAST Friday night the Newcastle International Photographic Exhibition, which is held in the Central Exchange Art Gallery, was opened by the Mayor of Newcastle, Mr. Thomas Bell. The Exhibition will remain open until Saturday, May 3rd.

In the Exhibition nearly a thousand photographs are upon view, and most of them of excellent quality. As at other good exhibitions, prints on albumenised paper are far less numerous than would have been the case some years ago, yet the proportion of warm-toned photographs is large, the idea being somewhat prevalent that platinum prints are, in some instances, too cold for artistic portraiture. Among the exhibits are prints of a pleasing brownish colour, obtained by Blanchard's platinum-toning method. Mr. Lafayette, Mr. F. W. Edwards, Mr. J. P. Gibson, and others, exhibit many of the photographs which they placed on view at the recent Crystal Palace Photographic Exhibition. Some fine specimens of artistic photography produced by photo-mechanical processes are placed on view by Messrs. Boussod, Valadon, & Co. (Goupil & Co.), Messrs. Braun and Co., Dr. P. H. Emerson, Mr. W. L. Colls, Messrs. Aitken, Dott, & Son, and the Autotype Co. Pictures by foreign exhibitors are not numerous; they come almost exclusively from America, and as they are hanging upon the same screen as a number of Rejlander's photographs, they are subjected to fierce competition so far as attracting public attention is concerned, but they are of excellent quality. One photograph of a little girl drinking out of a large mug, with her two little black eyes shining over the white edge of the mug like beads, is specially noteworthy in the American collection.

There are but three or four stalls devoted to apparatus in the Exhibition, and they contain nothing particularly special in the way of novelties. A little tin washing trough for plates, invented by Mr. Tylar, is on view in one of them; it is remarkably simple in construction, and, when placed under running water from a tap, is designed to tilt itself over, and empty itself of water every now and then, resuming, meanwhile, its normal position.

The Newcastle and Northern Counties Photographic Association, which has opened the present Exhibition, was founded in 1881, and has now about 110 members. Its president is Mr. A. S. Stevenson, of Tynemouth, who also took an active interest in the earliest Newcastle Photographic Society, founded a quarter of a century ago. One of its vice-presidents is Mr. J. P. Gibson, of Hexham, a skilled landscape photographer, who has contributed much excellent work, including some cloud studies, to the present Exhibition. The other vice-president is Mr. H. R. Proctor, F.C.S., who treats photography from a chemist's point of view. The secretary to the Association is Mr. Edgar G. Lee, with whom, for the purposes of the Exhibition, Mr. James Brown has been appointed adjoint secretary. The Newcastle Photographic Association has seven indoor and five outdoor meetings during the year, and in the winter months it has three or four lantern demonstrations, open to members and their friends, in the Lecture Hall of the Newcastle Literary and Philosophical Society. These lantern meetings are found to be highly popular, and to contribute to the welfare of the Association to a considerable extent. In Newcastle it is found that, as a general rule, professional photographers can afford to pay a higher annual subscription for membership than can the amateurs, consequently some time ago the annual fee for membership was reduced to one-half, to the increase of the number of the last-mentioned class of workers.

Mr. A. S. Stevenson is a model president, who works actively, and exerts himself to bring new members to the Association. He is a veteran in our ranks, for in 1852 and 1853 he lectured on "The New Art of Photography" in the hall of the Literary and Philosophical Society at Newcastle. A preliminary meeting to form a "Northumberland and Durham Photographic Society" was held in the rooms of the Literary and Philosophical Society of Newcastle-on-Tyne on the 21st April, 1854.

Mr. Robert S. Newall was in the chair, and amongst those present were W. B. Scott, Alex. S. Stevenson, J. W. Swan, Geo. S. Brady, John Mawson, W. S. Parry, Dr. Embleton, J. W. Swinburne, John Storey, G. C. Warren, A. G. Gray, and J. Brown. At an adjourned meeting Mr. Newall was elected President, and Messrs. Stevenson and Brady, Secretaries, Mr. Stevenson to act also as Treasurer. The Committee consisted of J. W. Swinburne, W. B. Scott, A. G. Gray, Jun., John Mawson, J. W. Swan, John Brown, and W. S. Parry. At subsequent meetings various papers were read; one of them was by Mr. G. S. Brady, on "The Application of Photography to the Delineation of Microscopic Objects"; Mr. J. W. Swan read a paper on "The Province of Photography"; and in February, 1855, the Society held an exhibition of photographs, in conjunction with a *conversazione* of the Literary and Philosophic Society. From the removal of members and other causes the Photographic Society after a time ceased to exist.

Last Friday evening, before the formal opening of the Exhibition, a dinner of the members of the Society and their invited guests took place at the Moseley Street Café, with the President of the Society, Mr. A. S. Stevenson, in the chair. Upon his right was the Mayor of Newcastle.

The Chairman read the following letter from an artist, Mr. Arthur H. Marsh:—

"I am interested in photography for its own sake and for the sake of art generally. I wish your exhibition every success. My excuse for writing to you on this subject is that having done a little in photography myself during the last four years, I have become convinced that for the artist the 'detective' is the camera of the future. I know to my cost the utter impossibility of successfully catching groups of figures in the field and on the seashore, boats, animals, &c., that are constantly moving, and many of which have disappeared altogether before the operator emerges from under the focussing cloth. But a 'detective' camera does away with all this by being always in focus beyond a given distance, and wasting no time in changing slides, &c. When so many distinguished photographers are gathered in the neighbourhood I think it would be interesting and useful certainly to members of my profession if they would give the benefit of their experience, and tell them which is the most serviceable instrument of this class for taking instantaneous studies out of doors. The American Kodak has one great advantage in containing the means for taking so large a a number of pictures. I need not say that for this purpose the more inexpensive the camera the better." [The letter was handed to Mr. Lange for future consideration.]

The Mayor of Newcastle, in response to a toast from the Chair, said that he had much pleasure in being their guest that evening, and as chief magistrate of the city he had pleasure in offering the visitors a hearty welcome. The Society had provided, he was told, an especially interesting photographic exhibition for the people of Newcastle and its vicinity, an exhibition which the judges had told him to be of a high order. He had not yet seen it himself, but was informed that it was one worthy the position which Newcastle enjoyed in this country. He was pleased to hear that representatives of the art of photography were there from the whole country; some of them, indeed, had travelled long distances to be present. Some of the photographs also had come from foreign countries, and the pictures sent from America were among the best the art could produce, so he felt sure that the Newcastle Photographic Exhibition would have all the success it merited. Newcastle, indeed, always rose equal to the occasion. Exhibitions of late years, now that art and science are making such great strides in all directions, have become almost a national necessity, and he hoped that the present one in Newcastle would prove satisfactory to its promoters and friends. He had much pleasure in proposing the health of the judges of the pictures at the exhibition, Messrs. Paul Lange, William Lang, junr., and John W. Wade, who had come long distances to give the benefit of their ability and experience.

Mr. Paul Lange said that when he came to Newcastle he was not prepared to see all that he had seen, and he thought that the Exhibition which would be opened that evening was one of which Newcastle might well be proud. They had, in the midst of them at Newcastle, workers in the photographic art such as were equalled at very few places in the United Kingdom. Among the professional members of the Society were some of great ability. Such workers tended to raise photography, and photography had a great future as an art; he believed that it would become capable of producing results which would equal the work of any painter who ever lived. The pursuit of photography had an elevating power, and the fathers of families could have no better desire than for their sons to pick up photography, not necessarily merely as a hobby, for photography will become an art some day, and it always improves the mind of the worker, and his appreciation of the beautiful. None could portray the beauties of nature without being influenced for good. Every father who has a son who picks up photography should encourage him to live up to it. He considered photography to be still in its infancy, and that in Newcastle that evening they would show by their Exhibition that of late years it had much advanced. Their mayor had been good enough to undertake to open the Exhibition, and that would give it prestige. The Society was also greatly indebted to the actual workers in the undertaking, to the general executive, to the two secretaries, and to Mr. Gibson (vice-president), who all deserved to receive gold medals. The only dilemma the judges were in was that of so distributing the awards as to please everybody. He did not believe that such judges ever existed; but they had tried their utmost; as far as was in their power they had gone by merit only, and their decisions had been unanimous.

Mr. J. P. Gibson, in responding to the toast of the executive, spoke highly of the work done by the two secretaries, Mr. Lee and Mr. Brown, and their energy in getting the catalogue out in time for the opening of the Exhibition.

The Chairman then proposed "The Press," coupled with the names of Messrs. Harrison, Hastings, and Welford, who briefly responded; after which Mr. William Lang proposed the health of the President of the Newcastle and Northern Counties Photographic Association.

Mr. Stevenson, in response, said that few things would give more pleasure in life than the practice of the art they followed. There was no art, no employment, which tended more to elevate the character or give healthy employment than photography, which combined science and art in a way no other employment did, and it always gave him the greatest pleasure to meet photographers. In them he found men of intelligence—men who had an eye to the beauties of nature, men who saw with the inner eye where the beauties of nature lay, and had the great pleasure of revealing them to their fellows. Art and photography were immediately allied. He did not go so far as to think that photography would ultimately annihilate the work of the artist. He believed that it would aid him in many ways, but would never come up to the transfiguration of the beauties of nature which artists could depict. They had been asked there to meet the judges and show kindly appreciation of the work they had done.

Mr. H. R. Proctor gave the health of the Mayor, a toast which was received with cheers, after which Mr. Lange called for "one cheer more for all the little Mayors."

The Chairman: "Well, there's something in that, for three of them are photographers."

The Mayor stated that they had started with the intention of having but two toasts, and now they were quadrupling them. (The Chairman: "The mair' the merrier!") He thanked them, and said that he was extremely pleased to be with them all that evening, especially in connection with photography, a subject which had taken hold of the minds of the

people to a considerable extent of late years, so that nobody now cares to go meandering in the country without taking his camera with him. In this way photography added a new charm and interest to life.

The company then adjourned to the Exhibition, and the following speeches, which we quote from *The Newcastle Chronicle*, were made :—

The Mayor said that photography interested us and made our lives much more pleasant than they would otherwise be. In opening that exhibition, he felt that he was engaged in a very important work. Their friends, Messrs Barkas and Son, gave them a great many interesting entertainments, but they never provided anything so engaging and at the same time so interesting and important as that exhibition was. It was not of local interest only ; it was of national importance. He understood from the judges, whose acquaintance he had made that night, that it was a collection which compared favourably with, and almost surpassed in quality, any exhibition that they had had an opportunity of witnessing during some years past. The photographic press in London was also represented there. All of them who were in the habit of travelling—whether as tourists, pedestrians, as cyclists, or in any other capacity—must find that their little tours were much enhanced if they could carry with them a camera, and bring back with them pictures of the places they had visited. It was an inexpensive art, an art that was easily acquired, and it was an art that carried with it a great deal of interest. It had entered into our every-day life to a most remarkable extent. It had enabled us to form a most intimate acquaintance with almost all peoples and all countries. They seemed to know intimately the Emperor of China, or the Emperor of Russia, or Prince Bismarck, or Mr. Gladstone—just as well as they would recognise their friend the Sheriff of Newcastle. And if they cared to collect landscapes drawn from the centre of America or the centre of Africa, they had no difficulty in doing so. Photography was an art which had made enormous progress during the last twenty or thirty years. It was an art which was resorted to by the architect, the artist, and the engineer ; and, in fact, in pure science it had become almost invaluable. The astronomer, by the aid of photography, had been able to map the stars. They only wanted now to be able to reproduce colours. He had very great pleasure in declaring the exhibition open, and in doing so he desired to mention that the arranging of the Exhibition had been largely carried out by the secretaries, Messrs. Lee and Brown, aided by Mr. Gibson. He thought that, on behalf of the committee and on behalf of the visitors, thanks were due to those gentlemen. He concluded by proposing a vote of thanks to the judges.

The Sheriff seconded the motion, which was carried.

Mr. Paul Lange, in responding on behalf of the judges, said that in coming to Newcastle they did not quite expect to see such a treat in the way of an exhibition as they had seen and judged that day. He thought that the Newcastle people ought to be proud of the works that had been produced amongst them. They had among them a contingent of photographic artists such as very few societies in this kingdom could boast of. As president of the Liverpool Society—a purely amateur society—he would be proud if they had there such talent ; and he hoped that this cultivated and elevating hobby, as they called it, amongst amateurs, would take root amongst more of them. They saw around them pictures which very few towns could show, and he hoped that the people of Newcastle would appreciate the efforts of their townsmen. He wished every success to the Newcastle Exhibition.

Mr. Paul Lange then delivered a lecture on "A Tour in Norway," illustrated by over 130 slides.

The following are the awards of the judges :—

Classes (A to Q) open to Professionals and Amateurs.

The gold medal for the best three pictures in the exhibition is awarded to J. Lafayette, of Dublin. The following were the prize-taking pictures out of twenty-three exhibits by this contributor :—Portrait of Mrs. Langtry (211), portrait of Miss Moody (213), portrait of a lady and child (215). Mr. Lafayette thus secures the highest award of the exhibition. The gold medal is awarded by the Association for the best three pictures irrespective of class. The silver medal, together with a bronze medal, is presented by Mr. J. P. Gibson, of Hexham, for a series of three portraits. The winner of the bronze medal is Mr. W. J. Byrne, Richmond, Surrey, with No. 177—three portraits "direct and untouched" ; 179, six "At Home" panels representing the present Emperor of Germany at Osborne ; and 180, ten "At Home" panels representing various people, taken by daylight at the sitters' residences.

The following is a list of prizewinners according to classification, excepting, of course, class D, which has been dealt with in the preceding paragraph :—

Class A. — Landscape (above whole-plate). Silver medal—Green Brothers, Grasmere. Nos. 44, 45, 46. Views of Stybarrow Crag, Ullswater; Blea Tarn, Langdale; and Derwentwater and Skiddaw from above Lodore. Bronze medal—Mr. J. P. Gibson, Hexham, for "The Thaw" (18), "Autumn Haze" (21), and "September" (22).

Class B.—Landscape (whole-plate and under). Silver medal—Mr. J. P. Gibson, Hexham, for three out of a very remarkable exhibit of forty-seven frames, viz., "Out for a Holiday" (65), "The Banks of Tyne" (70), and "A December Morning" (77). Bronze medal—J. E. Austin, West Court, Detling, Maidstone, for "The Last of the Ebb" (120), "Listening to the Bells" (121), and "By the Tow Path" (122). Extra bronze medal—J. G. Bullock, with "Moosehead Lake, from Kineo" (132), "On the Wawasett" (133), and "Birch Trees at Kineo" (134). Medals presented by Mr. Auty, Tynemouth.

Class C.—Silver medal (for best landscape printed on gelatino-bromide paper, direct or enlarged—both original, negative and print to be the work of the exhibitor) presented by J. B. Payne, Newcastle—awarded to Messrs. Auty and Ruddock, Tynemouth, for view on the Irthing (175).

Class E.—Best portrait printed on gelatino-bromide paper, direct or enlarged. Silver medal presented by J. Wilson Swan, M.A., Newcastle—awarded to Messrs. Auty & Ruddock, Tynemouth, for "Miss Maudlin" (284).

Class F.—Architecture, interior or exterior. Silver medal (for series of three)—Richard Keene, All Saints', Derby, for frame of six interiors of Derbyshire churches (318). Bronze medal—W. Parry, South Shields, studies of St. George's, Jesmond (Nos. 329, 330, 331).

Class G.—Series of three instantaneous pictures. In this class a silver and a bronze medal were offered, but the judges award a silver medal each to W. Parry, of Shields, and Lyd. Sawyer, Newcastle, whose winning exhibits are considered equal. Mr. Parry's pictures are numbered 358, 359, and 360 ; Mr. Sawyer's, 370, 372, and 376.

Class H.—Genre. An extra silver and an extra bronze medal are awarded in this class. Silver medal awarded to F. Whaley, Doncaster, for "Your Turn Next, Sir!" (389). Extra silver medal—R. S. Redfield, Philadelphia, U.S.A., for "Victuals and Drink" (463). Bronze medal—W. W. Winter, Derby, for "Does Granny like Butter" (418). Extra bronze medal—F. M. Sutcliffe, Whitby, for "Excitement" (381).

Class J.—For best enlargement (any subject except portrait). Silver medal—T. G. Whaite, Carlisle, for a view of Dinant Cathedral and Market Place (500). Bronze medal—Green Brothers, Grasmere, for "Y Tryfan and Llyn Ogwen, North Wales" (489).

Class K.—Cattle studies. Silver medal—J. E. Austin, Detling, Maidstone, for "Cooling Waters." Bronze medal—Ralph W. Robinson, Redhill, Surrey, for "Suspicions" (512).

Class L.—A genre competition for the best study illustrating verse 17, Canto I., of Scott's "Lady of the Lake." There were only three entries, and the judges made no award.

Class M.—Best enlargement upon Ilford bromide paper. Gold and silver medals presented by the Britannia Works Company. Gold medal—W. W. Fry, Tynemouth, for view of Cullercoats Bay (539). Silver medal—H. Dudley Arnott, Gorleston, Great Yarmouth, for "Main Entrance, Somerleyton Hall" (538).

Class M.M.—Best series of three prints on Alpha paper. Gold and silver medals presented by the Britannia Works Company. Gold medal—F. W. Edwards, Peckham Rye, London, for five bas-reliefs after G. Tinworth, the well-known sculptor, and a reproduction of an old engraving, "Hector Rebuking Paris" (554, 555, 558). Silver medal—J. E. Austin, Detling, Maidstone, for "Rest and Refreshment" (550), "Waiting her Turn" (551), and "Early Spring" (552).

Lantern Slide Section.

Class N.—Landscape, best series of six. Silver medal—R. S. Redfield, Philadelphia, U.S.A., for No. 663. Bronze medal—G. W. Wilson and Co., Aberdeen, for No. 669.

Class O.—Series of six instantaneous slides. Silver medal—Henry Little, Twickenham, London, for No. 681. Bronze medal—W. Parry, South Shields, for No. 683.

Class P.—Series of six architectural slides. Silver medal—G. W. Wilson and Co., Aberdeen, for No. 696. Bronze medal—Jas. A. Sinclair, Bootle, Liverpool, for No. 694.

Class Q.—Best six slides on the Mawson lantern plates. Gold and silver medals presented by Messrs. Mawson and Swan. Gold medal—J. E. Austin, Detling, Maidstone, for No. 700. Silver medal—W. Parry, South Shields, for No. 710. Extra silver medal—Edgar G. Lee, Cullercoats, for No. 708.

Class U.—Stereoscopic slides on glass. Silver and bronze medals presented by J. Hedley Robinson, Tynemouth. Silver medal—H. G. Ridgway, Sunderland. Bronze medal—F. Howard, Wallingford, Berks.

Classes Open to Amateurs Only.

Class R.—Series of three landscapes, half-plate or under. Silver and bronze medals presented by Mr. Alex. S. Stevenson, J.P., Tynemouth. Silver medal—C. Court Cole, Folley Bridge, Oxford. Bronze medal—J. W. Evans, Wolverhampton.

Class S.—Series of three architectural studies, interior or exterior, half-plate or under. Silver medal—C. R. Pancoast, Waterbury, Conn., U.S.A. Bronze medal—Ernest Beck, Sheffield.

Class T.—Three instantaneous pictures, half-plate or under. Silver medal—Ernest Beck, Sheffield. Bronze medal—Martin J. Harding, Shrewsbury.

Class V.—For best landscape by an amateur member of the Association. Silver medal—James Brown, Newcastle-on-Tyne. Bronze medal—Geo. Proud, Newcastle-on-Tyne.

The judges were Messrs. Paul Lange, William Lang, Jnr., and John W. Wade.

PHOTOGRAPHY IN FICTION.

In a holograph letter preserved among the Cotton MSS. in the British Museum, written by Henry VIII. to his "owne good Cardinall Wolsey," the king, after thanking him for his many services, beseeches him to "take some pastime and comfort, to the intent you may the longer endure to serve us, for always pain cannot be endured." This somewhat selfish application of the old proverb, "All work and no play makes Jack a dull boy," might also be used by the general public to the pains-taking photographer, toiling continually in optical and chemical research. This good, general public—"the many-headed beast," as it has been called by poets without sufficient respect—may be conceived as addressing the photographer thus: "Do you also take some pastime and comfort in your scientific labours, to the intent you may the longer endure to take our portraits!" And such photographers as will not be moved far away from their camera and their chemicals may, it is hoped, find a pastime and comfort of kin to their photographic pains in the present paper.

A certain Octavius Winslow, D.D., the author of many pious homilies, printed, many years ago, a sermon on "The Coming of our Lord, the Hope and Consolation of the Bereaved." In this sermon, in the course of what he calls a cursory reply to the interesting but obscure question whether mutual recognition will form part of the rapture of the glorified saints in heaven, he tells us that no being and no transaction will be forgotten, and that a remarkable discovery, said to have been made recently in the anatomy of the eye, supplies a striking illustration of this thought. "It has been discovered," says Dr. Octavius Winslow, "that the last image formed upon the retina of the eye of a dying person remains impressed upon it as on a Daguerrean plate." Thus, if the last object seen by a murdered person was his murderer, the portrait drawn upon the eye will remain a fearful witness in death to detect the guilty and lead to his conviction. "If," says the Reverend Octavius, "such be the ineffaceable, indestructible impressions of last objects upon the eye, how much more ineffaceable, unalterable, and indestructible must be the impressions of the mind." The fervour of the ecclesiastic may excuse in the above extraordinary sentence the faults of the logician.

More than one fiction has been founded on this "remarkable discovery" in the anatomy of the eye. Some thirty years ago an extraordinary tale, depending for its chief interest on a photographic experiment, appeared in a periodical of the period. It is a tale of two lovers, with whom all proceeds smoothly for a time. The parents are favourable to the marriage, and no obstacle arises to oppose their wishes, until unfortunately the expectant bride is one day found strangled in a wood. The lover for a year or more before the murder has taken a great interest in photography, and while contemplating the corpse of his mistress an idea—for perfect love, we are told, excludes every other feeling—occurs to him that a photograph of the retina of the eye might be magnified so as to present a distinct image of the last object depicted upon it. Upon this idea he engages a surgeon to remove one of the eyes of his late beloved from its socket—for perfect love excludes every other feeling. Having taken a number of negatives this eye on glass, it is restored to its proper place. By a judicious combination of lenses, and by very slow degrees, he finally obtains an enlarged representation of the

features of the murderer. The rest of the tale, which is a long one, is made up with a recital of his adventures in a single-handed search for the assassin—under the guiding light of his photographic polar star—through Paris, Baden, Berlin, Vienna, and other places till he arrives at Venice, where he at last discovers the object of his inquiries by a chance encounter at a ball. The murderer turns out to be the brother of his late betrothed, who has assassinated her with a Venetian dagger for the sake of her money, and is at the time of his detection married to the amateur photographer's sister. This introduces a complication. The sister, on hearing of her husband's delinquencies, becomes insane, the criminal is suffered to escape, and the author thus concludes his story: "I have no hesitation whatever in saying that in all cases where death occurs in broad daylight, and especially when it is caused by similar means, the last object on which the eye rests will be found depicted on the retina after death, and from darkness may be brought into light."

In all fictions of this class, and they are many, the delusion is what Bacon would call an idol of the market. People not accustomed to inquire with the ancient Bereans whether these things are so, not uncommonly suppose that impressions on the retina of the human eye are permanent, or that final impressions are so, or, at least, that final impressions endure some considerable time. And so, as in the tale, we read of reports of the capture of murderers through their likenesses being left in the eye of their victims, and afterwards transferred to paper by an ordinary photographic process, which gives a sort of carte-de-visite, showing not only the threatening aspect of the assassin, but also his form and clothes, together with pistol, knife, dagger, or other lethal weapon which he has employed. Now, a little consideration would soon expose the fallacy of this conception. A person entering a room having a plane mirror opposite the door of entrance is, of course, reflected therein, but with that person's disappearance the reflection also immediately disappears. If it were possible to photograph from the looking glass the reflection of that person after he has left the room, then, indeed, it might be a rational undertaking to attempt to photograph the impression supposed to be left on the retina of the dead. It may be true that the image on the retina does not subside and vanish for the fraction of a second, but that fact does not altogether justify the doctrine of the country magistrate who, when consulted as to the advisability of calling in the aid of the camera for the detection of a culprit, sagely observed that such a proceeding would be useless, as the man was already four days murdered, and the picture on the *cornea* of the eye vanished, as scientific men were well aware, after a period of forty-eight hours. The author of the tale already quoted asserts that the duration of the image is affected by the condition of the humours contained in the eye, and that when death is caused by strangulation, the eye becomes charged with a viscous secretion, which is not withdrawn, but coagulates and hardens, so to speak, as vitality is expelled, and so the last image impressed on it is retained precisely as the picture is retained on the photograph which the light has printed on it with the most delicate gradations of tone.

(To be continued.)

Photographic Society of Great Britain.—A technical meeting will be held on April 29th, at 8 p.m., at 5A, Pall Mall East, when the subject of "Celluloid Films" will be brought forward.

DETECTIVE PHOTOGRAPHY.

BY J. C. HANNYNGTON, MADRAS.

To detect or identify the lad who purloins your fruit whilst you are absent at morning service, is simple work.

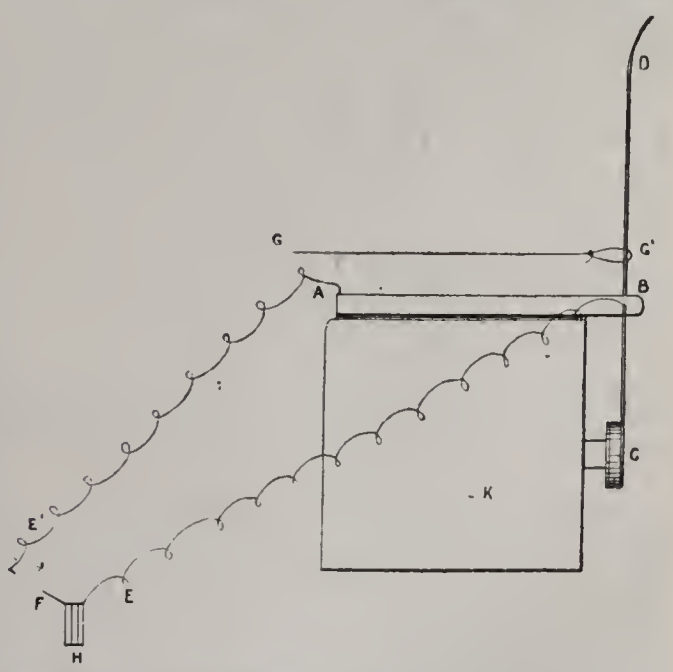
The camera, in some unobtrusive form, is concealed in a position which commands the approach to the forbidden fruit; the shutter (a simple drop) is kept fixed for action by a wedge, which wedge is attached to a hair line (a single thread of woman's hair will suffice) which is stretched across the path along which the approach to the tree must be made.

As the thief walks along the path he touches the line, the shutter is released, and the exposure made. When it is desired, however, to secure a photograph of any person or animal which may pass along a given path by night in the dark, the procedure is more complicated.

The camera commanding the approach must be placed as above described. If it is certain from which direction the approach will take place, one camera will suffice; but if the direction of approach is uncertain, two cameras may be necessary to secure a front view of the subject.

It will be necessary to secure the picture by a flash-light, and the conditions required are that the lens shall be uncapped at the moment the flash takes place, and at the moment the subject reaches a given point within the range and focus of the lens. It will not do to leave the lens open all night, lest it should be frosted by dew or exposed to the morning light.

It is easy to arrange a line and trigger on any path,



so that any creature passing along the path will pull or release the trigger, and the trigger may be made to fire a gun, explode a mine, or fire a flash light of any kind.

The following method is simple and effective, and may be varied according to the ingenuity of the operator. On the top of a camera, K, or preferably detached from it, is fixed a rod of wood, A B, with a pivot at B, upon which a lever DC carrying the lens cap at C, swings easily. The lever CD is of metal, and is placed in electric communication with one pole of a battery, H, by the wire E. The wooden rod, A B, carries at the end, A, a metal point or bar which is in electric communication with the other pole of the battery through the wire AE'. When the lever, CD, is depressed so that the metal thereof at D

touches the point or bar A, the circuit of the battery is completed, and a fine platinum wire at any interval, F, in the wires EE', will be made red hot.

There may be any number of intervals, F, each being constructed of fine platinum wire, and, if the battery be of sufficient intensity, the wires at all the intervals will be simultaneously and instantly heated. The lever, CD, is so arranged that when in its normal position the weight of the cap C will keep the cap C' entirely over the lens of the camera, and so completely exclude all light or damp from the lens. GG' represents a line of hair, cord, or wire, having at the end G' a loop which passes over the lever, CD.

If the line, GG', is pulled back, it depresses the end D of the lever CD, and raises the cap, C, until the lens is wholly uncovered, and finally the end of the lever DC will come in contact with the point A, the electric circuit will be completed, and the wires at the intervals, F, will be heated. The line, GG', is extended round trees, or in any convenient manner, until it crosses the route by which the subject to be photographed will pass, and is then made just taut, and fastened securely.

It is clear that any person or animal passing along the route and coming in contact with the line, must stretch the line so that the loop G' must go back, carrying with it the lever, CD, until the electric contact is made.

Immediately subsequent to this, the loop, G', is carried over the end, D, of the lever, and the cap, C, swings back by gravity, and re-covers the lens securely. At the intervals, F, are placed, on the platinum wires, charges of gun-cotton and magnesium powder, or any other form of flash-light which may be preferred, and, as these charges are fired whilst the lens is fully uncapped, a photograph can be taken. The height of the line should be adapted to the subject, the height of a man's knee being most generally useful. The charges and intervals should be so arranged that the light of the flashes, whilst fully illuminating the subject, do not strike on to the lens of the camera. The system of laying the detector line is merely a modification of the method of setting alarm guns, in every-day use for poachers.

In practice, it will be found necessary to pass the line, G G', through a loop somewhat below the level of the wooden bar, AB, as otherwise the lever CD will not be sufficiently depressed.

Oldham Photographic Society. — The hon. secretary forwards us a list of outdoor meetings for the coming season. One page of the programme contains the photographs of the officers of the Society by the Vice-President, Mr. W. Thompson, which are very good.

The Photophane Printing and Publishing Company send us a prospectus from which it appears that the company has been formed to take over and further develop the business now carried on by Mr. Andrew D. Edward and others, together with the photographic business and plant of Mr. F. W. Edwards, of Peckham Rye, the president of the East Dulwich Photographic Society, and the recipient of twelve medals at photographic exhibitions, the last being a gold one awarded him at the present Newcastle Exhibition. Photophane is described in the prospectus as a "process for mechanically printing photographic negatives," and is briefly thus described :—"A negative being taken in the ordinary way, instead of being printed by the action of light on sensitized paper—every copy taking hours to print, and eventually fading by the influence of the same power which printed it—is printed on a sensitized, *i.e.*, a photophane, plate. The plate is then placed on a machine, and copies printed off at the average speed of about one thousand per day."

LIMITATIONS IN THE TREATMENT OF SUBJECTS BY FOCUS.*

BY T. R. DALLMEYER.

There are only five treatments of the subject by focus possible :—First, the pinhole ; second, sharp photographs throughout ; third, contrasted definition between different planes with an aplanatic lens ; fourth, the introduction of positive spherical aberration ; and fifth, the introduction of negative spherical aberration. The last I do not intend to speak of, as it is of course the converse of the fourth, but is a treatment that is hardly ever required in practice.

First, the pinhole. I have spoken of the imaginary pinhole for mathematical accuracy, and the practical pinhole is an instrument that coarsely imitates it, every mathematical point in the object being represented by a cone of rays limited by the aperture of the pinhole itself, and the distance of the sensitive film from the pinhole, the pencils being represented by a series of small circles, becoming greater in diameter the greater the obliquity, or the more the angle of subject included. Theoretically, the foreground is exaggerated in size in true drawing, and the distance dwarfed and better defined ; but the pencils are so small that one would not appreciate it. The general effect is one of *uniform softness through all planes ;* it is seldom art, for the unaided eye cannot receive the same impression.

Second, sharp photographs throughout. It is well known that if the nearest object in a picture to be taken is sufficiently distant that the rays coming from it to the lens may be considered practically parallel, all planes more distant will be sharp ; or there is for every lens a plane at some distance distant, beyond which everything may be considered as topographically sharp. The nearer this plane is desired to be for a given lens, the more it must be stopped down, or the less does its intensity become ; if this is so arranged that at the normal distance of vision the out-of-focus circles of indistinctness throughout the picture do not exceed one-hundredth or less part of an inch, or the circles subtend an angle of less than two minutes of a degree at whatever distance the picture be viewed, such a picture, to all intents and purposes, is a truthful record in drawing, granting that the angle included be no more than the eye is capable of taking in ; or, on the other hand, that it be viewed at a distance of the focus of the lens itself.

This rigid exactitude, and the brilliant results obtained, are pleasing and popular mementoes, but can hardly be termed art. It is the simplest form of all photography, for the instrument gives an exact copy of what is placed in front of it, and no personal judgment is wanted to produce any truthful effect, such as the scene in reality conveyed to the brain by the eye itself. I will dwell on this later, and prove the contention.

Under the same heading as universal sharpness naturally comes the uniform out of best focus treatment with the aplanatic lens. This effect is easily produced by the instrument under conditions precisely the same as those just mentioned, and then to slightly wheel *out* the camera back. The evil in such a case to be guarded against is that this process should not include a foreground nearer than the first plane to be depicted, or it will have a better focus, and probably attract undue attention. The distance at which the picture is eventually to be viewed will, of

* Continued from page 305.

necessity, have a great influence on the amount of out-of-focus effect allowable. It is a parallel with the pinhole and (in one way) the uniform sharp treatment, and I therefore place it under the same category, *pro tem.* The process tends from original definiteness to pass *uniformly* to indefiniteness and weakness, from structure to destruction of structure. The points in the object, instead of being concentrated to points in the image, have passed their best focus, and are diffused into uniformly illuminated circles of a weaker character. It may be said to give a uniformly broader treatment of a subject, but as it rests somewhere between perfect concentration and brilliancy, and destruction of structure and consequent weakness, it must tend, as a process, to uniformly weaken. It is defined and determined by the size of the out-of-focus circle of uniform indistinctness chosen, or ascribed to the pencil, after having passed the plane of best definition.

Third, contrasted definition with an aplanatic lens. That this may occur in any photograph, the lens employed must be of such a focus and intensity (or ratio of aperture to focus) that the plane in the object that is most favoured by definition is so situated that planes nearer to or further from it have conjugate planes distinctly and appreciably different from that on which the chosen plane is received by the plane of the plate.

As the plate is a fixture, points in these out-of-focus planes will be represented by circles of indistinctness, varying in size according to their distances from the chosen plane of finest definition.

It follows then that, strictly speaking, for mathematical measurement on the one plane of the plate, the drawing is untrue as regards the out-of-focus planes, and increases in this inexactitude, and, in weakness, the more they are removed from the plane of chief interest. I refer you to the first seven plates as showing the tendencies, but it must be borne in mind that equal movements of the camera back inside the focus lose definition more rapidly for the foreground than the same distances outward would affect the background.

Under this heading I also include contrast in definition when the chief feature of interest is not at the best focus given by the lens, or when this feature is once focussed for as best, the camera back is slightly wheeled *out*, as in the second part of the previous head. This treatment requires very careful adjustment and choice of subject, for if any portion of the picture intervene between the subject of chief interest and the camera, it must be better defined than that intended to be of chief interest, and detract from its value as a work of art by diverting the attention to objects practically out of the *picture*.

The difficulties of adjustment between the limits of out-of-focus effect, so as to subdue certain unimportant planes without carrying the tendency to destruction of structure too far, has made this process capable of engaging the skill and judgment of the artist to a much greater extent than the more limited methods previously described. This treatment is undoubtedly far *truer* in its rendering of what the eye actually sees, if the treatment of the limiting out-of-focus planes is not carried to a too extravagant degree. For *truth, as the eye sees*, the palm rests with this treatment, or with—

Fourth, the introduction of spherical aberration. Here the individuality of the treatment by the instrument is again different. As stated before, slightly beyond the least circle of aberration a focus, still more or less definite but softened, is formed by the inward concentration of the image-forming rays more pronounced and powerful than the weaker marginal rays. The latter, not coming to the same focus, produces a faint halo that tends to soften the image, but still *structure* is maintained here. This halo becomes more and more pronounced the greater the amount of spherical aberration introduced; but, at the same time, the greater become the limits between the planes (or the measure of longitudinal aberration) through which the plate can be moved still consistent with partial definition maintaining the structure of the image. But as there is an inward tendency on the further side of the least circle of aberration when positive spherical aberration is present, there is also an outward concentration of rays on the nearer side, tending toward a more rapid destruction of the image than is the case with an aplanatic lens. However, this detriment is not an important factor: first, because the best focus with a lens in which spherical aberration is outstanding is beyond the least circle of aberration, the definition at the least circle of aberration itself comparing very favourably with an out-of-focus circle of the same transversal measurement by an aplanatic lens; and secondly, this outward concentration corresponds in the image to foreground, or to objects nearer than that of chief interest, and this, as a rule, is a negligible quantity compared with the better maintenance of structure in the background or receding planes. By spherical aberration, then, there certainly is *depth* of definition, and in portraiture no artist denies the advantages of the resulting softness, and blending into background as compared to the contrasted definition by an aplanatic lens through such small limiting planes; the eye certainly never saw such contrasts in a single figure as the aplanatic lens of great intensity and long focus gives in a parallel case.

We have now discussed the various treatments possible, and it now remains to select that or those that most nearly represent what the eye sees.

I have several times come across the expression that to produce an artistic photograph we have not to consider only what the eye *can* see so much as what we wish it to see. This is undoubtedly true, but I am not content that the question of the scientific bearing of *vision* on this subject should be waived. I have not read up all the focus controversies, but propose to discuss and analyse a few vital points in the most recent contribution on the subject to the Camera Club by Mr. Burton. 1. One of the tenets of the naturalistic school is that no part of a photographic picture should be as sharp as modern photographic lenses (aplanatic) are capable of making it. Mr. Burton contends that the eye can define equally as well as such a photographic lens when focussed as sharply as possible, and says were this not the case the eye would be equally incapable of defining the reproduction. This is an undoubted error. The use of small stops in aplanatic lenses, even for one plane alone, certainly gives a definition far finer than the eye ever can reach, eg., the reproduction of print in a photograph beyond the distance of distinct vision (explanation on blackboard). "Mr. Burton says the oft-repeated statement that the eye, having certain optical defects, does not define as well as a photographic lens, is a thing simply not true, and recently disproved." He does not quote his authority, but Helmholtz distinctly contradicts this in facetious and no measured terms. To make the comparison above referred to fair, both object and the photographic image must be viewed under the same angle. The conclusion I have come to in cases of normal good vision is, that the image can be seen much

sharper than the object would appear to the most perfect eye. 2. Mr. Burton says that another tenet of the naturalistic school is that only the principal object, or the object of greatest interest, should be nearly as sharp as the lens can make it, and contends that "if an attempt be made to support it on scientific grounds, that attempt must of necessity fail, for there is no optical defence for it."

This is another error. It can be proved by trying *artificial means* to *make* the eye see what the lens can see. The same process must be applied to both eye and lens to place them on an equality in this respect:—Stop them down! The eye unaided has a continually varying focus that adjusts itself to plane after plane as occasion may require. By giving it a so-called fixed focus, the same effect of sharpness through all planes is arrived at as with the stopped-down photographic lens. To prove this to oneself, look through a pinhole close to the eye—a pretty large pinhole will do—and hold some object quite near the eye, with a distant distinct background, and look at the near object. The background and intermediate planes will be equally well defined. Now remove the artificial iris, and the near object alone is distinctly visible. The reverse of the effect is, of course, the case if the eye be focussed for the distant plane, the near one then being out of focus. An artificial diaphragm to the eye of course enables one to see very much nearer than would otherwise be possible, and also enables a short-sighted person to see to a distance. The eyelids, with a short-sighted person, often almost unconsciously serve the purpose of the artificial diaphragm when their glasses are not in use. Binocular vision in sight, too, of course has an important bearing on this head, particularly in the representation of near planes. The axes of the eyes are directed convergently towards one particular point in binocular vision, every other point in the scene producing different images on each eye, causing indistinct double images. The more the eyes are directed to distant objects the less noticeable does this become, the angle subtended by their separation becoming less and less. The treatment of planes parallel to the axis, or marginal definition, is more difficult to attempt on scientific grounds; but as the eye sees distinctly only through a small angle, it seems feasible (and it certainly is noticeable in nature) that there should be a slight marginal falling off of definition in the lens. If the lens of the eye gave a flat field throughout the one plane focussed upon, sharpness through this would undoubtedly be the desideratum. Mr. Burton is the only writer I have found who speaks as an authority against the scientific aspect of the tenets of the school of naturalists, and I regret that he is not here to argue on his side for, or concede the points in, the question.

The single eye then, in a fixed position, and more remarkably in binocular vision, undoubtedly sees nature under conditions of contrasted definition, and hence any method that rigidly gives uniform definition throughout all planes must fail to be artistic.

As to how the method of contrasted definition is carried out by the lens employed must be a matter of individual impression, and the focus and aperture of the lens so adjusted that the image is in effect the nearest possible to that the artist feels and wishes to convey. In this connection the broader treatments, by slightly out-of-focus effect, or introduction of spherical aberration, produce results that artists alone can decide whether or no they compare favourably or not with the broader treatments by the pencil or brush. The answer to this question must decide how far photography may progress as a fine art.

The naturalistic school have shown results that cannot be denied to be eminently artistic, and there is without doubt the qualification of greater scope in their rendering. Dr. Emerson has produced work ranging from the beautiful in bright results to the sublime in the dreamy impressions of twilight and the impressionists' school. As the subject has appealed to the students of this school, so have they rendered it, within the limits of the definite powers of their instruments. There is no hard-and-fast line of one particular treatment, and my object has been to indicate the ground entered upon by leaving the limited and narrow treatment of universal sharpness, a treatment that is a triumph as an instrumental record, but, if taken alone into consideration, is detrimental to that art progress which all of us, anxious for the higher development of photography, have so earnestly and sincerely at heart.

Books Received.—*Photographie Aerienne*, *Photogravure sur Verre*, *Traité Encyclopédique de Photographie*, *Sun Artists* for April, and some new numbers of the *Amateur Photographer's Library*, all of which we hope to notice next week.

The *American Druggist* says that a paste made of rice flour and water, slowly heated to the boiling point until the proper consisteney is obtained, will not discolour articles pasted together, and will stick tighter than a poor relation.

The Birmingham Photographic Society.—The presentation of the Crystal Palace Challenge Cup to the Birmingham Photographic Society took place on Monday last at a dinner held at the Colonnade Hotel, New Street. The cup was officially presented by Mr. Henshaw Russell, who was accompanied by Messrs. S. G. Wollaston, J. F. Peasgood, and W. Brooks. Mr. J. B. Stone presided.

Messrs. Thomas's Prize Competition.—The prize competition inaugurated by Messrs. R. W. Thomas and Co. for the best photographs taken on their plates was held at Gloucester Mansions, Cambridge Circus, London, on April 15th, 16th, 17th, and 18th. The judges were Messrs. Valentine Blanchard, F. de P. Cembrano, J. Gale, Philip H. Newman, and Andrew Pringle. The following prizes were awarded:—Class I.—(10) "The Brent, Kingsbury," silver medal, F. D'Arcis; (40) "Newlyn, Cornwall," bronze medal, J. B. B. Wellington. Class II.—(51) "The Pedlar," special genre class gold medal, Ralph W. Robinson; (55) "An Idle Moment," bronze medal, R. H. Lord; (60) "The Latest News," silver medal, J. B. B. Wellington. Class III.—(80) "St. Anne's Gate, Salisbury," silver medal, J. B. B. Wellington. Sub-Class.—(66) "Reredos, Salisbury Cathedral," bronze medal, J. B. B. Wellington; (71) Frame, three prints, "Norwich Cathedral," silver medal, H. Dudley Arnott; (72) "The Great Pillar, Clapham Cave," (73) "Eldon Hall," do., (74) "Beehive," do., (75) "Pillar Hall," do., (76) "Reflections," do., (77) "Inverted Forest," do., special silver medal, G. Towler. Class IV.—89) "Try again," special genre class silver medal, R. H. Lord; (91) "Granny and her Spinning Wheel," special genre class bronze medal, W. H. Geddes and Son. Class V.—100) "Ready to Start," (101) "Leap Frog," silver medal, W. Jerome Harrison; (107) Hand-camera shots, "North Wales Coast," bronze medal, M. J. Harding. Class VI.—(113) "Large Marine Engine," bronze medal, W. H. Geddes and Son. Class VII.—(118) "Smack at Sea, Towing out a Screw Steamer," bronze medal, H. Dudley Arnott; (120) "The Land's End," silver medal, J. B. B. Wellington. Class VIII.—125) Set of twelve slides, certificate of merit, Lieut.-General Dawson, C.B.; (136) Set of twelve slides, gold medal, Edgar G. Lee; (139) Set of twelve slides, bronze medal, G. E. Thompson; (141) Set of nine slides, silver medal, J. B. B. Wellington. Sub-Class I.—151) Set of six slides, silver medal, A. A. Carnell. Sub-Class II.—None. Class IX.—(152) Eight transparencies, silver medal, Auty and Ruddock; (153) Eight stereoscopic slides, bronze medal, H. G. Brierley.

EMPLOYERS AND EMPLOYED.

BY C. BRANGWIN BARNES.

An attempt has recently been made to start a trades union amongst photographers, and I cannot but think the proceeding an ill-advised one, because since the early days of the art-science, there has up till now been a thorough *entente cordiale* between photographers and their assistants, and until the issue of the trades union manifesto I had heard of but little, if any, dissatisfaction amongst photographic employées. Truly, here and there might be found a stray grumbler, and, for the matter of that, so there might amongst the ranks of the employers. I have heard a photographer express an opinion that there is not a thoroughly good and efficient printer to be found in the United Kingdom, and I have also heard a printer state that there are no employers capable of appreciating a good man when they have found him. Some employers have an idea that all their assistants think about is to leave off work at a certain hour, and to draw their salaries as pay-day comes round: but I opine that most photographic assistants have far higher notions of business and honour than that. One of the most vexed questions between the employer and his assistants has for some time been that relating to specimens, and I should personally like to see the matter thoroughly threshed out in the light of day—*i.e.*, in the columns of the Photographic News—to hear what both sides have to say. When a photographer advertises for an assistant, he usually requires to see specimens of his work, and therefrom arises the question, Whence are those specimens to come?

In nine cases out of ten, all the specimens an operator, a printer, or a retoucher can obtain are spoiled prints, which are hardly the sort of thing required. There has never been an understanding as to whether an assistant is entitled to specimens, or if so, to what extent. There are employers who strictly prohibit their hands from taking prints, whether spoiled or not, for use as specimens: there are also a few who, when an assistant is leaving, offer to provide him with any he may require. Is not the whole question of specimens a farce? If an operator is seeking a situation, what is easier than to send specimens taken by someone else, and purchased by him purely for that purpose? That this is done every day of the week I quite believe, and must at the same time admit that, though the action is reprehensible in the extreme, yet the employer who advertises for specimens is himself to blame. Where is the need of specimens at all, if the reference from the last employer be satisfactory, and that employer be known to turn out good work? Surely those are sufficient grounds for giving a man a trial, without expecting him to send specimens of work, which may be his own or not. One photographer of standing told me that he never looked upon specimens he received from applicants for a berth as samples of what they could do, but merely as samples of their taste; if they sent him good and artistic pictures, he judged that they were artistic themselves, or they would not have selected them.

If an assistant has no right to specimens of his work, I hold that an employer has no right to ask for them: added to which, they are perfectly unnecessary, and cause considerable trouble. Suppose an operator out of a situation answers some four advertisements, where are the specimens to come from to enclose with all his four applications? At the most he would have only one set, and they would probably be sent to the advertiser he would be least likely to suit, and retained by him three or four days, by which time the other situations would be filled up, and very likely a berth lost simply because the operator was an honest man, and did not pilfer from his former employer a sufficient number of prints to send to several persons at one time. The foregoing is merely my opinion. I am in hopes that others may speak out on the matter, and that some arrangement may be definitely arrived at between employers and employed.

Another point which I wish to advocate is the payment of operators by results, in such a way that the best worker may obtain the best income. An operator may receive a stated salary every week of the year, whether business be good or bad, and it is contended that he has a right so to do, as it is not in his power to influence business. My idea is that it is vastly in his power so to do, and it will be found that the operator who is paid by results—that is, a salary and commission—will not only increase his own weekly earnings, but will make business to do so. A word in season, spoken by the operator, will often induce a sitter who has visited the studio with the intention of taking, say, half-a-dozen cartes, to increase the order to a dozen, or to have cabinets in preference to the smaller size, and now and then an order for an enlargement may be obtained in the studio. I would also respectfully incline to the opinion that the operator who pushes his employer's business in this manner deserves a percentage on that business, and that the employer will find it materially to his interest to allow him one. There are times when the operator may fail to obtain an increased order in the studio, but his trial will only serve to clear the way for the reception-room attendant, who may now succeed where he has failed. This same reception-room attendant, if a man or woman of business, has many opportunities of pushing trade, and suggestions as to enamelling, tinting, and so on, often have the effect of adding to the amount of cash taken from each sitter. Then there is nothing to prevent him, or her, from introducing novelties in the way of frames or albums, and here, as in the case of the operator, a small commission on sales would be found to have a stimulating effect. The mention of the fact that old or faded photographs may be copied, often reminds a sitter that he has an old portrait of some deceased relative or friend, of which copies have been asked for, and, perchance, an enlargement may follow. It should always be borne in mind that one enlargement pays better than two or three ordinary sitters for small work.

In conclusion, I would express my opinion that a general introduction of the system of payment by salary and commission would effectively and surely cut the ground from under the feet of would-be trades unionists, and by so doing further strengthen the bond of good will which, I maintain, has always existed between photographic employers and employed.

On Thursday evening, May 1st, Capt. Abney will read a paper at the Camera Club.

Number 644 of the *Photographisches Archiv* is accompanied by an illustration—a woman's portrait—issuing from the studio of Herr J. Schmidt, of Frankfurt-on-M. The extremely careful and exact reproduction of the negative has been furnished by the Phototype Office of Johannes Beyer, in Zittau. Herr Beyer, who some years ago purchased the interest of the firm of Alphons Adolph & Co., has enlarged this concern, and fitted it with all necessary new appliances. Of the phototypic ability of the firm a proof is given in the illustration.

Notes.

The full text of the resolutions passed by the Committee appointed by the International Congress in connection with the Paris Exhibition appears in the *Bulletin de la Societé Francaise* for March, so may be now more readily accessible in this country than the Government report itself, published some weeks ago. A summary of the conclusions arrived at with regard to the various questions submitted has already appeared in these pages, and we need not go over the ground again. It is worth while noting, however, that the philological studies of the Committee appear to have caused them some anxiety. As will be remembered, one of the questions to be discussed and settled was a system of photographic nomenclature, and if it is an absolute necessity that the rough and ready and familiar—though, possibly, inaccurate—terms in daily use should be discarded, then no doubt the Committee have devised the very best scientific substitutes possible. But even science is sometimes baffled, and the word "photo-collographic" has been too hard a nut to crack.

This word has the drawback of being intractable to all efforts to shorten it. The consequence is that its obstinacy has forced a series of kindred subjects to be termed "photo-plastographic," "photo-glyptographic," "photo-typographic," and "photo-chromographic," whereas could an abbreviated equivalent have been found, we should have got *photo-plastie, photo-glyphie, photo-typie*, and *photo-chromie*. One would have thought that "photo-collie" would have got over the difficulty, but this does not seem to have occurred to the Committee, and so the polysyllabic burden has been borne.

The report of the lecture given at the Anthropological Institute last Tuesday, by M. Jacques Bertillon, on the method now practised in France of identifying criminals by comparing their measures with those of convicted persons in the prison registers, will be looked forward to with much curiosity by those interested in the subject. The registers contain the measures of tens of thousands of persons together with their photographs, yet M. Bertillon's method enables the reference to be rapidly effected. It is now pretty well acknowledged that a photograph alone is not to be depended upon as a means of identification, but we are not quite sure whether a measurement is a safer guide. What guarantee is there that the measurer will not make a mistake? Professional measurers who make clothes frequently fall into an error, and there is no reason for believing that a police measurer will be any more accurate than a tailor. Everybody is familiar with the curious fact that while the memory sometimes plays tricks in regard to recollection of faces, it rarely does so in the case of sounds. The face alters with age, but the voice remains pretty much the same. This seems to indicate that a system of identification will not be complete until the phonograph is made use of. Let the sound of every prisoner's voice, and his pronunciation of certain words, be preserved, and additional testimony of identification will be always at hand.

We have on more than one occasion drawn attention to the difficulties under which artists labour when a retouched photograph is sent to them to copy. The grievance is not confined to this country, and we find the *Inland Printer*, an American journal, and one especially noteworthy for the excellence of its photo-mechanical reproductions, following on the same lines. It is quite true that the retouched photograph is an abomination to the artist who has to copy it for newspaper purposes. When all the salient lines of the face are so softened as to be almost obliterated, when an artificial sparkle is given to the eye, and a line of light introduced on the nose, so as to effectually put that feature out of drawing so far as correctness is concerned; then the artist's task of translation is difficult indeed. It is, in fact, impossible to convey much of whatever resemblance the photograph may have to the original, because everything is so hazy, so nebulous. The best likenesses are those which seize the characteristic expression of a face, often conveyed by some little lines near the mouth or eyes, which the retoucher does his best to destroy, because he thinks they are not flattering.

And, unfortunately, this is not the worst. During the last two or three years a craze has sprung up for photographs in so-called "natural colours," ranging from the crystoleum process to Mr. Mayall's latest "discovery." These coloured portraits are terribly misleading, for not only is the expression altered, but often a totally false idea conveyed. In fact, to use the words of the *Inland Printer*, "they are to the artists like so many portraits of the figures in Madame Tussaud's."

The utilisation of one's features as an advertisement is quite a sign of the times. Nothing, in fact, is sacred to the enterprising advertiser. We have seen in England portraits of well-known professional ladies figuring in connection with certain advertisements, but in these cases, so far as we know, the ladies in question have derived no benefit from the exhibition of their features, though it is quite possible that in return for their testimonials the advertiser may have shown his gratitude in a substantial form. They manage these things better in America, as the face has now a distinct advertising value. As a case in point, we may cite the fact that the features of Miss Nellie Bly, who achieved notoriety by her race round the world, will soon be known to every smoker of cigarettes in the States, since a firm of cigarette makers has arranged to pay her a very large sum for permission to use her photograph as the trade mark of a new brand of cigarettes.

THE MATHEMATICAL CALCULATION OF EXPOSURES.*

BY ALFRED WATKINS.

In spite of the imperfections and the jokes levelled at exposure tables, they have proved an aid to many who feel the want of certainty, and the weakness of the older methods. Five axioms may be laid down as the "Grammar of Photographic Exposure":—

Axiom I.—Five primary factors, each quite independent of the others, govern a photographic exposure. They are:—(A) The actinic force of the light falling upon the worst-lighted part of the subject. (P) The sensitiveness of the plate used. (S) The capacity of the subject, or its most non-actinic part, for reflecting sufficient actinic light to the lens to form a photographic image of suitable intensity. (D) The size of diaphragm in relation to the focal length of the lens. (5) The distance of the subject from the lens.

Axiom II.—The value of each of the factors, as affecting the exposure, may be expressed in numerical terms.

Axiom III.—The proper exposure for any given conditions being ascertained, the correct exposure for every other possible combination of conditions or factors may be calculated by mathematical means.

Axiom IV.—The quantity of actinic light reaching the plate, reflected from all parts of the subject, or even one part of the subject, is no guide to the duration of the exposure.

Axiom V.—Two ultimate factors determine the duration of a photographic exposure on any plate, viz.:—(A) The quantity of actinic light reaching the plate, reflected from that part of the subject which reflects least actinic light, and in which detail is required to be rendered. (S) The duration of this light necessary to impress upon the plate an image, approximating as nearly as possible, in inverse intensity, to the visual image of the object in question, is the correct exposure.

For factor A a chemical actinometer is best, a photometer in which the eye is used for the estimation, the light being unsatisfactory for this purpose. The bromide of silver actinometer, as advised by Captain Abney, is simple and effective, the number of seconds taken to discolour it to tint giving the A value.

The only proper way to test the light is just where it falls upon the subject. An actinometer will soon become as indispensable to a photographer as a thermometer is to a chemist, and the usual advice to test the light in the open, and if you are about to take an interior, to calculate what proportion of the light reaches the subject, is just as absurd as for a chemist wishing to ascertain the temperature of a mixture he is heating to put a pyrometer in the heating flame, and then estimate how much of the heat is absorbed, instead of trying the actual heat of the mixture.

Factor S deals with the error into which all compilers of exposure tables have fallen into in mixing up the quite independent factors of lighting and subject.

In practice, it is necessary to give a shorter exposure for white objects in which detail is required than for objects of average colour, and a longer exposure for dark-coloured objects; hence the need for a table of subject values.

The factor of distance affects the exposure; over distant objects the atmosphere adds reflected light to the image and shortens the exposure. In the case of very near objects the camera has to be racked out, and the exposure is increased. It is found convenient to draw up a scale of subject numbers for all coloured objects and varying distances, thus combining the last two factors.

A set of six prints from negatives of widely varying subjects, the exposures calculated by the new exposure-meter, and all developed together in one dish, were handed round by me. They varied in character from a cloud picture to a copy of a dark terra-cotta bust in a room.

My new exposure meter is a small, circular, brass box, having at one end the actinometer, at the other a chain pendulum for timing both actinometer and camera exposures, while round the circumference are four movable rings, each bearing a pointer for the factors A, P, S, and D; when these are moved opposite their correct values, a fifth pointer, E, gives the correct exposure.

The average time taken to test the light, and to find out the correct exposure, does not exceed thirty seconds. The approximate plate numbers for different makers of plates will be given in the instructions, but photographers are advised to make a test to ascertain for themselves what plate number gives a negative of the kind they require with the developer they are in the habit of using.

A rather subtle point is touched upon in axioms IV and V. More than one photometer is made based upon the idea that the quantity of light reflected from the object and reaching the plate is an exact guide to the exposure. This is quite a mistake, and three different pictures were thrown by me on the screen, one with a large quantity of white in it, another with a large quantity of black, and a third with an average amount; the part of the picture in each case which determined the proper exposure was a patch of dark detail, and the exposure for all three would be the same. Any photometer, however, estimating the light reflected from these subjects, would give different and misleading results. Again, if three different shades of grey paper be copied on three plates, with three exposures varying in inverse proportion to the quantity of light reflected from the papers, the three resulting negatives would be all of exactly the same intensity, which would not be the result required.

* Summary of a paper read before the Hereford Photographic Society.

Mr. W. I. Chadwick, who has been Hon. Sec. of the Manchester Photographic Society for fifteen years, is, we are informed, resigning his office.

Exeter Photographic Society. — President, Dr. Cheese; Vice-President, Major Dowdall; Hon. Sec., Rev. J. Sparshatt, of Fairfield College, Alphington Road, Exeter; Treasurer, Mr. Lake, High Street. Meetings, first Tuesday in each month. Next excursion, May 10th, to Silverton. Headquarters, the College Hall, South Street. Notices posted at Mr. Lake's. Visitors to Exeter requiring use of dark room are requested to write to secretary or treasurer.

Number 16 of the *Deutsche Photographen Zeitung* for the present year contains a notice of a memorial tablet of the late Herr J. B. Obernetter. The memorial has been executed at the cost of the German Photographic Union. Herr Obernetter died on the 13th April, 1887. The memorial is somewhat late, indeed, but yet better late than never. The principal movers in this affair are Herr Fr. Müller, Herr Werner, and Herr Zschokke. The memorial was presented by these gentlemen to the deceased's widow with a suitable verbal accompaniment in his praise. A laurel crown was also given on the same occasion by Herr Werner. The tablet bears the following inscription suitably displayed:—"To Herr J. B. Obernetter, Photographic Chemist, in grateful memory of his services in the furtherance of Photography, this memorial tablet is dedicated by the German Photographic Union, 1890."

THE LATENT PHOTOGRAPHIC IMAGE.*

BY C. H. BOTHAMLEY, I.I.C., F.C.S.

VERY contradictory statements have been made respecting the action of alkaline bromides. Many writers have stated that they destroy the latent image, whilst others assert that they merely retard development. I immersed exposed plates of various kinds in a 10 per cent. solution of potassium bromide for periods varying from five to twenty minutes. They were then thoroughly washed and developed. Potassium bromide does *not* destroy the latent image. Of course if the soluble bromide were not thoroughly washed out of the film, development might be retarded to such an extent that no image would appear until after a long time, and possibly this is the explanation of the erroneous statements referred to.

It follows, therefore, that the latent image is destroyed by halogenising agents, and also by potassium dichromate, even in complete absence of soluble haloid salts or of free acids. It is not destroyed by alkaline bromides, and apparently not by nitric acid, hydrobromic acid, or hydrochloric acid, but the effect of these substances, as well as of potassium iodide—which seems to prevent the production of a developed image without actually destroying the latent image—requires further investigation.† Ozone and hydrogen peroxide are also stated to destroy the latent image; but the published experiments are very meagre in details, and there is no evidence that any special precautions were taken to avoid secondary actions, or to eliminate the possible influence of minute traces of impurities. It is worthy of note that, according to Hodgkinson, silver chloride darkens readily when exposed to light in presence of hydrogen peroxide.‡ I am of opinion, therefore, that the action of these re-agents also requires further investigation; but until the chemistry of hydrogen peroxide and ozone is better understood, no very conclusive results are likely to be obtained from their effects on photographic plates.

In all previous experiments in this connection it is very doubtful whether sufficient attention has been paid to the possible influence of minute quantities of impurities. Probably in some cases all the re-agents or materials were pure in the usual sense of the term, but latterly chemists have been learning that substances which they commonly regard as pure still contain sufficient foreign matter to exert a most powerful influence on their behaviour, and in the particular investigations under discussion the very highest attainable degree of purity must be aimed at. The quantity of matter composing the latent image is very minute; hence the relative effect of minute quantites of foreign substances may be very considerable.

All the decisive evidence at present in our possession points to the fact that the formation of the latent photo-image is a process of photo-chemical reduction, the effect of which can be undone by treatment with halogenising agents, or with certain substances generally believed to exert an oxidising action.

About three years§ ago Carey Lea showed that latent images, capable of development and reversal in the same manner as the latent photo-image, can be obtained by treating sensitive films of silver salts with a solution of a hypophosphite, or an alkaline solution of grape sugar or milk sugar. Nitric acid and solutions of the haloid salts of the alkalies had the same effect as on latent photo-images. Carey Lea's experiments were made with the silver salts on paper. I have repeated them with ordinary gelatine plates with precisely similar results. The reducing agent (sodium hypophosphite or a solution of milk sugar made alkaline by caustic potash) when brushed on the plate, produces no visible effect; but a dense deposit can be developed. These latent images thus formed are destroyed by potassium dichromate, but not by dilute nitric acid or by alkaline bromides. Potassium iodide affects them in the same way as the latent photo-image. (Examples shown).

Latent images, capable of development, are also formed as a result of a shearing stress applied to the sensitive film. This was observed by Carey Lea* in the case of wet plates, but was first carefully investigated by Abney.† The effect is easily observed by writing on the surface of an ordinary plate with a clean glass rod, using moderate pressure, and then placing it in a developer. Abney found that the material of the rod used for writing has no influence on the result; the effect, if sufficient pressure is used, is transmitted through paper. Sensitive and less sensitive forms of silver bromide behave similarly; the latent image formed is destroyed by potassium dichromate; the effect is not so much on the surface on the film as lower down or near to the glass, for if the film is moistened, superficially melted, allowed to set and then developed, the sharpness of the image is scarcely affected; but if the film is completely melted the developed markings are blurred. He also was unable to observe anything of the nature of phosphorescence when the writing was done.

Several points in connection with these phenomena seemed worthy of further investigation. Details of the experiments I shall describe in another place. I found that with one and the same plate the effect gradually increases with the pressure, but that there is no connection, as might have been supposed, between the sensitiveness of the plates to light, and the minimum pressure required to produce a developable image upon them. (Examples shown.) At present, I have not been able to trace any connection between the minimum effective pressure and the hardness of the film. I confirmed Abney's statements that the material with which the writing or "shearing" is done is without influence on the result, provided that it is a sufficiently hard substance: that no phosphorescence can be observed when the film is scratched; and that the latent image is destroyed by potassium dichromate. I also examined the action of various other re-agents, such as bromine and potassium bromide and iodide, and found the results to be identical with those given by the photo-image. Independent confirmation of Abney's statement that the effect is greatest in the lower part of the film, was obtained by a method quite different from that which he used. After some plates had been subjected to various degrees of shearing stress, they were exposed to light for a very short time. One half of each plate was then dipped in a very dilute solution of potassium dichromate for a short time, washed, and developed. It was found that the superficial latent image produced by light

* Continued from page 304.

† I may add that I am engaged with experiments in this direction.

‡ *Photogrdphic News*. xxxi. 370.

§ *American Journal of Science*, 1887, and English photographic journals of the same year.

* *American Journal of Science* [2] xlii. 198.

† *Photographic Journal*, 1883 and 1881; *British Journal of Photography*, xxx. 418; xxxi. 167.

had been completely destroyed, whilst the deeper-seated effect of stress was only slightly affected.

Latent images, which behave in a precisely similar manner with various re-agents, and are therefore presumably of very similar, if not identical composition, can be produced in at least three ways:—(1) by the action of light; (2) by the action of chemical reducing agents in the dark; and (3) by shearing stress. The second mode of production is easily intelligible; the production of chemical change by shearing stress at first sight seems difficult to understand. The researches of Spring have shown, however, that many chemical changes in solid substances can be produced by the application of great pressure. As a rule, pressure promotes combination, but there are certain cases where a compound is decomposed when strongly compressed. According to Spring, if the volume of the compound is less than the sum of the volumes of its uncombined constituents, pressure tends to produce combination: if, on the other hand, the sum of the volumes of the uncombined constituents is less than the volume of the compound which they form, pressure will tend to decompose it. The effect of pressure on chemical changes is, in fact, strictly analogous to its effect on the melting point of solids. At present we do not know the relation between the space occupied by the materials of the latent image, and that occupied by the original gelatino-bromide. If the former is less than the latter, the formation of a latent image by stress is only a special example of Spring's second law, and the apparent difficulty disappears.*

(To be continued.)

PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Comparison of Developers—Toning and Fixing Bath.

Comparison of Various Developers.—Much has been written of late in German periodicals about developers and developing, the question as to the best method of bringing out the latent picture, and to the most efficient reducing agent, seeming to interest at present more than ever. There is a German proverb, that a good thing cannot be told too often, and so I shall complete my previous communications by giving an abstract from a very interesting paper read before a small circle of Berlin professional photographers by Mr. F. Gaedicke, whose name is sufficiently well-known in the photographic world.

The four developers now most commonly in use—ferrous oxalate, pyro, hydroquinone, and eikonogen—were compared with each other, and the plates to be treated with the solutions were divided, for experiment, into three series; the first of them having received only one-fifth of the normal exposure, the second the normal exposure, and the third four times the normal exposure. Each series and each developer was treated under its most favourable conditions, so to the ferrous oxalate developer two drops of an accelerator consisting of hypo and potassium bromide were added; to the hydroquinone developer, four drops of a 40 per cent. potassium-lye; and the eikonogen developer was used as is recommended for instantaneous exposures, together with the preliminary bath consisting of hypo and bichloride of mercury. The plates were developed until a slight greyish appearance indicated the first signs of the approaching fog. The sensitometer consisted of one to sixteen layers of tissue-paper, and, as source of light, a flat gas-burner was used, which was turned down until there was no more roaring of the flame. The results of the experiments are shown by the following table:—

A. Under-exposed plates.—Exposure 1 second at a distance of 28 inches from the plate, *i.e.*, one-fifth of the normal exposure.

No.	Development.	The image appears within	Time of development	Sensitometer No.	Character of the image, and notes.
1	Ferrous-oxalate, with addition	9 seconds	5 minutes	14	Yellow fog; 1 and 2 are but slightly different.
2	Pyro-potash	12 ,,	3 ,,	14	Red fog.
3	Hydroquinone with potash	20 ,,	3 ,,	15	Clear.
4	Eikonogen with potash and preliminary bath	6 ,,	3 ,,	14	Yellow fog.

B. Normal-exposed plates.—Exposure 1 second at a distance of 12½ inches from the flame.

5	Ferrous-oxalate, plain	12 seconds	3 minutes	16	The negatives were all good and harmonious. By transparent light, the pyro-negative was brownish-black, the others bluish-black, therefore of better printing quality. The iron negative was the least clear one.
6	Pyro-potash	8 ,,	2¾ ,,	16	
7	Hydroquinone	25 ,,	3½ ,,	16	
8	Eikonogen-soda	12 ,,	3 ,,	16	

C. Over-exposed plates.—Exposure 4 seconds at a distance of 12½ inches from the flame, *i.e.*, four times the normal exposure.

9	Ferrous-oxalate, with 4 drops potass. brom., 1 : 10	18 seconds	3½ minutes	16	1 to 8 but little graduated; flat and useless.
10	Pyro-potash, with 8 drops pot. brom.	20 ,,	2½ ,,	16	Better graduated than No. 9; a little too hard, but usable.
11	Hydroquinone, only old solution, with 8 drops potass. brom.	60 ,,	5 ,,	16	Normal negative, the best of this series.
12	Eikonogen-soda, with 8 drops potass. brom.	30 ,,	3½ ,,	16	Flat and useless.

All the developing solutions, of which, in all cases, 40 c.c. were taken, had been allowed to stand for 24 hours after the preparation, because pyro acts much more energetically if freshly prepared, but always older solutions are to be taken into consideration. To the *ferrous-oxalate developer*, in the case of the under-exposed plates, 2 drops of a

* I gave this explanation of the effect of shearing stress in a lecture before the Leeds Photographic Society early in 1888, but did not publish it. Professor Meldola refers to Spring's researches in the same connection, but less specifically, in his "Chemistry of Photography," p. 192.

solution of 1 gramme of hypo and 6 grammes of potassium bromide in 60 c.c. of water were added; in the case of the over-exposed plates, 4 drops of potassium bromide, 1 : 10; in the case of normal exposures no addition was made. In the case of *hydroquinone development*, 20 c.c. of an old solution, 20 c.c. of a fresh one, and 4 drops of a 40 per cent. potassium-lye were used for the under-exposed plates; for the normal exposures, two-thirds of an old solution, one-third of a fresh one, and 4 drops of the potassium lye; for the over-exposed plates only old developer, with 8 drops of potassium bromide, 1 : 10. In the case of *eikonogen development*, the preparation with potash and with the preliminary bath (hypo and bichloride of mercury) was used for the under-exposed plates, the preparation with soda in two solutions for the normal exposed plates, and the same preparation, with 8 drops of potassium bromide, 1 : 10, for the over-exposed plates.

As the table shows, all the developers gave good results in the case of normal exposure; but as normal exposures in practice do not form the rule, but, on the contrary, the exception, the results of over and under exposure are more important. For over-exposure the eikonogen developer was the worst, hydroquinone the best. In the case of under-exposure only the hydroquinone developer gave a clear negative; all the others were yellow or red fogged, and inferior for one sensitometer number. It follows therefrom that the hydroquinone developer is decidedly the best one, as it is also the cheapest one, because in most cases an old solution may be used. Pyro solution does not keep well, and it is necessary to work with separate solutions. Also eikonogen solutions do not keep as well as hydroquinone solutions, and are liable to fog the plates after a few days. In all, the results are the following:—1. Ferrous oxalate. Good, bluish-black negatives, which, however, if no preliminary bath is used, are harder than those obtained with the alkaline developers. The developer is very poisonous. For the case of heavy over-exposures it is little suitable. 2. *Pyro-potash developer.* The most energetic developer; gives a good, soft, brownish-black negative. Two separate solutions. In the case of over-exposures it may be used with potassium bromide. The negatives dry more readily than all others. 3. *Hydroquinone.* The image appears later than with the other developers, but it is developed out in the same time. The negative is mostly denser than with pyro and eikonogen. It is bluish-black, and prints well. If the solution is cold, it develops very slowly; it should therefore have an average temperature. 4. *Eikonogen.* In the beginning it develops quickest, but in order to obtain vigour, it requires as much time as iron and hydroquinone. The keeping qualites of the mixed solutions are very doubtful, and even with the separated solutions fog sets in after a short time. The developer is about five times as dear as the others. In the case of over-exposure it is less useful than pyro and hydroquinone. It is a great disadvantage that the eikonogen is highly sensitive to the influence of ammonia. The final result of these experiments is therefore: *that at present the hydroquinone developer is to be preferred to all others as decidedly the best one.*

The Best Combined Toning and Fixing Bath for Gelatino-Chloride Paper.—Mr. R. E. Liesegang, a young, but very serious investigator, has made careful experiments in order to find out the most efficient combined toning and fixing bath for prints on gelatino-chloride paper. He recommends the following one:—

Solution No. 1.

Hyposulphite of soda	200	grammes
Alum	80	,,
Nitrate of lead (pulverised)... ...	2	,,
Boiling water	400	c.c.

The solution is allowed to stand for two days; then once more 400 c.c. of boiling water are added, and the solution is filtered. Meantime, the following solution is prepared in a bottle:—

Solution No. 2.

Sulphocyanide of ammonia	160	grammes
Water	1,200	c.c.

Solution No. 1 is mixed with solution No. 2, and then added:—

Solution of gold chloride (1 per cent.) 10 to 20 c.c.

With this bath the prints take any desired tone within three to five minutes.

BOTANICAL PHOTOGRAPHY.

BY JULIUS F. SACHSE.

The first three months of the year are in this latitude generally supposed to be the least favourable for the amateur photographer, and the exercise of his hobby. The fields and pastures are black; hillsides and ravines, so inviting in summer, are now bleak and desolate; and the trees, under whose grateful shade we rested during our summer outings, are now leafless and bare. Christmas-tide, with its joys, is past and gone; the various Christmas trees, with their gaudy dressings, our presents, groups, and visitors, have been "taken" by Blitz or Sun, and most amateurs count their winter's work completed. Some enthusiastic votaries have kept their practice alive by copying pictures, old documents, maps, seals, or objects of vertu or antiquity, and other subjects, not forgetting sundry interiors. Still, as such work partakes more of the dull routine of labour than pleasure, the interest in photography has naturally more or less flagged, while the amateur sets aside his outfit until spring shall come, when he can again strike out in pastures new, and find food for his camera.

To the "photographic studiosis," as a German contemporary designates the enthusiastic amateur, there is no need of waiting until the country is again clothed in pristine verdure. Our suggestions will apply to the whole guild of camera carriers.

There are but few persons, if we except the arborist, who have any idea of the difference existing in tree structure, or the diversity in shape and growth of the limbs of the various species.

Nothing will surprise the intelligent observer more than the marked difference between our common trees, which we have known since childhood, without taking special notice of their peculiarities, as can be seen by a comparison of eight or ten photographs of as many different varieties, the negatives being made at the present season, while the subject is bare and leafless.

The wide divergence in characteristics of growth, such as shape and bark, as shown by such comparison, will prove a revelation to many a well-informed person, and opens a wide and interesting field to the amateur photographer and student.

In our suggestion of this study we would advise a selection of marked, well-grown specimens, that can be taken on the plate so as to preserve all the features of the

tree without being secondary to any surroundings. It makes no matter whether the subject be a monarch of our primitive forest, or some favorite specimen of ornamental growth, introduced from foreign climes; each individual variety has its peculiar characteristics. Photograph the tree in a strong light, so as to bring out the detail of the surface. It would be well to carefully note the distance from the butt of the tree, or the point of the compass, if there is no other way of locating the spot where the tripod was set; this note is for reference in the future, so that after the spring has opened, and the trees are once more clad in their verdure, another trip can be made to the same spot, and a plate made of the same tree in its glory. This study can be further supplemented by photographing the tree while the buds are bursting, when the leaves are out, and then again in the fall, when the leaves are either in their autumn glory or after they are brown and falling, using orthochromatic plates; further, if the above suggestion be carried out, after the leaves have again fallen, a fifth plate can be taken of the same subject, and then compared with the first plate; it will show the marked changes and growth which have taken place within the year, and which are not perceptible to the eye.

It will be seen that for these comparative plates to be of value great care should be taken to set the camera at the same point for the different exposures.

To any amateur having a taste for such research and experiment, we would point out the interesting groups of flowering trees, where not alone the tree structure, but the flowers, the leaves, and the fruit all tend to form an interesting group of subjects for the camera.

Take, for instance, the common Horse Chestnut (*Æsculus Hippocastanum*), a large symmetrical tree. In a photograph taken at the present time, we would have the structure or framework of the tree; the next plate we would suggest when the tree is in blossom, covered with a wealth of erect spikes or panicles of flowers, which stand out in bold contrast with the bright green foliage; then for a third plate, the same subject after the fruit is well formed, and the foliage has reached its fullest development.

Any one who takes up the study of this subject will also find the bursting leaf-bud, the young leaf, the flowers separate and in panicle, the developed leaf, the green fruit burr, as well as the burr when opened by the frost, exposing the ripened fruit, all picturesque subjects for the camera.* A series of photographic studies of this kind, carefully executed, would form an album far more interesting and instructive than the ordinary view or portrit album, so common and so listlessly gone over by the visitor to whom it is shown, and who, for politeness' sake, goes over page after page without noticing what the pictures represent.

In the same group of trees with the example mentioned, we would call attention to the Catalpa (*C. Syringæfolia*), with its large, heart-shaped leaves, and large pyramidal clusters, a foot long, of white and purple flowers; the Paulownia (*P. Imperialis*), a magnificent tropical looking tree, with leaves twelve to fifteen inches in diameter, and large clusters of lilac flowers; the magnificent native "Tulip Poplar," so called (*Liriodendron Tulipifera*), with its erect growth, broad, glossy, fiddle-shaped leaves, and beautiful tulip-shaped flowers and curious seed-pods; not forgetting the Magnolias, Conspicua, Acuminata, but especially the "Macrophylla," or large-leaved, with leaves two feet in length, and a profusion of dull white flowers, of the size of a man's hat. These specimens will suffice for one group.

Then we have the various native forest trees, such as the Oak (*Quercus*), the Maples (*Acer*), Ash (*Fraxinus*), Locust (*Robinia*), Elm (*Ulmus*), Linden (*Tilia*), Poplar (*Populus*), Gum (*Liquidamber Styraciflua*), and many others, all having characteristics which may be plainly shown with the camera.

The various fruit trees, Cherry, Peach, Plum, and Apple, all form beautiful subjects. In connection with this group of subjects, we will state that on one occasion when we asked a gentleman, who has one of the largest collections of lantern slides in the country, the question, which he considered the finest slide in his collection, he unhesitatingly answered, "An apple tree in full blossom." He further volunteered the information that he had eight slides of this subject made from as many different negatives.

Our field of study can be extended to the large family of flowering shrubs, or minor trees, as the Dogwood (*Cornus*); the weeping trees, as the Ash, Beech, Birch (*Pendula*), &c., the Rose of Sharon (*Hibiscus Syriacus*), Hydrangea (*H. Paniculata Grandiflora*), Lilac (*Syringia*), Purple Fringe (*Rhus Cotinus*), and many others.

It will be seen by reference to above list (although not a hundredth part of what we might have made it) how great this field is for study and development, and well worthy of the attention of all intelligent amateurs, especially the lady votaries of our art; and this independent from the fact that it would be the means of leading many persons to a closer study of the secrets and beauty of nature.

At the same time we cannot refrain from cautioning the neophyte, if he wishes to take up this study as above suggested, from attempting too much at the start; it is better to complete two or three sets thoroughly and correct, than undertake a dozen or more subjects, and complete none.

The plan pursued by the writer is first to select the specimen tree; then after a satisfactory position for the camera has been obtained, plumb the camera with a plumb-line, the same as a surveyor's level, then drive a large peg directly under the centre,—this securely marks the location for any subsequent exposures—then level the camera, pointing as near the centre of the tree as possible; the centre can also be marked by tacking a small piece of white fabric on the tree on a level with the lens.

A matter of value, in connection with the subject of photographing leafless trees, is the preservation of the outlines of historic trees—once landmarks in the history of our country or of its progress—guide posts, which are getting less and less every year, as they succumb to the ravages of time, or fall prey to the rapacity of man. As yet there is still a number of such trees throughout this country, and the searching out and tracing the traditions clinging to these silent monitors by the road-side, or as they stand alone in the field like a grim sentinel, will be found an enjoyable divertisement.

I should be pleased to receive and note any results from our readers who may take up this special line of photographic study, as outlined in above suggestions.—*American Journal of Photography.*

* The leaves, buds, flowers, and other detail are pinned against a white or neutral tint background, and focussed on the plate as large as possible without crowding the plate.

PHOTO-MECHANICAL PRINTING.

It has long been a hobby of ours to speculate on and wish for the coming of the "good time" when the making of the negative and the production of prints therefrom shall be divorced from each other, as much as at the present time are the work of the engraver and the plate printer. We say advisedly "the good time," as we fully believe it will be equally good for the photographer, the public, and true art itself.

Silver printing has served its purpose, and done more than anything else in connection with the art to bring about the great popularity which it has enjoyed during the last thirty years. It came at a time when art culture was at a low ebb, at least amongst the great mass of the people; and by its beauty and delicacy of detail fascinated, where breadth and true artistic effect would have fallen flat and remained unheeded.

Now, however, there is a gradually increasing evidence of a higher degree of art culture, and a daily increasing appreciation of the more truly artistic qualities of several at least of the numerous processes of mechanical printing, some of which have been already brought to a high degree of perfection.

The "good time coming," and which we hope will come soon, will be one in which the photographer will be relieved from all the drudgery and cost of printing, and the constant worry incident to blisters, tears, mealiness, and the thousand-and-one cares and troubles of the printing and finishing departments; and, free to give his whole heart to the production of the negative, with the handing over thereof to the sitter, and the receiving of a handsome fee therefore, his responsibility will end.

The sitter, in possession of a negative, will, on examining the results of the various mechanical processes, select that which pleases him best, or is most suitable for some special purpose, and hand it to the printer with an order for such a number of copies as he may require. It is true that the processes suitable for this kind of work are, as yet, too expensive; but those who have watched the development of mechanical printing, from Talbot's earliest efforts through all its various stages to, say, the "tree study" by Ives' process in the March number of the *American Journal of Photography*, or the prints in the Gutekunst souvenir noticed in our last issue, cannot doubt but that something equally good and suitably cheap is but a matter of time, and in the near future.

Of course, we are quite prepared to hear the "craft in danger" cry. No new development or great improvement in mechanical process has escaped that. When it was proposed to supersede stage coaches by railroads, it was declared that horses and men would both find their occupation gone, but the railroads employ hundreds of both, where tens only were required. In the town in which our early years were spent, we remember, when it was proposed to substitute power for handloom weaving, that five hundred weavers saw nothing but starvation or the poor-house before them; and yet, within a very short time after their introduction, they gave constant and better paid employment to fully five thousand hands; and so it has always been; wherever a suitable division of labour has been made and suitable machinery introduced, the result has been a large increase in the numbers employed, and better payment for the work.

We have said that the change would benefit the photographer, the photographed, and art itself. It would benefit the photographer by enabling him to give his undivided attention to the production of the negative, and by saving the expense of a staff of assistants and the heavy outlay for stock, &c. Like his brother artists of the brush and modelling tool, his work would be done by his own hands, and imbued with his own individuality, and would be paid for in at least something like a relation to its artistic value. The picture-loving public—not the mere photograph-loving, but the *picture*-loving public—of the near future will be able to appreciate the difference between negatives that are the outcome of genius, either inborn or acquired, and the work of those who do not possess the one and are too lazy to study till they obtain the other, and the latter will deservedly go to the wall.

If the photographer, with no wages to pay and no stock to buy, who makes even half-a-dozen negatives a day and gets a minimum price of five dollars for each, does not think he will be better off then than now, he need not read any farther, as this is not written for him, but for his more reasonable brethren.

Then, as for the general public, the patrons of the photographer, the "good time coming" will benefit it by enabling it to secure pictures impressed by the style and individuality of those whom it most admires, and printed in style and colour according to its fancy, and with the assurance that such prints shall be as permanent as the paper on which they are made. Nor need they be confined to one particular style. From the one negative they may have made, at so much an inch, photogravure plates, tye-printing blocks, &c., to be kept on hand for such purposes as may from time to time be required.

Nor will true art itself be less a gainer by the change. An educated and cultured public will cease to regard a photograph as an article of manufacture, like a pair of boots or a spring overcoat, and worth only a tradesman's profit over the cost of material and labour; but will look upon the negative as a valuable family possession, the outcome of a combination of artistic ability and technical skill of their favourite artist photographers.

Under such circumstances it must be that certain men will make their mark as head and shoulders above their fellows, and although we may not live to see it, we believe the time will come when their productions will increase in value like the works of the old masters, or the fiddles of the Cremona makers, and, like the "Strades" and "Amaties," be worth much more than their weight in gold.

Photographic Club.—Subject for discussion on April 30th, "The Development of Unknown Exposures"; May 7th, "Lenses for Instantaneous Work." Saturday outing, April 26th, Buckhurst Hill; train from Liverpool Street at 2.8.

Anhydrous Sulphite of Potassium.—The crystalline sulphite of potassium ($K_2SO_3.7H_2O$) contains seven molecules of water, and is rapidly altered on exposure to air, losing water, and becoming gradually oxidized to sulphate of potassium. The well-known firm of Kahlbaum (Berlin) now puts the salt on the market in an anhydrous condition. In this form it is perfectly stable. It would be of advantage to have sulphite of sodium in the same anhydrous form.—*American Druggist.*

Clearing Collodion.—A correspondent of the *Druggists' Bulletin* says that a transparent collodion is in use in Paris which is not only perfectly clear, but remains limpid for an indefinite time. It is prepared by shaking an officinal collodion with quartz sand which has previously been washed and carefully calcined. The action is purely mechanical, the suspended particles adhering to the grains of sand, and settling to the bottom of the container in a gelatinous mass.

Correspondence.

THE PROPOSED ILFORD SCHOLARSHIP.

Sir,—I am sure you will join with me in deploring the conclusion reached in this matter, as shown in subjoined letters, and will allow me to say, through your next issue, that I can only look forward with hope to the good time to come when we shall have more cohesion between the various societies, more unanimity of purpose in the endeavour to add to the dignity of photography, and less airing of presumed personal grievances and idiosynerasies. Then the amateur and professional, as such, will exist no longer, but all will be photographers without any invidious distinction, other than merit, and all will form a race, by training and education, infinitely superior to their fellows of to-day. The Britannia Works Company hoped that their offer of a scholarship would have been the foundation stone of such a Utopia; but it seems we are ahead of our times; no one seems equal to the task of laying that foundation stone aright.

When any society or committee of leading men see their way to fitly use the gift, it will be ready for them.

John Howson.

Britannia Works Company, Ilford, E., April 21st.

Dear Sir,—With reference to your letter of the 29th ult., I am directed by the Council of this Society to send you a copy of the following resolution which, was passed yesterday evening:—"That the Council of the Photographic Society of Great Britain, while thanking the Britannia Works Company for their offer, regret that, after the due consideration, they are unable to accept it."

Photographic Society of Great Britain. A. M. Mantell, *Sec.*

To J. Howson, Esq., Ilford.

Dear Sir,—I thank you for your letter of yesterday, and share the regret of the Committee at the non-acceptance of the proposed scholarship. If I may be permitted to express an opinion on the matter, I feel that there is a great want of due regard to the interests of photography when a free and absolutely unfettered gift of £100 per annum to benefit the art science cannot find a recipient. John Howson.

To Captain Mantell, Secretary P.S.G.B.

DEVELOPMENT IN TWO SOLUTIONS.

Sir,—At page 152 of the last Year-Book of Photography is an interesting article, by B. J. Edwards, on "Development." This article, however, contains one small paragraph which might be expressed more clearly, and I venture to hope that he will publish his exact meaning for the benefit of amateurs anxious to learn. I refer to the last paragraph but one, on page 154, beginning, "It will be obvious," &c.

Would Mr. Edwards kindly explain what he means by a "similar solution," and how in particular would he recommend "Beach's Developer" to be used so as to carry out the same principle?

Beach's Two-Solution Developer.

	No. 1.	
Water	2 ounces	1 ounce = 437½ grs.
Sulphurous acid ...	2 ,,	
Sodium sulphite ...	2 ,,	
Pyro	218 grains	
	No. 2.	
Carbonate of potash	3 ounces	
Sodium sulphite ...	2 ,,	
Water	7 ,,	

The above solutions are recommended to be used for normal exposures, thus:—Soak the plate for one minute in a mixture of 30 minims of No. 1 with 2 ounces of water. Pour off the mixture, add 40 minims of No. 2, and continue development.

How should the "second developer or intensifier" be made? Does the "full dose of pyro" mean that mentioned at top of page 154, viz., 16 grains to the ounce? How much ammonium bromide or potassium bromide to the ounce, and what increase (if any) of carbonate of potash to the ounce? X.

THE CRYSTAL PALACE CHALLENGE CUP COMPETITION.

Sir,—We should think that your readers will be with us in feeling very much surprised at the trifling evasions of the Crystal Palace Executive. It is usually considered that in disputes there are two sides to a question, but here we have apparently an exception to this rule. Spite of the amount of reputation which the management must know they have at stake in this matter, they have never from the beginning of the correspondence replied *with proof* to any one of our charges.

They say in their last communication that they "deny unequivocally the allegations," and "that the Company is in a position to prove that such allegations have absolutely no foundation in fact." Then their course is clear: *let them bring forward this proof*, and we shall feel satisfied. This is what we have all along fruitlessly asked for.

At the same time we are anxious to know what they will prove. Our last letter is *not* an allegation, but a string of plain facts, laid before your readers with no unnecessary comment.

Perhaps they will prove that we sent no pictures at all. Will they deny that we wrote asking them to lay aside the four pictures which they—but not their rules—objected to? Will they deny the letter from one of their own judges, stating that only part of our pictures were judged? Will they deny their own letters accepting our pictures as in form? These are our "*allegations*," and unless Messrs. Wollaston and Peasgood are prepared to bring forward some of this *proof* which they profess to have, it is useless to reply further to their present valueless statements.

Specifications Published.

7,071.—*April 27th*, 1889. "Spreading Gum, Paste, and like Liquids, and Stoppering the Bottles containing such Liquids." Adolph Buhler, Reichenhall, Bavaria, late Captain in the Bavarian Army.

My invention relates to an improved device for enabling gum, paste, and similar liquids to be evenly spread, the said device serving also the purpose of an efficient stopper for the bottles containing such liquids.

It is well known that when spreading gum or similar liquids by the use of a brush in the ordinary manner, the brush at first usually contains too much of the liquid, and therefore lays it on too thickly and uneveuly, and if the brush be wiped against the bottle neck to free it from a superfluity of liquid, the cork of the bottle is liable to stick fast in the neck thereof. To avoid the latter difficulty, loose covers, such as metallic capsules, are used, which have the objection that the liquid in the bottle, through exposure to the air, thickens in a very short time. Even the recently proposed elastic gum bottles which terminate in a slit conical tube, and which are used directly for spreading the gum by giving the bottles a slight pressure, do

not well answer the purpose, as the gum soon hardens at the outlet and clogs it up.

By my invention the hereinbefore described objections are overcome.

My improved device comprises a tube which is so fitted in the corks of the bottle that it can be easily removed therefrom and replaced.

The tube is advantageously of cylindrical form, pointed at its lower end, where it is provided with several small perforations. The tube is preferably fitted with a collar at the upper end, in order to prevent the point from coming into contact with the bottom of the bottle.

The upper end of the tube, which is open, has an india-rubber cap which serves, firstly, to suck a quantity of the liquid into the tube; and secondly, when softly pressed, to cause the liquid to issue through the perforations in the tube and become evenly and slowly spread.

Instead of employing an india-rubber cap the tube may be constructed with a piston similarly to a syringe, or the tube itself may be made in the shape of a plunging-syphon. As the hole in the cork is made to just fit the tube, all the gum which may be on the outside of the tube is removed by the cork when drawing the tube out for use. The tube can, however, be fastened to the cork, and as it is not necessary to scrape or wipe the tube against the bottle neck, the cork will not be liable to stick.

After the tube has been used for spreading the liquid, it is pushed down again through the cork into the bottle, until the collar rests tightly on the cork, thus forming a secure stopper and preventing the drying up and thickening of the liquid. If the india-rubber cap of the tube, when pushing the latter back into the bottle, be compressed by the fingers, the liquid will enter the tube as soon as the pressure of the fingers is removed, and the tube will thus be always ready for use.

Instead of using the conical point of the tube for spreading the liquid, this may be more evenly affected by adapting special spreading devices to the latter, such as a brush, a piece of elastic attached to a spring wire, a piece of sponge or a rubber roller, it being necessary for this purpose to somewhat modify the shape of the end of the tube.

7,759. *May 9th*, 1889.—"A Combined Umbrella Walking-Stick." Gwendoline Peyman, South Bank, Milverton, Leamington, Warwickshire.

We print this patent because umbrella walking-stick camera stands have been found useful in photography. The inventor says:—

This invention consists in combining an umbrella with a walking-stick in such a manner that the combined article can be used for an umbrella or for a walking-stick.

In carrying out my invention, in some cases I form the umbrella on a tube, such umbrella-tube sliding over a tubular or solid core.

I form the walking-stick hollow, and place the umbrella and core inside the walking-stick in such a manner that the walking-stick can be used for ordinary purposes.

When I wish to use the umbrella, I push the sliding tube and umbrella out at the end of the walking-stick until the umbrella shade is entirely outside the walking-stick; I then draw back the umbrella tube over its core, and push the walking-stick concentrically up or inside the shade, and expand the said shade over the extreme end of the walking-stick, and then use the walking-stick as a handle for the expanded shade or umbrella.

The hollow walking-stick must be of a suitable transverse section to receive a collapsed umbrella; the umbrella would, of course, be made of the thinnest material so as to collapse into the smallest possible dimensions.

8,603. *23rd May*, 1889.—"The Production of Phototypes." Johannes Adalbert Fischer, Merchant, Leipzig, Saxony.

In the art of printing, the usual method of producing images in imitation of photographs has been to print the images on specially prepared sheets—chalk or chromo-paper sheets—the said sheets being prepared with a suitable mass on their entire surface, which could only be done at considerable cost. On the other hand, in attempting to transfer the images on ordinary printing paper, there arose the difficulty that, owing to the absence of the so-called chalk base, the sheets could not be sufficiently polished or glossed to obtain the desired effect.

In order to simplify and cheapen the said printing process, I proceed as follows:—Any ordinary printing paper is coated with a suitable ground glass—or the latter is pressed on—but only within the outline of the images, after which the images are printed, and then the surface is polished or glossed.

The images or phototypes thus produced are similar to photographs or heliotypes, but can be produced more cheaply than those which were made by preparing the entire surface of the paper.

The inventor claims:—

An improvement in the production of phototypes, which consists in providing the paper with a base of a suitably prepared mass within the outlines of the images only, then printing the image, and subsequently polishing or glossing the surface by a polishing or glossing machine.

2,776. *February 20th*, 1890.—"Photographic Lens Shutters." Frank Bishop, of the firm of Marion and Co., 22 and 23, Soho Square, London, Dealers in Photographic Materials. A communication to him from abroad by the firm of Voigtländer and Son, of Brunswick, Germany.

The inventor claims:—

1. In a photographic lens shutter composed of segments or plates pivoted to an annular frame, and simultaneously moved about their pivots, the construction of the said plates of such form as to open or separate from each other at the centre, and at practically the same instant or immediately afterwards, in the direction of the circumference in the form of curvilinear, ray-like extensions of the central aperture.

2. The combination, with the herein-described shutter, and its spring-actuated crank motion provided with a shouldered discs, of the spring-actuated detent adapted to engage with either shoulder of the said disc, and arrest the shutter in either of two positions for the purpose specified.

3. The combination, with the herein-described shutter, and its spring-actuated crank motion, of the spring-actuated detent adapted to engage with the spring motor, and arrest the shutter in either of two positions, and of the trigger lever provided with an adjustable escapement piece adapted to act on the detent, and disengage it from the spring motor with whichever shoulder it may be in engagement, and capable of being so set as to keep the detent out of engagement with the spring motor during the whole motion of the shutter, or allow the detent to immediately fall back into engagement with the spring motor, so as to arrest the shutter when it reaches the fully-open position.

4. In the herein-described shutter-actuating and releasing mechanism, the combination, with the trigger and escapement piece, of the cam or eccentric for adjusting said escapement piece in either of its two positions.

2,781. *February 21st*, 1890.—"Cramp for Glueing Picture Frames." George Ott, of Ulm, on the Danube, Germany, Manufacturer.

This invention is a device intended to facilitate the glueing of frames for pictures and such like, and the compression of mitred quoins.

The inventor claims a mitre cramp for picture frames or the like consisting of a frame with an open space furnished with rabbets, a slide provided with two movable cheeks having dents arranged at an angle of forty-five degrees, a spring, screw, cheeks, for the purpose of joining quoins of bands or frame bars to be glued or otherwise secured together, the whole combined and operating substantially as set forth in the specification.

Camera Club Notices.—Saturday, April 26th, first excursion of the season, Nutfield—leader, Rev. C. F. Fison; Thursday, May 1st, 8 p.m., Captain Abney will read a paper—subject to be announced later; Monday, May 5th, 8 p.m., opening of exhibition of Mrs. Cameron's photographs; Monday, May 5th, 8.30 p.m., smoking concert—last of the season.

Proceedings of Societies.

Camera Club.

Thursday April 17th; Mr. A. Stroh in the chair.

A *lue noir* on "Amateur and Professional Photographers," by Mr. W. Adcock, was read by the Secretary in consequence of the absence of the author through illness. In the paper Mr. Adcock stated that he was dealing with a delicate subject. He was an amateur himself, and he had never received a penny for anything he had done in photography. Amateur photography was said to reduce the trade of the professional worker; also to exercise an influence adverse to him by conveying an idea to the public of the low cost to him of the articles he produces; it was likewise said that amateurs injured him by giving photographs for sale for charitable purposes. It was said that these influences, in addition to the rent, rates, taxes, and wages which the professional photographer had to pay, had rendered it difficult for him at the present time to keep a special staff for special work. His (Mr. Adcock's) sympathies in this matter were with the trader, whose difficulties he believed to be increasing year by year. As to the charge of injuring private trade by giving prints for sale at bazaars in aid of charities, the end seemed to justify the means. In such cases he employed a trader to produce from his negatives all the prints he required for the purpose. He thought that amateur photographers should buy as many photographs from traders as if they had never taken up the subject. He also thought that when the friends of an amateur wanted prints from negatives he had taken of them, the amateur should give the negatives out to a trader and let him supply, on reasonable fixed terms, whatever prints might be required. Amateurs should try to give professionals all the support they could, and obey the golden rule of doing unto others as they wished others to do unto them.

Mr. Pringle and Mr. Webber expressed approval of much that had been said by the author of the paper, after which the discussion drifted into the minor question of the separation of amateurs and professionals at competitive exhibitions; a vote was taken on the point, and the meeting was unanimous in the opinion that no such separation should be made.

The Chairman held that if any injury were done by the amateur to the professional, it was very slight, and in portraiture, the most profitable branch of photography, the professional has every advantage, for he has a studio and means of lighting such as an amateur never dreams of possessing. He himself had been started in amateur photography by a professional. He was at the seaside at the time, and went to get his portrait taken. In time the prints were sent to his hotel, and when he looked at them he could not recognise himself in the least; it looked like a portrait of the Prince of Wales, and he had been given somewhat of a Roman nose; all his friends laughed at the picture. He went to the photographer and asked him what he meant. This time he saw the proprietor, who said, "Oh! I suppose you want a likeness. If so, you must give me another sitting." He then sat again, and the result was worse than before; consequently, when he returned to town he thought that he would try what he could do himself, so he bought a little apparatus and started as an amateur. He did not think that he had ever done any harm to a professional photographer, and he did not believe that amateurs as a class did any harm to professionals. He thought that were it not for amateurs, photography would not be at its present state of perfection. If they slightly injured those of the professionals who turned out inferior work, where would be the manufacturers of apparatus and photographic goods were there no amateurs? Altogether, he thought that they did the photographic industry more good than harm.

London and Provincial Photographic Association.

At the meeting on the 17th inst., Mr. C. H. Cooke occupied the chair.

A question was asked in reference to the price of aluminium.

Mr. A. Haddon said that at a previous meeting he stated that he believed it could be bought at about 6s. per lb.; this price, he had since ascertained, was below its present market value. In ingot it could be bought for 15s.

Mr. T. E. Freshwater, referring to the permanency of silver prints, said he had recently opened a tin case received from Naples in which some silver prints had been packed since 1880; the image had quite faded.

Mr. W. E. Debenham said he had a batch of silver prints that had been lying by since 1882; they had been kept flat, but up to the present time they showed no trace whatever of fading except that the paper had turned a little yellow.

Mr. J. S. Teape showed a changing bag which could be easily made. It consisted of two thicknesses of black satteen cloth folded and sewn; the ends were left open, through which the hands were inserted, the changing being done entirely by feeling. He had used it frequently in the field for changing plates, and had found it perfectly safe.

Mr. W. E. Debenham had used a similar bag for changing plates out of doors. To insure the plates being put into the dark slides film side down, he attached a small strip of gummed paper to the back and over-lapping one of the sides of each plate; when putting the plate into the slide this strip of paper was torn off.

Mr. Everett suggested backing the plate. The rough side would be a guide in changing entirely by the feel, and would also act as a protection.

Mr. T. E. Freshwater showed several bromide prints of sunset pictures. The negatives were taken on Easter Monday at six o'clock in the evening. In exposing, the cap was taken quickly off and on the lens, using *f*/22 stop. He also showed some prints from negatives of the landslip at Walton-on-the-Naze. Referring to the newspaper reports of this matter, Mr. Freshwater drew attention to Burnt House Farm shown in one of the pictures as still standing, whereas the reports stated that this place had been destroyed by the catastrophe.

The Chairman asked whether paper packed between plates would be likely to cause abrasion of film.

Mr. Debenham thought not, unless a great weight was put upon them.

Mr. A. Cowan said that this method of packing had advantages over the paper clips at the edges of plates; packed in the latter way plates were more easily broken.

Mr. J. S. Teape said that in grooved boxes it was sometimes very difficult to get the side plates out of the box; to obviate this he simply cut the corners off the box.

Mr. Drage said that when in New York he bought some plates which were packed with a strip of cardboard at the edges; when developed the film that had been in contact with the cardboard was found to be full of holes.

Mr. A. Haddon remarked that at the last meeting a lantern-slide cover-glass, showing a deposit, was exhibited by Mr. York, but as the crystals were rubbed off before passing round, the members had no opportunity of examining it. He showed two glass globes blown by him some time ago; on the inside of each an arborescent growth had commenced. Mr. Haddon said that he had found this growth sometimes commence within twenty-four hours, but only with soda-glass. He remarked on the absence of any crystalline formation in incandescent lamps. From this he inferred that a certain amount of moisture must be present to form the deposit. In the case of the globes passed round, this would be supplied by the breath in blowing them.

Derby Photographic Society.

The monthly meeting was held in its Rooms, Derwent Street, on Thursday, the 17th inst.; Mr. Thomas Scotton presided.

Mr. R. Keene read a paper, in the course of which he said that he had no new theories to propound, no new cranks in development, as we were so well provided with photographic literature that everything new was published as soon as it left the hands of the inventor; but he would give a short sketch of the troubles and trials of a photographer who practised the art some thirty or forty years ago. He dwelt upon the trouble and time of cleaning and coating glass, and keeping in order the silver bath, as compared with the dry plate process. He exhibited a 15 by 15 camera of some twenty years or so

back, and compared it with the beautifully made instruments now in use, stating that a kit of that period would weigh about three cwt., and now we can get the same result with only a weight of ten pounds. The paper was interspersed with lively anecdotes, and was both interesting and instructive. He advocated a system in the exposure of plates, and not to take everything indiscriminately, but to study the locality well before taking the camera out.

A discussion followed. A number of prints by the Graphotone Company was exhibited.

NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

AT the meeting of the above Society on the 14th April, Mr. H. M. SMITH, of the Eastman Company, attended to show some Kodak cameras, which have already been described in these pages.

Mr. WALKER spoke of the difficulty in obtaining a supply of the rollable celluloid film with promptitude.

Mr. SMITH said that in future the Company hoped to be able to meet the demand, as they were entitled to one-third of all that manufactured in America, and were completing the enlargement of their English works.

In answer to questions, Mr. Smith said that the shutter of the Kodaks worked at about one-fortieth of a second, and that its speed may be altered by releasing the spring: this the Eastman Company are always willing to do free of charge.

The SECRETARY said that there had been complaints of markings said to arise from electrical causes.

Mr. SMITH responded that there has only been one batch yielding such markings, and it was from this, unfortunately, that Mr. Walker took those negatives which he exhibited at the Camera Club. The defect was due to coating the celluloid under as high tension as if it had been paper. Recently the machinery has been altered, so that there is little probability of any films being defective from that cause.

On April 28th Mr. F. L. Pither will lecture on "Art in Photography."

PHOTOGRAPHIC SOCIETY OF JAPAN.

A MEETING of the above-mentioned society was held in the Public Hall, Yokohama, on the evening of Saturday, 22nd inst., Mr. J. JOHNSTONE in the chair.

After the minutes of the previous meeting had been read, the following candidates were unanimously elected members of the Society:—H. E. Watanabe, Hiromoto (President of the Imperial University), Professors B. Koto, J. Milne, and Aug. Revilliod, Mountjoy Squire (Commander, R.N.), and Messrs. J. Fraser, G. Scott, A. Futami, T. Tanaka, T. Enami, S. Nihara, A. R. Lamb, and W. Willett.

A lantern exhibition was then given. Prof. MILNE opened the proceedings by a lecture on earthquakes, illustrated with maps showing the distribution of volcanoes and of districts subject to seismic phenomena throughout the world, and more particularly through Japan, and by a set of slides from photographs of the destructive effects of earthquakes in all parts of the world. Some of these showed the danger of arched structures where earthquakes prevail, others how fractures follow vertical lines of apertures in buildings, and one how the end house of a row may be, so to speak, heaved away by the momentum of the others, which themselves remain intact.

After this there was an exhibition of a popular nature. There was a large attendance of members and visitors who seemed to thoroughly appreciate the pictures, but, unfortunately, the proceedings were considerably curtailed by a mistake of the exhibitor, who threw the words "good night" on the screen while there were still many slides to be shown. The audience rose and were out of the hall before there was time to explain the matter. The lantern was (with the trifling exception mentioned above) ably handled by Mr Takashima Matsuchi.

MESSRS. NEGRETTI AND ZAMBRA request us to publish that they pay a large sum for the exclusive right of taking photographs in the Crystal Palace and grounds, as certain enquiries have recently been made about this matter.

Answers to Correspondents.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

E. C. (Burslem).—*Elastic Collodion.* Probably the best way of tempering collodion, and conferring upon it a superior degree of elasticity, is to add a very small proportion of castor oil, which is freely soluble in alcohol. This does not wash out when subsequently immersed in water, but remains permanently in the film. Only by trial—using, of course, a minimum—can you find out what quantity to add to the normal collodion to modify the film in accordance with your requirements. We should not be inclined to recommend camphor for this purpose, because of its volatility leading to alteration by atmospheric exposure.

PHOTOPHANE.—We really cannot undertake to advise about investments. You have the Prospectus, and this gives you ample means of pushing your own enquiries.

LEDBURY.—*Grains and Grammes.* Our Correspondent points out the disadvantage of adopting the contracted mode of spelling the word "grain," for with many writers who do not take the trouble of dotting the "i," there will often be a doubt about the manuscript as to whether grain or gram is intended. For this reason we have always advocated the retention of the French method of spelling the word "gramme," so as to avoid error from this cause, and give the printer specific guidance.

M. P. G.—*Oxalate of Silver*, when exposed to light, undoubtedly gives off carbonic acid, and leaves residual silver in the blackened product. From this decomposition you cannot very well argue against the oxychloride theory, there being so little analogy between the two cases; the oxalate carrying its own reducing agent, whilst none is present when the white chloride of silver is exposed to light, unless water takes part in the reaction, as has been asserted.

F. C. S.—*Impure Sulphites.* You are, doubtless, alluding to Mr. Bothamley's statement on this head. If so, you have only to test for *sulphates*, which may creep in from atmospheric oxidation, by adding to the aqueous solution of the sulphite a considerable excess of hydrochloric acid, and then testing with chloride of barium. Be careful to use pure water and HCl, and do not leave the sulphurous acid liquor exposed to the air, for it is certain to absorb oxygen, and so pass on to sulphate.

OLD HAND.—Change of name. You are never likely to hear again of Mr. Russell Manners Gordon under his old name, for the distinguished amateur bears now the Portuguese title of the Marquis de Torrebello, and resides in Madeira.

T. A. B.—*Citro-Chloride Paper.* The following proportions for a plain paper are given by Herr A. Ost, of Vienna, in Ernst Lietze's Manual of 1888. Salting solution, one part of common salt in thirty parts of water. Sensitizing bath—

Nitrate of silver...	1 part
Water	12 parts
Citric acid	1 part
Alcohol	1 ,,

Mr. Bedford described his mode of working albumenised paper with separate baths at the March technical meeting of the Photographic Society. See also page 274 of the NEWS for April 11th.

W. H. B. (Cambridge).—*Reduction of Over-Intensified Negatives.* 1. Those which have been made too dense by treatment with bichloride of mercury and ammonia may be reduced again with weak hypo, or even with very dilute hydrochloric acid. 2. Negatives originally under-developed, and therefore hard, may be improved by Mr. Farmer's process, which consists in soaking them in hyposulphite to which a small quantity of a lemon-yellow solution of potassium ferricyanide has been added. Furthermore, in printing from hard negatives, try Mr. Cowan's method of sunning from the back as a mode of toning down the violent contrasts,

J. D. and AMATEUR received.

VOL. XXXIV. No. 1652.—*May* 2, 1890.

CONTENTS.

IMPROVEMENTS IN THE MOUNTS OF LENSES.

A MEETING, the results of which are likely to be of considerable benefit to photographers in this and in some other countries, was held last week in London under the auspices of a committee of the Photographic Convention, and a long report thereof is given in these pages to-day. A fair number of representative opticians accepted the invitation of the committee to be present at the meeting, the object of which was to consider the subject of standards for photographic lenses. From the general drift of the conference, it seemed that there was little chance of the opticians being likely to agree to issue diaphragms with apertures made in accordance with one particular standard, but when it came to the question of establishing a system of uniform standard flanges, there seemed to be a fair chance of agreement, and some practical steps are about to be taken to achieve the desired result. To the photographer this means that hereafter he may be relieved from the necessity of carrying an unnecessary weight of wood and brass, in the form of adapters or extra camera fronts, and that one of his objections to adding to his stock of lenses will be removed. Another blessing which may result from the meeting of last Friday will be the general introduction of camera screws of uniform dimensions.

The consideration of the subject of standard bayonet joints for lens mounts, in place of the ordinary screws, was considered by some of those present to be too large a question to take up now, but it is evident that the time lost by a photographer in screwing and unscrewing lenses, especially when they have fine threads, is a grievance, and sometimes causes the loss of a picture. Mr. G. L. Addenbrooke once exhibited at the Photographic Society some lenses specially mounted, so as not to be open to the objection just mentioned, and he has stated that he never knew what comfort in landscape photography was before he had those lenses made. If they were to be examined at the adjourned meeting of the opticians next week, their criticisms of them would be of public interest. Mr. Dallmeyer expressed the opinion last Friday that screw bayonet joints were better than pin bayonet joints for lenses.

Various opticians are feeling their way in the direction of adopting aluminium mounts for lenses, and some lenses so mounted are in the market, as already published in these pages. Some opticians are hesitating in the matter because they think aluminium to have an uncertain character, for opera-glasses are often returned for repairs because their aluminium mounts get out of order. Cases are known in private life of such mounts oxidizing somewhat suddenly into white clay, when accidentally subjected to unfavourable conditions. Defects of this kind are more likely to become evident when the mounts are made of bad aluminium, and as good aluminium is twice the price of bad, it is evident that the latter may often find its way into cheap opera-glass mounts, which are largely made in France. In fairly trying aluminium for lenses, the best only should be used. Pure aluminium has much the same physical characteristics as pure copper, but differs from copper strongly in its chemical characteristics. This is especially noticeable in its electro-chemical relations. To favour the use of aluminium in lens mounts, only the best metal should be employed, and the user of the lens should take reasonable care not to store it in a damp place.

Perhaps an alloy of aluminium may be found which will be better for lens mounts than the pure metal; but it must consist almost entirely of aluminium, or the saving in weight as compared with the weight of brass will be insufficient. A firm in the North once made harness of an alloy of aluminium and bismuth, which alloy was subject to slow oxidation, so that the harness could be polished simply by rubbing off with leather the thin coating of white clay formed.

MR. EIFFEL A PHOTOGRAPHER.

An exhibition of competitive designs for the "Great Tower" in London has been opened at the Hall of the Drapers' Company in Throgmorton Street, the place in which the coming City Photographic Exhibition is to be held. The promoters, "The Tower Company, Limited," of whom Sir Edward Watkin is said to be the leading spirit, have offered prizes of five hundred guineas for the best, and of two hundred and fifty guineas for the second best design and estimate for a tower of not less than 1,200 feet in height. The curious show of designs is well worth seeing, and will be open from Monday until Friday next week, between midday and five o'clock in the evening, admission free. On Wednesday next the doors will not be closed until ten o'clock at night.

Mr. Eiffel has thus found his imitators. It may not be generally known to the followers of the art-science that Mr. Eiffel is an amateur photographer, and that a photo-mechanical print from one of his negatives was issued some months ago in the *Revue Suisse de la Photographie*. The scene represented was a "Festival of the Grape Growers," in which the peasantry were represented enjoying high jinks at what may be called a harvest home in the wine districts.

The most remarkable specimen of retouching—if so it may be called—which we have ever seen, came from Mr. Eiffel, and was the work of a professional photographer in Paris. When the Eiffel Tower was three parts finished, we spent some weeks in studying the details of its construction, and after returning to England, received a large photograph of the tower from Mr. Eiffel. The photograph was not quite up to date, having been taken a fortnight previously. On representing this to Mr. Eiffel, he asked for its return, and it was sent to him.

A few days later the same photograph came back to us in a case by express passenger train, with the tower represented as it stood the night before the photograph last left Paris. By the skill of the hand-artist, so much of the tower had been added to the original photograph, that the picture extended off the albumenized paper, and some one or two inches of the picture were thus upon the mount itself. The work had been beautifully done; the top of the tower matched the lower part in colour and photographic appearance with surprising fidelity. Those photographers who do not like to call this an instance of retouching are at liberty to call it an example of the lateral extension of the photographic image.

Photographic Club.—Subject for discussion on May 7th, "Lenses for Instantaneous Work;" May 14th, "Photographic Definition."

Mr. Stanley.—In a graphic description of the explorer's arrival at Dover, a daily contemporary says:—"Just before the company on deck made a movement for the shore, an enterprising photographer succeeded in taking a picture of the group. He was in the nick of time. He seemed to be quite satisfied. But if the photographer got all he wanted from Mr. Stanley, it was more than anybody else got. The interviewers got nothing from him, except that he felt well enough, but that he wanted rest. They bored him."

THE GERMAN PHOTOGRAPHIC UNION.

The following notice has been sent to us of a meeting of German photographers and an exhibition at Eisenach, under the presidency of K. Schwier, a photographer of world-wide celebrity. The nineteenth travelling meeting of the German Photographic Union will take place from the 27th to the 29th of August, 1890, in Eisenach.

An exhibition is again, as formerly, connected with this meeting, in which both members and non-members are allowed to take part. To this the members of the German Photographic Union are hereby kindly invited. Non-members will be gladly welcomed as guests, but they must present themselves personally to the directorate. Notices should be sent to the Court photographer, C. Remde, Eisenach, or to the president, K. Schwier, Weimar.

The Ordering of the Entertainment.

Tuesday, August 26th.—In the afternoon at 1 o'clock, a reception of the guests at the railway station: members of the local committee will attend to meet the train; their mark of distinction will be a dark green and yellow ribbon. In the evening at 8 o'clock, issue of entertainment tickets in Gröblers Restaurant (Zimmermann). For members and those belonging to them, the price of these tickets will be ten marks, for non-members thirteen marks.

Wednesday, August 27th.—In the forenoon at 8.30, opening of the nineteenth Travelling Meeting in the hall of the Clemda.

Commencement of the Order of the Day.

At one o'clock, the opening and official inspection of the exhibition in the manufactory; at 2 o'clock, a general departure for the Wartburg; official inspection of the Wartburg. Taking of groups. Evening concert in the Wartburg.

Thursday, August 28th.—In the forenoon at 8.30, continuation and conclusion of the Order of the Day. At 12 o'clock, a breakfast at the Tivoli. At 1 o'clock, a promenade in the environs of Eisenach. In the afternoon at 6 o'clock, a general entertainment at dinner, and a sociable meeting in the hall of the Clemda.

Friday, August 29th.—In the forenoon, at 10 o'clock, meeting and breakfast at Gröbler's Restaurant (Zimmermann). At 11 o'clock, a general excursion by carriages to Wilhelmsthal. At 2 o'clock, a general lunch at the same place at 1.50 marks a head. At 3 o'clock, a farther expedition to Ruhla, and thence back again to Eisenach. At 8 o'clock in the evening, a meeting in the Clemda, and announcement of the decisions of the committee appointed for the distribution of the prizes. Conclusion of the nineteenth Travelling Meeting.

The Order of the Day.

August 27th, at 8.30 in the forenoon:—*(a)* Transaction of necessary business. *(b)* The inquiry box; every member of the directorate is willing to receive inquiries. *(c)* Opening and inspection of the Exhibition. At 1 o'clock the Exhibition will be opened for those who take part in it.

Wednesday, Aug. 27th, from 1 o'clock to 2.30.

Thursday, Aug. 28th, from 1 o'clock to 6 o'clock.

Friday, Aug. 29th, from 1 o'clock.

On Friday, Aug. 29th, from 1 o'clock at noon; on Saturday, Aug. 30th, from the same hour; and on Sunday, Aug. 31st, the Exhibition will be also open to the public.

The Exhibition will be divided into three principal groups, containing fourteen divisions, having relation to the following prizes of honour, medals, and diplomas:—

The First Group.—Particular announcements and institutions:—(*a*) Constant.—(1) A gold, a silver, and a bronze medal, given by the Festge Institution, for the three best collections of picture groups of two persons in cabinet form; open to members and non-members of the German Photographic Union*; (2) The gold medal of the Kindermann Institution, for the best collection of single portraits of the size above mentioned, open to members and non-members of the German Photographic Union*. (*b*) Occasional.—(3) A prize of honour given by Herr F. Brandseph, Sen., and Herr H. Brandseph, Jun., of Stuttgart, consisting of a silver cup (of the value of 200 marks), for the best collection of landscapes in cabinet form, open to members and non-members of the German Photographic Union*; (4) The Eisenach Institution of Herr C. Kindermann Hamburg, consisting of a complete travelling apparatus, 13 by 18 c.m., of the value of 200 marks, for the best collection of a day's work (24 cabinet portraits), from smaller studios, open only to members of the German Photographic Union*; (5) A prize of honour given by Herr Fr. Ritter v. Voigtländer, of Brunswick, consisting of 300 marks, and another of 200 marks, for the best taking of a group; open to members and non-members of the German Photographic Union.*

The Second Group.—General Union Announcements:—These are intended for members and non-members of the German Photographic Union; professionals, amateurs, and manufacturers may take part in them. (*a*) Constant; (6) A silver medal for a new rapid copying process. The successful inventor will not be bound to communicate any of the mysteries of his invention:* (*b*) Occasional. Here are announced as first prizes, silver and gold medals with diplomas attached; as second prizes, bronze medals; as third prizes, diplomas. The number of these distinctions will be left to the sole direction of the awarders of the prizes. These prizes will be conferred:—In Section A (for pure photographic work); (7) For the best photographs in the portrait department, either enlargements or direct pictures. The enlargements must, however, be executed in the studio of the exhibitor; (8) For the best specimens in the landscape department, among which are to be included studies of architecture and instantaneous takings of movable objects; (9) For distinguished performances by amateurs; (10) For distinguished scientific work, whether of a photographic or literary character. In Section B (for photographic work and reproduction); (11) For the best photograph in the department of reproduction; (12) For the best specimens in the field of new mechanical printing processes. In Section C (13) for special works, improvements, meritorious manufacture of photographic utensils (backgrounds, decorations, furniture, cameras, &c.), praiseworthy exhibitions of raw materials (chemicals, papers, cartoons, &c.) With these last a judgment of the Examining Committee of the German Photographic Union must be sent in, upon which the awarders of the prizes can rely in their decision.

To the Exhibition under the first and second groups every kind of photograph is admitted, also all appliances necessary or useful to the photographic art—such as chemicals, apparatus, backgrounds, &c.

According to No. 6 of the regulations, to the prize competition in group A7—10, as also to the institutions 1—5 (so far as the contrary is not expressed), only such photographs are admitted as have never been before shown in any exhibition, and have been prepared since the last travelling meeting of the German Photographic Union at Weimar. It is requisite for competitors to declare that these regulations have been complied with. There can be no exception to them under any pretext whatsoever.

All photographic pictures must be sent in a condition suitable for exhibition, that is to say, in frames or as collections in a portfolio. It is preferable for pictures to be framed without glass, that they may be more conveniently judged.

Pictures will, in the Exhibition, be divided into groups, &c. For this reason, landscapes, portraits, &c., should not be mounted in a single frame, but they should be framed separately, every kind by itself.

The Third Group.—Exhibition for foreigners:—(14) To satisfy numerous requests, and to maintain the friendly relation of the German Photographic Union with foreign photographers, the committee has decided upon making a special department of the Exhibition for their interests. To this all foreigners (non-members of the German Photographic Union), especially our American and English colleagues, are hereby invited. In the conditions of competition in this group, No. 6 of the above-mentioned regulations must be carefully attended to. Photographs exhibited in this group may have been exhibited elsewhere, but it is desirable that in this group also no older work than that of last year should be represented. Contributors to the third group are not bound to pay anything for space, but it is earnestly desired that the objects sent in should be left to the travelling care of the German Photographic Union, in order that they may be seen by those members of the Society who have not been able to visit the Exhibition.

In this group also gold, silver, and bronze medals, as well as diplomas, will be offered for prizes (as above).

For works, &c., in all the groups which are not successful enough to win a prize, honourable mention may be obtained.

In addition to this, especially deserving performances in any part of photography which are not included under any of the above-mentioned numbers may be especially rewarded by the consent of the directorate.

The prizes offered by the Union will only be given in cases where the exhibits reach the highest (and not the relatively highest) degree of excellence in their respective divisions.

The awarders of the prizes will consider in the first place the knowledge of technique, and artistically good execution. These features will be of the first importance in all the prize distributions.

Preliminary applications with respect to the exhibition are to be addressed to the President of the German Photographic Union, Herr K. Schwier, Weimar. Applicants included in the provisions of the second group (7 to 13) will receive thereupon application tickets, which are to be sent, after being filled up, to Herr C. Remde, Eisenach, up to the 15th of August. Exhibitors included in the third group may apply without any form.

The delivery of the exhibits must be made between the 20th and 25th of August, at the exhibitors' own cost and risk, to Herr Otto Volpel, in Eisenach. Works intended for the Sections 1 to 5 of the first group, as well as of Number 6 of the second group, are to be sent to Herr C. Remde, Eisenach, without any previous application. Upon each package is to be marked clearly, "For the German Photographic Union." Every exhibit and every

* All particulars may be obtained on application to the President.

frame—with the exception of pictures belonging to the Institutions 1 to 5—must bear upon their backs the address of the exhibitor. Every box and every cover must bear the same address on its inside. The exhibitions will, according to their estimated worth, be insured on the part of the German Photographic Union against danger of fire and water. No further accountability will be admitted. It is better, when possible, to send amount for the space required with the application. The charge for space to members of the Union is three marks for every square metre: to non-members five marks for every square metre of table, wall, or ground superficies. Every commencement of a square metre will be reckoned as a full square metre. Applications for space over ten square metres will be entitled to ten per cent. discount.

For members of the German Photographic Union included under the second group, Division A, Nos. 7 and 10, as also Division B, Nos. 11 and 12, the two first square metres will not be reckoned. From foreign exhibitors, so far as they come under the third group, no space hire will be exacted. Candidates coming under the six institutions (Nos. 1-6), will pay no space hire. The reckoning of the space hire is regulated (except in the case of unusual claims) after the actual space occupied by the pictures or frames. Applications or deliveries arriving too late can only be furnished with spaces remaining unoccupied.

The return of the goods will be at the cost of the exhibitor, after reimbursement of charges at the conclusion of the exhibition, by Herr Otto Volpel, in Eisenach.

Remittances of money must be directed to Herr L. Frank, in Eisenach.

From the afternoon of the 29th August, till Sunday the 31st August inclusive, the exhibition will be open to the public. The exhibitors are therefore required to allow their exhibits to remain on view until the exhibition has closed.

The awarders of prizes, who are chosen according to the statutes regulating the Exhibition, consist of nine persons; of these, three are chosen by the directorate. The Travelling Association then announces a list of eighteen persons chosen by acclamation, and of these the remaining six persons are chosen by the exhibitors present. These nine officials are the awarders of all the prizes. They must, according to Nos. 2 and 3 of the business regulations, form three groups, each group consisting of three persons.

The first of these groups has to judge about the Sections—I.; the second about the objects exhibited in II. A and B; and the third group has to judge about the objects exhibited in II. C. and III. The resulting judgments of these three groups will be afterwards proved and confirmed by the Collective Jury. The Collective Jury may substitute a gold for a silver medal, as an award of the highest distinction.

The critical meetings of the Exhibition will relate to—

(*a*) Lectures and Discussions.

An Entertainment Lecture will be delivered by ———. There will also be introduced to the assembly ———.

(*b*) Communications respecting the adjudicated awards and prizes for all objects exhibited will be announced on Friday, the 28th August, at eight o'clock in the evening.

The Directory of the German Photographic Union—K. Schwier, Weimar, President. The Local Committee—C. Remde, Eisenach, Court Photographer.

THE FOUNDING OF THE LANTERN SOCIETY.

The inaugural meeting of the new Society bearing this title, and having for its chief objects the development and popularisation of the optical lantern, took place in the Theatre of the Society of Arts on Friday last, when some 200 visitors attended.

The chairman of the council, the Hon. Slingsby Bethell, prefaced the demonstration by an apology for the impromptu nature of the programme, which, he said, was due less to a lack of resources than to an earnest desire to make an early beginning, with the view to placing the claims of the new body well in the foreground. Having explained that the session proper would commence on the 1st of October next, and that all applications for membership received in the interval would be treated as belonging to the year then to be entered upon, he appealed to all present who were interested in the optical lantern to bring the claims of the Society before their friends at the first fitting opportunity, and continuing, said it had been agreed that the programme of the Society might best be carried out:

1. By the engaging of premises in some central position in London, at which the meetings of the council and of the Society might be held.

2. By acquiring suitable apparatus for the purpose of giving exhibitions of general and scientific interest to both members and their friends.

3. By obtaining the services of specialists in every branch of art or science suited to optical demonstration.

4. By offering—as far as the funds of the Society will permit—remuneration or awards for the development of the optical lantern, and of all apparatus pertaining thereto.

5. By imparting instruction to those who are desirous of learning how to effectively manipulate the optical lantern, to produce slides and apparatus, and to efficiently employ the same both in private and in public.

6. By assuring for the members of the Society special and advantageous terms from manufacturers and others for the purchase or loan of apparatus and slides.

7. By forming a large and comprehensive loan collection of lantern transparencies pertaining to art, science, and kindred subjects; such loan collection to be placed at the disposal of every member, upon conditions to be laid down by the council.

8. By providing a means of inter-communication between the members of the Society, whereby each member may be made acquainted with the private collections of his fellow-members, and may be able to negotiate a mutual loan if so desired.

9. By arranging an interchange of demonstration between photographic, microscopical, and other societies interested in optical lantern work.

The Chairman further remarked:—

"The marvellous powers of photography to illustrate and bring home to the mind in the most striking and faithful manner, especially by means of the optical lantern, the glories and beauties of nature, the treasures of art, and the wonders of science, induced us to hope that, by drawing together persons thus interested, a powerful society may be formed on an intellectual, educational, and scientific basis, with a recreative and social side, and of which our present meeting is but a crude and incomplete example.

"Although not a club in the usual sense of the word, still we hope soon to have a suitable habitation, where meetings of members will be held, papers read, discussions encouraged, and some photographic work carried on.

"Composed, as I believe we shall be, of scientific and practical men, of professional as well as of amateur photographers, of those learned in chemical, microscopical, and optical science generally, constructers and designers of every description of apparatus, we shall endeavour at least to benefit and instruct each other, if not those unconnected with us, and bring to greater perfection in all its phases and aspects—technical as well as artistic—this particular branch of the art and science which we have adopted for study.

"Another aim that the Society has in view is the formation

of a large loan collection of lantern slides, complete in its classification, arrangement, and method of illustration.

"As we advance, scientific and photographic societies, educational bodies, schools, and institutions will have facilities of affiliating themselves to us, and thus obtaining much assistance from our extensive photographic library, so to speak. Members will, of course, receive this privilege to a larger extent, and many more, for eventually we hope to offer them additional advantages, viz., the use of dark rooms and laboratories for all photographic operations, the production of lantern slides in particular.

"America has already made great strides with the optical lantern, so we shall endeavour to put ourselves *en rapport* with our cousins across the Atlantic, and to interchange with them for photographic illustrations of *their* grandest wonders of nature representations of some of *our* homely but lovely scenery.

"Welcoming, as members of the Lantern Society, all thus interested, we shall develop, I trust, into a large and influential body, competent and willing to place any fresh knowledge and experience that we may acquire within the reach of others of like tastes.

"Finally, growing in strength, we may number amongst our body members, practically and scientifically, more learned in particular branches of science, who will come forward and initiate us into the meaning, mysteries, and beauties of many of our unappreciated photographic illustrations."

Following the address of the Chairman, which was cordially received, there were projected upon the screen about 130 fine slides divided into three different lots, and comprising—Views by Ferrier and Soulier, of Italian and Swiss scenery, ice scenes in Swiss mountains and at Niagara; astronomical photographs of the moon and of the eclipse of the sun, taken with the Lick telescope; views of the Forth Bridge and of the engine room of the *City of Paris* after the accident to her machinery; representations of old lace from the South Kensington Museum; a large collection of Woodbury slides of Indian and Syrian Temples; types of heads; views of English Cathedrals, both interior and exterior; insects mounted direct on glass; views of the Paris Exhibition; and a large collection of landscapes from all parts.

In the interval that elapses before the programme of the Society is entered upon in earnest, the Council will be busily engaged in drafting bye-laws, selecting suitable accommodation for the future home of the Society, and the Honorary Secretary, Lieutenant C. E. Gladstone, R.N., will be pleased to forward full particulars and applications for membership, upon receipt of a post-card at 6, Bolton Street, Piccadilly, London, W.

THE PHOTOGRAPHIC CONVENTION AT CHESTER.

THIS Photographic Convention for 1890, under the presidency of Mr. C. H. Bothamley, will be held at the Town Hall, Chester, on June 23rd to 28th, 1890, inclusive.

The Council consists of Messrs. Conrad Beck, W. Bedford, C. H. Bothamley, F. A. Bridge, J. J. Briginshaw (Hon. Secretary and Treasurer), F. P. Cembrano, E. Clifton, E. W. Cowan, A. Cowan, T. R. Dallmeyer, G. Davison, A. R. Dresser, F. Evans (Local Hon. Secretary, Eastgate Buildings, Chester), W. P. J. Faweus, S. H. Fry, Friese Greene, A. Haddon, F. Haes, H. M. Hastings, Adolph Levy, A. Mackie, E. W. Parnell, A. Pringle (Chairman), T. Samuels, J. Traill Taylor, G. Watmough Webster, and J. B. B. Wellington.

SUPPRESSION OF HALOS IN PHOTOGRAPHIC PROOFS.—*Paul Henry and Prosper Henry.*—The authors succeed in avoiding these halos by covering the back of the plate with a layer of normal collodion holding in solution a small quantity of chrysoidine. This varnish having an index of refraction little different from that of glass, completely suppresses the halos.—*Chemical News.*

LANTERN SLIDE WORK.*

BY GODFREY BINGLEY.

WHAT I have to say this evening will, in a great measure, be based on my own short experience, and though what I may bring forward may be "stale, flat, and unprofitable" to many of the older members of this Society, I trust that it may be of some little assistance to any who have not yet attempted to make lantern slides. For some reason or other, only a small proportion of the members of this Society sends in lantern slides to our annual lantern exhibition. Certainly there is no better or more pleasing way of showing photographs than by exhibiting them on a screen with the aid of the optical lantern; the fact that so many people go to our lantern exhibitions is in itself a proof that this branch of photographic work is appreciated, and to the photographer the artistic qualities and *failings* of his work become more manifest when seen enlarged on the screen, than when viewed on a small print. Before proceeding farther, it may be well to allude to the best size of camera to work with, as some amateurs do not care to make anything but lantern slides. Small cameras are made to take a plate $3\frac{1}{4}$ square, and although this small-sized camera may do for ordinary landscape work, it is practically useless for instantaneous photography, such as marine and seaside studies, cattle pieces, and other moving objects. Many of you, no doubt, who work quarter-plate cameras, have found them too small for this class of work, and have been considerably disappointed, when the plate has been developed, to find nothing but a barren waste of water, or a field with the surrounding fence the only subject on the plate. I would therefore advise nothing less than quarter-plate, or 5 by 4.

Lantern slides are made either by "direct contact," or by "reduction" from the negative by re-photographing from the negative by means of the camera and a reducing frame.

Slide making by "direct contact" is the plan most generally adopted by amateurs, because of the ease with which it can be done by artificial light; but I very much prefer, however, making slides by "reduction," especially if working from a half-plate, or larger negative. No doubt very good slides are made from quarter-plate negatives by "contact," but how few pleasing ones are made from the larger sized negatives in this way, for when taking a view with the camera, you study the proportions and composition of the picture in relation to the size of the plate you are working, and not simply with the idea of printing out a picture $3\frac{1}{4}$ square; it is only by "reduction" you can get the full value of your negative on the lantern plate. Another advantage obtained by "reducing" is that a soft slide may be made from a hard negative, and also good slides from poor and faulty negatives, negatives from which it would be impossible to make a slide by "contact," or even to get a passable silver print from. In "contact" printing, the length of exposure required of course varies according to the make of plate used and the density of the negative. I think it is best to have one fixed distance from the light for exposing the slide, and to vary the *time* of exposure according to the density of the negative, rather than vary the distance. If the *distance* the frame is held from the light be varied, always remember that the length of exposure will increase as the squares of the distances the frame is held from the illuminant, and not in a numerical ratio; for example, if an exposure of

* A paper read before the Leeds Photographic Society.

10 seconds at one foot distance is sufficient, and the distance is increased to 3 feet, an exposure of 90 seconds will be needful.

For making slides by "reduction" some sort of reducing frame is required to hold the camera and negative: the apparatus is, however, very simple. It consists of a baseboard on which there is a sliding block to carry the camera at one end, and at the opposite end a deep box about ten or twelve inches square, open at the end next the camera, the other end holding a sliding carrier in which to place the negative.

"Reductions" are best made by daylight. The plan I adopt is as follows: Having placed my reducing frame, on which I have fixed a quarter-plate camera, in front of an upper window (in the lower square of which I have inserted a sheet of ground glass for the purpose of diffusing the light), I place the negative in the sliding carrier and carefully focus it, then stop down the lenses to U.S. 16, and expose the plate in the usual way. The exposure, of course, varies according to the light and density of the negative as in "contact" printing; at this time of the year the exposure will vary from 30 seconds to a minute with a fair average negative. A long exposure and retarded development will give warm tones; a short exposure and active development will give black tones, and I find the tones are always warmer if the exposures are made on a bright, sunny day, than even with a long exposure on a dull day. I advise, however, that workers should adhere to one *standard strength* of developer; and for "contact" printing one *fixed distance* from the light for exposure, and produce the tone desired solely by the time of exposure. If this plan is adopted I am sure much more satisfactory results will be obtained than by continually altering the strength of the developer, and varying the distance the plate is held from the light.

Most of the slides prepared by professionals are made by the collodion or wet plate process; very fine slides are also made by collodio-albumen.

It is generally considered that there are no lantern slides at all equal to those made by one or other of the collodion processes. No doubt for brightness and "sparkle" collodion slides are difficult to surpass, but there is often a want of half-tone about them, consequently little gradation between the high-lights and shadows. The gelatine plate is running the collodion process a very hard race; and I venture to think—though it may be considered somewhat heterodox to even throw out the mere suggestion—that for softness and half-tone the gelatine plate holds the field. I do not propose to enter into any details of the working of the collodion processes, neither do I intend to say anything about preparing gelatine plates, as I have had no experience in any of these branches of photographic work. I know there are several of our members present who prepare their own plates, and who have in the past given us the results of their experience. There are many good makes of plates on the market, and for those who do not care to make their own, I would say try several makes, and then stick to those you find give you the best results. I may say in passing that gelatino-chloride plates are of no use for reducing, as they are far too slow.

Lantern plates are usually developed either by ferrous oxalate, pyro and ammonia, pyro and washing soda, or hydroquinone. Formerly ferrous oxalate was the favourite developer for lantern plate work, but it is not so much used now. The tones produced by it are always of a cold grey, and considerable care is required when working with it, for the slightest contact of hypo will cause a fog to spread over the plate. Pyro and ammonia is a favourite developer with many workers; some add a little carbonate of ammonia to obtain red tones. A very good developer, and one easy to work with, is washing soda and pyro. It gives pleasing tones, but it has, however, the disadvantage of often leaving a yellow fog on the plate, which must be removed by a clearing solution, and, unless considerable care is used in clearing, many of the finer details may be entirely removed; and if allowed to remain in the solution too long, the plate loses its sharpness, and looks flat when shown on the screen.

Hydroquinone has now come into great favour as a developer for lantern plate work, and is the one I prefer to all others. It gives absolutely clear glass, and the slides require no clearing after development, unless they have been taken from thin or faulty negatives, when a little local clearing by means of a camel's hair brush may be required.

The formula that I like the best is one given by Thomas and Co. with their plates, viz.: —

No. 1.—Hydroquinone	...	...	160 grs.
Sulphite of soda	...	...	2 ounces
Brom. amm.	...	...	20 grs.
Citric acid	...	...	60 ,,
Water	...	...	to 20 ounces
No. 2.—Carbonate of potash	...	...	2 ounces
Carbonate of soda (crystallized)		...	2 ,,
Water	...	...	to 20 ,,

Use an equal quantity of each.

I generally develop four plates with 2¼ ounces of solution. I have developed as many as ten, but four are quite sufficient, for after that number the developer becomes very slow, and has a tendency to "block" the shadows.

Eikonogen is said to produce similar results to hydroquinone, but I have never tried it.

It is better to develop slides by artificial light rather than by daylight passing through some non-actinic medium; for daylight is so variable in its intensity that it renders it difficult to judge the proper density of the slide in consequence; whereas, by artificial light, you can have one fixed standard, and develop the slides to pretty nearly an equal density. It is desirable to develop a little denser than required, as the slide loses a little of its density in the fixing bath. Immediately after placing the plate in the developing solution, pass a camel's hair brush (kept in a cup of water near the developing dish) rapidly over the plate, to remove any small air-bubbles which may be on the surface of the film. After development, the plate requires a good wash under the tap, and should then be placed in the fixing bath:—

Hypo	...	...	...	...	1 ounces
Water	...	...	...	...	20 ,,

And allowed to remain there for a few minutes after all whiteness has disappeared, so as to ensure thorough fixation. Wash again after removal from the fixing solution, and place it for a short time in a saturated solution of alum to harden the film. If working with hydroquinone, on no account place the plate in the alum solution *before* fixing, or you may obtain a result not to be desired.

If from any error in exposure, or if the slide is taken from a thin negative, causing it to be opaque when there ought to be clear glass, this opacity may be removed with a

little care and patience by the aid of the following clearing solution :—

Sulphate of iron	3 ounces
Alum	1 ounce
Sulphuric acid	1 ,,
Water	20 ounces

Pour a little of this solution into a small dish, and place a basin containing clean water near; then, holding the plate in the left hand, with the sky or fogged part slanting downwards, so as to prevent the clearing solution running into the details of the picture, paint with a small brush the clearing solution over the fogged part of the plate until it becomes quite clear, frequently dipping the plate into the water during the process to prevent the clearing solution spreading over the plate. Any over-dense shadow may also be reduced in this way. Before doing this, take care that the slide has been in the alum bath. Lantern slides must be quite free from fog or veil; the above method will quite remove this defect, and, if care is used, the details of the picture will not be injured. After fixing and clearing as above-mentioned, the slide should be washed for a few hours in the same way as an ordinary negative. On taking the plates out of the washing trough, it is advisable to give each a good rinse under the tap, so as to remove any particles of grit that may have been deposited on the film from the washing water, and then place them on edge to dry—not in a rack—where they will be kept quite free from dust.

There are several methods of toning slides, but I have not tried any of them, for I much prefer the rich brown, or even the black tone of the ordinary photograph, to the red or other tints that may be obtained by toning, and I believe there is considerable risk of a toned slide fading away.

When the film is thoroughly dry, it is ready for mounting for the lantern. I am sorry to say there is often but little care exercised with this part of the work, and many an otherwise good slide is completely spoiled by the careless and slovenly way in which it is mounted. The photograph and cover glasses should be absolutely clean, and free from all dust and finger marks: and here I would say a word as to the thickness of the cover glasses. Very thick glass adds much to the weight of the slides, as you will find to your cost if you have them to carry far. The *extra thin* covers are the nicest, but, unfortunately, they soon break when using the slides: even the pressure of the fingers will do this; therefore, I would say, use a medium thickness of glass, and take care to have it free from scratches and air-bubbles. The paper mask to be placed between the photograph and the cover glass should be of suitable shape, and carefully adjusted to the size of the photograph; on no account use the circular masks, as this shape is most inartistic, and frequently quite spoils the picture. The masks having one white side and the other coloured are the best, as the white side is an indication to the lantern operator as to the side of the photograph to be placed next the light, and it also enables the name of the slide to be written upon it. The binding strips should be neatly put round the edges of the slide, and two white or coloured discs placed on the two top corners of the front of the slide, to show at a glance which is the top of the view; then carefully remove all finger and gum marks, and the slide is complete.

We have to thank Mr. Walter Colls for an excellent print of Dr. Emerson's "Breezy Marshland."

PHOTOGRAPHIC EXHIBITIONS IN INDIA.*

In photographic circles, both at home and in India, there exists much divided opinion on the subject of exhibitions and awards. One section is totally averse to both, another would hold the one and withhold the other, a third is strongly convinced that both exhibitions and medals are as the breath of our nostrils, whilst a large and growing section believes that the present system of awards must be purified and elevated. Without expressing a decided opinion on the question one way or the other, it will afford food for reflection if the system on which the Society has hitherto held its exhibitions is examined. Those diligent members who study the rules are doubtless aware that one of the objects of our Association, as laid down in the constitution, is to hold exhibitions of photographs and photographic apparatus. It is not stated how often; but they are to be held in Calcutta. As a matter of fact, these exhibitions have been held regularly every year since the resuscitation of the parent society in 1887, and since then no little money—let alone time and energy—has been spent in carrying out this object. For instance, at the late exhibition, no less than six gold and eighteen silver medals were awarded; and, as there were only sixty-four competitors in all, no one is likely to turn round and accuse the committee of dealing them out with a niggard hand. Of this number of competitors nineteen only were of the so-called professional class, whilst forty-five were amateurs. With this preponderance of the amateur over the professional, it might naturally be supposed that the amateurs would have carried off at least half the medals, but this was not the case. No less than five gold and nine silver medals went to the nineteen professionals, and only one gold and nine silver to the forty-five amateurs. But the members of the Society come out of the analysis even worse than this, for only six medals rewarded them for all they contributed, and not one of these was in gold. With such a result staring us in the face, it may well be asked if the proportion of medals offered to Anglo-Indian amateur photographers was generous enough to foster that emulation which, some say, only medals can impart.

On the other hand, there is a strong feeling amongst those who say they know that, if medals are not freely offered to outsiders of both classes of workers, our exhibition walls will be covered with silver prints of that respectable mediocrity which they suppose is the supremest effort of the Anglo-Indian amateur photographer. Now this contention is not unreasonable if the only way of alluring the best pictures to our walls is by a liberal offer of medals. But is this the case? If the best pictures are necessary for educational purposes—and this may be granted—every one of the pictures sent by the home professionals might have been purchased and sent out to us at probably less cost than we actually paid under the present system. And as regards the local professional photographers, who contributed not a little to the embellishment of our show, I have been told by one of the largest winners amongst them that they are not likely to feel aggrieved, should the Society decide to exclude them from medal-winning, so long as they are all placed on the same footing. It is sufficient inducement to them, I am assured, to be allowed to exhibit their works in an attractive form, with the name of the firm displayed over them. There should be no difficulty in arranging to have this done. And the

* From the *Journal of the Photographic Society of India*, April.

amateurs at home and in America whose works contributed so much to our pleasure and profit, how are they to be rewarded, if not with medals? This is the real difficulty; and, if it is wished that the best works shall grace the walls of our exhibition, the Society must be careful how they treat their brethren who have become masters of photography. In this matter it may be submitted that there is a discreet middle course in which to steer. We should welcome the works of every well-known amateur, no matter what his particular school is, because there is good to be got from the study of all good pictures, and be prepared to offer inducements to amateurs to exhibit such as are acceptable and fitting in the circumstances of each case. So competition should be optional. To all who care to compete, let medals be given; and to those who do not, let the Society engage to pay all expenses of the exhibits to and from Calcutta. If this is done, promising every care and attention to prevent damage or loss, and engaging that these honourable exhibits shall be well mounted and hung, there is every reason to believe that the applications for space will be as great, if not greater, than they have ever been before.

In arranging an exhibition on these lines, precautions would have to be taken to divide off the exhibits so that no invidious comparisons could be made between the medalled pictures—presumably second-rate—of, let us say, the writer, and a greatly superior one of the same class of, say, Dr. Emerson sent *hors concours*.

This is a matter in which the members themselves are directly interested—one, if I may say so, of almost vital importance to the Society—so that its discussion in the columns of the Journal is earnestly invited, seeing it is likely to be of the greatest value to the Committee when they next meet to settle the prospectus of the next annual exhibition.

CROSSING NATIONAL FRONTIERS WITH DRY PLATES.

Photographic Scraps for May contains some useful information for Continental tourists, and states that in Sweden and Norway the photographer will have no difficulty at the Custom House, provided the photographic baggage is not too large; but as good stocks are kept in the country, it is not necessary or advisable for a traveller to burden himself with large quantities. There is no restriction on the taking of photographs in the streets or country, but, naturally, for church or museum interiors, one requires to obtain permission, not difficult to obtain as a rule. In Russia, things do not go so smoothly with the tourist. Photographic apparatus for tourists' *own use* is charged with a duty equal to about 8d. per English pound, and plates with one of about 3½d. per pound. Photography on its amateur side is so little known to the Russian Custom House officials that they have not the faintest idea of the sensitiveness of plates or papers to the light; consequently the poor traveller has a rough time of it, unless forewarned. To take views almost anywhere, one requires the permission of the authorities, and, to obtain this permission, tourists should obtain before leaving home a certificate from the Russian Consulate in England, that the bearer desires to take photographs, is an amateur, and proposes to use such photographs only for his own pleasure. In Holland and Belgium, plates carried by tourists are liable to pay ten per cent. duty. As a rule, the Customs do not insist upon opening the boxes; but, as the revenue officers are apt to suspect smuggling in every form, they may at times examine the plate boxes; still, it will be done politely, and in a properly appointed dark room. In France, plates, on entry, whether for the traveller's own use or as merchandise, are dutiable to the extent of 18·50 francs per 100 kilos, equivalent to about 3s. per pound English. Apparatus, if well worn, and clearly for personal use, is passed free of duty; if new, ten per cent. is levied. Usually the Customs officials are most easy about the enforcement of these duties, and about the examination generally, when it is plain that one is not other than an amateur; but the tourist who goes loaded with heavy photographic impedimenta may find he has to pay these legal, but seldom imposed, duties. Most officials have by this time learnt the disaster which follows the opening of plate-boxes in an ordinary room, and are daily becoming more complaisant with amateur photographers, and seldom or ever does any trouble arise. As to the taking of photographs, but little restriction is imposed, as long as fortifications are avoided. In Italy, plates are dutiable to the extent of 1s. per kilo, or, if accompanied by a certificate of origin from the Italian Consulate in London, of 3d. per kilo. Apparatus for personal use is not charged for. If the camera is new, the Customs may insist on a duty being paid, but will, if requested, give a certificate, on the production of which the duty will be remitted on leaving the country. The officials are very tender with amateur photographers, and a few boxes of plates, and any apparatus, may be readily passed without either trouble or payment of duty. Photography may be freely practised in any and every town the informant thinks, with the restriction not to approach too near fortifications. He recommends the use of hand cameras, which the populace have not yet learnt to recognise as such, as a tripod and large camera always collect a crowd of ever-present idlers. In Germany, the actual imposition of duty leviable on all plates is more honoured in the breach than in the observance, whilst apparatus enters free. The Customs are well used to tourists carrying cameras, and no difficulty is met with. If the traveller should be asked, as a matter of form, to open a box of plates, he is taken courteously to the dark room; the examination is made promptly, and, with many apologies, he is speedily released. If fortifications are avoided, there is practically no limit to the opportunity for taking photographs, unless it is in some of the watering-places, where permission must be asked for, and is readily obtained. In Switzerland, the favourite hunting ground of tourists, photographic and otherwise, the greatest attention is given to the needs of photographers, and the Customs allow both apparatus and plates carried by tourists for their own use to pass free of duty. Photographing seems absolutely free from restriction throughout the country. Greece offers a wide and interesting field, and the Custom House people offer no difficulty in the way of free import of tourists' apparatus and plates. Visitors should not carry too many of the latter. There is no restriction on the taking of photographs, and it is needless almost to say that Athens and its neighbourhood offer sufficient scope for weeks of pleasant labour. The ruins of Olympia in Western Peloponessus, the Vale of Tempe, and the monasteries of Kalembak in Thessaly, the Islands of Corfu and Zante, with Eleusis and Dafne, are all easily reached. Travelling in Greece, even in districts remote from the beaten track, is quite safe. For farther information see *Photographic Scraps*.

PHOTOGRAPHY IN FICTION.*

ANOTHER interesting story of an equally speculative character, though of a totally different kind, is told in an American magazine. A photographer, who calls himself a photographic artist—explaining that this title costs nothing, and affects people with much the same sort of respect as those well known combinations of letters B.A., F.S.A., M.A., F.R.G.S., D.D., with many others—is invited down to a small country village to photograph a Church inside and out. The lady, the deceased incumbent's daughter, a certain Miss Jones, who has invited him, is taken suddenly ill on the day of his arrival, and is unable to see him. Not to waste his precious time, the photographer takes portraits of the present incumbent—to be sold after to his flock for money to be spent in repairing the church—of two children, and a pair of lovers. Every professional knows both these last to be among the worst of subjects. The lovers insist on arranging each other; the children cannot be arranged at all. The result is commonly disastrous. Even if a good picture be obtained, people paying for the work are mostly dissatisfied. The mother finds the true image of her spoilt brat different from her ideal. The face of the beloved is not, for the lover, sufficiently heavenly; but the eye of the camera is not like that of the mother or the lover—it is not blind. If, on the other hand, a bad picture is the reward of the photographer's toil, then is the wrath of Romeo a terrible and awful thing, while Juliet weeps silently as she gazes in disgust upon her distorted image. As for the spoilt child, after spoiling in its turn some half-dozen plates, seven devils enter into it, causing its last state to be worse than its first: and, in the end, with some twenty eyes—a very Argus—and about ten times that amount of fingers—a very Briareus—it reflects, collectively, the portrait of a catherine wheel in mid-effervescence. To return, however, to the story. The lady recovers. The photographer is placed outside the church in the very worst position. That ecclesiastical building is sacrificed to an elaborate stucco tomb, with a narrative of the many virtues of the lady's father, the Rev. Jeremiah Jones, M.A. In the inside of the church, the operator, placed once more in the worst position, is instructed to make a picture including the pulpit, the vicarage pew, and the communion table, adorned on either side with the commandments blazing in gold on an amethyst ground. In vain the unhappy photographer explains that the amethyst will turn to opal, and inky sable occupy the place of gold. The lady is not to be moved by what she doubtless considers baseless representations to defraud her of her stipulated right. Difficult, indeed, is it to persuade her that it is impossible to include in the same picture the font, which lies at the other end of the sacred edifice. But this being at last accomplished by the rhetoric of the photographer, he sets at once to work. The windows of this church are filled with wondrous creations in green and yellow glass, not altogether the best light for photography, but bravely the artist struggles on. During some twenty minutes' exposure, he beguiles the time by reading the names of the pew occupiers printed on their respective pews, the gorgeous decalogue, one or two commemorative tablets, and a neatly written placard attached to a pillar conveying the information that a man may not marry his grandmother. Marvelling much at this, he moves to put on the cap, when suddenly the "church-going" bell, as Cowper calls it, begins to toll. Though a lion be in the path between the artist and his instrument when the time is come to affix the cap, yet will he affix it. The inhabitants of the hamlet cluster together at the church door to learn the meaning of this unwonted bell-ringing. Among them appears Miss Jones herself, majestic but angry. "What irreverent action is this?" asks the lady. "How should I know, madam?" replies the astounded photographer; adding in an injured tone, "and, as for irreverence, have I not been standing here for half-an-hour with my hat off in a draught as bad as that of a blacksmith's bellows?" It is afterwards found that some of the village fry have rung the bell, but the photographer has gone in a pet to develop his picture. It grows, considering the difficulties he has had to meet, well. The carefully worked cover of the communion table—the long loving labour of some pious Dorcas—commences its second birth; the carved oak rails emerge one after the other in satisfactory sequence, the decalogue appears—alas! no longer aglow with its original glory—the vicarage pew, and the pulpit. Yes, the pulpit; but what is this spectral figure which rises out of it? An old gentleman with a black mole, in a black gown, with white hair and in white bands. The photographer marvels, but presents in due course, the photograph to Miss Jones. "Ah!" shrieks that lady, "it is—it is papa!" and faints forthwith. "I keep," says the photographic artist at the conclusion of this little American tale, "I keep that negative among my curiosities."

This paper might perhaps, in the reader's estimation, be called "Fiction in Photography" with a nearer approach to descriptive truth than is made by its present title, "Photography in Fiction." Several other tales may be found by any who care to search for them, which in no degree lessen or detract from the fitness of the former heading. One, for instance, tells of a young girl about to become a bride, who, chancing to take refuge under a poplar during a storm, received an image of that tree through her petticoats on her left leg, leading afterwards to a remarkable identification. Tales of the photographic effects of lightning are indeed frequent. Besides the well-known anecdote of the boy who climbed a beech on a Sunday for the sake of robbing a bird's nest, and was punished with a distinct view of a bough and a bird's nest on his right cheek—a gruesome spectacle, and a warning to all who chanced to meet him—we have the story of the sailor who went through life with the picture of a horse-shoe affixed to the mast-head on his back; of the respectable tradesman who bore the device of a couple of sovereigns on his side, supposed to be taken from these two pieces of metal in his purse; and—though this last story seems, as regards its genuineness, open to doubt—the story of the unhappy lover who died of love, and bore, as the doctor who anatomised him after death discovered, the portrait of his lady's face distinctly photographed on his heart.

* Continued from page 313.

NUMBER 6 of *The Photographer*, published at Cincinnati, Ohio, issues as its supplement a specimen of engraving by the Photo-Engraving Company, of New York, the subject being an unacknowledged reproduction of Mr. H. P. Robinson's picture, "He never told his Love," here entitled—perhaps more appropriately—"A Morning Chat."

DINGLER'S *Polytechnischer Journal* says that to persons unaccustomed to it, ammonia in the atmosphere becomes mischievous when present in the proportion of 0·05 per cent.; 0·06 per cent. will kill most animals in an hour and a half. Up to 0·03 to 0·05 per cent. the system can become accustomed to ammonia; but beyond that proportion the ill effects very rapidly come on.

Notes.

It would be interesting to have a little more information concerning a process of photographic reproduction invented by Mr. Henry Sutton, of Ballarat, Victoria. It has been stated that "The inventor follows a method essentially different from those hitherto used. He makes his prints on gelatine, but not by means of dots or lines, nor even by the process for printing with fatty inks. He utilizes the ordinary gelatino-bromide plates, and impressions them in front of the object to be reproduced. The surface of the image is simply covered with a piece of gauze, and afterwards developed and fixed in the ordinary manner. The plate is then placed for five minutes in a bath of water heated from 79° to 80° F. The excess of water is removed by a sojourn of ten seconds in alcohol. After drying, the plate is placed in a copper planchet, heated to 212° F. over a Bunsen burner. This degree of heat is maintained for about two minutes. The plate is then ready for the printing press."

Professor C. Michie Smith, at the last meeting of the Royal Society, described a curious application of photography to scientific research. The object desired was a method of determining surface tensions by measurement of ripples. Ripples are set up on the surface of the liquid by means of a tuning fork, and the surface is then photographed along with a suitable scale. The lengths of the ripples can thus be obtained by micrometic measurement of the negative. This, we fancy, represents the latest instance of the long list of instances in which photography has been utilised to solve some problem of science.

It is stated that the great and unprecedented rise in the price of platinum is causing much anxiety. The various platinum printing processes have been received with such favour by the photographic public that the demand for the metal has, during the past four months, much exceeded the possibilities of supply. As we mentioned some time ago, there was for a few days literally a famine in platinum, the manufacturing chemists being unable to make the photographic salts in sufficient quantities to meet the orders of their customers. They have now got over this difficulty, which of course was only a temporary one, but the inevitable has come about—a great rise in the price, the quotations now being about forty per cent. higher than they were a year ago.

The awkward point in the matter is that platinum, unlike a chemical product, cannot be cheapened by the increased demand. It must be sought for, and dug from the mines, and up to the present moment the uses have been so limited that it has not been worth while for anybody to "prospect" likely sources for its discovery. No doubt this will be done now that photography promises to be an outlet for its utilization, but meanwhile the supply, to use commercial phrase, is "short," and likely to be so. A financial paper suggests that some of the active minds engaged in mining matters might do worse than embark in the search for platinum. If so, perhaps platinum may be discovered in "paying quantities"—at least, this is what the prospectus of any platinum company is sure to say.

Artists are less fortunate in their actions at law when the point at issue turns upon the faithfulness of a portrait than photographers. It is a curious fact that in the disputes as to the fidelity of a photograph which have found their way into the English County Courts, not one case in twenty has been decided against the photographer. It may, of course, be that the photographer starts with the advantage of the generally received dictum that photography cannot lie, but too much stress must not be laid on this, as we may presume a judge is not to be biassed by outside opinion, but will decide every case on its merits. However this may be, the fact remains as stated.

Nor do we think that if English County Court judges imitate the example set them recently by a Berlin legal authority, the result would be any different. In this case the fidelity of a portrait in oils was in dispute, and the judge in question adopted the course of directing the lady to array herself in the dress in which she sat to the artist. The plaintiff obeyed, with the consequence that the judge gave a verdict in her favour. It is a common thing, as most photographers know, for a lady to find fault with her photograph, not because the face does not please her, but because the dress does not "come out" as she expected. Hence, if an order similar to that of the Berlin judge were enforced, the chances of a victory would be still more problematical than they are at present. On the whole, photographers need not fear the consequences of the Berlin episode.

A good deal of complaint is being heard as to the way the frames of the pictures sent in to the Royal Academy are treated. An artist friend the other day had his picture returned, which he did not mind so much, as it was within the right of the immaculate Forty to reject it; but what he did object to was that the frame—an expensive one—was irreparably damaged. It is well known that the pictures are stacked one against the other, and that, to get some particular picture, the carpenters will not hesitate to walk over the stacks, much as a cat walks the tiles, but scarcely so lightly. If they wore slippers not so much harm would be done, but, in the case of hob-nails, the frames suffer. When complaints were made two or three years ago to the Photographic Society that the frames were damaged, we believe the Council compensated the owners. The Royal Academy is above this consideration, and all the artist can do is to suffer in silence, or write to the newspapers.

THE PHOTOGRAPHIC CLUB.

THE annual report, list of members, rules, and proceedings of the Photographic Club, for the year 1889, has just been issued. This popular Club was established in 1879. On the title page its honorary officers are stated to be:—*Trustees*—William Bedford and Frank Haes; *Committee*—W. Benham, F. P. Cembrano, H. E. Davis, E. W. Foxlee, A. Mackie, E. A. Newell, J. B. B. Wellington, and J. W. Zaehnsdorf; *Curator*—H. M. Hastings, F.I.C.; *Recorder*—E. Clifton; *Librarian*—C. E. Hesse; *Secretary and Treasurer*—F. A. Bridge, East Lodge, Dalston Lane, E. The meetings of the Club are held every Wednesday evening at Anderton's Hotel, Fleet Street, London. The treasurer's report sets forth that the year ends with a balance in hand of £129 17s. 6d., and that it has other funds and property.

The longer papers read at the meetings of the Photographic Club have for the most part been published in these pages, but a variety of useful information will be found in the official reports of its meetings.

In the discussion on "Purifying Water for Photographic Purposes," Mr. A. M. Levy said that, roughly speaking, there were three kinds of impurities in water—insoluble substances, which might be removed by filtration; soluble substances, such as chlorides of sodium and magnesium; and gaseous matters. The latter might be ammonia or carbonic acid, and might be got rid of by boiling the water for about half-an-hour. The addition of a little carbonate of soda would precipitate the chlorides. The usual amount of solid matter in the water supplied by the London water companies was about two grains to a gallon. The impurities in water varied considerably according to the local conditions of supply; sometimes water contained as much as twenty-five to thirty grains per gallon of calcium or magnesium salt. A ready method of estimating the quantity of magnesium or lime salt was by means of Clark's test. A solution of definite strength was made of Castile soap in spirit; this was added, drop by drop, to a measured quantity of the water to be tested until the froth formed on shaking was permanent. The amount of the salts present was arrived at by the amount of soap solution used. He considered the most convenient method of purifying water for photographic purposes was boiling it for half-an-hour and then leaving it to cool. It was an advantage to boil the water in a kettle that was already encrusted with scale. In reply to questions, he said that the addition of a small quantity of alum would precipitate organic matters, as also would iron chloride; but such treatment was more suitable for ordinary purposes than for photographic ones. Permanganate of potash would also get rid of organic matter. The hon. secretary stated that solutions were sold to prevent the incrustation of boilers. He had seen some dark fluid which was reported to have been very effectual. Mr. Levy said that there were scores of such in the market. The acting ingredient in all was carbonate of soda; they were coloured to fancy.

In the discussion on "Copying Engravings and Woodcuts for Lantern Slides," Mr. A. Cowan said that if the originals were faulty, as many woodcuts were, it was impossible to get a good solid picture from them. The little ink on the dark parts allowed the white paper to show through. This, when magnified, became much more apparent. If the lines in the original were continuous the copy would be all right. Mr. T. C. White thought it probable that a negative made from a tracing in ink would be better than from the original. Mr. E. W. Foxlee stated that some years ago he had made some 10 by 8 transparencies from pictures in *Punch* for showing on the 30 foot screen at the Polytechnic Institution. As the lenses used in the lantern were not achromatic, it was possible one fault hid the other. He did not think there would be any difficulty in copying a well-printed engraving or woodcut. Mr. Woods said that there was no fault of this kind in copies of copper-plate engravings. He thought the texture of the boxwood on which the woodcuts were made might influence the result. Mr. A. Mackie thought that much depended on the paper on which a woodcut was printed. If a rough paper were used, the ink did not reach the hollows in the grain. The American illustrated periodicals were printed on very smooth, hot-pressed paper, and the impressions were very perfect. Mr. J. Nesbit found that Mawson's photo-mechanical plates were excellent for work of this kind. For making drawings for copying there was nothing better than Stevens' ebony stain; it left a splendid solid black, and dried very quickly. Mr. Foxlee thought wet collodion the best for this class of work. Mr. Richmond said that he obtained good results on ordinary Ilford plates developed with ferrous oxalate and intensified with mercury. He had also found that Mr. Wellington's method of intensifying answered well. He had somewhat modified and, at the same time, he thought, simplified the formula. His modified formula was—

A.—Silver nitrate	... ...	100 grs.
Water	... ...	7 ozs.
B.—Ammonium sulphocyanide	... ...	240 grs.
Water	... ...	7 ozs.
C.—Hypo.	... ...	240 grs.
Water	... ...	7 ozs.

For use, take one drachm of each of the three solutions in the order named, and apply to the plate. He preferred a fairly long exposure.

THE LATENT PHOTOGRAPHIC IMAGE.*

BY C. H. BOTHAMLEY, F.I.C., F.C.S.

THE composition of the material composing the latent image is as yet an unsolved problem. It is generally regarded as being identical with the dark products obtained by the more prolonged action of light, and this view is supported by the fact that they are affected in the same way by many re-agents. Carey Lea's observations (*loc. cit.*) that a brief action of reducing agents on silver compounds produces invisible but developable images, whilst prolonged action produces visible images, and that in both cases the images are identical in behaviour respectively with the invisible and visible latent images produced by light, is also very strong evidence in favour of the same conclusion, but their identity is not yet proved. The resistance of the latent image and of the darkened products to the action of nitric acid render it highly improbable that they consist of metallic silver; and it was for a long time supposed that they were sub-salts of silver corresponding with a sub-oxide Ag_4O, described by the chemist Wöhler. According to this view, the latent image consisted of a minute quantity of silver sub-chloride Ag_2C, or sub-bromide Ag_2Br, or sub-iodide Ag_2I, containing half the quantity of halogen present in the ordinary salts. Attempts to obtain Wöhler's sub-oxide have been made

* Concluded from page 321.

without success by Newbury, Muthmann, von Pfordten, and Bailey and Fowler, and, of course, attempts to make the sub-chloride from it have failed also. The methods used for the purpose of obtaining the sub-oxide were, however, not such as, reasoning from analogy, were likely to be successful. They all depended on the possibility of stopping the reduction of an ordinary silver salt when half the radicle had been removed, without at the same time producing any metallic silver. Even in the case of well-known and stable compounds this is a matter of much difficulty, and when dealing with a substance such as ordinary silver oxide, itself extremely easily reduced to the metallic state, the difficulty of definite partial reduction becomes enormously greater. Moreover, chemists are acquainted with many cases in which the haloid salts of an element are much more stable than the corresponding oxide—the mercurous salts which are analogous to the silver salts afford an excellent example—and, therefore, the non-existence of a silver sub-oxide is no proof of the non-existence of silver sub-chloride, sub-bromide, or sub-iodide. This question remains for further investigation.

Carey Lea found (*loc. cit.*) that by the action of reducing agents, such as ferrous hydroxide, alkaline milk or grape sugar, &c., on silver salts, he obtained products very similar in properties and composition to the dark products produced by the action of light. They are very slowly attacked even by strong nitric acid, but more rapidly by potassium iodide, and are decomposed by ammonia, sodium thio-sulphate, &c., with separation of metallic silver. He regards the two sets of compounds as identical in character, and considers them to belong to the indefinite class of compounds known as "lakes," or, in other words, as compounds of silver sub-salts with varying proportions of the ordinary salts, the compounds having a much higher stability than the sub-salts themselves. In order to recall the mode of formation of the dark products, which vary in composition according to the conditions of their preparation, but always contain less halogen than the normal silver salts, Carey Lea proposes to call them photo-salts of silver; thus, photo-chloride, photo-bromide, photo-iodide, &c. We do not know, however, that these bodies are really "salts" in the usual acceptation of the term; and although the names are very good, it would be better to speak of them more generally as photo-compounds or photo-products.

Hunt stated* that when silver chloride darkens in presence of air and moisture, half the chlorine is replaced by oxygen, and researches by Hodgkinson,† the details of which are not yet published, led him to the conclusion that the darkened silver chloride is an oxychloride of the formula Ag_4Cl_2O, formed from four molecules of silver chloride AgCl. AgCl. AgCl. AgCl., by the substitution of an atom of oxygen for two atoms of chlorine, thus AgCl. Ag. O. Ag. AgCl. Experiments, the details of which have not been published, cannot of course be criticised or properly appreciated; but it is very difficult to believe that a silver oxychloride could form in presence of strong nitric or hydrochloric acid. It is also important to observe that the supposed oxychloride is not a reduction product of silver chloride, but a substitution product, the quantity of chlorine and oxygen in the formula given being sufficient to neutralise all the combining power of the silver. Silver oxide is known to be readily reduced to the metallic state by developers; and if we assume that this reducibility of the oxide is transferred to the oxychloride, which would be the case if the compound had the constitution represented by the formula given, the formation of the oxychloride would certainly explain the production of an image on development. On the other hand, it is equally well known that silver oxide is very readily attacked by acids, and it is not easy to see how an oxychloride could retain the instability of the oxide in presence of reducing agents, and yet offer so great a resistance to the action of acids. If further experiments prove that the darkened products are really an oxychloride and an oxybromide respectively, it is not at all probable that they will have the constitution which has been suggested.‡

It seems quite certain that the presence of oxygen is not essential to the formation of a dark photo-product from a haloid silver salt. Dry silver chloride darkens readily when exposed to light under benzene† or in hydrogen,‡ or apparently in presence of any substance which can take up chlorine, whether the particular substance contain oxygen or not. It is obvious, however, that we are not entitled to assume that the products formed are identical, and the behaviour of a substance out of contact with air and moisture gives no direct evidence as to its behaviour when oxygen and water are present.

It has not yet been definitely proved—indeed, from the nature of the case, absolute proof is almost, if not quite, impossible—that the material composing the latent image is identical in composition with the visible products found by the more prolonged action of light, although the various facts previously referred to furnish very strong evidence that this is the case.

The exact point which we seem to have reached is this, that the latent image is a photo-chemical reduction product containing a lower proportion of halogen than normal silver chloride, or bromide, or iodide, and much more easily reduced to the metallic state; but the problem of its composition and constitution still remains to be solved.

THE PHOTOGRAPHIC SOCIETY OF INDIA.—The steady progress of this Society, as recorded in its journal, is evidenced by the accession of thirty-six new members since January.

THE CAMERA CLUB.—The fifth of the series of photographic exhibitions at the Camera Club will be open on and after Tuesday, May 6th, to visitors on presentation of their cards. The exhibition will consist of photographs by the late Mrs. Julia Cameron, and by the kind co-operation of Mr. H. H. Cameron the Club is able to exhibit a fully representative collection. Amongst other pictures will be the portraits of Sir John Herschell, Lord Tennyson, and Robert Browning, produced by Mrs. Cameron more than twenty years ago. The pictures will be on view for about two months.

A NEW REAGENT FOR PYROGALLOL.—At a recent sugar meeting of the Mulhouse Industry Society, M. Matthieu-Plessy described a new reagent for cane sugar, grape sugar, and pyrogallic acid, consisting of a solution of lead paranitrate ($PbHNO_4$) in an excess of melted ammonium nitrate (*Mon. Scient.*, December, page 1,146). It is prepared by melting 51 parts of ammonium nitrate, and adding to it 34 parts of lead nitrate and 21 parts of lead hydrate. The reagent melts at about 115° C., and in contact with glucose it gives a cherry-red colour; with cane sugar the colour of *café-au-lait*; and with pyrogallic acid a chrome-green colour.—*Pharm. Journ.*

A MEETING ABOUT LENS STANDARDS.

The Lens Standard Committee of the Photographic Convention having publicly asked all photographic opticians interested, to meet it at the Mona Hotel, London, to consider the subject of standard diaphragms and flanges, the meeting took place last Friday night. Mr. A. Haddon occupied the chair, and among the opticians present were Mr. T. R. Dallmeyer, Mr. Conrad Beck, Mr. J. Turnbull (Wray and Son), Mr. W. Taylor, Mr. H. W. Hobson, Mr. T. P. Watson, Mr. A. Rayment, and Mr. M. J. Swift.

The Chairman stated that the committee had been appointed at the Birmingham meeting of the Photographic Convention in 1888, to consider the lens standards of the Photographic Society, and what improvements might be made therein. It had previously done a certain amount of work. The results of their deliberations that evening would be brought before the Convention at its meeting this year in Chester. He hoped that the opticians present would be led by the voice of the majority. He could not see why photographers should have to carry about in their apparatus a greater weight than is necessary of wood and brass.

The Chairman then distributed some printed copies of the original report of the Lens Standard Committee of the Photographic Society, as follows :—

"We, the Members of the Committee appointed by the Council of the Photographic Society of Great Britain to consider and report upon the best means of attaining uniformity in the construction of apertures in the 'diaphragms of lenses,' 'flanges,' and 'camera screws,' have now the honour of communicating the result of our investigations. Our aim has been, as far as possible, to combine the nearest approach to scientific accuracy with practical utility. Had either consideration exclusively engrossed our attention, modified recommendations might have resulted. Dividing our Report into three divisions, the first section has reference to 'Lens Diaphragms,' the second to 'Flanges and Adapters,' and the third to 'Camera Screws.'

"*Lens Diaphragms.*—With regard to Diaphragms, we recommend—1st. That the aperture of the standard-unit diaphragm should have a diameter equal to one-fourth the equivalent focus of the lens, and be marked '1,' the approximate equivalent focal length of the lens itself being engraved on the mount. 2nd. That diaphragms with smaller openings should have apertures diminishing in area to the extent of one-half from the unit standard downwards, and be marked successively 2, 4, 8, 16, 32, 64, &c. These numbers would indicate to the practical photographer that if a given sensitive film requires with the unit stop an exposure of one second, the introduction of a smaller one would necessitate an exposure of as many seconds as the numbers marked on it ; in other words, each stop would require double the exposure of the preceding one. Should a lens not admit of a diaphragm with an aperture as large in diameter as one-fourth its focal length, nor exactly any one of the above-mentioned sizes, we still recommend that all the apertures be made in uniformity with the above scale, with the exception of the largest, which should be marked with the number its area requires in relation to the unit diaphragm. In the case of a lens having a working aperture exceeding in diameter one-fourth its focal length, the diaphragm should be marked in fractions (as ·5, ·25, &c.), in uniformity with the standard apertures, according to the sizes of their relative apertures. We further advise that diaphragms required to be made with apertures intermediate to the standard sizes should invariably be marked with numbers corresponding to the ratio of their area to the aperture of the unit diaphragm.

"*Flanges.*—We advise the construction of flanges with internal and external screw threads of a standard series, for attachment to cameras having screw threads adapted for screws, 1½ in., 2 in., 2½ in., 3 in., in external diameter, and made with twenty-four threads to the inch 3½ in. The 3½ inch to have twenty-four threads to the inch on the inside, and twelve threads to the inch on the outside. If larger ones are required, we recommend that they increase in size one inch in diameter, from four inches upwards, with twelve threads to the inch both internal and external. We also recommend the manufacture of a series of adapters, with inner screws made to carry any existing lens, and with outer ones corresponding to the next or other larger size of the standard flanges above described. Hereafter, whenever practicable, the screws cut on the mounts of all newly-manufactured lenses should be suited to one of the above-sized standard flanges.

"*Camera Screws.*—With regard to camera-screw connections, we recommend that henceforth all screws fitted to cameras either for attachment to the stand, for fixing rising fronts, or for other movable parts, should be either $\frac{3}{16}$, $\frac{1}{4}$, $\frac{5}{16}$, $\frac{3}{8}$ of an inch in external diameter, and in pitch of thread and other details in accordance with the generally recognised Whitworth standards for the above-mentioned sizes.

"The Council of the Photographic Society of Great Britain having accepted this Report, have directed that a series of standard flanges and camera-screws be constructed and kept in the custody of the Society, and be called "The Photographic Society's Standards." Upon application to the Secretary, these standard flanges and screws will be shown, and printed copies of this Report be given to those manufacturers of lenses, flanges, and camera-screws who may be desirous of adopting the above standards.

"*The Gallery, 5a, Pall Mall, S. W., July,* 1883."

Mr. W. Taylor said that he thought the fixing of lens standards to rest entirely with the public. To make a change would involve each optician in much expense, so any change must come by the optician feeling that if he is not up to the times, the times will leave him behind. His firm used the standards of the Photographic Society, and did not see that there was any advantage in making a change, for to change a system of lens fittings meant a change of all patterns, the abandonment of old stock, and involved other losses, which few opticians would voluntarily agree to make. Interchangeable screws on gas-pipes are one thing, and lens screws are another ; the latter are far more difficult to make, and many of the standard microscope screws in the market are not so well made as would please a good mechanic. They exceed the proper limits of error. In some of them he had found an error of $\frac{1}{100}$ of an inch, and that was a serious thing. If any society wished to alter the present system relating to photographic lenses, steps would have to be taken to provide members with standard gauges, and the means of correctiug those gauges when they began to wear. He thought the Whitworth thread to be good and suitable for lenses. Some photographers wished bayonet fittings for their lenses ; such fittings were liable to become unsteady ; the turning of them out was not convenient to the lens maker, and they were far more difficult to make interchangeable. The lens screws adopted in the system of the Photographic Society are coarse, and this to some extent meets the requirements of the man who wants a bayonet joint to save time. His firm so made their lenses that any number of them would screw into the same flange upright, and this was a subject which should be considered when dealing with interchangeable fittings. The gauges for making the screws should be true to $\frac{1}{10000}$ of an inch.

Mr. Conrad Beck remarked that in the cutting of standard screw threads for the microscope, the point of the tool wears, so causes an inaccuracy at the bottom of the thread, which in other parts is of the right size ; therefore special means have been devised for afterwards cutting out the surplus metal at the bottom of the thread.

Mr. M. J. Swift did not think a little shake in the screw of a lens mount to be worth considering at all ; the mount is not particularly faulty if it holds tight.

Mr. T. R. Dallmeyer did not think that any optician individually would go to the unnecessary expense of altering the whole of his system. He thought that any standard adopted should be universal, and not confined to England alone. The French Photographic Conference had done well to invite persons from other countries to meet and discuss this question of lens standards, for diaphragm apertures are not wanted only for England, but for every country. He had first suggested the decimal system for lens apertures, and the decimal standard

seemed to have been taken up by the French; indeed, he thought that it would be taken up universally. The Conference did not take up exactly his standard, but Dr. C. Fabre, who was a great authority, considered his (Mr. Dallmeyer's) standard to be better than that adopted by the French. Had he been at the meeting, he should have suggested the ratio for apertures of one over the root of ten, instead of one over ten. The tendency of the times at home and abroad is towards the decimal system, and he thought that that system should be employed for lens stops. He thought that a bayonet guage would be convenient and valuable, but that they should have a screw bayonet catch, and not a pin bayonet catch. He also thought that they should follow up what had been done by Continental scientific men, and that a system based upon the English inch would not be likely to become universal.

Mr. W. E. Debenham hoped that the Committee had had the French report, from which it appeared that the English Society's standard had never been mentioned at the Paris Conference. That Conference had considered and rejected Mr. Dallmeyer's standard of *f* over ten, but had adopted the decimal standard. Lens mounts made according to the standard *f* over four of the Photographic Society are now largely made and sold, so the fact should have been brought under the notice of the Conference. He did not see why a good and exceedingly convenient standard, once made and adopted, should be thrown aside without very strong reasons. Very likely the decisions at the last International Conference might be thrown aside when the Conference meets at Brussels.

Mr. Dallmeyer said that one over the root of ten was "the" decimal standard, and that one over ten was "a" decimal standard.

Mr. Arthur Rayment was then invited to speak by the Chairman, and replied that he came to listen, and not to talk.

Mr. T. P. Watson said the same.

The Chairman then read the following letters :—

Dear Sir,—We, as manufacturers and dealers, find that the standard flanges $1\frac{1}{2}$, 2, $2\frac{1}{2}$, 3, &c., with the Whitworth threads, are generally approved of, and almost the first question buyers put now is, "Are these standards?"

Charles Reynolds & Co.

72 and 73, Fore Street, London, E.C., April 25th.

Dear Sir,—I regret very much that a very important engagement, of which I was unaware when you honoured me with a call, will not allow me to attend the discussion this evening.

If I had been able to attend, the points I should have pressed would have been these:—

1. That all flanges should be made in progressive sizes of $\frac{1}{4}$ inches, as 1, $1\frac{1}{4}$, $1\frac{1}{2}$, and so on.

2. That a universal pitch of thread be used for flanges having an aperture up to $2\frac{1}{2}$ inches, viz., a pitch of 18 threads per inch.

My reasons for the above propositions are :—

In regard to No. 1.—That as many makers have issued a large number of lenses having flanges of varying apertures, and threads of varying pitches, it would become quite easy for any maker to manufacture adapters that would screw on to all existing lens mounts, so as to make them fit a standard flange.

In regard to No. 2.—The screw pitch I have chosen is technically known as $\frac{5}{16}$ Whitworth, or $\frac{3}{8}$ gas. The screw chasers for working these threads can be obtained at almost any decent tool shop, and being a Whitworth pitch, is almost universally used. The depth of the thread being only $\frac{1}{32}$ of an inch, it also admits of fairly light flanges being used without the danger of the bottom of the threads being cut right through the body of the flange.

Again regretting my inability to attend, I am, yours truly,

David W. Noakes.

Billingsgate Street, Greenwich, London, S.E., April 24, 1890.

Mr. Conrad Beck thought the questions before the Committee to depend largely upon an arrangement between manufacturers. Could they, by meeting, arrange any system mutually satisfactory? In the matter of aperture dimensions he did not think that they should agree. As regarded lens-screws, he did not think that so much accuracy as in microscopic apparatus was necessary, especially with the majority of cameras at present in use. The great difficulty in the way of adopting standard flanges is, that at present there are a great number of flanges in the market which they would still have to make lenses to fit after new flanges had been adopted. In any new system the flanges now employed should be utilised as much as possible, rather than that fresh ones should be stamped; therefore it seemed desirable to ascertain what flanges are now mostly in use. After a time the tendency would be for the public to come gradually to the standard sizes.

Mr. William Bedford remarked that before the Photographic Society framed its system of standard apertures, the late Mr. Dallmeyer had a standard system of his own; but when the Committee of the Photographic Society met it obtained little assistance from professional opticians, who were not represented as they should have been. The Committee fixed on the standard of *f* over four. He thought that too much might be made of the decimal system, because when the sizes of stops are once fixed, the practical photographer does not want to know what their dimensions are; indeed, the change to *f* over the root of ten would be of no value whatever to the professional photographer. As regarded flanges, the Committee of the Photographic Society did not consist of first-rate mechanics, but it satisfied itself what the diameters should be. He agreed with Mr. Taylor, that this part of its report might be improved by additional definitions. If the Convention had standards made, opticians, perhaps, would have no difficulty in getting similar standards made by the same firm. He believed that Mr. Dallmeyer would find that this system has come too late, because the system recommended by the Photographic Society has spread, not alone in this country, but throughout America and largely in Continental Europe.

Mr. Dallmeyer thought that in selling lenses it would be well to state the intensity ratio every stop represents; such information ought to be conveyed.

Mr. F. A. Bridge remarked that stops were not always made accurately.

Mr. Taylor said that some opticians took into consideration the fact that the light is condensed by the front lens of a doublet. He had not suggested that lens screws should be accurate to $\frac{1}{10000}$ part of an inch, but that the standard gauges should be so made.

Mr. Beck said that if the committee would decide upon the sizes, the matter of making the lenses interchangeable might be left to opticians, because the Whitworth standards in ordinary use are available.

Mr. A. Cowan stated that when Whitworth made the standard gauges for the Photographic Society, it was understood that he was also ready to make them at any time for opticians.

Mr. Dallmeyer then moved the following resolution :—

"That this meeting recommends that a meeting be called of as influential a body as possible of manufacturing opticians, to decide upon the most convenient series of sizes for standard flanges and camera screws that shall be most suited to meet existing conditions of their manufacture. These standard flanges at present to be limited in number, and, when decided, to report to the Committee of the Photographic Convention of the United Kingdom. It is also suggested that the question of means for their adoption be decided upon. That this meeting be called for the 9th of May, at this hotel at seven o'clock."

Mr. Conrad Beck seconded the motion.

The Chairman remarked that the question of standard diaphragms was of much less interest to photographers than that of standard flanges. He should be glad if opticians would bring their lenses, and compare dimensions.

Mr. Conrad Beck thought that all the lens makers in this country might be invited to state on what system they graduated their stops.

Mr. Dallmeyer's motion was then carried unanimously.

The Chairman then successively took the votes of the meeting as to whether it preferred for lens apertures the ratio of *f*

over the root of ten, *f* over ten, or *f* over four, and those present voted almost unanimously in favour of *f* over four.

The meeting was then adjourned for a fortnight.

Last Tuesday, the Chairman of the Committee sent the following circular letter, on behalf of the Committee of the Convention, to a number of opticians :—

"Dear Sir,—I am directed to forward to you the enclosed resolution passed at a meeting held on the 25th inst., at the Mona Hotel, Henrietta Street, Covent Garden, and to solicit your co-operation. The next meeting will consist almost exclusively of opticians, and, in order to facilitate matters, it is desirable that you should bring details of internal diameters of flanges, number of threads to the inch, and any other details you can furnish in connection with the attachment of all classes of photographic lenses to cameras as now issued by your firm.

A. Haddon, *Chairman of the Lens Standard Committee.*
Royal Naval College, Greenwich, S.E., April 29th, 1890."

THE PERMANENCE OF PHOTOGRAPHIC PRINTS.

BY PROFESSOR H. FOL.

Prints on albumenised paper are so well known, and have been so often spoken of, that it is not necessary to revert to this subject. Those who buy, and those who sell such prints, know well enough how long they last; the preference given to this process, therefore—a preference especially remarked in the smaller towns, and among the lower classes—can only be attributed to the force of habit, or the absence of taste. It is different in the case of those photographs called permanent, which are now made by very different processes. This assertion of permanence is as admirable as it is in the case of the reproduction obtained by means of fatty ink in the press, as well as of those produced by photo-engraving, collotypy, and phototypy. There remain, therefore, but three principal methods to be investigated: the bichromatized gelatine (carbon) process, the platinum process, and the gelatino-bromide and gelatino-chloride of silver process.

An image may change in three ways :—

1. The dark portions may fade.
2. The background may become darker.
3. The print may leave the support.

It is well known that albumenised paper combines these three objectionable features.

The carbon process suffers from the third of these troubles. The image is simply stuck to the support, and although a separation is not of frequent occurrence, it is not possible, however, to guarantee that it will not occur. This same trouble is again found in Woodburytypy, or in the collodio-chloride of silver process. In platinotypy, neither separation of the film nor weakening of the image is to be feared, but rather a darkening of the background, as it is impossible to entirely prevent the penetration, into the body of the paper, of the solutions containing iron and platinum. In truth, the iron salts may, however, be entirely removed by careful washings with water containing a little chlorhydric acid; in this connection there can be no danger, except for want of care. It is not the same thing with the platinum salt. This last possesses the disagreeable property of entering into a combination so resistant with the gelatine or the resins with which most of the papers are sized, that no acid washings can remove this combination. Such papers containing platinum acquire in time a yellowish-green tone, which completely spoils the primitive image. It is not necessary, however, to wait several years to ascertain if platinum prints will yield to this danger. To make sure of this, place the image in water containing sulphuric acid, and allow it to remain twenty-four hours, as Pringle has recommended; if the paper contain chloride of platinum, it will then show a rather dark yellow tone. It is rather difficult to find, among dealers, papers free from this objection. It is unnecessary to insist on the fact that all platinum paper should be prepared with arrowroot, and *not with gelatine.*

Among the numerous photographers who use this process, there are but few who take this precaution, and who, consequently, can attach much importance to the permanence of the platinotypes found in the trade? How can it be otherwise, since the Platinotype Company, of England, founded by Willis, exclusively uses paper prepared with gelatine?* The public is ignorant of the technical side of the question, and judges the whole process from some specimens that have already become green. It would be very desirable if photographers and amateurs were able to prepare by their own hands the true platinum paper. The magnificent labours of Pizzighelli and of Hübl would enable them to do this without difficulty, if Pizzighelli would only complete his information on the preparation and the quantitative analysis of iron solution, so that a professor of chemistry were not the only one able to understand them.

As regards the gelatino-bromide and the gelatino-chloride of silver processes, they seem to fill, or to be able to fill, the three conditions of permanence—provided, however—

1. That the gelatine film is solidly attached to the paper.
2. That the iron contained in the developer has been completely eliminated by the acid washings.
3. That the image has been sufficiently fixed in the hyposulphite.
4. That the hyposulphite has been completely removed by a thorough washing.

These four conditions met, the developed silver salt prints may offer the best assurance of permanence. The thing presents itself rather differently with the gelatino-chloro-citrate of silver prints (aristotypes) that have not been developed. Most of the prints that have been made within a few years have, doubtless, kept well, even in their fine details, but some of them show, here and there, yellow spots. It would be necessary to make more extended investigations to determine if the trouble comes from an insufficient elimination of the hyposulphite, or if the prints, without defects in their preparation, would still be liable to the reproach of want of permanence.—*Revue Suisse de la Photographie.*

The Leeds Photographic Society.—The president of the Leeds Photographic Society is Mr. Thomas W. Thornton; vice-presidents, Messrs. Thomas Dawson and C. H. Bothamley; librarian, Mr. T. Butterworth; hon. treasurer, Mr. G. H. Rodwell; the hon. secretary, Mr. S. A. Warburton, 9, Banstead Terrace, Roundhay Road, Leeds; and the committee, Messrs. Godfrey Bingley, F. W. Branson, W. Denham, E. H. Jacob, and the officers of the Society. The following are its arrangements for the remainder of the year:—June 5, "Sources of Pleasure in Landscape," Mr. Thomas Dawson; July 3, technical exhibition; Aug. 7, outdoor excursion; Sep. 4, "Demonstration on Alpha Printing," The Ilford Company; Oct. 2, "Watchwords for Workers" (picture choosing and picture making), Mr. Atkinson Grimshaw; Nov. 6, open lantern exhibition in the Albert Hall: Dec, 4, "Some Photographic Art-Notes," Mr. Frank Kidson, and annual meeting.

* The Platinotype Co. carefully avoids the use of paper containing gelatine.—Ed.

PHOTOGRAPHIC LENSES.*

BY THOMAS R. DALLMEYER.

PHOTOGRAPHIC lenses in general are optical systems for the formation of real images. The perfection of the image, its exact resemblance to the object, and its distinctness, will depend on the exact conveyance of all the rays of pencils emanating from every point in the object into strict mathematical points in the image, or the nearest approximation to such points as may be. If aberration is present, due to improperly chosen curvatures, or improperly combined materials, the resulting image will lose in its distinctness, and may become useless. The object, then, in constructing lens systems is the best possible destruction of aberrations, both chromatic and spherical. With this in view, we have to consider: first, the proper selection and perfect homogeneity of the materials employed; secondly, the best selection of curves ascribed to the material; and thirdly, mechanically, a strict maintenance of the "figure" (as it is technically termed) of the curves when the material is properly polished. As it will not be possible in the time allotted to this paper to touch on the mechanical processes employed, I will mention here that this, of course, is a very important consideration.

Glass is a very perfectly elastic substance, and if in the processes of sticking the glass on to polishers the material becomes "biassed," however perfectly the curve may then be polished, the glass, on being released from the polisher, will spring back, and the true curve will no longer be maintained, and will give rise to an unexpected appearance in the image technically termed "unnatural" aberration. Similar effects occur from bad workmanship in polishing, the polish not being distributed equally. Such defects are quite inadmissible, for although not visible by ordinary reflection, the polish appearing very good, a critical examination of the image will show the deleterious effect.

In the application of photographic lenses for ordinary purposes, we ask the instrument to do practically what is theoretically an impossibility. An imaginary perfect lens can only truthfully depict one plane at a time, every other plane being out of focus; when, however, the lens is used under conditions that all rays coming from points in the object are so situated that they are practically parallel; or the circles of confusion in the plane of the image, when removed from the plane for parallel rays, are so small that they are undistinguishable from points visually, the general appearance is one of uniform sharpness. In ordinary lens construction the rays are usually considered as parallel; but in large portrait lenses the means should be given, if sharp images are the theoretical desideratum of correcting the spherical aberration introduced for nearer planes.

There are great advantages, you will be aware, from rapid lenses or brilliant images. Herschell points out that the brightness of an image is proportional to the quantity of light which is concentrated in each point of it; and, therefore, supposing no aberration, as the apparent magnitude of the lens which forms it, seen from the object $\times \frac{\text{area of object}}{\text{area of image}}$. Or, since the area of the object: that of the image :: (distance)^2 of object from lens: (distance)^2 of image; and since the apparent magnitude of the lens seen from the object is as its $\left(\frac{\text{diameter}}{\text{distance of object}}\right)^2$, the brightness or degree of illumination of the image is as the magnitude of the lens seen from the image alone, whatever be the distance of the object. Now the apparent magnitude of the lens seen from the image is always much less than a hemisphere. Therefore (leaving out the loss of light by reflection and refraction), the illumination of the image is always much less than that of the object.

I mention these facts at the outset for the reason that you may clearly understand that it is quite impossible for the lens with a large ratio of aperture to focus, or one that aims at attaining a maximum brightness of image (such as are used in portraiture), also to maintain, at the same time, the uniform qualities above referred to in a lens, the ultimate employment of which is to depict, with sufficient exactitude or definiteness, objects in different planes. With the decrease of brightness, or aperture, comes a reduction of the angle at which the extreme rays cross, increasing thereby the limits through which the plane of the plate may be moved for similar diameters of out-of-focus circles; but, as the depth increases by the proportion, the diameter of the lens is diminished or stopped down, the brightness decreases as the square of the intensity ratio, or the ratio or aperture to focus. As the ultimate applications of various optical systems are at the outset understood, a knowledge of geometry and analysis will enable the optician to construct different forms that shall be particularly suited to the end to be attained.

I take it for granted that you are all acquainted with first principles and first approximations in the refraction of light at plane and spherical surfaces, and are familiar with the fact that the different coloured rays of which white light is composed are unequally refracted in their passage through a refracting medium, giving rise to chromatic aberration.

As stated before, our effort is, as far as possible, to destroy in the final image of every system the aberrations arising from spherical forms of the lenses and chromatic aberration. The process necessary to destroy the latter being the easier defined, we will approach it first, and return to the headings.

1.—*The Proper Selection of Materials.*

It is well known and easily demonstrated that a single lens cannot be made free from either spherical or chromatic aberration for parallel rays. (A study of the different forms of single lenses and their adaptability to different photographic purposes is very interesting and instructive, and we will run through them briefly when on the subject of spherical aberration.) If, however, we combine two or more lenses of different media, we have the means of annihilating both aberrations simultaneously. The elimination of chromatic aberration is rendered possible by the property of refracting substances of dispersing colours in a very unequal degree, though the difference in the refractive power is comparatively slight.

Taking the D line of the spectrum as brightest visually, and the G or H line as that of the most chemically active rays, in order that a lens may be of value in photography—or be actinic—it is most essential that these lines be combined, whatever may become of the rest. Thus, two lines can be combined with two different kinds of glass, and n lines may be of course combined by employing n different kinds of glass.

For example, take Chance's ordinary hard crown glass, the refractive index for line D = 1·517116, and for the

* A paper read at the Society of Arts last Wednesday night.

line G, 1·528348; for dense flint, for line D, 1·622411, and for line G, 1·646071. The difference, then, between these lines is, for the crown glass, ·011232, and for the flint, ·023660. The dispersive power of the flint between these particular lines is more than twice as great as that of the crown.

Now, you know that if a number of lenses are placed in contact (supposed infinitely thin), the focus or convergence of system is equivalent to the algebraical sum of the components of the system. It can be shown for two kinds of glass, such as the above; the chromatic aberration can be destroyed, or actinism (the coincidence of chemical and visual foci) be maintained; the glasses must be unequally dispersive, one convergent or positive, and the other divergent or negative. The system can be made free from chromatic aberration, and convergent if the lens formed of the less dispersive power is positive, and is divergent if the lens formed of the less dispersive power is negative. In every case the ultimate rays from the lens converge to form a real image, so that (unless in the lens-system a negative element is introduced as a corrector) it will be found the positive element is always composed of the less dispersive medium.

Recent improvements in glass manufacture necessitate the expressions of "positive" and "negative" elements in lens systems, instead of the flint and crown, and to these I am about to refer. My late grandfather, in a paper contributed to this Society on "Practical Illustrations of the Achromatic Telescope," says of glass then known: "The flint is easily distinguished from the crown by its superior specific gravity, arising from the quantity of lead which enters into its composition. Thus, the glass which is called flint glass has, in fact, a smaller proportion of silica than crown. It obtained this title from the care employed in selecting the flint with a view to the purity of the glass, and the term has since become so extensively adopted as to be now almost European." Again, "discs of homogeneous flint glass, more than four or five inches in diameter, are exceedingly rare, and very costly." The advances in the art of glass-making have been very great since that time. By the skill and enterprise of Messrs. Chance, of Birmingham, Pfeil, of Paris, and most recently the elaborate work of Professor Abbe, assisted by Messrs. Schott and Gen. of Jena, the means at the optician's disposal is now placed in a much more satisfactory position.

(To be continued.)

Photographic Society of Philadelphia.—At the meeting of the Society on April 1st, the chairman announced the sudden death of their President, Mr. Frederick Graff, which occurred on Sunday morning, March 30th. For nearly thirty years his official connection with the Society had been continuous—as chairman of the meeting called to organize the same, then as vice-president, and serving two terms as president. He was indeed regarded as its father. To his untiring zeal for its welfare the Society is in a great measure indebted for the high position it holds in the photographic world. At the meeting on April 2nd, the following minute was adopted and ordered to be published, after which, out of respect to the memory of their deceased president, the Society adjourned:—"The members of the Photographic Society of Philadelphia desire to testify to their sense of the great loss they have sustained in the death of their President, Frederick Graff. They feel that by his death not only have they lost a most efficient presiding officer, but that each one has been bereft of a dear friend, a sage counsellor, and one who gave of his very best to promote the interests and well-being of the Association."

THE SOCIETY OF ARTS.

Last Wednesday night, at a meeting of the Society of Arts, under the presidency of Capt. W. de W. Abney, F.R.S., Mr. T. R. Dallmeyer read a paper on "Photographic Lenses" (see page 344). In the course of the lecture, he exhibited a cemented double-concave lens, which gave a positive focus, because of the optical properties of the three glass elements of which it was composed.

Mr. J. Traill Taylor, upon being invited to speak by the Chairman, said that he would rather see the discussion taken up by members of the Society of Arts who did not make optics a special point, as the meeting might then be of more interest to them.

Mr. W. E. Debenham was glad of the tribute which Mr. Dallmeyer had paid to Professor Petzval, whose optical achievements had enabled photography to make great advances in the days of slow processes, and he was sorry that Steinheil's name had not been mentioned, for the lens Steinheil invented had been more adopted by photographic opticians than any other. He did not think that any improvement had been made in the portrait lens by the late Mr. Dallmeyer's modification; the Dallmeyer lens had certain advantages, but, balancing one thing against the other, his admiration of the work of the late Professor Petzval was as great as ever.

Mr. J. T. Taylor asked, in connection with the nodal points of Gauss, and in the case of a rapid rectilinear lens, from what point in that lens should distant rays be measured? He asked the question because he thought that theory and practice did not quite agree in the matter. Carey Lea placed the point between the combinations, but nearer to the back lens than the central position. Could Mr. Dallmeyer tell them how to cure the sweating of glass? He had a lens which was in the constant habit of getting damp. Someone had recommended boiling it to remove the hygroscopic constituent from the surface.

Mr. Conrad Beck said that the focus of a doublet should be measured from a point slightly nearer to the back than the front lens. The focal length could be ascertained by the use of a very thin single lens placed so as to throw an image of a distant object so that it shall be of the same size as the image thrown by the double lens. Most of the Jena glasses useful to photographic opticians will not stand the action of air, but the new glasses open up an enormous field of optical research, and their properties require a vast amount of investigation before their utilitarian value can be known.

Mr. L. Scott said that paragraphs had been published in newspapers about Jena glass giving the power of making lenses with both surfaces flat or nearly so, yet with the power of converging or diverging rays of light. Was that true? He had found that he could make more rapid exposures, sometimes to the extent of twenty-five per cent. quicker, by cutting off the yellow rays from his lens by means of a glass trough containing a dilute solution of ammonio-sulphate of copper.

Mr. Dallmeyer remarked that he had not much to which to reply. Mr. Traill Taylor knew the answer to his own question about measuring the focus of doublets, and had published two methods in his own paper, whilst he (Mr. Dallmeyer) had published therein a third. Dr. Hopkinson had done something to get rid of the sweating of glass. The only effectual way was to sandwich such glass by cementing it between pieces of other glass which did not sweat. By using only blue light with lenses, the screen cut off the green and other rays in white light which otherwise would act upon the plate; he thought it best to use the whole of the light available, and not a part thereof. In reply to Mr. Debenham, he was proud of the advances his (Mr. Dallmeyer's) father had made in optics, whatever opinion others might have about them.

The Chairman, when measuring the focal length of a double lens, preferred to employ a pinhole rather than a thin single lens; the pinhole must be so placed as to give an image of the same size as that thrown by the doublet. The distance varies when the focussing has to be done over a near instead of a distant object. He had had some little experience with Jena glass, and had found that it would not bear the atmosphere at all. Some time ago he required for a special purpose a lens

in which rocksalt should form a part, and a friend made him such a lens sandwiched; that lens was made five years ago, yet is perfect at this day, notwithstanding the hygroscopic properties of rocksalt. Ammonio-sulphate of copper solution cut off many of the rays which are active photographically, so he was surprised to hear that it shortened the exposure. He could understand it if the operator were using iodide of silver, because the red and yellow rays have a reversing action, and the plate would be protected therefrom by the blue screen; without such protection they might undo some of the work done. An increase in exposure might, perhaps, with iodide of silver, be obtained to the extent of one or one-and-a-half per cent, but not twenty-five per cent. He should not like to recommend anyone to try the blue screen method, except for experimental purposes.

Specifications Published.

3,103. *March 4th*, 1890.—"Machines for Applying a Coating of Mucilaginous Substance." CHARLES HUDSON and JOSEPH SPOOR HUDSON, 3, Langdale Terrace, Stockton-on-Tees, Cardboard Box Makers.

This invention relates to a machine to be used for spreading a coating of gum, paste, glue, or other mucilaginous substance to the underneath side of paper, cardboard, and the like, and to the delivery and transit of the said coated article to some place where it is required for use or placement, and also for cutting the said paper when such cutting is necessary, as in the case of wall papers, or for narrow strips for cardboard box makers.

The inventors claim:—

1. The use of endless strings in grooves around the coating roller, for the purposes described.

2. The combination of a pasting roller for coating paper at the underneath side, with endless carrying bands.

3. The combination of a coating roller for coating paper at its underneath side, with means for turning the paper the coated side uppermost.

4. The combination of a mucilage roller for coating paper at its underneath side, with endless take off strings, and means for turning the paper the coated side uppermost.

5. The combination of a coating roller for coating paper at its underneath side, with means for turning the paper the coated side uppermost, with carrying apparatus.

6. The combination of cutting apparatus with coating roller.

7. An apparatus for cutting strips of paper, and roller for coating the same, with means for taking the paper off the finishing roller, and carrying it away; also for turning it the coated side uppermost, substantially as described and shown.

Correspondence.

THE CRYSTAL PALACE CHALLENGE CUP COMPETITION.

SIR,—The Newcastle exhibitors complained that some of their pictures were excluded from the Challenge Cup Competition, and I thereupon immediately checked off, by their list and the catalogue, every picture as hung in the three alcoves set apart for them. *Not one was missing*, but, in addition, two of those which had been previously shown at the Crystal Palace were included. As, however, no mention of the disqualification of those two, or of any others, was made to a single judge, it is not easy to see how the presence of two additional pictures was prejudicial to the interests of the Newcastle Society.

The entire number of the Newcastle pictures—Mr. Sawyer having substituted two new for two old ones—was submitted to the judges for their consideration, and the responsibility of the Executive was then and there brought to an end.

J. F. PEAGOOD.

Crystal Palace Company, Crystal Palace, S.E., April 26th.

THE PHOTOGRAPHIC CONVENTION.

SIR,—The fifth annual Photographic Convention will be held at the Town Hall, Chester, on June 23rd to 28th inclusive. The proceedings will be opened by a *conversazione*. During the week, papers by eminent authorities will be read, and an exhibition of novelties in photographic apparatus will be held. Sub-committees appointed to consider the questions of lens standards, and weights, measures, and formulæ will present reports.

Excursions to various places in the neighbourhood have been arranged. The scenery around Chester is universally acknowledged to be exceedingly picturesque and beautiful, and replete with historical interest, and it therefore presents unusual attractions to the photographer.

The annual subscription is 5s., and admits to all the privileges of membership. Members who desire to read papers or give demonstrations are requested to forward their names at an early date. A detailed programme will be forwarded as soon as final arrangements are complete.

The council trust that the good work already done by the Convention will commend it to your support, and they hope to have your assistance in increasing the number of its members.

J. J. BRIGINSHAW, *Hon. Sec. and Treas.*

ON Thursday, May 8th, there will be an exhibition of lantern slides at the Camera Club, from negatives recently taken by Mr. J. R. Rodgers and Major Nott in Egypt, and by Mr. H. M. Elder in Madeira.

PHOTO-MECHANICAL PRINTING.—An article published in this journal last week about photo-mechanical processes was quoted from *The Beacon*, of Chicago, the mention of which circumstance was omitted in error. Shortly, a series of articles on the same subject, by a writer experienced in photo-mechanical processes, will appear in these pages.

Proceedings of Societies.

Photographic Society of Great Britain.

The technical meeting of this Society was held on Tuesday evening last, the 29th ult., Mr. T. Sebastian Davis in the chair.

A kodak of larger size than those previously exhibited was shown by Mr. Jackson. The camera was made to take a roll-holder having forty-eight films of size 7 by 5, and when fitted for use weighed five pounds and a quarter. The diaphragm plate was in the form of a quadrant pivoted at the angle. Many film negatives that had been taken with the apparatus were handed round, and the chairman enquired what method of development had been employed.

Mr. Jackson said that he had used pyro and ammonia for some, but for the most part the negatives had been developed with pyro and a mixture of potash and soda.

The Chairman asked whether Mr. Jackson had used quinol.

Mr. Jackson replied that the action of quinol was too slow. Great density could be got with it if it was desired. In developing these films it was necessary to carry on the action until the image was almost gone, as it lost so much in the fixing bath.

Mr. Arnold Spiller enquired whether Mr. Jackson had found any method of varnishing satisfactory.

Mr. Jackson had not succeeded with varnish. For drying the films he used in the first place a bath of methylated spirit, glycerine, and water. After a short stay in this solution the films were pinued up by a corner to dry, and when dry were rolled with the films outwards and kept so for about a couple of hours.

Mr. Spiller thought the use of glycerine introduced the danger of taking up silver from the paper used to print on.

Mr. Jackson said that the glycerine could be removed from the surface of the films by wiping them when dry with cotton wool. The films were made in various speeds ; those used for the negatives now shown were of about twice the rapidity of the stripping films.

Mr. Friese Greene showed a film about 20ft. long, with a series of negatives on it. For developing such long strips he used a dish in which several glass rods were fixed horizontally at a little distance from the bottom of the dish. The film was wound in and out of these rods, and the dish waved during development.

Mr. Spiller had been able to get very dense negatives on celluloid films by using eikonogen in conjunction with caustic potash or soda. The films being very hard, would stand strong alkali better than most emulsions.

Mr. W. England showed some negatives taken on thick celluloid films.

Mr. T. Samuels thought films of this substance much better than the thin ones previously shown, which were very difficult to develop.

Mr. W. E. Debenham pointed out the advantage of thin films when collotype or other mechanical processes were to be employed.

Mr. Spiller had found no difficulty in developing thin films.

Mr. Jackson said that the method he used was to place about a dozen films, one on the top of the other, in the developing dish. They were kept face downwards, and moved, as in toning prints, by taking up the bottom one, and laying it on to the top.

Mr. W. England showed an arrangement for holding a celluloid film in a dark slide of larger size than the film itself. Three strips of thin card were glued on to a thick card in such a way as to go round three sides of the film to be used. On these strips were other strips, overhanging the film for a distance sufficient to ensure holding it in. He also showed a sheath made with a card back, and furnished with edges of ferrotype plate, under which the edge of the film was slipped.

Mr. A. Cowan showed some plates illustrating the effect of orthochromatising ordinary plates. He first showed a pair of plates, one of which had been orthochromatised and exposed for a minute under a negative at a window covered with four thicknesses of yellow material. There was found to be a fully printed transparency on development. The companion ordinary plate similarly exposed showed but a very faint image. The sensitiveness of the orthochromatised plate for ordinary daylight was, however, much diminished, as was shown by a pair of negatives and by plates exposed under a sensitometer screen. The action of the yellow had been much exalted, whilst the general sensitiveness was lowered. It had been said that there was great difference of orthochromatic effect as the daylight was bright, or inclined to be yellow. In exposures, however, that he had made at 12 o'clock in the day and at 7 in the evening, he had not been able to discover any relative difference in the sensitiveness of the orthochromatic and ordinary plates.

Mr. W. E. Debenham considered that Mr. Cowan's experiments showed conclusively the efficacy of the orthochromatising solution that he had employed. He noticed a strong pink colour still left in the plates, much stronger, he thought, than would be the case with any commercial plates.

It was mentioned that the subject of stereoscopic pictures and apparatus would be brought forward at the next technical meeting, to be held on the 27th of May.

Camera Club.

April 24th.—Capt. W. de W. Abney in the chair.

Mr. T. R. Dallmeyer, in continuation of his paper on "Limitations in the Treatment of Subjects by Focus," said that he did not pretend to any more knowledge of art than was included in any educated man's curriculum with a taste for the fine arts. He had been criticised for entering upon points outside the limits of the province of an optician. He had, however, endeavoured to show the tendencies of the focal treatment of subjects, starting with that of sharp focus, which of itself was a mathematical triumph, and had then indicated the instrumental possibilities outside this treatment to produce results more in accord with the artist's taste. "Sharp all over" photographs are truer *in drawing* than those of contrasted definition. Major Nott had taken up the opposite position to Mr. Davison, perhaps rather extremely. He (Mr. Dallmeyer) did not agree with the general statement of Captain Abney, that a photograph sharp all over is seen in parts with the same amount of "fuzziness" as in nature, when the eye is directed chiefly to the principal object, and when the photograph is of large size, say 20 by 15, with a focal length of lens of 30 inches. In fact, this must entirely depend upon the distance of the nearest plane included. Binocular vision will make this distance greater than monocular vision, as portrayed by the photographic lens. The artist, Mr. Davis Cooper, had had the misfortune to lose the sight of one eye, and had arrived at the definite conclusion that, within a distance approximating closely to sixty yards, there is an alteration in the focus of the eye for different planes, becoming more striking the nearer the planes approach to the eye : beyond that, no appreciable difference exists ; this, of course, may vary with different eyes. In Capt. Abney's case, if the nearest plane were 2,000 inches distant, uniform definition through all planes must obtain, and to get uniform sharpness in nearer planes, the lens must be more and more stopped down. If the eye were focussed in the nearer plane chosen, it would have a different focus than for those most distant, and this does not so nearly approach to the handling by an artist. He (the speaker) thought knowledge of the "sight-stop" for extreme distance to be of value to the artist, as the largest stop he should employ. More stopping down introduces "local colouring," making the photograph too topographical to be called artistic ; the focus of the lens should rest where the eye wishes to rest, and give the picture desired by the individual. Mr. Davison was surprised at his statement of what was and what was not art, but mere mechanical excellence, he (the speaker) fully admitted, will pall upon people, and those who too much advocate it will be left "hoist with their own petard." Although his views might not be serviceable to him commercially, and might be misinterpreted as departing from a scientific and mechanical height, he, for

one, elected to go forward, in order that a still wider application of lenses *per se*, perfect mathematically, might, by intelligent use, serve the double purposes of the two extremes of artistic and scientific requirements.

London and Provincial Photographic Association.

At the meeting on the 24th inst., Mr. W. H. Prestwich occupied the chair.

Mr. T. E. Freshwater exhibited a book of silver prints of Chester and neighbourhood by Mr. G. W. Wilson, of Aberdeen. Mr. Freshwater thought it might be interesting to the members of the Photographic Convention visiting the next meeting at Chester.

The Hon. Sec. showed a lantern slide of Burnt House Farm. The negative was taken last September, previous to the landslip. He also passed round a case of photographic enamels by Lafon de Camarsac and Joubert, the property of the Photographic Club, presented by Messrs. F. Haes and A. Cowan.

The exhibit gave rise to a discussion as to the relative merits of the powder and substitution processes.

Mr. A. Cowan said the powder process had the advantage of simplicity, and the results, in his opinion, were certainly equal.

Mr. W. H. Harrison remarked upon the condition of the ancient enamels at the British Museum, the enamel of many of these being cracked in several places. He considered this might be due to the unequal expansion and contraction of the metal support and the enamel under the influence of changes of temperature.

Mr. T. E. Freshwater showed the silver prints referred to at the previous meeting that had been packed for several years in a tin case. It was found that some of the prints were quite perfect, others having faded.

The Chairman said that from his experience, he believed silver prints made on ready-sensitised paper were more permanent than those made on freshly-prepared paper. It was difficult to understand why a batch of prints produced under the same conditions were not always all equal in permanency.

The Hon. Sec. exhibited some results in copying pictures with ordinary and isochromatic plates. In one case there was a marked difference in favour of the isochromatic plate. In the other instance—the subject being a water colour with purple sky, and same colour reflection in the water—it was generally considered that the ordinary plate gave the best result. In one of the prints there was a vast difference in the rendering of a small cloud in the picture.

Mr. W. E. Debenham said he had used collodion on his lens and an eosine bath with excellent results; with one maker's ordinary plate he had used a yellow screen with good effect.

Photographic Society of Ireland.

A technical meeting of this Society was held on Thursday evening, 24th inst., at 15, Dawson Street, Dublin, Mr. Greenwood Pim in the chair.

A joint paper on "The Utility of Hand-cameras on Tour," by Mr. M. Hedley and Dr. J. Alfred Scott, was read by the latter, and slides of pictures taken in Scotland last year by the authors were exhibited by means of the lantern, and were much admired. After the paper,

The Chairman asked Dr. Scott what proportion of exposures, time or instantaneous, were the best?

Dr. Scott, in reply, said that only 18 out of 169 plates exposed were time exposures, and that they invariably turned out very good. In reply to Dr. Cosgrave, Dr. Scott said that his lens was a cheap French R.R., with full aperture of *f*/6: but he found that *f*/12 gave a general "all-round" focus, and told better for transparencies.

In reply to Mr. Strangways,

Mr. Hedley said that he used one of Lancaster's "Instantographs," placed in a common pine box, with Lancaster's ordinary revolving shutter.

The Chairman then exhibited Ferrero's film carrier; Fallowfield's detective camera was shown by the Rev. Canon Bagot; Shew's "Eclipse" camera by the hon. sec.; and Dr. J. A. Scott exhibited a hand camera of his own manufacture, based on Rouch's model.

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

Amateur.—*Inside Painting of Studio and Dark Room.* Provided you select a light tint it is almost a matter of indifference what shade of colour you adopt; probably pale blue or stone colour would be most suitable for the studio, and in certain cases one might be disposed to give a top coating of luminous paint to show a light throughout the night. The dark room should be painted No. 1 chrome yellow.

J. D. (Glasgow).—*Truncated Bellows for Camera.* Following the directions in the Year-Book for 1889, pages 173 to 180, it would be quite easy to make a pattern first in cartridge paper, and settle the measurements for a 12 by 12 bellows in this way before cutting out your material. We admit the figures in the plates and explanatory drawings are not very intelligible, but most of them can be read by a lens.

J. D. (South Shields).—Your Ligroine lamp ought to find a ready sale at cost price. Offer it by advertisement. A second letter duly received this week.

Antiquary.—*Roman Baths in the City of Bath.* Enquire of Mr. A. F. Perren, Milsom Street, who took several photographs, both of the square and round baths, when they were first opened.

B. C.—*Botanical Photography.* Your question is answered, and other points of detail referred to, in Julius Sachse's admirable article in last week's News, page 322. Begin at once, or you will lose the earlier phases of development.

K. Schwier (Weimar).—Is thanked for sending further details of the Voigtländer, Festge, and Kindermann competitions, medals and money prizes to be given at the forthcoming (August) meeting, in Eisenach, of the German Photographic Convention. The general particulars are incorporated in the prospectus appearing in our pages this week.

F. C. S.—*Chlorine Water Actinometer.* Professor Alexander Pedler, of Calcutta, has investigated the action of sunlight upon chlorine water, with the result that he found oxygen escaping with effervescence; but he does not go to the length of asserting that the measure of the oxygen collected is a true photometric indication of the intensity of the solar radiations. The equation $2H_2O + 2Cl_2 = O_2 + 4HCl$ was established in the main, but there are secondary changes resulting in the production of hypochlorous and chloric acids, which detract from the amount of free oxygen disengaged during this reaction. The ultimate change is, however, more complete when dilute solutions of chlorine are employed, so that further experiments are required for the purpose of fixing the limit at which the chemical decomposition of water by chlorine becomes a reliable measure of the actinic force.

A. L. (Otago, N.Z.)—*Benzoline Saturator.* Having read the account to which you referred us, we cannot suggest any cause for the failure of the apparatus, but should be inclined to blame the benzoline. It would be well to interpose a Mangham jet, or cylinder plugged with copper wires, and capped at both ends with copper or brass gauze, to overcome the risk you encountered by the flame passing back. You might then find it advantageous to warm the benzoline saturator, for it is evident that you had an excess of oxygen. Having already an ether vapourizer, you might try the ethobenzene light, which is highly recommended in the same account.

H. T. L. (Westport, N.Z.)—*Staining of Negatives whilst Printing.* Gelatine negatives are much more difficult to protect than collodion, on account of their greater prominence. In a damp climate you should print them with a plate of tale between, as is often done with valuable negatives here in England.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1653.—*May* 9, 1890.

CONTENTS.

AN INTERNATIONAL PHOTOMICROGRAPHIC EXHIBITION IN ANTWERP.

A COMMITTEE has been formed to organise an International Exhibition in Antwerp, devoted to microscopical science in all its branches, on the occasion of the third centenary of the invention of the microscope. The Exhibition will be divided into two sections, the one retrospective, the other a display of microscopes by actual makers, also accessory apparatus and photomicrographs. During the Exhibition lectures will be delivered, illustrated by means of the photo-electric microscope, and among the subjects included will be:—"The History of the Microscope," "The Use of the Microscope," "The Projection Microscope and Photomicrography," "The Microscopic Structure of Vegetables," "The Microscopic Structure of Men and Animals," "Microbes," "The Adulteration of Food and other Substances."

The Executive Committee consists of M. Charles de Bosschere, *President*; Dr. Henri Van Heurck, Director of the Botanical Garden of Antwerp, *Vice-President*; M. Charles Van Geert, jun., Vice-President of the Floral Circle of Antwerp, *Secretary-General*; and M. Edmond Grandgaignage, Director of the Superior Institute of Commerce, Antwerp, also M. Gustave Royers, Chief Engineer of the City of Antwerp, *Members*.

The Executive Committee says that it is unnecessary to state the importance of the microscope, for without it none of the natural and medical sciences could have reached the altitude at which they stand to-day; without it we should not know the structure of plants, of men, or of animals, and the modifications which take place in our tissues under the influence of certain diseases would be unknown. Several diseases which the presence of microbes enables us to detect at an early stage, would otherwise be mistaken for unimportant maladies of another character. Without the microscope forms of life innumerable would remain unknown to us; take, for instance, the infusoria, the diatoms, and the bacteria. Numerous adulterations of articles of commerce, which are now detected with ease by means of the microscope, would otherwise remain undiscovered. But why continue this long enumeration? Suffice it to say that without the microscope we should not now be better instructed in the natural and medical sciences than were our fathers one or two hundred years ago.

The Committee adds that the compound microscope was invented by Hans and Zacharias Janssen, of Middelburg, and the researches of Professor Harting result in assigning the date of 1590 to the invention, which date is admitted by competent authorities. For a long time the inherent defects of the compound microscope forced students to make general use of the simple microscope, until about 1824, when Charles Chevalier finally established the compound microscope by the union of two brilliant ideas, the combination of isolated achromatic lenses in a compound objective, and turning their plane faces towards the object. In the previous year, 1823, Chevalier conceived the happy idea of superposing achromatic lenses in the microscope of Selligue. The Committee concludes by saying that the project of celebrating in 1890 the third centenary of an invention which has produced a veritable revolution in the scientific domain will receive, without doubt, the sympathetic approbation of all men of science, as well as of the great army of amateurs now "passionately" engaged in research carried on with the aid of the microscope.

Such is the original scheme of the Committee; but a few days ago, Dr. Van Heurck told us that its carrying out is postponed until next year. The City of Antwerp has promised to subscribe fifty thousand francs towards the Exhibition, and to give the use of a building for its purposes, in which building four thousand square metres of space will be available. The Government of Belgium was fully expected to subscribe fifteen thousand francs towards the undertaking, but at the last moment it declined, and as the Committee wants another fifteen or twenty thousand francs to carry out its plans, the Exhibition is postponed until 1891. The idea is to keep the Exhibition open for three months, July, August, and

September, we presume for the benefit of tourists who pass backwards and forwards through Antwerp in such numbers in the autumn. Antwerp is one of the favourite landing-places in Europe of American tourists, many of whom book there direct from New York, and year by year the number of English passing through Antwerp is increasing, by reason of the good accommodation provided of late years on the Harwich route, combined with moderate fares. The general public cannot be expected to wax enthusiastic over photo-micrography, although brilliantly illustrated lectures may help to rouse them from their torpor; neither can it be expected that skilled microscopists could make it convenient to be in Antwerp on or about a particular fixed date, hence the keeping of the Exhibition open for a long time is more likely to meet their requirements. Zeiss has expressed his interest in the Exhibition and willingness to exhibit therein.

On the occasion of the opening of public exhibitions, the reception of visitors by the city of Antwerp is usually of the most hospitable character. Some of us will not soon forget the receptions given by the venerable Burgomaster and others at the inauguration of the Antwerp International Exhibition several years ago.

PHOTOGRAPHERS AND CROWDS.

Crowds, especially of street boys and street girls, have been the deadly enemies of architectural photographers for all time, and many have been the devices for clearing an open space in front of the camera. One of the most time-honoured is that of mounting a large lens at the back of the camera to draw the crowd in that direction, whilst the view really desired is taken by the small lens in front.

A few days ago two English photographers planted their cameras on opposite sides a deserted space in Ghent to take an adjacent church; instantly, of course, children dropped from the clouds, emerged from the earth, concentrated from all possible directions, and each operator had his crowd around him. One of them folded his arms, leant against a wall, and gazed steadfastly at his friend in the distance; the children soon grew tired of gazing at an operator doing nothing, then cleared off to watch the more active manipulator; the first one, thus relieved, then made his exposure.

The same day, when taking another view, one of these photographers discovered that a boy in the crowd prided himself on his dancing; that boy was immediately offered the sum of one penny to dance several yards behind the camera. The delighted boy entered into the contract, and executed a kind of Belgian "fling" which drew the crowd to the back of the camera. The view was then taken.

In the old cities in Belgium and Holland architectural photographic work is somewhat more easy than in towns in England, because there are so many canals and rivers about. For this reason numerous picturesque views are obtainable when the lens is pointed over the parapet of one or other of the bridges.

THE ROYAL ACADEMY OF ARTS, 1890.

BY THE REV. F. C. LAMBERT, M.A.

We have been so long accustomed to be told that "the Academy this year is certainly not up to the average," that it will be quite refreshing, for once in a way, to omit that time-honoured enigma, for it is by no means an easy thing to reply to the obviously pertinent question, What do you mean by the average?

It is not an unnatural presumption that the readers of these notes are for the most part interested in the making of pictures by some of the various photographic processes of the day, and their interest in the pictures now on view in Burlington House will concern them chiefly for such degree of sympathy as the aforesaid paintings will conjure up in the photographic eye.

The writer has little or no sympathy with that type of cynic who is blind to all aspects of criticism save that of fault-seeking—finding or inventing which has but little benefit in it beyond flattering the vanity of the defect discoverer; but, on the other hand, rather with him who

> "Finds tongues in trees; books in running brooks,
> Sermons in stones, and good in everything."

There are but few, if any, pictures in this vast gathering from which nothing may be learned, if even it be what to avoid, what not to do, or how not to do it, although there are vast differences in the lessons, as in the long scale of tones and subjects of nature herself; yet it is always a lasting and solid consolation to the humblest follower of Art in nature that she has yet secrets which he has just as good a chance of discovering as any other user of human eyes, and be his nugget small, yet so long as it has the ring of truth, he may take to himself the consciousness of having added to the wealth of the world.

The number of works included in the catalogue is, perhaps, somewhat less than in some recent years; but probably, if the cream be less in quantity, it may be compensated for by its quality.

Perhaps it may be as well at the outset to state that the following remarks are not an attempt at what is usually termed art-criticism—which is too often but an ill-matched patchwork of ignorance, flattery, smartness, and art cant—but rather an attempt to suggest to my photographic friends what is worth while their seeing for themselves, so that they may *think* for themselves also.

Gallery No. 1.—No. 4 ("The Loving Cup," Seymour Lucas, A.), is rather of the sharp-all-over sort, a crisp picture, and suggestive in its arrangement of secondary detail. No. 5 (by G. A. Storey, A.R.A.), "The Hungry Messenger" is its title, and the hero of the act the messenger himself, a half-starved Puritan, having delivered his missive to a Roundhead commander, accommodates his appetite from his neighbour's plate, an incident of a somewhat comic nature, which is enhanced by the earnest look on the reader's face.

Simple and natural incidents are such as, perhaps, best lend themselves to photography, and thus this picture may suggest a new direction to some one for a subject-picture through the camera.

At this end of the room, rather high up, are two studies of lions' heads (No. 7, "The King of Beasts," P. H. Fisher, and 94, "Duke," P. G. Cooper) which strongly remind us of some shutter pictures taken in the Zoo, not long ago; also No. 8 ("Bosom Friends," a couple of dogs, by C. P. Garland), all show what important part photography is destined to play in pictures of "objects in motion,"

"lively" subjects generally. In No. 9 ("The Broken Pitcher," C. G. Hards) we have a favourite incident which is becoming classical; it would seem as though no exhibition is complete without it. No. 18 ("Dinah Morris Preaching," C. Gregory) is an admirable subject for the study of pose and grouping; note the man in background, the critical semi-defensive angle of his legs. No. 19 ("The Cast Shoe," R. W. Macbeth, A.) purchased by the Chantry Bequest, reminds one strongly of some place not a hundred miles from Cambridge; the inn sign "five miles from anywhere and no hurry," has a familiar sound. Note how the man holding the horse connects the two groups of figures and leads up to the theme, and how the one secondary small figure at the side looking at the spectator carries one's eye into the picture at once.

Somehow we do not take kindly to No. 20 ("A Daughter of the Ghetto," Luke Fildes, R.A.); it seems to bring to our mind the word "retouching." Before leaving this corner, take a glance at No. 14 ("Lilies," Blanch Jenkins), a child's head lighted from the back, and note the luminosity of the face in shade. Try this lighting at various angles in the studio: *verb. sap.* Passing on to No. 25 ("The Moon is up, and yet it is not Night," Sir J. E. Millais, R.A.), we have a masterly hand, familiar to all in portraiture figure, giving us a landscape well worth careful study. The photographic eye says, "nothing is in focus except the stag's head, and that isn't very sharp;" but stand back a yard or two, and if there isn't "focus," there is *air, breadth, simplicity, quietness*; a ground fog just creeping up in the distance. Perhaps the somewhat regular band of undergrowth, arranged somewhat like an arc of a circle of which the spectator imagines himself the centre, is not quite satisfactory—nevertheless, a picture; a lesson in tone and the power of simplicity. Close by, No. 26 ("La pia de Tolomei," Edwin Long, R.A.) is one of the figure studies which this artist has taught us to expect. The various ornaments, decorations, designs, symbols, &c., on the breast seem to rather distract one from their number and sparkle. The hands are worth studying. Just at first No. 30 ("The Revenge," James Kay) calls to mind Turner's "Fighting Téméraire"—a vigorous conception, and boldly carried out, if, perhaps, with a somewhat lavish hand in strong colour.

No. 31 ("Homewards," E. A. Waterlow, A.) must surely bring to mind many a spoilt plate—many an attempt (and failure) to catch the bright gleam. In looking at No. 36 ("By Quiet Waters," J. E. Grace) one is tempted to say, "Try another cloud negative." The sky seems too fiery for the title, or the subject, and gives one an impression that it does not belong to the rest of the picture. No. 40 ("His Playthings," K. Earle) reminds us of many a photograph where an attempt is made to "make a picture" by just collecting a few odd "properties" and "getting them all in." The clouds, again, in No. 43 ("The White Mill," David Murray) seem to come too forward—seem much nearer than the mill sails, in fact. And again in No. 57 ("Moorland," C. H. H. Macartney) the clouds don't seem "to belong."

No. 59 ("The Young Duchess," H. Schmalz). It seems a pity to have put "patches" on such a sweet face, and given such a twist to the neck, that one's admiration melts into sympathy for the sitter's discomfort—"Eh! surely?" And, again, the English face in the Japanesque get-up in No. 65 ("A la Japonaise," Mary Groves) seems to appeal chiefly to our consciousness of the general *un*fitness of things generally.

No. 66 ("A Florentine Fruit Shop," P. W. Adam) is an apt illustration of another kind of unfitness of things. We like softness, even "out of focus," at the proper time and place; but the accepted definition of that ugly word, "Dirt," shows us that there is "a place for everything"; and we don't somehow feel thoroughly satisfied in our minds as to whether those yellow objects are oranges or balls of wool.

In No. 67 ("First Words of Love," C. E. Perugini) we think that it would have been better if *one* of the two were a little more like speaking, and not both apparently in considerable doubt as to "what to say next." The Romeo-and-Juliet theme seems a never-failing one; perhaps such ideal themes may justify idealisation of treatment.

No. 68 ("A Placid Morning," H. W. B. Davis, R.A.), takes us to open air again. What we like best is the transparency and luminosity of the shadows on the cattle, and one bit of the foreground water: but the sky and distance do not make us feel the "palpitating air of early dawn."

No. 69 ("Polo," J. C. Dollman) brings to mind the question as to whether it is desirable to represent violent action in works of art, and again, if so, whether the "critical moment" is the best one to select. We do not affect a knowledge of horse-flesh or anatomy, and therefore will be content with saying that some of the animals seem in "funny" positions; but here we must call in Mr. Muybridge as our court of final appeal as to the possibilities.

Nos. 74 and 80 ("Augustus Holden," and "Sir D. A. Smith," by W. W Ouless, R.A.), we have two very suggestive portraits, both well worth study. The fur in No. 74 is particularly "furry," although *every hair* is not painted singly as some would insist upon.

No. 73 ("Good Luck," Lyell Carr) certainly does make one feel cold, although the sun-cast shadows on the snow cheer one somewhat.

No. 76 ("All Hands Shorten Sail," F. Brangwyn). This is a picture to be well looked at, but we will defer saying more until we come to others by the same artist.

No. 81 ("Davy Jones's Locker," W. L. Wyllie, A.) certainly upholds the view that there are "as good fish in the sea, &c.," and at this particular point they seem to be more than plentiful.

No. 75 ("Last Night's Disaster," J. C. Hook, R.A.) must not be passed over. The figures at work digging out the sand from the tide-cast boat certainly strike us as the best part. The sky and sea both seem hard, and not inviting of attention.

No. 82 ("A Foretaste of Summer," L. C. Nightingale) comes as a note of warning; too many horizontal and vertical lines are not often pleasing, and we could have imagined the swans a bit more feathery. No. 86 ("The Fringe of the Forest," F. S. Richardson) is fuzzy enough to satisfy the pin-holiest of pin-hole advocates; and No. 88 ("Across the Common," Claude Hayes) is also, as Mrs. Gamp would put it, "likewise so disposed."

No. 89 ("Snakes," Estelle d'Avigdor). There are several of these weird semi-mysterious dark pictures this year. We should have liked this one better had we been more satisfied about the bit we took to represent a patch of open sky, up in one corner.

No. 91 (Portrait, by W. Carter) is well worth careful looking at; excepting the colouring, we like it. The pose is easy and natural, balance of the head is good, and the

hands are easy; generally, the treatment is broad and simple, and its simplicity gives it weight.

No. 96 ("Among the Brambles," Val. C. Princeps. A.). We don't quite know whether to look at the brambles, or the young ladies, or the small boy who is staring at us, and so we feel constrained to pass on into the next gallery.

PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

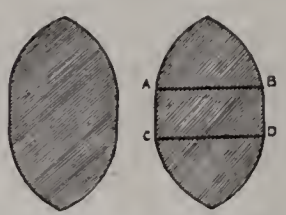
Death of M. Peligot—Bridal Medal—Photographs in Colours — Exposure Shutters and Chromo-Photographic Apparatus — Pellicular Films on Celluloid — Photo-Collographic Process — Halation — Coloured Screens — Instantaneous Photography.

At the opening of the meeting the Chairman announced the death of M. Peligot, president of the Society, and read the discourse which had been pronounced over his tomb at the funeral. Peligot was a great chemist. Although he had never devoted himself especially to photography, he not the less rendered service to this science, in which he was greatly interested. It is not yet known who is to succeed M. Peligot as president of the Society, but we have some reason to believe that it will be M. Janssen, who is a member of the Institute, as were Messrs. Regnault, Balard, and Peligot. It is a tradition of the Photographic Society to place itself under the highest possible scientific patronage by calling to the presidency a member of the Institute. No choice, moreover, could be more acceptable than that of M. Janssen, whose work in astronomical photography has been of such great importance.

On the occasion of the marriage of the daughter of the grand nephew of Nicephore Niepce, the Bureau of the Photographic Society made an offer of one of the medals struck on the occasion of the celebration of the fiftieth anniversary of photography. The medal bears the effigies of Nicephore Niepce and of Daguerre.

Photographs in colours, by M. Veresz, of Koloszvar, were shown at the meeting. Much has recently been said and published concerning these productions; notably in the Photographic News interesting articles have appeared, especially that by Capt. Abbey in the last number. We had expected to see something better than those examples which were exhibited, which add nothing new to what is already known on the question, except that they are on glass, and obtained with gelatine emulsion. We are certainly not amongst those who absolutely deny the possibility of the solution of the problem of photography in natural colours, no one having the right to say to science, "Thou shalt go no farther," but we may certainly affirm that the interesting researches of M. Veresz have not yet led to this solution so ardently desired.

General Sébert has made two very interesting communications. One relates to a method of studying the action of photographic exposure shutters. The apparatus employed for the purpose was shown. In this apparatus the effective work of the shutter registers itself. It is the application in practice of a method indicated by M. De Labaume Pluvinal at the time of the Congress. The apparatus consists of a kind of dark slide forming a camera, in the interior of which slides a light board worked by two springs. In front there is a circular opening closed by a metallic plate, across which is a very thin slit. If a piece of sensitive paper is placed on the thin board, and the whole is exposed to a powerful light whilst the board is moved by the springs, the various zones of the sensitive paper passed behind the slit, and if the light is equal throughout, its action is translated on the sensitive film by a continuous tint. On the contrary, if during the passage of the paper there are irregularities in the source of light, these irregularities will show themselves by inequalities in the zones on the paper. If it is desired to try an exposure shutter, it is placed in front of the opening, and by using a bifurcated tube we act simultaneously on the release of the board bearing the sensitive surface and on that of the shutter. At the same time a tuning fork is released, vibrating 100 to the second, and carrying a small hole at the upper end to allow light to pass. On the corresponding part of the sensitive paper a sinuous line is produced, each bend of which indicates the one-hundredth part of a second. We have thus simultaneously a graphic delineation of the work produced by the shutter, and of the time occupied. The line varies, according to the nature of the shutter. Those with vanes opening from the centre to the circumference, and closing from the circumference to the centre, without stopping, give an impression in the form of a lozenge with curved sides. But



if there is a stoppage—that is to say, an instant when the objective is left fully open—the figure takes the form shown—that of the preceding one, plus the rectangle ABCD inserted in the centre portion of the curvilinear lozenge. AC, BD, have a length corresponding to the duration of the full opening of the lens. With other shutters the forms are different, but analogous to the one described, the work with full aperture being always indicated by a rectangle in the centre of the field. On comparing various shutters with this apparatus, we find which is the one that, with the same duration of total action, gives the largest amount of work with full opening, and this is evidently the one which should be preferred. The sinuoidal trace gives the exact duration of each part of the exposure, and we have thus automatically registered the various phases of action. The idea of the registering tuning fork attached to this apparatus was given by M. Cornu.

The other communication, by the same author, relates to an apparatus for reproducing an object in movement at equal intervals regulated in advance; these intervals may be varied according to the requirements of the case. It is composed of six cameras furnished with shutters, which are acted upon successively by two needles carried on a rotating disc; the first needle opens each shutter, and the second closes it. The operation is performed in the fraction of a second, so that we can obtain the photographic registration of the various phases of the movement of a projectile, a torpedo, &c. The spring movement is supported independently of the cameras, in order to avoid shaking.

M. Grieshober showed some new pellicles of gelatino-bromide of silver on celluloid. The sheet of celluloid bears two coats of gelatino-bromide—one on the front, and one on the back; by this means halation is avoided, and, if the impression is divided between the two surfaces, the negative may be used on either side. Some of these pellicles were distributed among the members for experiment.

M. Balagny summed up his process of photo-collography

on pellicle covered with gelatino-bromide of silver. The coating of gelatine is attached to its pellicular support by a silicated solution. It is sensitized by bichromate of potash, and printing is carried out in the customary way. It is washed in the usual manner, and placed on a flat surface, where adhesion takes place by vacuum. The printing with fatty ink is effected in the usual manner. In short, the characteristic of this process is the use of flexible supports, gelatinized beforehand, and photo-lithography allows us to pull a certain number of impressions from each plate. We do not see the use of the bromide of silver, and we believe that an identical—or, perhaps, better—result would be obtained on gelatine alone. M. Balagny thinks that the silver increases the sensitiveness of the film. We have made the following experiment: A piece of Eastman's paper was freed from bromide of silver at one end by immersion in hyposulphite of soda; it was then washed, and the whole sensitized with bichromate of potash. After exposure to light, we could find no difference in the sensitiveness of the two halves. The use of bromide of silver appears to us so far to be a simple luxury without any advantage. M. Balagny proposed to practically demonstrate his very interesting process at a technical meeting of the Society.

The question of halation has been stirred up anew. We have observed that the remedy proposed by M. Cornu is not practicable on account of the non-drying nature of the essences he mentioned. Collodion with chrysoidine alone is not sufficient, a negative showing halo obtained when using this method having been shown by us. Finally, we have shown a negative without the slightest halation obtained on a plate the back of which was covered with collodion containing chrysoidine, to which was added another tinctorial substance in order to absorb almost all rays, methyl violet Further, as our experiments were made on Monckhoven orthochromatic plates, and through powerfully coloured screens, it is shown that neither orthochromatism nor the use of screens is a remedy against halation. The best remedy is a collodion which dries quickly, and is so coloured that all rays are absorbed. *Apropos* of coloured screens, we mentioned our experience with a continuating screen. An orthochromatic plate is exposed in the camera in the usual way with a suitable yellow screen; it is then exposed to light under a combination which only allows red and orange light to pass. The supplementary exposure is about four or five times as long as the camera exposure, but will vary according to the nature of the continuating screen. On development, the red is found to have acquired its proper value. With plates sensitised for red, the use of the continuating screen is still necessary, but for a shorter time. In connection with this subject, we also showed our sensito-colorimeter: but it would take too long to describe it now, and we shall return to it later.

M. Joseph Vallot indicated a process of photographing grottos by the aid of magnesium. He uses a lamp which allows two grammes of magnesium powder to be blown through at once. A good flash of about two metres in height is produced, and in this way he has been able to reproduce very successfully details of certain interesting grottos in Le Herault. M. Vallot showed conclusively by lantern projections the success he had obtained in the way indicated.

The Newcastle Photographic Exhibition will close to-morrow (Saturday) evening. At 7.30 p.m. there will be a vocal and instrumental concert in the building.

THE ROYAL INSTITUTION.

CAPTAIN ABNEY ON COLOUR.

Last Saturday afternoon, Captain W. de W. Abney delivered a lecture on the above subject, and began by remarking that he had previously explained to them how he measured the amount of blackness of a silver or platinum deposit by means of a rotating disc, and that the amount of blackness of deposit can be shown to scale. From any particular blackness the intensity of the light which produced it can be ascertained; when he had a variety of blacknesses he could compare them, and say that such and such an intensity of light produced each, so that it was really a quantitative process of measuring the chemical action of light. He had discovered that the deposit followed the curve of the law of error.

The law applies not only to platinum deposits, but to anything whatever reduced by the action of light; for instance, the fading of indigo follows the same law, but is so long in fading that a longer unit of time has to be selected. In the case of the fading of carmine, a convenient unit of time is one hour, and in the case of indigo six hours. In ordinary photography the units of time are changed, for when the light is feeble and the lens stopped down, they do not count by seconds, but by hours. For each pigment there are certain rays which are chemically active. Experiment shows that the intensity of light is interchangeable with length of exposure, yet a very small change can be measured by the spectrum method he had brought under their notice; for instance, it had been ascertained that the first change in carmine is the fading of the blue element it contains. The phosphorous oxide recently discussed at the Royal Institution by Professor Thorpe changes in the light first to yellow and then to red. People have taken it that the amount of apparent change shows the exact sensitiveness to light, but this is not the case: the observations had to be referred to the curve in the diagram before them, to learn the absolute sensitiveness to any part of the spectrum.

Captain Abney here exhibited some colours which he and another had exposed for eighteen months to the action of light, and said that month by month they had taken portions of those bands of colour, and measured them one after another by the method he had described. There are, however, some pigments with which it is impossible to deal in this way, because they take so long to fade; rose madder only begins to fade after the lapse of eighteen months, and medical men have not yet found out how to prolong life sufficiently to finish the experment with that substance.

The sum of the effects produced by the different rays is the same, whether the same rays act together or at a different time. This is perfectly true as a rule, but there are exceptions. There are rays of the spectrum which tend to undo, or mask, the effect of the other rays; the red will mask the work done by the blue ray, so that if the red is made to act upon a sensitive surface before the violet, the result is not the same as if they acted together, because, in the first case cited, the red has nothing to undo. In ordinary photographic work, the rays which undo the effect produced by the other rays may be neglected, as the influence is so feeble under the conditions. An image in red light may be projected upon a screen illuminated by white light, and a photograph of the red image be obtained, because the red rays undo some of the effects of white light by oxidising the film.

Captain Abney then photographed an image of the spectrum after passing the rays through green glass; he used bromide of silver paper, and developed by means of a brush. On the same sheet he also photographed the spectrum without green glass interposed. The result was that the green glass was seen to have cut off both ends of the photographic spectrum; the image produced subject to its intervention was shorter and feebler than that produced by the spectrum of white light. The lecturer said that if the effect of blue light upon a bromide of silver film be taken as one hundred, that of green light will be about twelve. On these principles the photographic intensities of light passing through coloured glasses could be measured.

The spectrum value of a sensitive salt can be increased. If a salt of silver be stained with certain fugitive dyes, the salt is increased in sensitiveness to those particular parts of the spectrum which the dye absorbs; a lake is formed in the first instance, and this gives nuclei upon which development can take place. He then showed the results of photographing a colour sensitometer by means of an ordinary plate and by means of an orthochromatised plate: he also exhibited photographs of a doll dressed in various colours, to show the results obtainable by different methods. The best result was obtained by illuminating the doll with mixed green and yellow light, then photographing it on a plate which had been treated with erythrosine and cyanine; in this experiment, the blue of the spectrum was, it will be noticed, eliminated.

He exhibited two photographs, upon silver plates, of the spectrum in natural colours, and remarked that the colours, though not strong, were clearly discernible. Such photographs, he said, were not new, but had been taken for forty years.

If three colours be taken, which, together, make white light, it is perfectly possible, by superposing them, to get what, to the eye, appear to be all the colours of the spectrum. He then, by mixing red, green, and violet rays, produced white light, and afterwards, by mixing them in another way, obtained a good representation of a complete spectrum upon the screen.

A photograph in natural colours, he said, was not due to the colours of thin plates. At present it appears to be highly improbable that photography in natural colours will ever be of commercial value. Colour is mostly produced under red light by an oxidation process, and by oxidising, the molecule becomes of such a shape as to reflect red light. Violet light has a reducing action; in fact, he had sometimes produced white, by red and blue undoing the action of each other. Thus one end of the spectrum tends to undo the work of the other end. The investigator on photography in natural colours, whose work is now attracting attention, is simply repeating the experiments made years ago by Mr. George Wharton Simpson. If once a man succeeds in completely solving the problem of photography in natural colours, he ought to make a fortune first, and be hanged afterwards, for the discovery will be the destruction of all art feeling.

The Photographic Club.—Subject for May 14, "Photographic Definitions"; May 21, "Photo-Mechanical Processes."

Photographic Society of Great Britain.—Ordinary Meeting at 5A, Pall Mall East, on Tuesday, May 13th, at 8 p.m., when papers will be read on "Reflected Images in Optical Combinations, and their Effect on the Brilliancy of the Final Image," by T. R. Dallmeyer; and on "Photography with a Flash-Light," by W. England.

AN EXHIBITION OF MRS. CAMERON'S PHOTOGRAPHS.

An Exhibition of Mrs. Cameron's photographs was opened at the Camera Club last Monday, and highly deserves a visit from those who have been brought into photographic existence by the ease of the modern dry plate processes. To the older photographers the pictures are not new. The portraits by Mrs. Cameron are a powerful argument in the mouths of those who are adverse to excessive sharpness of focus in photographs: they are artistically beautiful in the highest sense, and some of them so resemble in style portraits by the old masters, that it is difficult to realise that they are not orthochromatic photographs of ancient paintings. One of the most striking portraits is that of the late Sir John Herschel, a pioneer in scientific photography, and a former contributor to these pages. Another is a likeness of Mrs. Cameron herself, with square-cut features, and an expression of spirituality and kindliness.

On Monday evening, Mr. Davison, in drawing the attention of the members to the pictures upon the walls of the Club, said that the task was a pleasant one, and that Mrs. Cameron was an enthusiastic worker; in putting up the pictures he felt that it would be easy to wax enthusiastic about them himself. Some of them contained eccentricities which had better have been left out, but in the main they must recognise the wondrous force of her portraits; she had seized the leading characteristics of each face, and had delineated them as could have been done better in any other way. She had advantages, for she mixed with artists, and she had models whose heads lent themselves to pictorial effect. The disadvantages of the time in which she worked were very great. She lived in the wet collodion days; her studio was a fowl-house converted for the purpose, and in that way she obtained her magnificent dark backgrounds for portraits. Sir John Herschel was an astronomer, and in his portrait there is appropriately something star-like in the disposition of the hair. Some female heads, from life, in the collection show wonderfully the characteristics of the pre-Raphaelite school. He felt it to be scarcely possible that the character of Thomas Carlyle could have been rendered with more force than in his portrait before them. The public are only now learning to appreciate the work of Mrs. Cameron, and he ventured to predict that they would see much more work of the same kind before many years had passed away. She publicly exhibited her works but rarely, and then, as is often the case, was not satisfied with the judges' awards. Among those who wrote to her about her photographs, sent to some exhibition, was a German, who sent to her the following letter, evidently aided in his literary work by a dictionary:—

"Mr. —— announces to Miss Cameron that he received the first half a pound note, and took the photographies as Miss Cameron wishes. He will take the utmost sorrow* to place the pictures were good.

"Mr. —— and the Cmitié regret heavily† that it is now impossible to take the portfolio, the rooms are filled till the least winkle.‡ The English Ambassade takes the greatest interest of the placement of the photographies of Miss Cameron, and Mr. —— sent his extra ordinarest respects to the celebrated and famous female photographs.

"Your most obedient."

---

* Care, which was the word needed, is expressed by "Sorgen" as well as sorrow. We invert the sentence, and we read, to have the picture well placed where the light is good.

† Regret heavily, severely, seriously.

‡ Winkle is corner in German.

She also once received the following communication :—

"Miss Lydia Louisa Summerhouse Donkins informs Mrs. Cameron that she wishes to sit to her for her photograph. Miss Lydia Louisa Summerhouse Donkins is a carriage person, and therefore could assure Mrs. Cameron that she would arrive with her dress uncrumpled.

"Should Miss Lydia Louisa Summerhouse Donkins be satisfied with her picture, Miss Lydia Louisa Summerhouse Donkins has a friend who is *also* a carriage person, who would *also* wish to have her likeness taken."

About this letter Mrs. Cameron records :—"I answered Miss Lydia Louisa Summerhouse Donkins that Mrs. Cameron, not being a professional photographer, regretted she was not able to 'take her likeness,' but that had Mrs. Cameron been able to do so, she would have very much preferred to have her dress crumpled."

Mr. Davison continued that he hoped that the Club would make use of all the instruction it could gain from Mrs. Cameron's pictures, and that in time, following on the lines of such work as had been occasionally done by Mr. Faulkner, Mr. Lyonel Clark, and others, they would see them not only equalled, but eclipsed.

STEREOSCOPIC PHOTOGRAPHY.*

BY G. F. POWELL.

First of all I begin with a lament that this branch of photography is not as popular as it deserves to be, and surprise that it has so long remained so. Secondly, I will try to account for its unpopularity.

1st. Fashion; it was once very popular, but fashion changes, and the pendulum has swung to the opposite side.

2nd. The degeneration of the subject and style. Of course I do not refer to the very beautiful glass transparencies which many remember with keen pleasure, but to the absurd and vulgar groups, which must have gone far to discredit the stereoscope in some minds.

3rd. I think many admirers of the stereoscopic picture must have been sadly disappointed by the slides sold, for doubtless many have been taken in by the fraud of making a so-called stereo slide without the double negative. Such, it is almost needless to say, are flat as a single picture, and to this we shall again refer.

These three causes have, let us hope, worked their own cure. The pendulum of fashion is on its return, the vulgar style is ignominiously dismissed, and, as a rule, photography is too much to the fore for unscrupulous dealers to pass off bad work on the public.

This brings us to what a stereo slide is, or rather should be, namely, two pictures taken separately from the opposite angles at the base of a triangle, the sides of which should converge to a point as nearly as possible the most distant in the view to which the camera is directed; the length of the base of the triangle varies considerably with the subject. A good rule is, for ordinary work, to have the lenses (if a pair are used in a rigid front) two and three-quarter inches apart, centre to centre, this being about the distance apart, centre to centre, of the eyes. A better plan is to have a special front with double rack-and-pinion, by which the lenses can be brought nearer or set farther apart as required. Of course when the two pictures are taken upon the same plate (any landscape slope will do, say 7½ by 5), the camera must have a central partition to prevent blurring, or over-lapping of the two pictures in the centre. A single lens may be used if a sufficiently long sliding front is adapted, which will allow the lens to be moved laterally from centre to centre of the halved plate; but this will only do for still life, or possibly for portraiture. But if this branch of photography is to be carried out satisfactorily, twin lenses are absolutely necessary, inasmuch as it is impossible to take moving objects for the stereoscope with one lens, and sea pieces lose all their value if a wave, for instance, is not taken by both lenses at the same instant.

The base of our triangle, or distance between the lenses, will vary slightly in ordinary land or sea scapes, according to the distance from the camera of some of the near as well as distant objects. And here I would remark that near objects are necessary to the success of the pictures, the principle of the stereoscope being what I call relative displacement of objects one to another when viewed by either eye or either lens separately. Hold up your finger or other small object before any other object, look with one eye and then with the other, and in turn different parts of the background will be covered by what is held up, so that with both eyes you, as it were, look round the near object or objects. This, though crudely explained, will possibly illustrate the principle of the stereoscope, and show that two separately taken pictures are necessary. When well placed or selected foreground objects are secured in a picture, the result in the stereoscope is that other objects and parts of the composition will fall back or assume their relative positions, and the effect desired is obtained. For some subjects (principally scientific) the base of the triangle or distance apart of the points for taking the two pictures is considerable, some thirty or forty yards for the Pyramids, to many hundreds of miles for the moon; and this reminds me that stereo work can be accomplished by a quarter or 5 by 4 camera, and taking two pictures by placing the camera at the different points as required, for ordinary work at the opposite ends of a graduated board fastened to the top of the tripod.

Any process for negative taking or printing will do for the work, but I consider that the transparency for the stereoscope is the perfection of photography; the roundness of life is given by the stereoscope to a friend's likeness, to a bit of lovely scenery, snow, hoar frost, or ice, which might pass unnoticed in the flat photograph, but which is absolutely charming in this instrument. Too much contrast is undesirable, and what looks flat and wanting in pluck and crispness outside the instrument may be exactly right inside. The stereo-photographer can often choose charming bits, which, as single pictures, would be passed over. To return to the negative; presuming it is double, on the single plate being taken, as usual, upside down, on placing it picture wise, the right and left pictures are reversed, and must be cut asunder for mounting, or the effect is the reverse of what is desired, or pseudoscopic. There is a way of folding a double-length strip of paper, and printing two copies, by which means the paper can be cut in the middle, and save the double mounting; but this requires calculation and care hardly worth an amateur's while, though valuable where many prints are required off the same negative. Glass transparencies, too, require great nicety and care, but which amply repay him. A word as to subject; choose such as are likely to please generally, and not one's self alone, and such as will, as far as possible, explain themselves.

* Abstract of a paper read at the Bath Photographic Society.

A STANDARD METHOD OF DEVELOPMENT.*

BY C. H. BOTHAMLEY, F.I.C., F.C.S.

No one, I imagine, would venture to propose a uniform method of development for all the varied subjects with which a photographer meets in ordinary practice. The nature of the subject, the conditions under which it was photographed, and the intention of the photographer, or, in other words, the character of the result which he desires to obtain, must all be taken into account in the subsequent treatment of the plate; and to develop all plates in the same way would reduce photography from the level of a method of fine art, which most of us hold it to be, to the level of a mechanical process, which some critics tell us it is.

There are, however, many cases, chiefly of a scientific character, in which a uniform method of development is desirable, if not indispensable. Stellar photography is probably the best example which can be cited. When testing plates, too, it is essential to operate under strictly comparable conditions. The necessity for adopting some constant method of development in the work on orthochromatic photography with which I am at present engaged, led me to give some attention to the matter, and this paper is mainly a statement of the chief points which seem to require careful consideration in this connection.

When attempting to select a standard method of development, we may direct our attention to: (1) The sensitiveness, as measured by the intensity of illumination or time of exposure required to produce an impression which can be developed; or (2) the gradation of the resulting image.

I may say at once that, in my opinion, it is not practicable to frame or adopt any standard developer which shall be generally applicable when gradation is the chief consideration. A developer which would be perfectly satisfactory for line subjects would be unsuitable for subjects in half-tone; a standard which would satisfy an operator who desires to produce soft negatives would not meet with the approval of an operator who delights in "pluck." Gradation depends not only on the mode of development, but also on the manner in which the emulsion has been prepared, and the physical character of the gelatine which has been used. Moreover, the relation between the gradations given by two different kinds of plates does not remain constant, but varies with variations in the composition of the developer. The most, therefore, that seems possible is to devise some standard method (or methods) from the point of view of sensitiveness, and then learn to deduce from the results obtained with it as much information as it can be made to give concerning the gradation-quality of the plates.

The problem consequently becomes narrowed to a method of development which will enable us to compare the sensitiveness of different plates, and to obtain from any plate the maximum amount of detail which it can be made to yield without fogging. Our object is to obtain a visible and printable deposit of metallic silver from every part of the emulsion which has been acted upon by light, without reducing those portions on which light has not acted. Development is a process of *selective* reduction, and this fact it is very important to keep in mind. We have likewise to bear in mind that many photographers, even scientific photographers, are not chemists, and have very little skill in chemical manipulations; they also have to rely upon the dealers in chemicals for the purity of their preparations.

A standard method of development, if it is to be really useful, and gain general adoption, must fulfil several conditions:—

1. It must be simple in execution.

2. It must resemble, as closely as possible, the methods used in ordinary practice.

3. It must involve the use of only such chemicals as can be purchased in a state of purity, and are not hygroscopic, or liable to undergo other alteration when stored with ordinary care.

4. The solutions required must be easily prepared, and not liable to alteration.

Ferrous oxalate dissolved in a solution of potassium oxalate fails to fulfil several of these conditions. Potassium oxalate and ferrous oxalate can, it is true, readily be obtained in a state of purity, but the preparation of a solution from these materials is a somewhat tedious operation. Ferrous sulphate is a more convenient iron salt in practice, but both the solid and its solution readily oxidise. This difficulty is removed to a considerable extent by the use of ferrous ammonium sulphate, but even this salt alters somewhat rapidly after being dissolved. The ferrous oxalate solution itself oxidises very rapidly, and the ferric oxalate which is formed is not only a vigorous retarder of development, but is also a reducing agent of considerable power. Lastly, we have to take into account the fact that this developer is rarely used for ordinary negative work, and even its use for positives is becoming less frequent.

Eikonogen is also unsuitable, because: (1) Its purity at present is a very variable quantity; and (2) Its behaviour with various accelerators, and under different conditions, is not yet fully understood.

There remain pyrogallol and quinol, and of these the former seems decidedly preferable, because, in the first place, it is the developer most largely used in actual practice; and, in the second place, its much greater solubility makes the preparation of solutions an easier and more rapid operation than when quinol is used.

Pyrogallol is readily obtained pure, and remains unchanged for a very long time in well closed bottles if kept out of contact with ammonia vapour.

The alkali employed as an accelerator may be ammonia, ammonium carbonate, sodium carbonate, or potassium carbonate.

The restrainer may be an alkaline bromide, or an alkaline salt of an organic acid.

Ammonium bromide is the most suitable restrainer when ammonia is the accelerator. It is readily obtained pure, and, although slightly hygroscopic, it is easily dried in an air bath, or by placing it on a clean plate on the top of a moderately warm oven. Potassium bromide, on the other hand, usually contains small quantities of bromate, and, not unfrequently, small quantities of caustic potash. If, however, sodium or potassium carbonate is used as the accelerator, and a restrainer is required, potassium bromide must be used, since ammonium bromide would be decomposed with formation of ammonium carbonate and free ammonia. Alkaline salts of organic acids are unsuitable for the purpose under discussion, because of the difficulty of obtaining them in a state of purity.

The French Exhibition in London will be opened early this month by the Lord Mayor. Its president is M. Gustave Sandoz, and its Director-General Mr. J. R. Whitley.

PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Heliochromic Experiments—New Collodion Emulsion Paper.

Since the results of Mr. Fr. Veress's attempts to produce photographs in natural colours have been published, the interest of the profession as well as of the public has been again directed to this mysterious branch of our art-science which, in 1839, Sir John Herschel pointed out as "only a question of time." Half a century has elapsed since then, and the problem is still unsolved. It is well known that by the investigations of Becquerel and other pioneers of our art-science, the possibility of reproducing colour by means of photography has been proved, but that they only partially succeeded in fixing their prints. Of late, Mr. Veress has, as the tests of Professor Vogel are showing, not yet obtained results which can be regarded as permanent, but Mr. Veress, whom I know very well, and who is as assiduous and as talented as he is modest, has never claimed to have solved the problem of heliochromy. On the contrary, he describes his labours as simple experiments, about which people make "too great a bustle," as he expresses himself in a letter. The partial success of these labours has incited other investigators to repeat the experiments of Niépce de Saint Victor and of Poitevin.

At the last meeting of the Society of Practical Photographers of Berlin, Mr. Gaedicke presented prints, produced by himself by means of the older methods, which exhibited a number of beautiful, brilliant colours. He said that they were produced on gelatino-chloride paper, which was previously exposed to light until it turned dark reddish brown, in order to obtain the sub-chloride forming the basis of these experiments. The paper was next, according to Poitevin, bathed for about two minutes by lamplight in a mixture of equal parts of a concentrated solution of sulphate of copper and of a five per cent. solution of bichromate of potash, then dried in the dark, and exposed to sunlight beneath coloured sheets of glass. In order to shut out the invisible ultra-violet rays, which in printing act injuriously, Mr. Gaedicke used a glass plate coated with a gelatine solution to which a trace of uranine or aesculine had been added. After drying, this glass is almost colourless by transmitted light; if, however, it is held in an inclined position and looked at from above, it appears, in the one case, beautifully green, in the other blue.

Dr. A. Miethe recommended, in order to conserve more fully the fluorescent qualities of the plates after drying, the addition to the gelatine solution of a small quantity of glycerine. He gave the following formula:—

Gelatine	2 grammes
Glycerine	2 ,,
Water	25 c.c.
Aesculine	0·05 gramme

The gelatine is dissolved at a low temperature in 15 c.c. of the water, then the glycerine and the aesculine, the latter dissolved in 10 c.c. of water, are added, and the whole is filtered through sheep's wool. With this solution the glass plates are coated rather thickly, allowed to set, and dried in a place free from dust. Through plates of this kind the ultra-violet rays still partially pass; in order to shut them out completely, it is necessary to combine with this aesculine plate another one, which contains 0·02 gramme of fluoresceine instead of the above given quantity of aesculine. The two plates with the film sides placed together, and the edges cemented with black paper, which may be coated with asphalt varnish, in order to protect the films against the influence of the air. If after some time the aesculine plate turns brown, it must be replaced by a fresh one. The pure aesculine as well as the fluoresceine may be procured from Dr. Schuchardt, of Görlitz. A combined plate of this kind may be placed over the printing frame, which contains the above described dark brownish silver sub-chloride paper together with the coloured sheets of glass, and the whole is then exposed to diffused daylight. Beneath a yellow sheet of glass the paper soon turns lighter, and after about half-an-hour it will be printed out, showing, if watched by lamp-light, a rather brilliant yellow tone. Beneath a ruby glass the paper acquires a brilliant vermilion colour; beneath a green glass a slightly brilliant olive-green; beneath a blue cobalt glass a darkish brown. The coloured prints keep for some time, provided that they are not exposed to direct sunlight, and if after printing they are washed several times in water which has been slightly acidulated with sulphuric acid. Dr. Miethe remarked that in his own experiments he used an ordinary collodio-chloride solution with silver in excess. He exposed it in a light coloured bottle to sunlight for several hours, shaking it from time to time; and then decanted it from the brownish sediment which was formed. Paper prepared with this collodion gives with rapidity bright colours beneath coloured gelatine films. Dr. Miethe tried to fix his prints with a solution of magnesium chloride, which has recently been recommended for this purpose by Mr. R. Liesegang, and to which he added alum up to three per cent. This fixing agent seems, however, not to fulfil the hopes which it afforded; in the case of Dr. Miethe's experiments, at all events, the vivid colours of the prints faded even in the dark, and after some days nothing but faint tints were visible, which, however, did not become weaker even after they had been exposed to sunlight for some hours.

It will be seen from these experiments that we at present have not advanced beyond the position of forty or fifty years ago. The possibility of reproducing natural colours by photography to a certain degree has been proved, but we are waiting for somebody who can invent the means of fixing the colours obtained.

A new collodion emulsion paper has been introduced by Mr. V. Angerer, of Vienna, which, as far as can be judged from a few experiments I have made with it, answers well. Collodion emulsion paper, in general, does not enjoy so much favour in this country as its mighty rival, the gelatino-chloride paper, probably because the treatment of the latter is more convenient. The collodion emulsion paper, during the different manipulations after it has become wet, is rather tender, and has a decided inclination to curl, particularly when the paper is somewhat thick. It should be carefully treated while in a wet condition, the collodion film being easily damaged, particularly around the edges. These insignificant defects of the chloride of silver collodion paper are, however, sufficiently compensated by the extreme sharpness of the pictures on the same, particularly in comparison with albumen paper, where the details in the deepest shadows are hardly visible. For toning, I use the sulphocyanide of ammonium bath, which is convenient in its handling. The prints tone extremely quickly, even in comparison with those upon gelatine paper, if toned in the combined toning and fixing bath. Enough care cannot be taken not to lose the beautiful purple tone of the collodion paper by the rapidly-following bluish-black.

Notes.

Photographers are not alone in the difficulty of deciding upon one uniform system of weights and measures. The subject is continually being alluded to, and it cropped up incidentally at the last meeting of the Photographic Society, when the much-abused English system found a champion in some respects in Mr. C. H. Bothamley. The American pharmacists are about to take the matter in hand, and it will shortly be discussed by the Revision Committee of the U. S. Pharmacopœia. Mr. J. W. England, writing on the subject in the *American Journal of Pharmacy*, advises the abolition of the "parts by weight" system, and the adoption of the French metric method. The metric system is supposed to be in use in America, but it is only so in name, for Mr. England says, that of nearly 500,000 prescriptions over which he has had supervision in preparation during the last five years, there have been but two metric prescriptions, and from enquiries he has reason to believe that the general experience differs but little from his. He points out that if the physicians do not lead the way, it cannot be expected that pharmacists, or chemists and druggists as we should call them, will trouble about the metric system. Photographers are much in the same position here; they are waiting for the dealers to initiate a simpler method. The French are in the happy position of having settled the question. Were they not, it certainly would have been one of the first things discussed at the International Photographic Congress of last year.

A fine set of illustrations from photographs are promised with Mr. Stanley's forthcoming article in *Scribner*. These photographs are of scenery upon which the eye of a white man never gazed previous to Mr. Stanley's visit. It would be interesting to know Mr. Stanley's photographic experience—whether he developed his plates on the spot, or whether he brought them away under lock and key to be developed at home. A word or two also as to how the natives regarded the camera would not be amiss.

The latest of American photographic notions—the costume album—has been ridiculed, but how valuable for the student of social philosophy, if the term may be used, would such a record of a quarter of a century's fashions be. The costume album, it may be as well to explain, is thus constituted. On the left hand page is the photograph; on the right is an artistic arrangement of the materials composing the costume which the photograph represents. The collector usually begins her album with her wedding dress, and proceeds with the various "confections" of the dressmaking art in which she indulges from time to time. Such an album would, we fancy, be productive of rather mixed feelings on the part of the persons concerned. To the lady it would afford, on the whole, a pleasant reminiscence, dashed slightly with a little bitterness, because dressmakers do occasionally make misfits; but to her husband, it can only revive recollections of the many cheques which the dresses represent. The student of whom we have already made mention would probably be the person who would gaze upon a "costume album" with unalloyed delight.

The fate of the *New York Illustrated Daily* is not encouraging to enterprises of a similar nature. It has died out, never, so we are told, to be revived. For a few weeks after it stopped there was a project to carry it on, but this was abandoned, and everything has been sold. Nearly a million of dollars was sunk in the paper, but it did not succeed because of the inferior quality of its illustrations. Photography has done much since the *New York Daily* was started to make such an undertaking possible, but the problem of combining very rapid printing with artistic results has not yet been solved, and this problem is at the present moment the stumbling block in the way of success. Given the necessary time, "process" work in the hands of those who know how to draw for its requirements has a chance of its own. The latest illustrated weekly paper started in New York is of a large size, and entirely illustrated by process cuts of a high class.

A photographic record is being kept of the progress of building the new library, Washington. A camera is planted on the roof of the building occupied by the architect, and a record of every detail of the condition of the work, the height of the walls, the piles of material, is thus preserved. The photographs are afterwards classified, are properly labelled, and can be produced for reference if any question arises as to what was done, or what was not done, at any stage of the work. Thus the camera acts as a check upon the contractor; but this is not the sole purpose for which the photographs are taken, as they are found to be a valuable supplement to the written records of the operations.

It is a pity this plan was not adopted when the foundations of the Board Schools about which so much has been said, were put in. Though the camera is not yet able to distinguish between good and faulty bricks, or real mortar and the "mic-mac" imitation, it would probably record not only the depths of the foundations, but the kind of soil upon which the bricks were laid. Contractors have a wholesome dread of the photographer. We knew a case where, on the roof of a new building falling, a photographer was called in to photograph the place, so as to produce evidence of faulty construction in case the contractor repudiated any liability. When the photographer appeared on the ground, the contractor's men, acting under orders, surrounded him, and effectually prevented anything being done, by upsetting his dark tent.

HOW ANSCHUTZ PHOTOGRAPHS THE LARGER WILD BEASTS.

About a quarter of a century ago an interesting article on the photography of brutes, written by Frank Haes, and read before the then North London Photographic Association, appeared in the Photographic News. The experiments of Mr. Haes seem to have been attended with no little difficulty and danger. In the first place, he complains that the prevailing colours, red and yellow, are not favourable for photography. Next, he was more or less unsuccessful, generally more, with the zebra and the ratel, the hyrax (the Biblical coney), and the kiwi-kiwi, the leucoryx and the Syrian wild ass, the dingo, and the Tasmanian devil. The chimpanzee was too ill-tempered to allow his portrait to be taken, and the innate modesty of the monkey possibly lay in the way of a successful picture. One variety of the simiæ, when everything was ready, would turn suddenly round and present a view which the artist by no means desired. Another variety would insist on looking steadily into the camera. The goats had to be held by the beard, the weak point of the goat, and the iguanas by the tail. The African python chose to tie himself in a very complicated knot, and the confusion of the armadillo was such that it was difficult to determine which was his worthier end. The clouded tiger could not well be taken inside his cage because of the bars, and the space he occupied was, says the author of the article, too small to admit of my introduction. There may have been other reasons for his not entering the clouded tiger's den, but he has omitted to declare them. The modesty of the monkeys has already been mentioned, but they appear to have been inferior in this virtue to the aye aye. This singular nocturnal quadruped, the cheiromys Madagascariensis, which Cuvier placed among rodents, but was referred by Sonnerat to the family of makis or lemurs, gave especial anxiety to the photographer. Its diffidence, whether natural or acquired, was extreme. When the camera was in readiness, and the door of its cage was opened, it immediately covered itself completely with its tail.

Brute photography is better managed now than then. In the Zoological Garden of Breslau, and elsewhere, many excellent portraits have been taken. Of the method adopted in taking a bear in Breslau, the following description is given in a German paper.

The present month's number—number 15—of the German *Photographic News*, presents its readers with two illustrated supplements: the one an instantaneous photograph of a bear by the well-known Ottomar Anschütz of Lissa, the Polish Leszno in Russia, some forty miles south of Posen, signed on a portion of rock which the animal is mounting, "Ottomar Anschütz, Lissa (Posen), 1888." Of this a photogravure has been printed by H. Riffarth, of Berlin. The other is a portrait, an original negative of Fr. Muller, of Munich. This is extremely well represented as a photogravure by the Art Publication Institute of Dr. E. Albert & Co., of Munich, and shows, says the German paper, what the treatment of Dr. Albert is able to effect in the ordinary taking of portraits. The treatment is even better adapted for this kind of photography, as we shall demonstrate, says the German *Photographic News*, in our next number, which will contain a group by Brokesch, of Leipsic.

With regard to the portrait of a bear, the reader is informed that the original sitter, or rather climber, is to be found at his present residence in the Zoological Garden of Breslau, which has been often visited by Herr Anschütz, as is well known, for the purpose of taking portraits of its inhabitants. We will, says the above quoted journal, give our readers some little insight into the plan adopted by Herr Anschütz of taking wild animals, which he has himself kindly communicated to us.

The usual method of taking savage beasts in their cages has a good result only exceptionally, for the three following reasons. The first reason is that the lighting arrangements are not generally of the most convenient character; the second, that the narrow space in which the animal is confined hinders its free and natural motion; the third, that the iron bars of the cage are altogether out of place in the picture. Herr Anschütz therefore constructed for himself in Lissa a large enclosure or keep, in which he was able to take the smaller animals in various ways to his complete satisfaction. Foxes, wolves, and apes were also well photographed in this improvised animal studio.

But for the larger ravenous inmates of the Breslau Zoological Garden this enclosure was clearly not suitable, and these inmates could scarcely be transferred from Breslau to Lissa. Herr Anschütz then conceived the idea of building a larger and stronger kind of keep in the Zoological Garden. Through the courtesy of the directors of the Garden in Breslau, Herr Anschütz was able at the beginning of the year 1888 to erect a firmly constructed keep of strong planks of a superficial area of some 140 square metres. This enclosure was open above, but the walls had a height of six metres, which fulfilled all necessary requisites.

In an additional wing on one side of the enclosure there are placed three cages serving for the sleeping apartments of the wild animals; on the longer side several underground passages lead into the enclosure itself. These are fastened with folding iron gates, and serve to facilitate the business of portraiture.

On the other side is an oblong aperture, furnished with an iron shutter. Here the apparatus is placed commanding a view of the enclosure. As soon as the animal comes into the space commanded by the camera, the portrait may be secured. The background of the enclosure is a painted landscape, which is varied according to the habit of life, colour, and size of the animal to be taken. Such variations harmonise naturally with the foreground, consisting of rock or stone.

When their photographs are to be taken, the beasts are caught and brought in a transport cage into the enclosure. After some time, and after they have become accustomed to their new apartment, they are photographed. The original pictures, as all of Herr Anschütz's studies, are of smallest size, and are afterwards enlarged.

A great difficulty often occurs in bringing the animals into the proper spot for their portraiture—that is, into the full sunshine. In this case hunger and thirst seem the only available roads to success. Living food is commonly distributed to the beasts on such occasions, whereby a more exact representation of nature, and an increased effect is secured. The photographing of bears, says Herr Anschütz, is an especially difficult undertaking, since these animals manifest great unwillingness to enter the photographic studio. Eight days were required to bring these refractory subjects before the photographic lens. Even fasting was unable to move their stubborn minds, and it needed an extreme degree of artifice to induce them to enter their respective cages. But *en revanche*, these bears

behaved themselves, after they had once got into the studio, in a manner which was morally beautiful. Their general deportment was far more decent than that of other beasts. And so Herr Anschütz was enabled to take over three hundred distinct likenesses of these regenerated brutes. Although, he says, I had on many occasions and with much zeal studied the characters of Mr. and Mrs. Bruin—or, as the Germans say, Herr Petz and Gemahlin—I was nevertheless much astonished with the variety of their gestures and the general many-sidedness of their demeanour. The different sentiments of the mind are in no other animal so clearly expressed as in the bear. On several occasions I have been much surprised by their power of observation, and I have come to the conclusion that the bear is the wisest of the beasts.

The German *Photographic News* promises a description at a later date of the instantaneous apparatus employed by Herr Anschutz, an apparatus which was shown lately at the exhibition at Weimar. The manufacturer has, it seems, some additions to make, which will considerably change the character of the instrument.

PHOTOGRAPHY IN NATURAL COLOURS AS EFFECTED BY HERR FRANZ VERESS, OF KLAUSENBURG.

BY DR. J. M. EDER.*

THROUGH the kind mediation of Herr E. Von Gothard, of Hereny in Hungary, I have received some photographs in natural colours by Herr Franz Veress, of Klausenburg; some of these photographs are on glass, and are to be viewed as transpareneies, whilst others are on paper, and show by reflected light.

The glass pictures show a beautiful ruby red colour; this indeed predominates for the most part in the diapositives as the ground colour. On this is seen a vividly coloured brilliant picture, in which especially, deep ruby and bright yellow are conspicuous, and contrasting with them are distinct blue-violet, and blue: green, on the other hand, is not represented in these pictures. The outlines of the photographic picture are perfectly sharp, and the different portions of the glass picture show with complete distinctness from each other.

The paper pictures have a greyish brown ground colour, on which the photograph in natural colours stands out; in this case also the colours from ruby red to orange yellow predominate, but in one of them there is also a decided violet blue. The photographs in question are to a certain extent fixed, since after a stay of some hours in a light apartment they did not show the smallest change. In addition to this, they had been examined by many persons in daylight without any special care being exercised, and were not injured thereby. I did not apply any more stringent test to ascertain their permanence under the influence of light, as I wished not to risk injury before showing them at the March meeting of the Vienna Photographic Society.

On the preparation of the sensitive surface, Herr E. von Gothard communicated briefly to me a few data. The sensitive compound is a silver chloride collodion, or gelatine emulsion of special preparation, spread upon glass or paper. The plates are exposed in a printing frame—the glass ones for two or three hours, and the paper ones for three days—under a transparent coloured drawing. The colour of the emulsion film is brownish red: the picture appears in a few minutes in a negative form, the dark places showing as white. The colours come out slowly, and then they are fixed in an alkaline bath, which makes the colours still more intense. In the camera, weeks of exposure are required.

Herr Veress has, however, found a sensitizer by means of which the exposure may be notably shortened.

It appears to me that this process of photo-chromy is a happy application of the photo-chloride of silver described two years since by Carey Lea, the same substance probably as that described fifty years ago by John Herschel (1840), Ed. Becquerel (1847, 1848, and 1855), Niepce de St. Victor (1851-1866), and which Zenker has dealt with in his "Photo-Chromie."

As far as I am aware, the application of colour-sensitive chloride of silver in the form of an emulsion has hitherto been but little if at all practised, and the skilful experimentalist Herr Veress owes the noteworthy success of his photographs in natural colours to this combination.

In view of the circumstance that Herr Veress, after a year and a half of experiment, can already show such results, it is to be hoped that the continuation of his researches will hasten the solution of the problem of photographing in natural colours in an important degree.

It is at present to be noted, that in spite of the imperfection of these first specimens, Herr Veress's experiments have met with success, especially in the ability to fix photographs showing the natural colours. Against this gain, the circumstance that all colours do not show with the same vividness is a consideration of less importance.

* Translated for the PHOTOGRAPHIC NEWS from the *Photographische Correspondenz*.

A NEW PHOTOGRAPHIC SOCIETY.—It is proposed to form a photographic society in Ealing, and it is probable that suitable accommodation for meetings may be obtained at the Local Board Offices, and a convenient dark room be fitted up for the use of members. Those wishing to join should communicate with Mr. H. W. Peal, 2, Craven Terrace, Ealing.

ROYAL INSTITUTION.—At the general monthly meeting held last Monday, with Sir James Crichton Browne in the chair, the following vice-presidents for the ensuing year were announced:—Sir Frederick Abel, C.B., D.C.L., F.R.S., Mr. William Crookes, F.R.S., Dr. Edward Frankland, F.R.S., Mr. William Huggins, D.C.L., Earl Percy, Mr. Basil Woodd Smith, Sir James Crichton Browne, M.D., treasurer, and Sir Frederick Bramwell, Bart., F.R.S., hon. secretary. Professor Tyndall was elected honorary professor of natural philosophy, and Lord Rayleigh was elected professor of natural philosophy. At the annual meeting held on Thursday, May 1st, the annual report of the committee of visitors for the year 1889 testified to the continued prosperity and efficient management of the Institution. The real and funded property now amounts to above £82,000, entirely derived from the contributions and donations of the members. Fifty-one new members were elected in 1889. Sixty-three lectures and nineteen evening discourses were delivered in 1889. The books and pamphlets presented in 1889 amounted to about 283 volumes, making, with 539 volumes (including periodicals bound) purchased by the managers, a total of 822 volumes added to the library in the year. The Duke of Northumberland was elected president, Sir James Crichton Browne treasurer, and Sir Frederick Bramwell, Bart., secretary. Mr. Louis Fagan, assistant keeper of the department of prints and drawings at the British Museum began a course of three lectures on "The Art of Engraving" on Tuesday, May 6th. Professor Dewar, F.R.S., commenced a course of six lectures on "Flame and Explosives" on Thursday, May 8th; and Dr. Charles Waldstein, director of the American School of Classical Studies, Athens, will begin a course of three lectures on "Recent Excavations in Greece" to-morrow.

THE PHOTOGRAPHY OF THE MORE REFRANGIBLE RAYS.*

BY V. SCHUMANN.

IN all the domains of science the method of taking photographic observations has of late years grown apace, and supplants more and more the ocular method. Of all the students of science, however, who bring photography into their service, there are none who can derive so much advantage from the photographic registration of observation as those who deal with the spectrum. The rays thought to be alone photographically active—those from the region of the blue and violet—have now, for some decades past, been fixed by the "never forgetting retina of the camera" for the observation of future generations. The red and yellow, on the other hand, first came into importance photographically since H. W. Vogel has shown that by treating photographic plates with suitable dyes—optical sensitisers—they may be rendered sensitive for the optically bright rays. Spectroscope workers, like Hasselberg, Rowland, and others, have made good use of the important discovery, and especially since the voluminous researches of Dr. J. M. Eder on optical sensitisers have been given to photographers, they having succeeded in photographing that part of the spectrum which was thought to be beyond their grasp.

Yet further. By the help of optical sensitisers (cyanin), Burbank has so far succeeded in securing the infra-red spectrum on gelatine plates, that his results show twice as many lines as those in the spectrograph taken some years earlier by Capt. Abney, which had so much enlarged the borders of the knowledge of the spectrum attainable by our science. We may well believe that photography, since in recent years it has made so much advance in this direction, may yet be made to work as far into the infra red as Langley, by means of his bolometer, has opened it out to us.

Invisible as is the infra-red in general, so on the other side of the spectrum is the ultra-violet. Invisible, however, only for our human eyes, by no means so for the photographic plate. On the contrary, there is a not inconsiderable array of sources of light that have their most powerful photographic action, not in the visible spectrum, but in that portion where, to our retina, total darkness reigns. To this class belongs particularly the light of the electric spark. Sunlight comes very near to it in this respect. It must, however, be well understood that the rays of the latter are very strongly influenced by the properties of the atmosphere through which they have to pass before they reach us. Of even greater influence than the atmosphere may be the nature of the media of which the optical part of the photographic apparatus is composed. This applies not only to photographic apparatus for spectrum work, but to photographic objectives in general.

All glass, optical glass not excepted, however colourless and however transparent to our eyes, absorbs, nevertheless, a considerable amount of the ultra-violet light. Many kinds of optical glass are so opaque to this kind of light that they obstruct almost the whole of the ultra-violet rays. To quote only one case, when the sun's spectrum is photographed with H. W. Vogel's small spectrograph, it is found that the spectrum picture ends at the same place as it ceases to be visible to our eyes. Such a spectrum picture, especially if taken to judge of the qualities of a colour-sensitive plate, has, on account of the partial suppression of the blue, violet, and ultra-violet rays which result from the use of the heavy flint glass of the prism and the apparatus, but a relative value. Only to the eye of one accustomed to working with the spectrum is there evidence in it which is understood. When, on the other hand, a person unpractised in spectrum photography uses apparatus of this kind for studying orthochromatic plates, he will be sure to read a degree of sensitiveness for the yellow and red rays which the plate does not at all possess. In this case *it is not the sensitizing dye which makes the plate sensitive to colour, but the heavy flint glass of the Amici prism* which reduces the blue and violet rays so far that they may only produce about half their proper action on the plate, whilst the red and yellow rays fall upon the coloured gelatine film almost unchanged. In such circumstances, it is easy to prepare plates that shall appear to possess enormous sensitiveness for the yellow rays. A photograph taken with Vogel's small spectrograph shows certain rays to be as much restrained as in a photograph taken with a lens, and through a strongly-tinted yellow screen.

When the prisms and lenses of a photographic spectrum apparatus consist of glass of the same amount of transparency for all rays as our photographic objectives, the photograph of the solar spectrum shows, with short exposure, a larger portion of the ultra violet rays in active force. From such a spectrum photograph the colour sensitiveness of orthochromatic plates, such as are prepared for our use, can be safely estimated.

The fewer rays that are withheld by the lens, the shorter may be the exposure of the plate. If the same subject is photographed with a lens made of glass and again with one of quartz, it is found that the last-named works considerably quicker than the other. Quartz allows the ultra violet rays to pass almost entirely. If a glass can be made which permits nearly the same amount of rays to pass as quartz does, the exposure required for taking a photograph will be considerably reduced from what it is at present.

(*To be continued*).

* Translated for the PHOTOGRAPHIC NEWS from the Special Supplement to the *Photographische Rundschau*.

PHOTOGRAPHIC LENSES.*

BY THOMAS R. DALLMEYER.

IN this country much valuable work has been accomplished by Dr. John Hopkinson and Professor Stokes, in obtaining convenient methods of expressing the measure of the irrationality of combinations of various glasses made by Messrs. Chance, of Birmingham. Dr. Hopkinson contributed a very important paper, especially to opticians, on this subject to the Royal Society in 1877, and in conjunction with my late father, worked out some important and valuable improvements in glasses for special photographic purposes, and succeed in practically curing several of the glasses then made from "sweating." Professor Stokes, too, suggested a titano-silicic crown that should be perfectly achromatic with a flint; this glass, however, was not found to be of much practical value. To express the irrationality, Dr. Hopkinson found a convenient formula that more accurately represented the facts from observations than the direct method of curve drawing, as the errors in this case would be greater than in those of observation. I refer those interested to the paper, but give you the results of that formula, which serve to show

* Continued from page 345.

how little there was to choose between the ordinary glasses made by Messrs. Chance. The figures show the measure of irrationality in a combination of each combined with a standard:—

Hard crown.	Soft crown.	Titanic crown.	Light flint.	Dense flint.	Extra dense flint.	Double extra flint.
—11·7	—10·7	—9·4	—9·4	—11·8	—11·9	—13·2

It will be interesting to compare some of the new glasses from Jena with these; and although they are presented in a less elegant form, the prospectus is a very practical representation of the qualities of the glasses, so I give the data of Chance's glasses in a similar form to those of Jena; but we will first make a preliminary investigation as to the conditions to be arrived at.

The dispersion, then, of colour produced by a positive or convex lens, may be neutralised by the addition of a negative or concave one, without cancelling the deviation of the rays, as the positive and negative lenses act with opposite effect. In other words, a compound lens may, by the proper adjustment of the *powers* of the separate lenses, be made achromatic or actinic, although if irrationality in the dispersion exists, only the union of a definite number of species can be combined, according to the number of different media forming the compound lens.

If the radii of a lens are r and s, in general approximation,

$$\frac{1}{f} = (\mu - 1)\left(\frac{1}{r} + \frac{1}{s}\right).$$

Herschel terms the reciprocal of the focal length the *power* of a lens, and this is seen to depend on $(\mu-1)$, which we may take as the measure of the refracting power of the substance of which the lens is composed, and the second $\left(\frac{1}{r} + \frac{1}{s}\right)$ the simplest measure of the joint curvature.

To determine the relation between the focal lengths of two lenses that shall be achromatic or actinic when in contact:—

Let $\frac{1}{\rho}$ represent $\left(\frac{1}{r} + \frac{1}{s}\right)$ and μ_1 μ_2 the indices of refraction for the two lenses for one species of rays.

Then if u be the distance from which the pencil originally diverged,

$$\frac{1}{v_2} = \frac{\mu 1 - 1}{\rho 1} + \frac{\mu 2 - 1}{\rho_2} - \frac{1}{u}$$

and similarly, if μ' represent the index of refraction for another species of rays,

$$\frac{1}{v_2} = \frac{\mu' 1 - 1}{\rho 1} + \frac{\mu'_2 - 1}{\rho_2} - \frac{1}{u}.$$

As v_2 is to be the same for both species, we get by subtraction, term by term, and representing $\mu' - \mu$ by $\Delta\mu$, we have

$$\frac{\Delta\mu 1}{f 1} + \frac{\Delta\mu_2}{f_2} = 0, \text{ or } -f_2 = f 1 \frac{\Delta\mu_2}{\Delta\mu 1}.$$

Now, in general, $f = \frac{\rho}{\mu - 1}$;

$$\therefore -f_2 = f_1 \cdot \frac{\Delta\mu_2}{\mu^2 - 1} : \frac{\Delta\mu 1}{\Delta\mu^1 - 1}.$$

Therefore the focal length of lenses are directly, or their powers inversely, as the dispersive powers of the media of which they consist.

Again, since $\frac{1}{f} = (\mu - 1)\left(\frac{1}{r} - \frac{1}{s}\right)$,

$$\Delta\mu \frac{1}{f} = \left(\frac{1}{r} + \frac{1}{s}\right),$$

$$= \frac{\Delta\mu}{\mu - 1} \cdot \frac{1}{f}.$$

That is to say, the chromatic variation of the power of a lens is obtained by multiplying it by the dispersive power of the medium,

$$\text{or } f_1 : -f_2 :: \frac{\Delta\mu_1}{\mu_1 - 1} : \frac{\Delta\mu_2}{\mu_2 - 1} \quad \ldots\ldots (1).$$

In like manner, by adding a third species of glass, we can satisfy a third condition, viz., that the third species should be united to the two former. And in general

$$\Delta\mu \cdot \frac{1}{f_1 f_2 \ldots fn} = n \frac{\Delta\mu}{\mu - 1} \cdot \frac{1}{f_1 f_2 \ldots fn}$$

The prospectus published by the laboratory at Jena is presented in a very practical form to opticians; the refractive index for the brightest line D being given, and the differences of the refractive indices for the four intervals, CF, A'D, DF, and FG'. The interval CF, containing the brightest portion, is sufficient to characterise the medium dispersion, and from the proportion of this to the value $\mu_D - 1$ there is given in a separate column the reciprocal of the relative dispersions or of $\frac{(\Delta\mu)}{(\mu-1)}$. The proportion of partial dispersions in the intervals A'D, DF, FG', are a sufficient guide to judge of the possibilities of successful combinations for achromatism. There are also given the numbers obtained by dividing these intervals of partial dispersion by the amount of medium dispersion for the interval CF, and a comparison of these quotients will show the tendency and amount of the residual secondary spectrum. The identity of corresponding quotients proves the possibility of achromatising without secondary colour.

Kinds of Glass.	Refractive Index for D.	Medium Dispersion C to F.	$\frac{\mu-1}{\Delta\mu}$.	Partial Dispersion A' to D.	Partial Dispersion D to F.	Partial Dispersion F to G'.	Specific Gravity.

* These intervals are taken from B to D, D to F, and F to G.

† These glasses are very soft or unstable when exposed to the air, and should be protected in use.

In the older products of glass factories it was quite sufficient to take the specific gravity of the various glasses, as a near approximation to any alteration in the optical properties of different meltings: a greater density indicating an increase of refractive index and dispersive power.

The figures in the list taken from the prospectus from Jena show that glasses are made of nearly equal relative dispersion, with considerable differences in partial dispersion; and, again, others in which the partial dispersion

is almost identical, with considerable variation in the relative dispersion. In those instances it is evident that the secondary spectrum can be abolished. There is, however, a residual tertiary spectrum in the couples referred to, but it is quite unimportant compared to the secondary spectrum left in a combination of ordinary silicate "crown" and "flint" glasses. In photographic lenses the object is to get all the chemically and visually active rays possible together, and with certain of the glasses of lower dispersion improvements may yet be made by a better correction, both in the chromatic and spherical aberrations of the eccentrical pencils in lens systems.

The first approximations in theory, both for aplanatism and actinism, are simple enough when the lenses of the systems are considered *thin*, and second approximations, for the central pencils, are given in most of the text-books in which *thickness* is taken into account, and are easily intelligible. In lenses required to be both aplanatic and actinic, we are not limited only to the central pencils, and it is of the highest importance that all incidences for the lens should give the same results as the central pencils, and it is the inquiry into the forms best suited to accomplish this that constitutes the optician's great difficulty.

As a matter of fact, it is impossible to construct an aplanatic lens that is free from chromatic aberration for a central pencil that shall be so when a pencil of rays meet the lens obliquely. Lenses may be considered as made up of an infinite number of prisms, and, as you are aware, achromatism is only possible with combined prisms for one particular incidence. Now, a parallel ray and an oblique ray must of necessity have different incidences on the surface of a system, and hence, if it is actinic for the parallel ray, it cannot be for the oblique ray, strictly speaking.

Forms of lenses than that most nearly approximate to the conditions throughout of equal incidences and refractions at emergence, will conform to the best conditions for actinism as well as aplanatism, as we shall see presently.

We have found, then, from first principles alone, that the main condition for actinism is only one of focal length to be ascribed to the various lenses of the system, and, for the best results, the powers of these components must be rigidly maintained, whatever may be the ultimate form or selection of curvatures adopted to best suit particular applications.

(To be continued.)

Camera Club Notices.—Thursday, May 15th, 8 p.m.—Informal meeting. Saturday, May 17th.—Excursion to Wrotham, for Igtham and district. Leader, Mr. D. Howards. Train from Victoria at 8.50; Holborn Viaduct, 8.45; St. Paul's, 8.48; Bromley, 9.20; arriving at Wrotham at 10.6, where a conveyance will be in readiness to convey the party to Igthaun. A later train leaves Victoria at 11.35, Holborn Viaduct at 11.30, and St. Paul's at 11.33. Very beautiful country, and picturesque and interesting subjects. Dinner at the "George and Dragon," Igtham, at 5.15 p.m. It is probable that some members may go down on the Friday evening. Those intending to join in this arrangement should notify the same on the list posted in the Club. Monday, May 19th, 8.30 p.m.—Lantern in operation. Evening for testing slides. Notice to be given to Mr. F. J. Roberts. Thursday, May 22nd, 8 p.m.—Mr. E. R. Shipton, "Cyclo-Photography."—Some recent developments, including an ideal cycle. Thursday, May 29th, 8 p.m.—Informal meeting. Saturday, May 31st.—Excursion to Pulborough and Fittleworth. Leader, Mr. Gale. Particulars will be posted in the Club.

Patent Intelligence.

Specifications Published.

5,118. *March 29th*, 1889.—"Transparent Printed Paper." William Lloyd Wise, 46, Lincoln's Inn Fields, London, Consulting Engineer and Patent Agent. Communicated from abroad by Joseph Mathieu Badon, of 59, Rue de Suède, à Saint-Gilles Lez, Brussels.

This invention relates to the production of transparent tinted paper having the appearance of stained glass, and to means or apparatus for its manufacture. Transparent tinted paper, according to this invention, is printed in a continuous form, after the manner of wall-paper, and by similar methods of printing. Like the latter paper, it may conveniently be made in rolls of eight metres length and fifty centimetres breadth.

The impressions which, as in lithographic printing, form a glaze—that is to say, do not run—may be made by various means, including blocks or cylinders, of which the printing or relief portions are formed of caoutchouc, or gutta-percha, covered with a thin coating of gelatine, applied either by immersion in a weak solution of gelatine mixed with a variable proportion of treacle, or of glycerine, or else by a brush. These printing portions can be supported and surrounded by sheets of copper, or fixed by one of the means indicated above. The coating of gelatine is intended to prevent the caoutchouc or the gutta-percha from being affected by direct contact with colours or inks made with oil or turpentine; further, the impressions obtained by this means are sharper and more regular than those obtained by caoutchouc or gutta-percha when employed alone.

Colours and inks made with turpentine or oil are employed for blocks and cylinders which are faced with caoutchouc or gutta-percha, and for blocks and cylinders of wood, or metal, covered with a coating of gelatine. Colours and inks made with water, to which gum, gelatine, glycerine, or like substance, is added, are employed for blocks and cylinders faced with caoutchouc or gutta-percha. Colours and inks made with oil, or made with water, serve equally well for blocks or cylinders which are faced with zinc.

For transparent paper printing, it is advantageous to employ the paper known as pelure. This paper, after having received the impressions to form the design, and the prints to imitate the lead and joints (of the stained glass), receives one coat of oil varnish on each face. When this preparation is dry, it is re-coated, also on both faces, with an adhesive medium composed of gelatine, which serves to fix it in place on the glass.

In applying the paper thus prepared, it is only necessary to moisten it with hot water; apply it to the glass which is to be decorated, and, to remove any bubbles of air, by passing over the paper a brush, a cloth, or any suitable body, in order to ensure complete adhesion without the necessity for using any other medium than that which is already on the product itself.

7,897. *May 11th*, 1889.—"Illusions Produced by Persistence of Vision." Eric Stuart Bruce, Gentleman, 10, Observatory Avenue, Kensington, London, W.

A narrow lathe of wood or other suitable material about an inch wide is made to revolve rapidly by hand power, an electric motor, or other suitable power, the effect being an almost invisible haze. But when the revolving lathe is placed in the path of the rays of light proceeding from an optical projection lantern in which there is placed a transparent picture, the image is apparently cast upon the air. In reality, portions only of the image are cast upon the revolving lathe in such rapid succession that they are united into the perfect whole by the retentive action of the retina of the eye.

In some cases of exhibition it may be desirable to obliterate the second image which, in ordinary circumstances, is cast upon the wall or other receiving surface behind the revolving lathe. This can be conveniently done by placing two sheets of ribbed glass, of which the exterior surfaces are covered with crumpled sheets of gelatine, preferably of a blue colour, behind the centre of the lathe at a suitable angle. The sheets of glass are sup-

ported on a stand which is capable of adjustiug the angle. The second image then falls upou the sheets of glass, and is so distorted by the angular position of the glass, and broken up by the crumpled surface of gelatine, that it is practically annihilated.

Proceedings of Societies.

The Camera Club.

May 1st.—Bedford Street, Strand, London. Mr. T. R. Dallmeyer in the chair.

Captain W. de W. Abney, F.R.S., president of the Club, then read a paper on "Pinhole Photography," a subject which he stated to be interesting at the present time, especially as one of the members of the Club is now taking pictures by the use of pinholes instead of lenses. He then set forth in detail how he had mathematically calculated the best size of pinhole to give the best picture when placed at a given distance from the plate, with the result that if that distance be ten inches, the diameter of the pinhole should be ·026 inch, or, roughly, a little over a fiftieth of an inch. Mr. Davison had pointed out to him a pinhole photograph in which near objects seemed to him more sharply rendered than those at a distance. When the objects are near to the lens, the best diameter of the pinhole differs a little from that just stated. Suppose the plate to be ten inches from the hole, and the object one hundred inches, then the best diameter of the hole is ·0246 inch. When the plate is fourteen inches from the hole, the best diameter of the latter is ·03 inch. In times past he had found the utility of pinholes for photographic purposes. Once at Zermatt he made a three hours' journey over a glacier with some ladies for the purpose of taking photographs, and, at the end of the journey, discovered that the lenses had been left behind. They lunched heavily, and some tins which had contained *pate de foie gras* were lyiug about. One of the ladies lent him a hair-pin, with which he pierced a hole in a flat disc cut out of the top of one of the tins; that hole, when measured long afterwards, turned out to be ·04 inch. They then took three or four photographs, and he had brought one of them to show to the Club. A large pinhole gives most gradation, a small one gives a "lumpy" image, so that the photographs decrease in quality when the piuhole is too large or too small. He did not like the pinhole photographs; but if anyone wanted fuzzy pictures, why not at once use a lens out of focus, and so avoid all trouble about pinholes?

The Chairman, after inviting auy member to speak, said that as no one had risen in response, he would make a few remarks first. Capt. Abney had treated in an analytical way what could be arrived at geometrically; he (Mr. Dallmeyer) had tried the latter method, and arrived at the same results. The apertures mentioned by Lord Rayleigh at the British Association had twice the diameter just given by Capt. Abney.

Captain Abney responded that Lord Rayleigh said nothing about what size of aperture would give the best image; he had merely maintained that a pinhole picture of suitable dimensions must be viewed at the distance at which the plate stood from the pinhole, to get rid of the appearance of fuzziness; thus, with a plate at nine feet distance, Lord Rayleigh used an aperture of one-sixteenth of an inch, and said that the resulting photograph should be viewed from the distance of nine feet. He had been searching for the greatest diffusion allowable.

Mr. Elder asked how it was that there was not a greater falling off of the illumination at the margins of pinhole pictures. A ray passing obliquely through the hole practically passes through a smaller aperture than does the central ray.

Captain Abney responded that the mathematics of rays of light passing through ellipses was a complicated subject, which the Camera Club would not thank him for putting before them. With an included angle of sixty degrees, little was lost in brilliancy or definition at the edge of the plate.

Mr. W. Willis asked what would be the result of the use of monochromatic light in pinhole photography, instead of light of all degrees of refrangibility.

Captain Abney responded that with monochromatic light improved definition would be obtaiued, aud that the aperture would probably have to be diuiuished by about one-twenty-fifth. In conuection with stellar photography he used monochromatic light, and a distinct difference in the diameter of the disc resulted; for such purposes he used light half way between G aud F; it was just over the blue lithium line.

Mr. Willis asked what mediuu he would recommeud for getting uonochromatic light by means of interposed glass.

Captain Abney used suitable true monochromatic light from the spectrum; he did not believe in using uedia. Aumonio-sulphate of copper solution gives a band, not a line, and with it interposed, he did not think that the pictures would be either better or worse. Sodium light is not mouochromatic; it gives red, blue, green also, but yellow in overpowering proportion. Lithium was the only substance he knew which would give a light approaching that which Mr. Willis wanted; it could be obtained by using a fairly strong source of heat, just strong enough with chloride of lithium to bring out only the red aud blue lines, aud in photographic work the red could be neglected. With care the oxyhydrogen flame would bring only the red and blue lines out with chloride of lithium, and the blue was perfectly monochromatic. Another way of getting pictures by means of small apertures was by using a fairly minute ring or zone in place of a pinhole, that is to say, something like a large pinhole with an opaque disc in its centre. This plan gives fairly good results; they are as good as with a pinhole of the best aperture, and the time of exposure is shorter under the same conditions of lighting.

Mr. L. E. Clift asked how Captain Abney made the pinholes of the dimensions he required.

Captain Abney did it by means of needles made into punches; he clipped the needles, and measured them micrometrically.

Mr. Lyonel Clark had experimented iu pinhole photography, and found that, generally speaking, his apertures had double the diameters of those used by Captain Abney, but the variation in the pictorial results was not very great. He usually gave about twelve minutes' exposure iu the winter. He had found that special punches were of no partieular use. Wills sold his tobacco in thin tinned sheet iron; the top of one of these tins could be taken, a hole "jabbed" through it with a needle, and the blurred end of the hole turned to the object. At first he made his punches properly from an engineering point of view, with the largest diameter of each at the cutting edge, but afterwards he found that "jabbing" a needle through the top of a tobacco box answered equally well.

Captain Abney had found that plan to sometimes cut off light from the side of the picture.

Mr. William England had found a piece of celluloid dyed black to be an excellent mediuu for piereing to get apertures for pinhole photography.

Mr. George Davison said that there was an advantage in giving long exposures in pinhole photography. Sometimes, with a large pinhole and bright light, the view included can be seen on the foeussing screen. Captain Abney held that the pictures of Alma Tadema were "nearly" as sharp as photographs; that word "nearly" made all the difference. Nine-tenths of our artists can paint sharper than they really do, but omit to do so on purpose; they invariably leave much detail out, which an ordinary photographer tries to get in. He thought uniform out-of-focus to be sometimes exceedingly desirable in landscape work, and better than a plane of sharpness across the picture at a particular distance. The object of relieving any one portion of a picture is to draw special attention to it, but that is not necessary in many cases. As to the advice of using a lens out of focus, he had tried that plan sometimes, and thought the results not to be so good as if he had used a pinhole, but he should prefer a lens if it would do the same work in a shorter time; the pinhole had, however, some advantages. It was neither costly nor heavy. Lenses were wanted into which spherical aberration could be introduced at will.

Mr. Rodgers remarked that Mr. Davison aimed at breadth, and had argued that it could only be obtained by sacrifice of detail. He (the speaker) thought that artists might give minute detail accurately without interfering with the general broad effect.

Mr. Davison replied that artists were the best judges in this matter, and they disliked photographs because they gave too much detail.

Mr. Willis was recently in the studio of a celebrated painter who had before him a picture with its foreground magnificently painted, but he ran his brush, charged with some transparent colour, all over that foreground; this had the effect of subduing it. Could not something of the same kind be done in photography? The eye is satisfied with the first glance at a picture in which the principal object is sharp, afterwards, as in looking at nature, it searches for detail, and is disappointed when it is not there.

Mr. Rodgers said that in the paintings of birds by Mr. Stacey Marks the amount of detail was extraordinary.

Mr. Humphery stated that paintings usually have to be viewed at a greater distance than photographs, and that the former are painted so as to give to those at a distance the appearance of great detail.

Mr. Davison exhibited a pinhole photograph which he said that he considered to be the best he had ever been able to turn out by any method.

The Revd. F. C. Lambert remarked that the whole point seemed to turn upon the words "correct detail." Artists do not want to destroy what is present, but photography in their eyes emphasises detail. He thought that detail should be subdued, and that a picture taken with a small stop gave an impression to the observer not conveyed by the scene itself. That something should be left upon which the imagination could play, was necessary in every work of art.

Captain Abney advised all tourists who went out to lunch, and to take pinhole photographs, to begin the exposure before lunch, and to finish it afterwards, to save time. About the year 1865 he travelled a few hundreds of miles in India to photograph some cave temples, and when he arrived found that he had left his lenses behind him, so happening to know about pinholes as lenses, he made a pinhole of about a tenth of an inch, with which he took some 10 by 12 inch photographs; that was in the wet-plate days. When he mentioned this at the Photographic Society it was hardly believed by one or two of the members, and some comments appeared in the Photographic News throwing doubt upon his statement; upon reading those comments he felt "corked."

Mr. W. H. Harrison: How long ago was that?

Captain Abney replied that it was about the year 1881, and the comments had been made by a mutual friend of theirs. He had forgiven, but had not forgotten. Some of those at the meeting were not sufficiently credulous to accept his statement. However, just afterwards, a photographer—Mr. Henderson—found that he could take pinhole photographs, and that settled the matter. Although science and art have to be combined sometimes, they did not seem to get on very well together, and he did not profess to be more than a humble student of art; his work was in another direction. Perhaps, however, scientific workers might help artists to obtain any amount of fuzziness in their pictures. Whenever, at exhibitions, painters turned out fuzzy pictures, he always looked at the frames, and not at the pictures.

Mr. Dallmeyer said that the sole object of Lord Rayleigh, in his paper read before the British Association, and published in the Photographic News, was to show where lenses became unnecessary. In a picture containing no leading feature or group in one plane, uniform softness all over is admissible; but all views are not of that description, and where there is some object present of particular interest, he thought that emphasis should be laid thereupon. As regards lenses for the purpose, when the apertures are small, there is a difficulty in introducing spherical aberration. A transparent diffraction plate placed across the aperture of the diaphragm will do something in the direction of yielding the desired result. A simple way of making such gratings is to draw a multitude of lines, and then photograph them.

Captain Abney remarked that Mr. Dallmeyer's father had made him a grating containing only one hundred lines to the inch, for use in the photo-heliograph at Greenwich; it certainly gave marked fuzziness.

London and Provincial Photographic Association.

At the meeting on the 1st inst., Mr. J. Traill Taylor occupied the chair.

Mr. H. M. Hastings exhibited a series of silver prints of the exterior and interior of Salisbury Cathedral, recently taken by him.

The question was asked whether varnishing a plate with a coloured substratum, previous to coating, would be a preventative of halation.

The Chairman thought there would be a risk of the colouring matter in the substratum being communicated to the sensitive film; for this reason he would prefer backing the plate.

The Hon. Sec., in developing some ordinary and isochromatic plates, backed, using yellow light, omitted to screen the light during the development of the isochromatic plates; the result was an excellent image of the backing of the film. He had been able, with certain makes of plates, to dispense with both yellow screen and back in copying paintings successfully.

Mr. W. E. Debenham preferred, when copying pictures, to illuminate the room with yellow light; he considered it better than the methods usually adopted, as no optical difficulty was introduced. The exposure, of course, was prolonged.

Mr. A. L. Henderson exhibited a stereoscopic negative of an out-door view taken during his stay in the West Indies. Across the plate was the figure of a hand with outstretched fingers. He said he had several more negatives taken at the same time, all showing this curious phenomenon; he was unable to account for it in any way. He had tried to produce the same effect since by placing his hand in front of the lens during an exposure, but had failed.

Mr. A. Cowan, commenting upon solutions of eikonogen frequently becoming discoloured, showed a bottle about one-third full of a solution of eikonogen that had turned quite black; he also showed another bottle quite full that was perfectly bright and colourless. He stated that the same solution had been poured into each bottle, and the bottles had stood side by side for a month. The bottle containing the dark solution had, during that time, been occasionally opened to take out some of the solution; whereas the other had remained corked and quite full the whole time. He thought this conclusively proved that the darkening action was due to the action of the atmosphere.

Mr. H. M. Hastings showed two lantern slides developed with the new developer graphol; also some bromide prints developed with an acid eikonogen developer, recommended by Mr. J. H. Voight, Chairman of the Photographic Society of Frankfort-on-Maine. It is claimed for this developer that it is rendered more energetic, and its keeping qualities much improved, in an acid condition. This is effected by the addition of hydrochloric acid. Mr. Hastings said he had developed eight plates in the same solution, which remained perfectly clear to the end; the last plate, however, took half an hour to complete development.

Newcastle-on-Tyne and Northern Counties Photographic Association.

At the Central Exchange Art Gallery last Friday evening, a lecture was given by Mr. J. P. Gibson, under the auspices of the International Photographic Exhibition, upon "Northumberland: Its Antiquities and River Scenery." Mr. Gibson, who showed a splendid collection of over 150 of his own lantern slides, at the outset dealt with the pre-historic races who dwelt in Northumberland, and he exhibited a slide illustrative of a hut circle. He proceeded to describe the customs of the people in the early ages, giving a pictorial reproduction of a human skull found in Tarset Burn. Next he dealt with the period of the Roman occupation, which he followed with views of the present day of the camps of Cilurnum, Housesteads, and Birdoswald. The Saxon age then formed the subject of his lecture, and Mr. Gibson illustrated his discourse with photographs of crosses and other antiquities found in the Hexham district. Mediæval antiquities were touched upon. Typical castles were shown, such as Seaton Delaval, Morpeth, Warkworth, Alnwick, Bamburgh, and Etal. Modern topics came

next, and the lecturer, working westward from Newcastle, found opportunity to give views of the birthplace of George Stephenson at Wylam, and Bewick at Cherry Burn. Bywell Church and Castle Aydon Castle, and Dilston were also treated upon. A brief sketch of the Derwentwater family was given. The scenery of the River Tyne and its tributaries was finally shown, beginning below Hexham, up the North Tyne to Bellingham, and on the shores of the South Tyne to Thirlwell Castle. There was a large attendance.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

ADJOURNED annual general meeting, Friday, May 2, at 181, Aldersgate Street, London, the president, Mr. J. TRAILL TAYLOR, in the chair.

The CHAIRMAN said that the business of the evening was the election of officers for the ensuing year. The new rules which had been passed by the meeting held on February 14 had just received the sanction of the Registrar-General of Friendly Societies, and the Association would in future be bound by them.

The following officers were then elected :—

President—Mr. J. Traill Taylor. *Trustees*—Captain W. de W. Abney, C.B., F.R.S., and Mr. W. S. Bird. *Treasurer*—Mr. John Spiller, F.C.S. *Committee*—Messrs. H. D. Atkinson, William Bedford, William Benham, E. Clifton, T. J. Collins, F. W. Cox, T. E. Freshwater, G. T. Harris, A. Mackie, J. D. O'Connor, J. S. Rolfe, and E. A. Whittemore. *Auditors*—Messrs. W. Holt, E. W. Parfitt, H. J. White, and J. W. Zaehnsdorf. The hon. solicitor, Mr. William Benham, was also reappointed, and the election of Mr. H. J. Beasley to the post of hon. secretary confirmed.

The meeting passed votes of thanks to the officers for the past year, and to the hon. solicitor for his special services.

Twelve new subscribers were enrolled.

All communications should be addressed to the hon. secretary, Mr. H. J. Beasley, 65 and 66, Chancery Lane, London.

THE HACKNEY PHOTOGRAPHIC SOCIETY.

THIS Society held its annual soirée on Thursday, May 1st, at Morley Hall, and about 400 visitors were present. Various friends contributed to the entertainment of the company, and the evening was brought to a close by an exhibition of members' lantern slides. The prize winners were Messrs. Fred Evans and Carpenter. The room was tastefully decorated with plants and flags. This concludes the first year of the Society's existence.

BATH PHOTOGRAPHIC SOCIETY.

April 24th.—Excursion to Box and district.

April 30th.—Ordinary meeting, Mr. PUMPHREY, president, in the chair.

Mr. J. A. Howe was elected a member of the Society.

The Hon. SECRETARY announced the receipt of a specially prepared copy of "East Anglian Life," presented by the author, Dr. P. H. Emerson. Some early volumes of the Photographic Society's Journal were also presented by Mr. Wheatcroft. Circulars relating to forthcoming exhibitions at Amsterdam and in the City of London, and other matters of interest, were drawn attention to.

Mr. G. F. POWELL then gave a paper on "Stereoscopic Photography" (see page 355).

The CHAIRMAN, in thanking Mr. Powell for his paper, said it was true stereoscopes had gone out of fashion, but pictures when suitably prepared to be viewed in them appeared more realistic than photographs generally. He thought the angle of base should be kept small, not exceeding the distance between the eyes. Whether the stereoscope would be resuscitated he could not say, but it was possible to purchase a cheap form, with half-a dozen stereoscopic pictures, for a shilling.

Mr. DUGDALE thought the reason stereoscopic photographs fell into disuse was largely due to the pictures being too wide —2½ inches was a convenient size.

Mr. AUSTIN J. KING, vice-president, thought stereoscopic photography might come again to the front if more perfect instruments were provided. The difficulty of adjusting one's sight to a particular form of instrument was an obstacle, for the two eyes do not focus quite the same. If both eyes do not adjust themselves, then the effect of rotundity does not become evident. Another difficulty, into which he would not then enter, was astigmatism.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

A MEETING was held on May 1st, with Mr. G. G. MACLAREN in the chair.

The manipulations of the new printing process, "Kallitype," were demonstrated. The process was said to be exceedingly simple, presenting few difficulties, to print very fast, and to be moderate in price.

A negative of the font in St. Mary's, Broughty Ferry, was shown. A small portion of two stained glass windows was included in the upper corners of the negative, and on the left side of the font near the foot there was a reflection of a panel of the window to the right. No explanation could be given as to the cause of the reflected image.

The following office-bearers were elected for the session 1890 and 1891 :—President, Mr. John Mathewson ; Vice-Presidents, Messrs. J. D. Cox and W. M. Martin ; Council, Messrs. W. Bertie, W. F. Hill, P. Kerr, G. D. Macdougald, G. G. Maclaren, W. Salmond, A. Stewart, W. D. Valentine, J. Welsh, and T. L. Wynd ; Secretary and Treasurer, Mr. V. C. Baird, Broughty Ferry, N.B.

PHOTOGRAPHIC SOCIETY OF PHILADELPHIA.

AN adjourned stated meeting of the Society was held on Wednesday evening, April 9th, Mr. JOHN G. BULLOCK, vice-president, in the chair.

A communication was read by the Secretary from the editor of the *Photographic Times*, presenting a copy of "Practical Photo-micrography," by Andrew Pringle. The Secretary also reported that, owing to the removal of the Society of Amateur Photographers of New York to new quarters, which would fully engross the attention of both officers and members for some months, it had been agreed to postpone the exhibition until the spring of 1891.

Mr. BROWNE spoke of the loss the Society had sustained in the death of its President, Mr. Frederic Graff, and said that it had seemed to certain of the members desirable that the position of President should be filled at once ; he therefore nominated Mr. John G. Bullock for the office. The nomination was seconded by Mr. F. T. Fassitt, and Mr. Bullock was unanimously elected President.

Dr. MITCHELL, of the Executive Committee, read a communication from Mr. Frank H. Rosengarten, entitled "The "Working Department of the Photographic Society of Philadelphia." The paper was a lengthy plea for enlarging the scope and usefulness of the Society, gave a history of previous efforts which had been made in this direction, and was accompanied by circulars and other data illustrative of the working of the Camera Club, of London.

Considerable discussion followed the communication, during which Mr. BROWNE called attention to the fact that before the end of the year the Society would have to consider the important question of a change of quarters. He thought a special committee might be appointed to consider all propositions made to it, and in this way relieve the Society from a great deal of discussion.

Dr. MITCHELL moved that the chairman appoint a special committee, to consist of the president, vice-president, secretary, and treasurer, and six other members, to consider and report to the Society the advisability of procuring other and more convenient quarters, and the institution and development of a suitable working department for the instruction and improvement of members in photographic work. This was carried.

Mr. CARBUTT, alluding to a letter he had read at a previous meeting, from Mr. Pancoast, in regard to keeping qualities of plates, showed a negative sent him by Mr. Pancoast,

taken recently on a Carbutt A plate which had been coated about 1884 or 1885. The negative showed no signs of deterioration on account of age of the plate.

Mr. BROWNE, referring to the appointment of a committee to ascertain the cause of certain deterioration in lantern slides, said that within the last two weeks he had examined a large number of slides with a table microscope having a two-inch objective. With a glass of this power, he noticed that in many cases the crystallization or cloudiness is formed on the cover glass, but not invariably so. It has been said that much of this difficulty arises from the quality or composition of the glass—that from the thin glass now used both for picture and cover emanates some chemical injurious to the slide. This might be so, but in his experience, which had been almost entirely with the quality known as "B. P. C.," he could not lay this fault to the glass. In examining the slides he found much matter evidently deposited from impure washing water, which seemed to consist of particles of vegetable matter, mud and sediment of various kinds which had not been perfectly washed off. He also thought that the central spots from which the crystallization started were sometimes due to hyposulphite of soda in the gelatine film. Years ago, having trouble of this kind, he had commenced using diluted cyanide of potassium instead of hypo for fixing slides. Slides so fixed did not show any of the faults in question. Much of the trouble, he thought, arose from intensification. The purchasers of commercially-prepared slides demand dense positives, which makes it desirable to use some form of intensification. Among the chemicals used for this purpose is sulphide of potassium, which to his mind is most objectionable. He had found the treatment with bichloride of mercury, followed by a bath of bichloride of platinum, to make a permanent and safe intensifier.

Mr. FASSITT had found the treatment with mercury invariably fatal to a gelatine slide.

Dr. WALLACE thought the question of fading depended not so much on the use of mercury as upon what the mercury was followed by. If ammonia were used, the result would be disastrous; but with cyanide of silver the picture would not fade.

Mr. CARBUTT, speaking of the use of cyanide of potassium for fixing gelatine slides, said it could be used if perfectly pure. The ordinary commercial cyanide contained caustic potash, which had a deleterious effect on the film. He recommended a solution of eight or ten grains to the ounce as suitable for fixing an ordinary gelatine plate with safety.

Mr. ROSENGARTEN said that most of the hypo used contained large quantities of foreign matter and impurities. In his own practice he used only the pure article.

Mr. BELL endorsed the remarks of Dr. Wallace relative to the use of mercury.

Mr. CARBUTT, claimed that there was no need to intensify lantern slides. He had been making some positives requiring great density; it was simply done with pyro, soda, and bromide. The action should be well restrained, and the exposure as full as subject and condition will allow. In the instance referred to nearly a minute elapsed before the image began to show. It was a positive made by contact. For the purpose of those using his process plates, the developer consisted of:—

Water	60 ounces
Carbonate of soda crystals	2 ,,
Sulphite of soda crystal	1 ,,
Bromide of soda or potash	60 grains

To each ounce of the above, 2½ to 3 grains of dry pyro are added. By this means perfectly clear glass in the transparent parts of the negative, and dense blacks, can readily be obtained.

THE GLOUCESTERSHIRE PHOTOGRAPHIC SOCIETY.

ANNUAL meeting, April 28th, 1890: the president, Mr. W. B. WOOD, in the chair.

The president, vice-president, treasurer, and committee of last year were re-elected. Mr. A. H. Church was elected hon. secretary. The retiring secretary, Mr. F. H. Burr, and the Rev. Mowbray Trotter were added to the committee. A warm vote of thanks was passed to Dr. Emerson for his valuable and useful gift, "Pictures of East Anglian Life."

The presentation print for 1890 was selected, the voting being in favour of a 15 by 12 platinum print of a view by W. C. Beetham. A lantern outfit, consisting of a pair of mahogany lanterns, with cylinders, regulators, and jets, was on view, and it was decided to purchase the same for the use of members.

The triennial exhibition (open) will be held in October and November, and prospectuses in accordance with recently expressed ideas will shortly be issued.

PHOTOGRAPHIC SOCIETY OF JAPAN.

A MEETING of the above-mentioned Society was held in the rooms of the Geographical Society, Kyo-bashi, Tokyo, on Monday, March 24th, at 1.30 p.m., Mr. EDMOND HOLMES in the chair.

The following new members were elected:—Messrs. R. W. Borthwick, H. Deakin, J. McDonald, C. Pope, T. P. Solomon, and A. C. Stern.

Mr. C. D. WEST showed a number of prints toned by Clark's new platinum toning process. In many cases there were, alongside of the platinum-toned prints, others from the same negatives toned with gold in the ordinary way. The platinum tones were blacker than the gold. There was some difference of opinion as to which were the pleasanter, but on the whole the verdict was in favour of the platinum. Mr. West explained that there was reason to believe the platinum-toned prints to be more permanent than the others. He found it inadvisable to use nitric acid in the bath, as recommended by Mr. Clark, at least with albumenized paper, as it gave yellow high lights. He preferred citric acid, and a bath comparatively weak in the platinum salt. The following formula was given; To each ounce of water add one half grain of chloroplatinite of potassium and four or five grains of citric acid. This bath keeps well.

Mr. A. J. HARE showed a number of prints toned after dissolving a quantity of common salt in any ordinary toning bath. The prints then went direct from the printing frames to the toning bath, and from the toning to the fixing bath, there being no intermediate washing. The following advantages were claimed for the modified process. Less over-printing is necessary; there is considerable saving of time; the tones are richer than when the paper is washed before reaching the toning bath, and there is much less tendency to run to "mealiness" in the shadows in the case of toning to a deep purple or black. The prints shown were done on the ready sensitized paper of the Japan Dry Plate Co., and the tones were pronounced exceedingly fine.

Mr. W. K. BURTON showed a sample of the more recently manufactured eikonogen. He had received a dozen or two of bottles of the substance, and in every case but one the colour of the chemical was nearly white; in the case of one single bottle, however, the eikonogen had turned quite black, although this particular bottle appeared to be as securely luted as the others. Mr. Burton had found this new eikonogen distinctly superior to the old, and considered that it had clear advantages over pyro for some kinds of photographic work.

A demonstration of "Photo-zincography" was then given by Messrs. W. K. Burton and Y. Isawa. This is a process whereby blocks to print type-high can be photographically produced from any line drawing or sketch. A very light print is taken from the negative on common photographic paper, but is neither toned nor fixed. The outline is gone over with a pen and the best quality of Chinese ink, and as much line shading is put in as may seem desirable, after which the print is put in a bath of a solution of bi-chloride of mercury. This quickly makes the photograph entirely disappear, the line sketch only remaining. If a photograph is not to be used the artist sketches directly with black ink on pure white paper. In either case the result is the same, a line sketch that is copied in the camera, the wet process being used by preference. The negative must be reversed, and the reversal is secured either by using a reversing mirror in copying, or by stripping the film of the negative from the glass and turning it over. A polished zinc plate is next coated with a mixture of albumen, water,

and bichromate of either ammonium or potassium, and when dry, is exposed under the negative, a faintly visible image resulting. The plate is then covered with a very thin uniform coating of a greasy ink applied by a roller, and is dipped in water. In a minute or two the ink begins to leave all the plate but those parts representing the lines, and, the action being helped by rubbing gently with a piece of cotton wool, there is soon an image in printer's ink on the zinc plate. The plate is dried, and a quantity of powdered resin is dusted over it; this sticks to the greasy lines, but not to the rest of the surface, and a slight heating is enough to incorporate it with the ink. There is now a sufficient "resist" to make it possible to etch away some of the metal between the lines, and the plate accordingly goes into a bath of weak nitric acid. There is only one reason why the etching should not be continued till the whole of the necessary relief is got at one operation, and that is that the acid has a tendency to "under-cut" the lines. It is, therefore, necessary to protect the edges as well as the tops of the lines. To effect this protection, the plate is taken from the bath after a very little relief has been got, is dried, and is heated just to that point at which powered resin will stick to the lines, but not to the rest of the plate. The plate is then again powdered with resin, and when the lines have taken all that they will, it is heated enough to melt the resin and make it run down the sides of the lines. The plate then stands an etching in a somewhat stronger bath, and the process is repeated five to ten times, according to the coarseness or fineness of the work. The lines thus obtained are firm and solid, but there are generally slight ridges running along the sides of them produced by the different etchings. To get rid of these the plate is cleansed of all resin, and is inked up with a smooth roller which touches only the tops of the lines. The operation of dusting with resin and heating is once more gone through, and the plate has its last etching, or last but one—for it is sometimes advisable to repeat this etching twice—when it is ready to be trimmed and mounted type-high for the printer. Samples of every stage of the process, from the original negative to a block that had been printed in a machine, and prints from them, were shown, and the process of developing the image on the zinc and of etching was demonstrated. The demonstrators explained that it was claimed that the whole process, from the taking of a photograph to the production of a finished block, could be gone through in two hours in England. They doubted this, but could easily do the work in from six to eight hours. The block really could be produced in two hours from the time of taking the exposed zinc plate from the printing frame. They farther explained that the advantage of the process was that an exact copy of any line subject, no matter how complicated, could be made in a few hours, either of the same size as the original, or smaller or larger.

THE publication of several pages of news is postponed until next week, because it has been found impossible to find space for them in this issue.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—First Saturday outing, May 10th, to Waltham; trains from Liverpool Street, 2.5 and 2.50.

THE offices of *l'Amateur Photographe* and of the *Bulletin des Sociétés Photographiques de France* have been removed to 24, Boulevard Saint-Germain, Paris.

THE British Museum (South Kensington) authorities have this week ordered a large number of Mr. Gambier Bolton's animal studies from life and skeleton series, to be framed and hung in the galleries of the Geological section; this is one of the first instances of the kind on record.

SHEFFIELD CAMERA CLUB.—The usual monthly meeting was held on the 25th April, when a students' night was given. Members were invited to bring objects of interest to be discussed by those present. A number of negatives were developed by several of the members.

THE formula of the acid eikonogen developer mentioned by that able experimenter, Mr. H. M. Hastings, at the meeting of the London and Provincial Photographic Association, was published some weeks ago in these pages in one of Dr. Gunther's articles, and seems to deserve practical attention.

Answers to Correspondents.

All Advertisements and communications relating to money matters, and to the sale of the paper should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

E. H. M. (Plymouth).—*Combined Fixing and Toning Bath.* With reference to Mr. R. E. Liesegang's toning bath, described in the NEWS of 25th ult., page 322, we should not be inclined to say that it would be permanent, for one cannot have hypo and gold together in the same solution without some of the gold separating out as a black deposit on standing, even in the presence of the sulpho-cyanide. Used immediately, as directed, it would tone quickly and fix the prints at the same time. See the first answer to an Irish correspondent in the NEWS of April 11th for a good toning bath for Aristotype, which could be used until exhausted, and be content to fix in a separate bath.

A. B. (Bishops Stortford).—*Portable Developing Tent.* The lightest and best material is a thin black mackintosh, such as used for overcoats, but this does not bear sun exposure very well or hard usage. A top covering of canary fabric would help to protect it. We are not acquainted with any paint or varnish that can be relied upon to keep out the actinic rays, when the material has to be constantly folded. A double fabric of black and yellow calico, or red union, is sometimes employed.

T. S. (Carlisle).—*Collodio-Chloride Prints.* 1. In the absence of details we can only say that the prints are excellent, and the process seems capable of giving vigorous impressions, like albumenised paper. One of the prints is iridescent; is this intentional, or the result of employing too thin a film of collodion? 2. The process would appear to be capable of professional employment like the Alpha paper.

L. T.—*Thermometer Scales.*—Your doubts are resolved by looking at the thermometer table at the end of the YEAR-BOOK. The 18 degrees evidently mean Centigrade, and are equivalent to 64½ degrees Fahrenheit, which is a manageable temperature at this season of the year.

S. M. (Brighton).—*Ammonia in the Camera.* Without trying the experiment, we cannot say whether the diffusion of ammonia fumes in the camera would have the effect of expediting the exposure with gelatine plates. It should be easy to test the point for yourself with brown paper, or an old blackened sponge, slightly moistened with ·880 ammonia, and placed within the camera. When ascertained, we should like to know the result.

MOUNTER.—*Chocolate Cards.* The colour may very possibly bleed out if you use oil of cassia in your starch paste, for the essential oils are powerful solvents of organic colouring matters. Encaustic paste, although containing these aromatic bodies, does not act in the same way, because of the protection afforded by the wax.

M. S. T.—*Operators' Specimens.* The question was threshed out a few weeks ago in the NEWS. There is no alternative but to accept the statement that they are the *bonâ fide* work of the applicant. We have known instances of high-class professional work being openly shown in specimen cases other than those of the real producer; the prints of an eminent Dublin firm being sometimes shown in London to attract customers.

RECEIVED:—Notices of the Chester Meeting of the Photographic Convention, June 23rd to 28th inclusive, C. H. Bothamley, F.C.S., President; and Camera Club exhibition of Photographic pictures by the late Mrs. Julia Cameron, now on view; of the lecture on "The Photographic Image," to be delivered by Professor Meldola, at the Royal Institution, on Friday, 16th inst.; also copy of "A Proposed Photographic Survey of Warwickshire," by W. Jerome Harrison, F.G.S., which has already appeared in our pages.

ADELPHI.—*The Lantern Society's Display* last Friday week was chiefly remarkable for the excellence of the electric lighting employed in the lantern, which gave a steady and brilliant image upon the screen. The high quality of most of the slides likewise contributed to the success of the exhibition.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1654.—*May* 16, 1890.

CONTENTS.

SOME OPTICAL CAUSES OF DEFECTIVE PHOTOGRAPHS.

THE optical cause of a curious defect which on rare occasions is found in negatives, was stated by Mr. Dallmeyer at a meeting of the Photographic Society last Tuesday night, and the information seemed to be new to most of those present. He said that each concave surface in the elements of any lens, which surface faces the sensitive plate, acts as a concave mirror throwing back some light upon the plate, and occasionally even a definite image. Mr. William Bedford remarked that he had sometimes been troubled by this defect, especially when taking interiors, a window in one part of the picture being sometimes faintly reproduced upon another part of the picture where it was not required, and he thought that Mr. Dallmeyer had satisfactorily explained the cause of the mystery.

One thing escaped the notice of the meeting, and that was the influence which the sensitive plate itself has upon the phenomenon, for it is evident that under the same circumstances a better negative should be obtained upon a matt-surfaced gelatine film than upon a bright surfaced gelatine film. The latter would tend to act as a polished plane mirror, and to increase the defect, besides wasting useful light which ought to be doing work inside the film. The matt-surfaced film would absorb more light, and that which it reflected would be more scattered in all directions inside the camera, than in the instance of a film with a better reflecting surface. The influence of the surface of the sensitive film upon the phenomenon, therefore, deserves experimental investigation.

Another cause of imperfections in photographs, to which too little attention is paid at present, then occupied the attention of the meeting, namely, the want of care commonly exercised in not screening the front of the lens from light not required to form the picture. Mr. William England called special attention to this in the wet-plate days when he was photographing in Paris, as we remember from having been so struck at the time by his advice as to have at once had one of the old-fashioned stereoscopic box-cameras in our possession fitted with an adjunct to comply, as far as possible, with the recommendations which he laid down.

What is desirable is, that the lens of a camera shall look through a rectangular aperture or "window" in front, which aperture shall cut off all light but that required to form the picture, and to get the best results in this way it is evident that the aperture should not be too close to the lens; it should be at that distance at which the straight edge of an opaque object would not photograph with too large a penumbra from its out-of-focus position. The screening of the lens from unnecessary light from the sky is of more importance than screening it from light coming from any other direction, and the plan is as useful in the studio as in the field. A little tunnel formed in front of the studio camera by black curtains also fulfils the function, as pointed out by Mr. Debenham, of reducing the number of brightly illuminated floating particles in the air between the camera and sitter. These particles reflect light into the lens, so the shorter the length of illuminated dirty air between the sitter and the lens, the better.

To one point of this subject, again, attention was not given by the meeting. It is not alone necessary that the rectangular aperture should be far enough from the lens to work with reasonable efficiency, but the power must exist of being able to shift the position of the aperture in a plane parallel with that of the camera front, in order that when the rising or falling front is brought into play, the whole system, including plate, lens, and rectangular aperture shall be properly centred.

We have often thought that the flat, vertical platform formed by the wooden face of the shutters of the Kershaw type, might be utilised by affixing thereto a suitable arrangement for giving a rectangular aperture well in front of the lens. The platform itself is already a little distance in front of the lens-hood, and more distance might be gained by suitable construction of the adjunct, which adjunct should be made of aluminium or other light material.

DIRECT PLATINUM PRINTING.

MR. OTTO SCHOLZIG has sent us some specimens of Dr. Jacoby's direct printing platinum paper, which has the usual characteristics of papers in which platinum black is thrown down by the agency of a ferric salt when acted upon by light, a class of papers in the preparation of which we have done a considerable amount of experimenting. We find that Dr. Jacoby's paper, like the others, requires a good light if fair rapidity be required in the printing, that vigorous negatives suit it best, and that excellent pictorial results can be obtained with it if attention be paid to the necessary conditions.

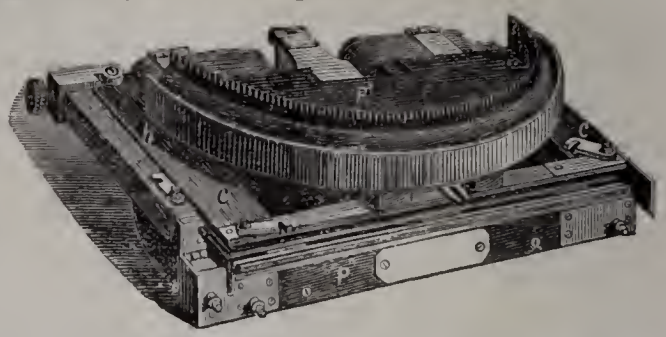
Dr. Jacoby recommends operators to keep the paper tightly pressed in a very dry and cool place, excluding air as much as possible; chloride of calcium tins are the best receptacles for this paper. Clear negatives with plenty of contrast and detail give the best results. He also says that in very dry weather the paper should be slowly passed over the steam of boiling water before putting in the printing frame, as the paper, when dry, will not print out to the full depth without the assistance of some slight moisture. If the paper be put in the frame quite dry, only a faint image will be obtained, which, after all details are faintly discernable, can afterwards be developed to the required depth by holding it over steam. In a damp atmosphere the paper will contain sufficient moisture, without steaming, to obtain the desired depth in the printing frame, and it is by fully printing-out in the frame and in good light that the best black tones are obtained. The pad of the printing-frame should be of india-rubber or other waterproof material to prevent irregularity in the depth of the picture. Prints of sufficient depth obtained either by direct printing in the frame, or by intensifying by steam, are to be put into two baths of diluted hydrochloric acid. The first, 1 part acid to 75 of water, five minutes; the second, 1 part acid to 50 of water, five minutes; then wash in water for fifteen minutes, till all traces of yellowness in the high lights have disappeared. Printing as well as fixing should be done on the same day.

A word of caution may be added about the steaming of the paper, when it is necessary. If this be overdone, and the paper made too damp, it is liable to stick to the negative at places, and to cause stains; hence it is safest to give too little rather than too much steaming, and to use varnished negatives.

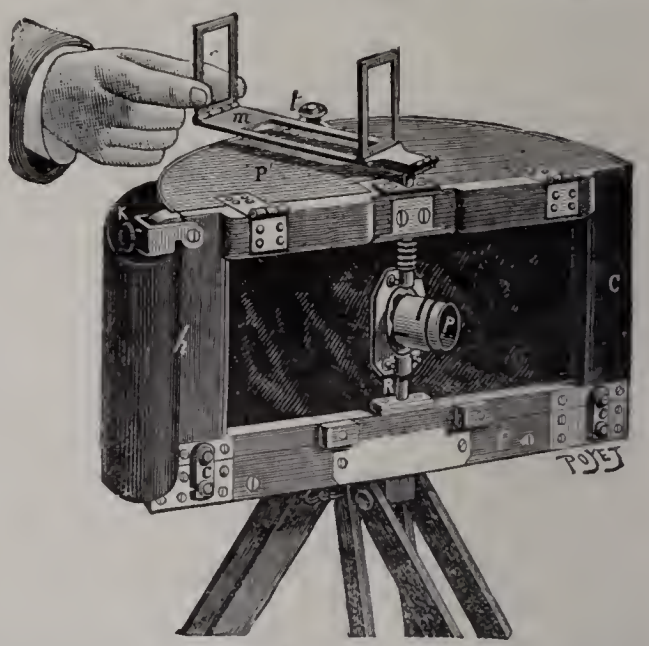
The advent of all direct printing platinum papers is to be welcomed, for it is high time that all photographic work should be as durable as that executed by means of printing ink, and that photographs liable to fade should be things of the past.

MOESSARD'S CYLINDROGRAPH.

MESSRS. GEORGE HOUGHTON AND SON invited us to inspect Moessard's Cylindrograph, a French panoramic camera, which was introduced a month or more ago into the United States, and is now obtainable in London. The instrument has certain points of resemblance to Johnson's pantascopic camera, but the motion is given by hand, and the image is thrown upon a curved surface, consisting of an Eastman flexible film in a flexible dark slide; the slide, with the film inside, bends like a long sheet of thick cardboard. In reply to our inquiry whether different parts of the plate received the same exposure when the latter was given by hand-power, the answer was that best method of exposure for uniformity is to move the handle backwards and forwards two or three times, with a short quick motion.



If it be desired to give more exposure to one end of the film than to the other—which may be the case with some subjects—it can be done, and this power the pantascopic



camera did not possess. Moessard's instrument is exceedingly light for a camera of the class, and it will give the complete circle of the horizon upon 2½ films, which means the use of three films in so doing. A doublet lens of eight inches focal length is employed, and the best parts of the lens are chiefly engaged in forming the whole picture in cameras of this class. Lightness for this class of camera, and simplicity, are the chief features of the instrument, illustrations of which are given herewith.

THE LONDON CHAMBER OF COMMERCE.—Mr. Kenric B. Murray, secretary to the London Chamber of Commerce, sends us an advance proof of the invitation card for the opening *soirée* of the City Photographic Exhibition. Its size is 9 by 6 inches, and represents a lady not dressed for the *soirée* standing by the river side arranging her back hair under cool conditions, whilst a number of little Cupids on the other side of the river are photographing her with a big camera which hampers them sorely; indeed one has to stand upon the back of the other to reach the focussing screen. The original of the clever design, as we happen to know, was scratched off-hand on blotting paper by one of the rising geniuses of the photographic world, whilst another genius present aided with his remarks; but we do not feel at liberty to give names without previous sanction.

CONVERSAZIONE OF THE ROYAL SOCIETY.

PHOTOGRAPHS AT THE RATE OF ONE HUNDRED PER SECOND—THE APPARATUS EMPLOYED—FALLING WATER DROPS PHOTOGRAPHED AT THE RATE OF TWENTY PER SECOND—PHOTOGRAPHY AN AID TO FORESTRY—NEW APPARATUS CONNECTED WITH POLARISED LIGHT—A NEW DIRECT-VISION PRISM SUITABLE FOR THE LANTERN—PHOTOGRAPHS OF THE SPECTRUM OF THE NEBULA IN ORION—STELLAR PHOTOGRAPHS—CLUSTERS IN THE SWORD-HANDLE OF PERSEUS—ALUMINIUM AND ITS ALLOYS—PHOTOGRAPHS OF THE EGGS OF THE GREAT AUK.

LAST Wednesday night, at a *Conversazione* of the Royal Society, Burlington House, Sir George Gabriel Stokes, Bart., M.P., President of the Society, received the members and the invited guests. Many of the objects of scientific interest, displayed in rooms of the Society, indicated the great utility of photography in various branches of science.

Mr. C. V. Boys exhibited some apparatus of considerable interest to photographers, by which he had taken negatives of an electric spark at the rate of from 80 to 100 per second, which is found to be the most convenient speed in practice, although the apparatus will make 2,000 or more exposures per second if need be. This is a modification of the method employed by Dr. Oliver Lodge to show the oscillatory nature of an electric spark formed under proper conditions. Six lenses are mounted on a disc, and are made to rotate; each forms upon a screen an image of the spark, which is drawn out by the movement of the lens into a broken band of light. The lenses are not at exactly the same distance from the axis, so that the band formed by one is not overlapped by the band formed by the next. Thus, the whole duration of the spark, from the first to the last oscillation, is observed or photographed. Single achromatic lenses are used in the revolving wheel, in fact they are the front lenses of opera-glasses; the small wheel carrying them is driven by multiplying gear, and can be made to turn with such velocity as to emit a musical note.

He also exhibited some photographs showing the formation of water-drops, taken, some at the rate of 14, and others at the rate of 20 exposures per second; the rate of 14 per second was rather too slow.

Water drops, half-an-inch or more in diameter, were allowed to slowly form and break away in a liquid of slightly lower specific gravity, namely, a mixture of paraffin and bisulphide of carbon. Photographs of these were taken as follows: they were illuminated by an electric arc and large condensing lenses, a camera was placed in front, and the view was rendered intermittent by a card disc with one hole near the edge made to rotate at from 14 to 20 turns a second. The exposure was about one eight-hundredth of a second. Forty inches of photographic plate were arranged in a long slide which could be drawn past by hand. Three of these multiple photographs were exhibited last Wednesday. The thaumatrope was made by sticking the separate parts of the last series round a card disc, and afterwards painting the surface black and white, following the outlines of the photographs exactly.

The thaumatrope, anciently so-called, clearly shows the gradual formation of the drop and the spherule, the oscillation of the pendant drop immediately afterwards, the rebound of the spherule from the pendant drop, the oscillation of the large drop as it falls, and its rebound from the water below into which it fell.

Other photographs exhibited were shadows of water jets cast upon a photographic plate by the action of a small distant spark, a method invented by Mr. Chichester Bell.

The remainder were photographic shadows cast by a water jet upon a rapidly moving plate by the intermittent light of an oscillating spark. These clearly show the movement of the separate water drops.

Mr. Boys, who is a Fellow of the Royal Society, and demonstrator to the Physical Society, always has something especially attractive to show at these Burlington House gatherings.

The Royal Meteorological Society exhibited the collection of photographs of meteorological phenomena described in these pages a month or two ago.

Professor H. Marshall Ward, of the Forestry School, Cooper's Hill, near Windsor, exhibited a selection of lantern slides enlarged from photomicrographic negatives, remarkable for their freedom from defects under the difficult conditions of production. The transparencies showed (1) the habits, and other peculiarities, of various trees from different parts of the world; (2) the comparative structure and anatomy of several European timbers; and (3) some of the more prominent features of diseases of wood, and fungi causing them.

Professor Sylvanus P. Thompson exhibited an optical rotator. This apparatus is for rotating the plane of polarization of light, and is intended to be used in conjunction with polarizing reflectors (black-glass mirrors and the like), which do not admit of being bodily rotated around the axis of the beam of light. The principle of the new rotator consists in the employment of two quarter-wave plates of mica, one of which is fixed at 45° across the plane-polarised beam of light, which it thus converts into circularly-polarised light. The second quarter-wave plate, which can be rotated by a simple gear, reconverts the circularly-polarised beam into the plane-polarised light, vibrating in any desired azimuth.

He also exhibited a new and simple straight-vision prism of value for use with the optical lantern and for other purposes; it is partly liquid and partly solid, and so constructed that much less light is lost by reflection from surfaces than in the case of direct-vision glass prisms. It consists of a single prism of Jena glass, of very wide angle, immersed in cinnamic ether. The materials having identical mean refractive index, rays of mean refrangibility pass straight through, but others do not, consequently a spectrum is obtained.

He also exhibited a natural diffraction-grating of quartz. This specimen of iridescent quartz exhibits diffraction-spectra corresponding to those of a grating ruled to 12,000 lines to the inch. A micro-photograph taken by Mr. C. L. Curteis, with a Reichert's apochromatic (3 mm.) lens, shows the nature of the minute structures of the specimen. For the sake of comparison, a diffraction grating of 6,000 lines to the inch, photographed on glass, was exhibited beside the piece of quartz.

Professor Sylvanus Thompson also exhibited a number of flat bottles, each containing two liquids, incapable of mixing, placed over one another. They were chosen so that each liquid absorbs all the rays that the other one can transmit. Though each was transparent, they were jointly absolutely opaque; they were also opaque when shaken up together.

Mr. J. Norman Lockyer exhibited photographs of the spectrum of the nebula in Orion. These photographs were taken in February with the 30-inch reflector at Westgate-

on-Sea; the exposures varied from two to three hours. The one taken with three hours' exposure (February 10th) shows abont fifty lines between λ 500 and λ 373, but many of them are only visible with difficulty, especially in artificial light. The Henry Draper Memorial photograph of the spectrum of P Cygni was shown for comparison, and it was seen that all the bright lines are amongst the brightest in the nebula. This argues in favour of the view that stars with bright-line spectra are of a nebulous character.

He also exhibited a photograph of the arc spectrum of manganese, showing the use of silver poles in eliminating impurities. This was one of a new series of photographs used in the preparation of a new map of metallic spectra with relation to the sun, Rowlands' photographic map of the solar spectrum forming the basis. The purest salts obtainable are volatilised in the electric arc between silver poles, and in this way the impurities contained in the ordinary carbon poles are eliminated. The silver poles were kindly prepared by Prof. Roberts-Austen, of the Royal Mint.

Mr. Lockyer lastly exhibited photographic comparison spectra of sun and arc, in the region *b* to *B*. These comparison photographs form part of a new series intended to cover the region which has hitherto been mapped by eye observations alone. The plates used were ordinary gelatine dry plates, treated with cyanine and erythrosine.

Professor W. Grylls Adams exhibited a new measuring polariscope, for measuring the angles between the optic axes of biaxal crystals.

Mr. Isaac Roberts exhibited some stellar photographs, one of which was a photograph with two exposures of the plate—the first of two hours' duration on the 29th January, and the second of two and a-half hours' duration on the 3rd February, 1889, the interval between the exposures being five days. The photograph is intended to illustrate a method for detecting variability in stars during short periods, and it indicates that ten faint stars in the region of the great nebula in Orion have changed in magnitude to the extent of from one-fourth to two-fifths the measured photographic diameters of the stellar images during the interval between the dual exposures.

We asked Mr. Roberts how he knew that the differences were not caused by minute local areas of lower sensitiveness of the gelatine plate. He admitted that more experiments were necessary to remove photographic doubts, and will hereafter have to be made, but a difficulty is that the opportunities for taking such photographs are of rare occurrence.

Mr. Roberts also exhibited a photograph of the two clusters in the sword-handle of Perseus, showing remarkable coronal and festoon-like groupings amongst the stars on several parts of the photograph. These clusters are quite free from nebulosity, and in this respect they differ from other clusters which he has photographed; for those clusters are involved in faint but distinct nebulosity.

Sir Henry Roscoe exhibited some specimens of aluminium and alloys manufactured by the Aluminium Company. They included—pigs of aluminium, 99 per cent. pure; castings in aluminium, rough and finished; specimens of aluminium, soldered; aluminium wire, sheet and drawn rod; aluminium medals, plain and gilt; cast aluminium bronze and brass, showing (*a*) tensile strength and elastic limit, (*b*) twisting stress, (*c*) thrusting stress, long specimens, (*d*) thrusting stress, short specimens; stamping in aluminium bronze, rough; 10 per cent. aluminium bronze, twisted cold; 5 per cent. aluminium bronze, worked hot and cold; aluminium brass, worked hot and cold; aluminium bronze and brass sheet.

Lord Rayleigh exhibited the polarisation of light by chlorate of potash crystals, also an instrument for testing colour vision.

Mr. Edward Bidwell exhibited 106 photographs of the eggs of the great auk. There are 67 recorded eggs of this extinct bird, of which 45 are in Great Britain, and 11 in France. The collection of photographs exhibited consisted of two views each of 53 of these eggs, photographed to scale by professional photographers under the personal supervision of Mr. Bidwell.

Dr. H. C. Sorby exhibited Chætopodæ, Medusæ, Ascidians, Nudibranchs, and other Invertebratæ, prepared as lantern slides, showing not only the general form, but also much of their anatomy. He says that some details may be brought out to greater advantage by means of a properly developed photograph.

PHOTOGRAPHIC LENSES.*

BY THOMAS R. DALLMEYER.

II.—The Best Selection of Curves Ascribed to the Material.

In photographic lenses the curves ascribed to the lenses are spherical, and this form of curve gives rise to what is known as spherical aberration or error, and its effects in single (uncombined or uncorrected) lenses are (*a*) indistinctness of the image formed for the axial pencil, (*b*) curvature of field, (*c*) astigmatism, (*d*) distortion. A perfect photographic lens would be corrected for all these errors; the corrections are approximated by combinations of lenses, and we will proceed to examine the conditions best suited to accomplish each.

(*a*) We have seen that no single lens can be made free from chromatic aberration, nor can it be free from spherical aberration. For a given material of definite refractive index the transversal and longitudinal measurements of the aberration vary with the shape of the lens, and, again, the spherical aberration varies with the aperture and the index of refraction of the glass.

For convenience in arriving at accurate results, it is best to separate the smaller errors, shown by a second approximation, from the main or first approximation. Thus, to arrive at a first approximation, we have the well-known formula connecting the radii and refractive index of the material with the focal length:—

$$\frac{1}{f} = (\mu - 1)\left\{\frac{1}{r} + \frac{1}{s}\right\}$$

Then, in a second approximation, we have two additional corrections to consider, viz., the thickness of the lens and the measure of aberration, t being the thickness, and y the semi-aperture—

$$\frac{1}{f} = (\mu - 1)\left\{\frac{1}{r} + \frac{1}{s}\right\} - \frac{(\mu-1)^2}{\mu}\frac{ft^2}{r^2} - \frac{\mu - 1}{2\mu^2}$$

$$\left\{\frac{1}{r^3} + \left(\frac{1}{s} + \frac{\mu+1}{f}\right)\left(\frac{1}{s} + \frac{1}{f}\right)^2\right\} f^3 \frac{y^2}{f} \ldots (2)$$

the negative signs indicating a diminution of the first approximate value.

The third term cannot be made nothing for any known material, but it is interesting to make this quantity a minimum with definite media of different refractive indices.

* Continued from page 363.

In most text-books this is done for glass of the nominal refractive index $\mu = 1{\cdot}5$. Taking a definite focal length and aperture for parallel rays, we have to decide what values to ascribe to the radii r and s, to satisfy the condition.

Calling the reciprocals of the focal length and the radii F, R, and S, we have

$$R = -S + \frac{F}{\mu - 1},$$

and using this notation,

$$R^3 + [S + (\mu + 1)F](S + F)^2 = \text{minimum}.$$

Differentiating, and substituting

$$-1 \text{ for } \frac{d R}{d S},$$

$$-3R^3 + 2[S + (\mu + 1)F](S + F) + (S + F)^2 = 0$$

and substituting again

$$-S + \frac{F}{\mu - 1} \text{ for } R$$

we get

$$\left\{ \frac{6}{\mu - 1} + 2\mu + 6 \right\} S = \left\{ \frac{3}{(\mu - 1)^2} - 2\mu - 3 \right\} F$$

here if $\mu = 1{\cdot}5$, $21S = 6F$, and hence

$$\frac{1}{s} = \frac{2}{7f} \quad \frac{1}{r} = \frac{12}{7f} \text{ or } r : s :: 1 : 6;$$

commonly known as the crossed lens.

Supposing the refractive index were higher, say 1·6, here $r : s :: 1 : 15$ to satisfy the above condition, and the lens assumes a shape nearer the convexo-plane lens.

For a given glass of known index of refraction, and assuming various ratios between the radii of curvatures, we can from equation (2) find at once expressions that show the amount of aberration in any chosen form. In speaking of lenses it is essential that the term used to describe the lens should define the surface on which the pencil of rays is incident; thus, a plano-convex lens means that the rays are incident upon the plane side, and a convexo-plane lens that the rays are incident upon the convex side.

Now taking the usual table thus calculated for ordinary forms of single lenses (for parallel rays), in which the refractive index $\mu = 1{\cdot}5$, and including the correction for thickness, let us see what we can learn here.

	Distance of least circle of aberration from approximate focus.		Diameter of least circle of aberration.	
Plano-convex lens	$\frac{27}{8}$	$\frac{y^2}{f}$	$\frac{9}{4}$	$\frac{y^3}{f^2}$
Equi-convex lens	$\frac{1}{6}t + \frac{5}{4}$	$\frac{y^2}{f}$	$\frac{5}{5}$	$\frac{y^3}{f^2}$
Convexo-plane lens	$\frac{2}{3}t + \frac{7}{8}$	$\frac{y^2}{f}$	$\frac{7}{12}$	$\frac{y^3}{f^2}$
Crossed lens	$\frac{24}{29}t + \frac{45}{56}$	$\frac{y^2}{f}$	$\frac{15}{28}$	$\frac{y^3}{f^2}$

We see that in each change of form the position and diameter of the least circle of aberration differs; the longitudinal aberration increases or diminishes as the square of the diameter of the aperture, and inversely as the focal length, and the least circle of aberration is proportional to the cube of the aperture, and inversely as the square of the focal length. Thus, for two similar lenses, in radii and glass, but one having twice the diameter of the other, the larger lens will have a longitudinal aberration four times as great, and the least circle of aberration will be eight times as great; and again, of two lenses of the same aperture, but one double the focal length of the other, the longitudinal aberration will here be the half (or inversely as the focus), and the diameter of the least circle of aberration the quarter (or inversely as the square of the focus).

Thus, to diminish aberration in a single lens, the only remedy is to stop it down, but this can never entirely cure it. Now, with a given material we have for a definite focal length the best form to ascribe to the lens to reduce the aberration of the central or axial pencil to a minimum, and we can further improve this by stopping the lens down. For photographic purposes we have now to consider the best form to ascribe to this lens to fulfil the other conditions that are also required for the formation of a distinct image. These investigations with a single lens are fully dealt with in Sir G. Airy's paper, "On the Spherical Aberration of Lenses," and for a fuller investigation I must refer you. The steps necessary are (1) to find proportion of the tangents of the angles made by the axis of a pencil with the axis of a lens before and after refraction; (2) the distance from the lens of the plane perpendicular to the axis of the lens at which the convergence of the rays, in a perpendicular or vertical plane, takes place; and (3) the distance from the lens of the plane perpendicular to the axis, and in a horizontal plane at which the convergence of the rays takes place. The difference of the positions of these planes of the primary and secondary foci gives rise to the effect of astigmatism. A geometrical illustration will probably explain the matter more clearly, and I think you will find these preliminary investigations of considerable use in the more complicated ones of combinations and systems of lenses to be dealt with later.

The effect of astigmatism in lenses appears to be little understood, so I offer you the following practical interpretation of the theoretical deductions above referred to in connection with Sir George Airy's admirable analytical treatise.

It has been frequently asked what coma and astigmation are. Coma is astigmatism, the vertical focal plane being corrected pretty accurately throughout the plane of the image, but the horizontal focal points being situated, off the axis, in very widely-different planes.

Take the plano-convex lens and the convexo-plane lens with a plate having a narrow slit cut across it in conjunction with the lens.

Now, in either case the vertical plane off the axis will have a certain curvature of the field, but the image for the oblique pencils will be distinct (in a sense). Now, if the plate be turned so as to take the horizontal focal plane at positions where the image was distinct for the vertical focal plane, it is no longer so for the horizontal plane, but a very strong coma is visible; with the plano-convex lens coma-*out*, and with the convexo-plane coma-*in*. Now, the vertical plane has less curvature of field than the horizontal, so that by cutting off the horizontal and using the vertical, coma ceases.

I may mention here that if astigmatism in a single combination or any system of lenses were entirely cured, there should be the same focus for both planes.

In testing lenses for astigmatism, this is a very powerful method of finding the amount. The effects of observing a point of light are very interesting, as is also the use, in double combinations, of an astigmatic stop.

(*To be continued*).

London and Provincial Photographic Association.—May 22, Mr. J. Traill Taylor will give a paper on "The Ethics of Photography."

THE ROYAL ACADEMY OF ARTS, 1890.

BY THE REV. F. C. LAMBERT, M.A.

Gallery No. 2.—On entering the second room we soon find a small picture from which to take a hint, No. 106 ("This Little Pig went to Market," J. T. Ross); note the unity of the group, and not one of them staring at the camera; *i.e.*, spectator—one face, or rather a part, is only seen. The subject is not one of any great rarity.

No. 109 ("May Day Morning," E. A. Abbey). We wonder if that "cock o' the walk" is only just waking up; it seems "too quite too" early, and something like general fog all over the pla—— canvas.

No. 110 ("The Abyss," J. T. Nettleship), "a quick plate and shutter." We only hope we may never see "the likes o' you" in nature: too suggestive of an after-a-lobster-supper-dream.

No. 115 ("Luxor," J. Farquharson). Note the strong values and sharp shadow—contour of strong sunlight.

No. 117 ("Bp. S. Alban's," W. W. Ouless, R. A.) is a vigorous portrait, but brings to mind the expression "as fresh as paint." Time will improve this painting.

No. 123 ("After Waterloo," A. C. Gow, A). As a general rule, we do not care for the usual gaudy glare of so-called military pictures, but this certainly is well worth careful study. The feeling of the general hurry-along, "the rush" under subdued excitement, is skilfully expressed. Note the general unity of the sub-groups, the diversity of expression under a common stimulus—the "order in disorder"—the general "go" of the whole picture, and yet all in a subdued key.

Nos. 124 and 666 ("Bp. of Durham, Dr. Westcott," "Late Bp. Durham, Dr. Lightfoot," both by W. B. Richmond, A). It is a melancholy and striking coincidence that within the same building, and from the same brush, we should have two bishops of the same see, and that these should be the two most justly-renowned scholars that the world has known. It is difficult to say which is the better likeness, for both are most masterly, and both very fine examples of the portraitist's art.

No. 131 ("Sandy Margin of the Sea," B. W. Leader, A). We like the sandy foreground much the best, for the distance is not distant enough to please; note that *some* of the foreground blades of grass and bits of "sea holly" are painted in detail, and others suggested only.

No. 143 ("Our Village," H. Herkomer, A.); and everyone of course asks, "Is it bushy?" Anyhow, it contains plenty to look at; at first one feels the groups are rather scattered about, disconnected, a village divided against itself. Note the kindly old grandfather and child; the boys enjoying the pleasures of imagination at "the" shop, and the prosperous buxom dame at the door. The red-haired girl in foreground seems a bit above her station in life, but is a fine study all the same. We don't quite realize "that house," at least not the hind part thereof, but suppose it's all right. Of the three sons of toil, the middle figure seems the nearest to our experience and idea of the working man. The foreground—and here we do really mean the foreground—might have been cut up a bit, wheel marks, &c., with possible advantage.

No. 150 ("A March Gloaming," J. L. Pickering) is a pleasant study—sombre in tone, quiet, broad, and simple, and we imagine might have been still more pleasing with a less noisy sky.

No. 151 ("How the Gossip Grew," F. D. Millet) contains much good still life painting, and yet, on the whole, is not satisfactory, possibly a case of "too much focus;" too much to carry away the eye from the leading theme; hence a note of warning!

No. 156 ("Cloud Chariots," W. A. Mackworth). The artist here gives a free lesson to some of his not very distant neighbours on the walls; although there is still wanting that feeling of the "arching vaults of canopied heaven."

No. 160 ("E. A. Waterlow, A.R.A." by L. Alma-Tadema, R.A.), interesting chiefly as being a portrait of one well-known painter by another equally "if not more so."

No. 166 ("Solitude," by the President) we reserve for the present.

No. 168 ("Evening," F. W. Jackson). The effect is quite in agreement with its title—quiet, calm, restful, and the sky pleases us well.

No. 175 ("Moonlight," &c., H. J. Stock). The poetic title prepares us for something rather weird, uncanny, and makes us repeat that we do not often see a picture lighted by sunlight which conveys the effect of moonlight.

No. 177 ("Karnac," J. Farquharson); see note on No. 115. These wonderful temple remains, all leaning over to the left, make us think about swing-backs, spirit levels, &c., and altogether leave an uncomfortable feeling of something wrong. Before leaving this room there is yet another picture, No. 129 ("If," Theodore Cook), which may be well seen from some little distance. The interior of a work room, with a lonely toil-burdened occupant at a sewing machine; the broken chair, and care-worn face, general surroundings, tell a tale, without words, of privation—gloom, doubt, if?

(To be continued.)

A STANDARD METHOD OF DEVELOPMENT.*

BY C. H. BOTHAMLEY, F.I.C., F.C.S.

Coming now to a consideration of the alkali to be used, ammonium carbonate may at once be rejected because of its great instability. Potassium carbonate has certain advantages over the sodium salt, but is less easily obtained pure, and is very hygroscopic. This last property renders its use impracticable to anyone but a chemist. Our choice therefore lies between sodium carbonate and ammonia. The former has the advantage of much greater stability, is readily obtained pure, and can be kept in well closed bottles without undergoing change. Sodium carbonate is commonly met with in three forms: the ordinary crystals, or decahydrate, Na_2CO_3, $10H_2O$; the crystalline monohydrate Na_2CO_3, H_2O, formed when the preceding hydrate is exposed to air until it crumbles to fine powder, and ceases to lose weight; and the anhydrous salt, Na_2CO_3. The molecular weights of the three compounds are respectively 286, 124, and 106, and hence one part of the anhydrous sodium carbonate is equivalent to 1·168 part of the monohydrate, and to 2·698 parts of the decahydrate. It is difficult to obtain either of the hydrates of absolutely definite composition, and consequently the anhydrous salt should be used.

Anhydrous sodium carbonate can be purchased of a high degree of purity, but, as a rule, will require drying at 150° C. or 300° F. It is best made by heating pure

* Continued from page 352.

* Continued from page 356.

sodium bicarbonate (sodium hydrogen carbonate) at 150° C., which expels all water and excess of carbonic acid, but does not produce any sodium oxide. The anhydrous salt should be kept in a bottle closed, preferably, with an india-rubber cork. It will absorb water again if exposed to air.

Ammonia, although much less stable than sodium carbonate, has much less action on the glass of the bottles in which its solution is kept. Moreover, it is very largely employed in practice, and the possibility of using it in a standard developer deserves careful consideration. The concentration of even moderately dilute ammonia solution is liable to variation, in consequence of the volatilisation of the gas. A determination of its strength is made either by taking the specific gravity—a tedious operation if done accurately, and of no value if done inaccurately—or by titrating with a standard acid, as in the ordinary process of acidimetry. The latter operation is very simple, and requires very little special apparatus, and no unusual manipulative skill.

Trituration of Ammonia.—We require a burette holding 50 c.c., and graduated in fifths or tenths of a c.c. (or 1,000 grains graduated in half-grains); a pipette with one mark holding 10 c.c. (or 100 grains); a measuring flask with one mark holding 1,000 c.c. (or 10,000 grains); a standard acid; and an *indicator* consisting of a solution of *aurin*, made by dissolving one part of the dye in 500 parts of dilute alcohol.

Oxalic acid is the most convenient acid to employ. The purest oxalic acid obtained from a first-class dealer in fine chemicals* should be used. It has the composition $H_2C_2O_4$, $2H_2O$, and 126 parts are equivalent to 34 parts of real ammonia, NH_3.

Dissolve 37·06 grammes of the pure acid in 1,000 c.c. of water; 1 c.c. of this solution is equivalent to 0.01 gramme of ammonia, NH_3. The solution should be kept in a cool place in the dark.

Dilute strong ammonia with fifteen times its bulk of water; measure off 10 c.c. by means of a pipette, and run it into a beaker or dish, in which you have previously placed about 50 c.c. of water. Add two or three drops of the aurin solution, and then, having previously filled the burette to zero with the acid solution, run the acid very carefully into the ammonia, with constant stirring, until the pink colour is just, and only just, discharged. Now read off the amount of acid which has been run from the burette; the number of cubic centimetres of acid required gives the number of centigrammes of ammonia, NH_3, in the 10 c.c. of dilute ammonia solution taken. Label this solution "Diluted Ammonia, No. 1," and put the strength on the label. From this it is easy to make up an ammonia solution of definite strength. It is desirable to repeat the trituration, and take the mean of the two results. If they do not agree, a third experiment must be made. Before the burette is filled with the acid solution, it should be rinsed out with a small quantity of the solution, which is then thrown away, and the burette is filled. The pipette should likewise be rinsed out with a little of the ammonia solution.

Pyrogallol should be dissolved in distilled water immediately before it is wanted, but the solution will keep well enough for a day or two in a well-closed bottle if it is kept out of contact with ammonia fumes. No acid should be added; there is no evidence that the acid is without decomposing action on the pyrogallol, and it neutralises part of the alkali used as an accelerator.

Sulphites are inadmissible in a standard developer. It is almost impossible to obtain them in a state of purity, and they are subject to continual alteration. Analysis of a large number of samples of commercial sulphites has taught me that even approximate purity and constancy of composition are only to be found in well-crystallised samples of the so-called metasulphites or metabisulphites, which are more properly called anhydrosulphites. Even in these cases the salt was never quite pure, and it altered continuously, though slowly. Variations in the composition of the anhydrosulphites affect the quantity of alkali which they neutralise, and hence, of course, affect the active strength of the developer. We are also, at present, without definite information as to the exact part which a sulphite plays in development, and the influence of different proportions of it.

Consideration of these points led me to the conclusion that a standard developer should contain—

A. Pyrogallol, ammonia, ammonium bromide; or

B. Pyrogallol, sodium carbonate, potassium bromide, or no restrainer.

It is well known that the action of a developer depends upon (1) its concentration; (2) the relative proportion of the constituents; (3) the duration of its action; and (4) the temperature.

A standard developer must be so compounded that it will reduce all silver bromide which has been acted upon by light, without reducing the bromide which the light has not altered, or, in other words, without producing chemical fog.

Messrs. Clark and Ferrero have calculated the relative proportions of the constituents of the more important of the various unnecessarily complicated developing formulæ which have been proposed. Examination of these numbers shows that a developer which contains in each fluid ounce 2 grains of pyrogallol, 1 grain of ammonium bromide, and 3 minims of ammonia solution ·880, may be taken as an approximate average. The use of such a solution as a normal developer has frequently been recommended by Mr. Andrew Pringle. If these quantities are calculated to parts in 1,000, and the proportion of real ammonia, NH_3, is substituted for that of the strong solution, we find that they agree approximately with a developer which contains in 1,000 parts by measure, 5 parts of pyrogallol, 2·5 parts of ammonium bromide, and 2·5 parts of real ammonia.

In accordance with one of the conditions previously laid down, that the standard developer should correspond as closely as possible with the developers used in ordinary practice, I adopted these proportions as a preliminary standard, and made a number of experiments with a view to determine how far this developer was applicable to plates of various kinds, and how far the results were modified by the conditions under which the developer was allowed to act.

Before describing the experiments and their results, it may be as well to point out that the methods in common use for measuring sensitiveness are not particularly accurate. In the Warnerke sensitometer screen, or the Spurge sensitometer, the difference between a sensitiveness of 1 and a sensitiveness of 2 is represented by three numbers or holes; in other words, they do not measure sensitiveness to less than about 33 per cent. of its value. Newall's sensitometer is capable of giving much greater accuracy,

* Becker and Co.; Burgoyne, Burbidges and Co.; or Hopkin and Williams.

but is not in general use. There is, however, no reason why we should not have a standard method of development in readiness for the improved methods of sensitometry which will some day be invented.

(To be continued.)

PHOTOGRAPHY IN MILAN.

A NEW photographic journal has just appeared in Milan. It is called the *Photographic Dilettante*, and is published with illustrations monthly, under the direction of Signor Dott. Luigi Gioppi. The editor, in presenting this journal to the public, speaks of it as an aspirant "desiring to become a direct emanation of the great art of light and shade." Without seeking to diminish in any degree the importance of the already existent photographic publications in Italy, the design of the present journal is, says Signor Gioppi, to provide, at a cheap price, a popular paper with essentially practical ideas for all who are interested in photography.

The title of the journal shows that it is chiefly intended for beginners and amateurs; but it will also have an interest for more advanced students and professionals who are desirous to increase their scientific knowledge or amplify their business gain. The variety and clearness of the illustrations will, it is hoped, says the editor, not only embelish, but assist the comprehension of the matter contained in the printed pages. Special attention will also be paid to all inquirers, in order to establish between this journal and the public a "moral chain of sympathy and affection" in an art which, says the editor, we love above any other.

At present the *Photographic Dilettante* is a "direct emanation" from the celebrated *Annales Photographiques*, an able and successful journal numbering amongst its contributors some of the chief scientific, practical, and amateur votaries of photography. But it is the purpose of the editor to add a large quantity of original matter suited to the tastes and wants of its community of readers.

The present number of the *Photographic Dilettante* for the month of May contains several interesting articles, such as "For Beginners," "An Historic Account of the Art," "Photographic Failures, and Means to Avoid Them," "Apparatus for Enlargements," "Instantaneous Photography," and "Photography with the Magnesium Light."

In "Photography for Beginners" is given an interesting anecdote communicated by Signor E. Beleurgey de Raymond. One of this writer's friends, an excellent musician, used to utter loud and continuous complaints about the rejection of his pictures. Every year several were returned to him with the fatal word *rifiutato*—declined—marked in monumental characters on their backs. His fellow-citizens, in consequence of this decree, were unable to admire his landscapes of a cauliflower green, and his horses of a pronounced jaundice yellow which caused astonishment to his cook. The musician could endure with patience abuse of his music, which was good, but the slightest disesteem of his pictures, which were bad, offended him beyond forgiveness. One day, as he was inflicting on Signor de Raymond his complaints against the obliquity of the judges of his productions, and the general degradation of taste of the people of his time, the latter asked him why he did not busy himself with photography: "With your artistic taste you would certainly obtain most praiseworthy results."

"You think so," replied the musician; "well, it might be, but photography is not art."

"It is at least very near it. Look at these photographs, for instance," and Signor de Raymond produced several views taken from the Valle d'Aosta in a masterly manner. "There," said Signor de Raymond, "is true feeling, and so true art."

"That is so," replied the musician; "but, for my own part, I aspire to something beyond that."

"Several months afterwards," says the narrator of the story, "I met my musician again with his whole being transfigured. He had set himself seriously to the practice of photography, and had already attained a fair *modicum* of success. This success was the death-knell of his pictorial daubs; no more cauliflower greens or jaundice yellows were declined by judges of deteriorated taste in art, and our musician became an amateur photographer of no small repute."

"I narrate this story," says Signor de Raymond, "to show that the learning of photography is neither long nor difficult; and, whilst to become a painter certain natural gifts are requisite, in addition to years of labour, to become a photographer is within the reach of almost everybody."

In the "Historic Account of Photography," M. Rizzardi recalls the observation of the astronomer, Arago, on the 10th August, 1839, that photography was the most marvellous conquest of the human mind; and that of Lamartine, who spoke of it, not as a trade, but a high art and phenomenon in which the artist has the sun for his fellow-worker. According to M. Rizzardi, the "first idea of the camera-obscura was incontestably that of the Neapolitan, Giovanni Battista Porta"—a name since ingeniously converted by some person better acquainted with biblical than Italian history into St. John the Baptist.

In the article entitled "Apparatus for Enlargements," the reader is informed that the ever extended use of papers of gelatino-bromide and chloride has determined the editor to produce a series of articles showing how these may be employed in printing by contact, and how they may be especially utilized for enlargements. "The press of space in our present number," writes the editor, "compels us to defer our first article on this subject to our next number in June; but an illustration accompanies the letter-press of a machine for enlargements, of which a detailed account will be given hereafter."

PROFESSOR MELDOLA'S lecture on "The Invisible Photographic Image" will be delivered at the Royal Institution to-night.

PHOTOGRAPHY AT ETON.—Last Saturday night, Mr. Andrew Pringle delivered an address on "The Pleasures, Advantages, and Various Branches of Photography" to a goodly number of Eton boys, in the new lecture room at the College. The lecture was illustrated with lantern pictures projected upon a specially prepared wall; such white walls for the purpose are now becoming common in scientific and other public establishments, showing the growing popularity and utility of the optical lantern. Mr. Pringle spoke under the auspices of the Volunteer Corps of the College, so he dealt more particularly with military photography, and the biunial lantern employed was skilfully worked by the sergeant of the corps. The speaker stated that he was a Harrow boy, and gloried in the generous rivalry between Harrow and Eton. Mr. Pringle ended by urging the formation of an Eton photographic society. The science master, Mr. Porter, then expressed his willingness to receive the names of intending members, and perhaps the suggestion will bear practical fruit, because about a hundred of the scholars possess cameras. The lecture was of a lively nature, and well received.

THE GLASGOW PHOTOGRAPHIC EXHIBITION.

The Seventh Annual Exhibition of the Glasgow and West of Scotland Amateur Photographic Association, just closed, was held in their own rooms, 207, West Regent Street. To call it an average exhibition would, perhaps, be overstating actual facts, for taking into consideration the membership, the exhibits in no way correspond to the continued growth of the Association. Perhaps it is almost too much to expect that pictures can be obtained annually in sufficient number and of sufficient merit to meet the requirements of an exhibition which is confined to members solely. These remarks are suggested by the conspicuous absence of work from those members who were the prize takers of former years. The works are missing of Snell, Anderson, Rennie, Coulson, Goodwin, and many others. It might be a judicious step to refrain from having an exhibition next year, or, if the members should still desire to continue the yearly show, let some classes be arranged for outsiders, so that additional interest might be imparted and a collection gathered that would attract the general public.

Taking the classes in the order in which they appear in the catalogue, first of all comes that of *Landscapes*. This is divided into two sections: Section A, for pictures whole-plate size and over; and Section B, sizes under whole plate. There are eight competitors in the former section, and David R. Clark, M.A., carried off the honours with his three pictures—"Summer Morning, St. Monance," "The Trysting Tree," and "Pittenweern." In addition, Mr. Clark has secured a medal for the most artistic picture in the exhibition, which has been awarded to "The Trysting Tree." The judges, perhaps, had little difficulty in arriving at their verdict in the case of the picture specified; it would hold its own in a much more strongly competed exhibition than the present. Mr. Charles J. Shaw secures second prize with his "Cottages in Landash, near Rothesay," "Old Pier, Landash;" while the third prize goes to Mr. George Sheriff, for his "Fisherfolk, Pittenweern," "Fishing Boats, Anstruther," "Willows on the Carron;" these have been printed by Blanchard's toning process. In Section B, ex-President Ralph H. Elder has been placed first and third for his "Views in Brittany," while Mr. John Morrison, Jun., is ranked second in order of merit. He has several sets of pictures in the class, all of a high order of merit, and all taken by the hand-camera. The successful three, however, are "Fishers," "Lake of Menteith," "Ploughing, near Kelvingrove Park."

Class 2—that of *Figure Studies*—is, as far as competitors are concerned, decidedly weak, there being only two entries. Mr. Clark scores here again with his "Two a Penny," "The Army of the Future," and "A Funny Story."

Class 3. *Instantaneous.*—As usually to be found in this class, there are one or two pictures which, strictly speaking, do not answer to the term instantaneous. George Sheriff has been awarded first place for "S.S. *Pioneer* leaving Oban," "Before the Wind," "Sound of Mull;" "S.S. *Mountaineer* leaving Oban;" and "The *Thistle*," "The *Ariel*," "The *Cruiser*," and "*Marguerite*" of Mr. T. Steven, Jun., are placed second. Yacht pictures and steamer pictures seem to be more or less played out, and it is somewhat remarkable that a series of hand-camera pictures by Mr. John Morrison, Jun., has not been recognised by those judging as worthy a place. Either of the frames shown by Mr. Morrison was worthy of recognition, the subjects chosen being in no sense hackneyed.

Class 4. *Portraits.*—As necessarily with amateurs, we must not look for a very high standard in this class. Although five entries, only one prize has been awarded, and this goes to Mr. Thomas Taylor, certainly the best shown.

Class 5. *Groups.*—Victor L. Alexander.

Class 6. *Animals.*—It is difficult to say why this class should not be a more strongly competed for class than it is. Mr. James Fleming takes first place with his Dog, Chickens, Pony.

Class 7. *Still Life and Interior.*—David R. Clark is again to the front. He shows three interiors of the Municipal Buildings, Glasgow, all 15 by 12 pictures. Second prize goes to T. Stephen, Jun., for his interiors of St. John's, Malta.

Class 8. *Enlargements.*—Generally one of the strongest classes in an amateur exhibition. The judges have decided to make only one award, and it goes to Mr. Archibald Watson, President, for Marble Staircase, Municipal Buildings, Glasgow; Falcide, Norway; and Corridor, Municipal Buildings, Glasgow. Some of the portraits enlarged would require to be hung very high indeed in order to minimise defects of original negatives.

Class 9. *Transparencies.*—Mr. Archibald Watson, President, is the sole prize taker in this class, there being only himself and Mr. John Morrison, Jun., competing. These exhibitors have made their transparencies on Mawson and Swan's plates, and very creditable productions they are. Lantern plate work being so much in the ascendant at present, it was a matter of astonishment to find this class of picture so poorly represented. Perhaps it would have been a little ridiculous to have given two prizes when only two men had entered the lists, but Mr. Morrison's three pictures have, owing to a lack of interest on the part of his fellow members, been somewhat shelved. They run Mr. Watson very closely, and had more entries been forthcoming, Mr. Morrison would have been pretty sure of second place.

Class 10. *Developed Prints.*—In this class the bromide print is predominant, although one or two specimens of platinotype are to be found. Mr. John Ure Primrose—or, to be more accurate, Councillor Primrose—is here at his best. He takes both first and second prizes. The pictures ranked first are those of "The Staircase, Municipal Buildings, Glasgow," and a "Drawing-room;" while those second include "Coming into Rothesay," "Off Dunoon," "At Hunter's Quay." The picture, "Off Dunoon," is particularly fine. On either side of a river steamer are grouped several yachts evidently becalmed, but most picturesque in their erect bearing with all sails set, the whole forming a most effective and telling piece of composition. About a dozen of frames have been sent in containing pictures which are not for competition, and among them Mr. Clark's exhibit is the most important. The picture entitled "Fisherman and his Wife" gained a medal at the exhibition held some little time ago at Castle Wemyss.

In conclusion, it should be mentioned that the judging was entrusted to Mr. Paton of Greenock, Mr. Allan of Ayr, and Mr. William Young, artist, all of whom have already officiated in a similar capacity at previous exhibitions of the Glasgow amateurs.

Notes.

The proprietor of a Transvaal paper, having offended the Government by an article vigorously attacking its policy, discovered himself in hot water. The authorities swooped down upon the printer, placed an interdict on the paper, and prevented a second edition appearing. The proprietor, however, was equal to the occasion, and had a copy of the first edition photographed. Proofs to the number of eight hundred were printed, and such was the demand for this journalistic curiosity that the *Transvaal Truth* in its photographic form was largely bought up at half a guinea a copy.

The "Automatic Photograph Company," which has, during the past few days, appealed to the public for £100,000 to enable it to start in business, has no doubt a very clever idea to work upon, but the pecuniary success does not appear to be so certain as the prospectus would have one to believe. It is, of course, easy enough to say that 1,000 machines producing half-a-crown a day will yield £45,625, because this is equivalent to two and two making four. What is not so easy to determine is the absolute certainty that 30,000 people daily, or nearly nine millions and a-half yearly, will stand in front of these automatic machines and be photographed. We fully admit that the novelty of the operation will attract the multitude at first, and that in favourable spots, and under favourable circumstances, the machines will be kept going; but that anything like the numbers will patronise them which the promoter of the Company confidently expects remains to be seen.

It may be doubted also whether £15,000—the sum estimated as covering "cost of collection, rentals of machines, depreciation, repairs, and management"—will be anything like an adequate amount. Nothing is said definitely as to the second item. The experience of other automatic machine companies goes o show that the rents charged by railway companies and others form a large proportion of the annual outlay, and we suspect that if £10 per machine per annum were put down as a yearly rent, it would not be under the mark. So far as can be learnt from the prospectus, the apparatus has not had the test which can alone be considered reliable—a lengthened public usage. The machine may be of an extremely hardy nature, and not at all likely to depreciate, or it may require frequent repairs, but on these points evidence is wanting.

What may be termed the photographic side of the prospectus appears to be equally open to criticism. Does it not seem strange that out of the score or so of press notices advertised, not a single photographic paper figures in the list? The inventor has carefully avoided experts, and he may have been prudent in so doing, but as we have not examined the apparatus, we offer no opinion on this point, and simply record the fact. It is comforting to know that "it is not pretended that the invention will materially interfere with high-class photography," but people are likely to have some curiosity as to "the secret of preparing the chemicals." "Hitherto," the prospectus gravely sets forth, "it has been necessary to use expensive materials, which has made it impossible to produce photographs at anything approaching the figure named. It will, therefore, be seen that the revenues of the Company can be largely increased by selling the chemicals for ordinary photographic purposes." Until one has had an opportunity of testing these mysterious "chemicals," the photographic public will not "see" this at all. But no doubt photographers will be glad to be convinced. The omission to mention the exact position of Mr. Ladislas Nievski, the "technical adviser to the Board" (and who is also a director and one of the parties to the contract) with regard to the Stereoscopic Company seems to be slightly misleading. Mr. Nievski is paraded as "chief photographer, London Stereoscopic and Photographic Company, Limited," and this has led the Stereoscopic Company to advertise that their name having been published in the prospectus of the Automatic Photographic Company "in connection with an operator who is no longer in their employ," it is necessary to state that neither directly nor indirectly have they any interest in or connection with the Automatic Company. No one will be surprised at this denial, and so far as the particular point is concerned, it would surely have been more ingenuous on the part of the Automatic Company to have prefixed "chief photographer" by the word "late."

A question as to the patent. The prospectus states "a case has been laid by the Company before Mr. Moulton, Q.C., and Mr. Goodeve, the well-known authorities on patent law, as to the validity of the patent, and they have given as their opinion that the patent is good and valid." No doubt; at the same time, it may be as well to remember that there is another automatic photograph machine in the field. This is the apparatus of M. Enjalbert, which was at work for some time in the Paris Exhibition.

The detective camera may be the forerunner of novel forms of art. We read in a fashion journal that there is a necessity for a new individual—one who might be aptly termed a lightning artist—who could paint with rapidity, and show immediately on large canvasses the very remarkable town-events which are occurring. The detective camera, it is discovered, is expressive and real in its results, but they are diminutive. With the assistance of a few pounds of bright colours, large cartoons might be accurately painted in by a lightning artist. This is all very well, but when the cartoons are painted, what then? Does it mean that a panorama or diorama of scenes in London streets is in contemplation?

CELLULOID AS A DRAWING AND PRINTING MATERIAL.

BY COLONEL J. WATERHOUSE, R.S.C., ASSISTANT SURVEYOR-GENERAL OF INDIA.

I HAVE lately been trying some experiments with celluloid films as a material for drawing and printing upon in connection with photographic processes of reproduction, and a brief account of the results may not be uninteresting. The advantages celluloid possseses as a drawing material are:—

1. Its great translucency, which enables tracings to be very easily made upon it, and also renders it an excellent material for being used as a transparency or transmitted positive or negative for photographic printing. The absence of all grain makes it much better for these purposes than paper or cloth.

2. Its impermeability to and unabsorptiveness of water or moisture, which make it quite free from any tendency to be affected like paper by hygrometric changes, or to be attacked by mildew and damp.

3. The fine matt surface, which takes pencil, chalk, or ink very readily, and can easily be renewed, if necessary, by graining with fine sand or emery powder.

4. The facility with which drawings can be washed off and renewed for purposes of correction or for making new drawings. The surface can easily be kept clean and free from dirt.

I have tried the films as obtained from America, in three thicknesses, the $\frac{5}{1000}$, $\frac{10}{1000}$ and $\frac{30}{1000}$ of an inch The first is about the thickness of thin paper, and is almost free from colour; the second, which seems to be the kind in ordinary use for negatives, &c., is about the thickness of a sheet of stout writing paper, and shows a light buff colour if laid on white paper; the third is about the thickness of an ordinary playing card, and shows a strong buff colour over white paper.

On account of its freedom from colour and great flexibility, which would permit of its being rolled without damage, the thinnest kind would probably be found the most suitable for drawing upon; but as the surface of the thin sample sent me was not so evenly grained as the others, I used the medium kind for the trials. It was found that a soft black lead pencil worked very pleasantly on the matt surface, and gave a fair opacity of line when viewed through the film, so that pencil drawings on this material might be copied in facsimile very easily by various photographic processes. Black chalk also works very well, and gives more opacity in the lines than lead pencil does. The softer kinds work better than the hard. With the latter, as with hard lead pencils, there is a tendency to make lines which polish the surface and render it transparent when viewed through the film.

Indian ink drawings in line can be made with perfect fineness and delicacy, either on the matt or polished films, with pen or brush; but, so far as I have tried, it is not easy to produce shaded or coloured tints in washes; the surface of the material is too unabsorbent, and cut-shades are produced on drying. Stippling or work with the air-brush would probably answer better for shaded drawings in Indian ink or colour.

Our trials have already shown that drawings in pen and ink and in chalk on celluloid can be reproduced very effectively by the photo-etching processes on copper, either by the direct methods, in which asphaltum or bichromated albumen is used as the sensitive surface, or in the manner used for ordinary half-tone heliogravure work with carbon tissue. In the latter case, the drawing must be reversed, unless the film of celluloid is thin enough to allow the drawing to be printed with sufficient sharpness through the film. The drawings would also be suitable for reproduction by certain of the block processes now in use, and blocks could be produced directly from the artists' drawings. For all facsimile work, negatives could easily be obtained, if necessary, by contact printing on dry plates.

The drawings can, in fact, be reproduced by any of the photographic processes now used for reproducing tracings; and as the material is perfectly free from all inequality of grains, is sold in large sheets, and will soon be available in continuous rolls, it seems likely that it might well replace tracing cloth or paper, for all copying or tracing purposes, and especially for tracings to be copied by photography.

The cost of the celluloid sheets in any case is not great, and if not required to be kept, the drawings can be washed off, and the same materials used over and over again. For sketching purposes the celluloid would be very useful, and could be made up into blocks, like paper. It would keep much better than the latter in a damp climate. For drawings for decorative purposes, the material could no doubt be also usefully employed.

For preparing factitious negatives celluloid also offers great advantages and facilities. In this way a drawing in Indian ink or other pigment can at once be turned into a reversed negative suitable for photo-mechanical printing by the collotype processes, or by any of the block processes depending on a direct photographic impression from the negative on a zinc plate, coated with asphaltum or chromated colloid. For this style of work, lamp or ivory black, with a little gum, is the best ink to draw with, Indian ink being rather inclined to become insoluble by keeping. As soon as the drawing is completed, it is evenly coated with a mixture of lamp-black and gold size, as recommended by Major Gore, R.E., or with printing ink and turpentine with a little gold size, so that it may dry quickly. As soon as this is the case, but not before, the film is placed in water, which will at once clear the ink off the lines of the drawing, leaving them quite transparent against the opaque ground. For fine work a little clearing of the lines with a soft sponge may be necessary.

The new films have been tried as a printing surface, in place of stone or zinc plates, and have been found to answer fairly well, excepting that it is very difficult to keep the ground clear and white, and free from a slight dirty tint. Gum and gelatine with various acids and with bichromate of potash have been tried as "etching" preparations, but so far without effect. If with further trial this defect can be overcome, the films might be very valuable as a substitute for stone or zinc in printing. With the delicate cream colour of the stone, which is so much pleasanter for draughtsmen's work than the dark grey colour of the zinc plates, they possess all the lightness, portability, and infrangibility of the latter, without their liability to corrosion. Their ready flexibility would be of value in printing from curved surfaces.

I have not yet had an opportunity of trying the films as a support for the gelatine printing surface in collotype work, but it seems most probable that the thicker kind of celluloid ($\frac{1}{30}$ of an inch thick), would be suitable for this purpose, and would have the great advantage over glass plates of not being liable to break. The transparency of the films would admit of the sunning of the gelatine coat-

ing from the back, in exactly the same way as with glass plates.

The celluloid films can be printed on from stone or zinc fairly well, though the ink takes some time to become thoroughly dry. Printing from copper plates was not found to answer. Type can also be printed from, but the impressions obtained were somewhat weak, and the type indents the films very much; but further trial might give better results. Such prints from type would be useful in a variety of ways, for typing names and titles, &c., on heliogravure plates, and for many other miscellaneous purposes. The impressions from type seem rather too weak to use at once for photographic printing, but they can easily be strengthened by brushing over them some red bronze powder or black lead.

The acquisition of a material like celluloid, obtainable in sheets of large size and fine surface, which is practically transparent, inextensible, and unabsorbent of moisture, nor readily acted on by most acids (acetic acid attacks and dissolves it), is a great advance for all work connected with photography and printing, and it seems probable that we may see a very large extension of its use in these directions before long.

CARBON PRINTING.*

BY E. BRIGHTMAN.

Carbon printing appears to receive less attention from amateurs than any other method of reproduction. The reason why this beautiful process is so neglected is, I think, because an impression prevails that the process is complicated, troublesome, and uncertain. To read a description of the method of working certainly might give one this impression; but the operations are all extremely simple, and with the introduction of the stripping and celluloid films, giving negatives that can be printed from either side, a second transfer is unnecessary: thus the process is greatly simplified.

The advantages of the carbon process are many:—

1. It is undoubtedly permanent.
2. Prints may be made in any desired colour.
3. Absolute uniformity of tone.
4. It can be adapted to all classes of negatives by variation in the strength of the sensitising solution. A thin and feeble negative will give a brilliant and rich print by using a weak bath for sensitising; and a hard, dense negative will yield a soft and delicate print by increasing the strength of the solution.
5. The results obtained by this process are equal, if not superior, to those obtained by any other method.

Against all these advantages we can only set down two drawbacks. The first is that the sensitised tissue will not keep in a ready prepared state for many days; in keeping, a decomposition takes place, which renders the tissue partly or entirely insoluble. Secondly, the action of light on the tissue is invisible, so that examination will not enable us to ascertain the progress of depth of printing; but by means of the actinometer we are enabled to guage accurately the time required to form the image, so that this cannot be considered to be a serious objection.

The carbon process is based upon the property of gelatine, gum, and similar substances, when mixed with bichromate of potassium, of becoming insoluble under the action of light.

Briefly described, the carbon process consists in adding carbon in the form of lampblack, or other finely-divided colouring matter, to a mixture of gelatine, which is evenly spread upon paper. This forms what is technically termed carbon tissue, which is rendered sensitive to light by immersion in a solution of bichromate of potassium. After exposure under a negative, this paper is soaked in warm water; the portion of the gelatine unaffected by light dissolves in the water, while the insoluble portion, or that which has been acted upon by light, together with the imprisoned colouring matter, remains attached to the paper, forming the varied gradations of light and shade in the picture.

To obviate defects experienced by Poitevin and L'Abbé Laborde, Swan introduced his patent process of double transfer.

The gelatine tissue, after exposure, was cemented by means of an india-rubber solution to stout paper. After the rubber cement was thoroughly dry, the print was immersed in hot water, and the paper which formed the original support of the gelatine film was washed away with the soluble gelatine, leaving the reversed picture attached by means of the rubber solution to the second sheet of paper. It is, of course, obvious that this gave a reversed image, requiring a re-reversal, which was effected by sticking the paper face downward to another sheet of paper by means of gelatine. When thoroughly dry, the upper sheet of paper was removed by softening the rubber cement with benzole, leaving the image or picture now properly reversed on a sheet of paper.

This method, though yielding fine results, was troublesome, slow, and costly; and it remained for Johnson, by his more simple method of double transfer, to bring the process to perfection.

* A paper read before the Bristol and West of England Amateur Photographic Association.

Lewes Photographic Society.—This Society has issued the following notices:—June 3rd—Paper on "Twelve Months' Experiences as an Amateur Photographer," by Mr. G. J. Wightman. June 21st—Excursion to Newick. July 1st—Paper on "Composition, Light, and Shade," by Mr. E. J. Bedford. July 19th—Excursion to Buxted. August 5th—Paper on "Printing Processes," by Mr. A. H. C. Corder. August 30th—Excursion to Hayward's Heath for Balcombe. September 2nd—Annual Meeting. September 18th—Excursion to Hailsham.

Aluminium.—According to the *Tribune*, of Rome, Georgia, as quoted by *Invention*, a rather important discovery has recently been made in Floyd County, in the shape, apparently, of a vein of bauxite, or cryolite, suitable for use in making aluminium. The *Tribune* appears to think that the vein contains pure aluminium, but even Georgia could hardly furnish such a wonder, and it will be quite sufficient glory for Floyd County to supply an ore capable of easy conversion into metal. The same journal speaks of a baton of aluminium, with regard to which it makes the following observations: "Lightness is a very desirable quality in a musical director's baton, as well as the metallic brilliancy of surface that shall easily catch and hold the eye of the performer. Aluminium is, therefore, a good material for the purpose, as is soon to be demonstrated. A baton of this metal, recently cast at the Pittsburgh Reduction Company's works, bears the inscription; "Presented to Mr. Richard Teckwer, February 24th, 1890, on the occasion of the XXth Anniversary of the Philadelphia Musical Academy, by the Counterpoint Class of 1890." The baton is 17in. long, and tapers from ¾in to 5-16in. in diameter, and though solid throughout, weighs only 3½ oz. It is beautifully engraved along its whole length, except about two inches in the centre, where the inscription is placed. It has bands of an alloy of gold and aluminium, and the whole surface is finely burnished."

THE CITY PHOTOGRAPHIC EXHIBITION.

A prospectus has just been issued about "The City Summer Photographic Exhibition," to be held under the auspices of the Photographic Trade Section of the London Chamber of Commerce. Among other matters, the circular gives the names of the members of the committee of the Photographic Trades' Section, as follows:—Messrs. Walter S. Bird (*Chairman*), Frank Bishop (*Deputy Chairman*), Thomas R. Dallmeyer, J. J. Elliott, Friese Greene, William Grove, F. W. Hindley, Bulmer Howell, Payne Jennings, H. S. Mendelssohn, J. Lillie Mitchell, L. Warnerke, Waterlow and Sons (Limited), Thomas P. Watson, and S. G. Buchanan Wollaston.

Mr. W. S. Bird states that the members of the committee have no interest in the coming photographic exhibition other than the general welfare of the trade and profession.

The executive committee of the exhibition consists of Messrs. W. S. Bird, *Chairman* (the Autotype Company), T. Watson (W. Watson and Sons), Payne Jennings, Frank Bishop (Messrs. Marion and Co.), and Conrad Beck (R. and J. Beck), and they state that the Photographic Section of the London Chamber of Commerce has received, through the medium of the Chamber, an offer from the Drapers' Company of the use of their Hall in Throgmorton Avenue for the purpose of an exhibition. They add that a photographic exhibition held in the centre of the City under such auspices cannot but be advantageous to the trade. The Banqueting Hall, a palatial apartment, will be reserved exclusively for apparatus, permitting a larger display than has yet been seen in London, while the Drawing Room, Square Room, Court Room, and the Corridor will be devoted to photographs by all processes. A soirée will be held on Friday evening, 30th May, at which the committee state that the presence of the Lord Mayor and many city and parliamentary dignitaries is expected. The exhibition will open on Saturday, May 31st, and close on the 10th of June; hours, 10 to 6; admission free. The Section will have to provide a large number of single and double screens, covered in cloth, giving some 2,000 ft. of space, and so arranged as not to impair the splendour of the apartments. The cost of picture hanging, soirée, advertising, paid assistants, and so on, it is calculated will be covered by a charge to exhibitors of two shillings per square foot, the minimum charge for any exhibit being ten shillings. It is anticipated, however, that the expense may be covered by about one shilling and sixpence per foot, and, if so, a due proportion of the fee paid will be returned to the exhibitor. Should the expenses exceed two shillings per foot, the excess will be met by a guarantee fund already subscribed by members of the Section.

Provision will be made, if possible, to accommodate show cases for apparatus. Sketch and measurements should be promptly forwarded. Applications for space, and for detailed particulars, should be made to Mr. E. Cocking, Photographic Section, London Chamber of Commerce. Mr. Cocking has been appointed secretary, and, by the courtesy of the Chamber, accommodated with office facilities at Botolph House. There will be no medals or awards; the display is not competitive, but to illustrate the best work—optical, mechanical, and artistic—of the photographic trade. There will be no catalogue. Exhibitors will be supplied with two sizes of cards to fill in title or brief description, with name and address, so that visitors can at a glance see the desired particulars. Exhibitors contracting for fifty feet of screen can direct the hanging, and have their names and addresses at the foot of the screen. As far as possible the works of each exhibitor will be kept together. Invitations to the soirée will be sent to each exhibitor and friends.

Mr. Frank Bishop wishes photographers who have not already done so to make their applications for space before all is allotted, and informs us that Messrs. Waterlow have prepared a fine invitation card, five thousand of which will be issued by the Chamber of Commerce to the leading merchants and traders of the city of London, for the opening soirée on the 30th inst.

A MEETING OF OPTICIANS ABOUT LENS MOUNTS.

Last Friday the adjourned meeting of opticians and of some members of the Photographic Convention Committee was held at the Mona Hotel, Covent Garden, London, with Mr. A. Haddon in the chair. Those present were Mr. T. R. Dallmeyer, Mr. William Beck, Mr. Conrad Beck, Mr. W. Taylor, Mr. H. R. Fairbanks, Mr. Rees Curtis, Mr. M. J. Swift, Mr. Hobson, Mr. Turnbull (Wray & Sons), Mr. T. E. Freshwater, Mr. F. A. Bridge, and Mr. J. J. Briginshaw.

The opticians decided unanimously as to the most suitable size of flange and character of threads for lenses of the smallest sizes; a second sized larger flange was then recommended for adoption by a majority, and certain dimensions for standard camera screws were unanimously recommended. What the various dimensions are we are not at liberty to state, because the meeting thought that publication now would be anticipating the report of the Committee. Mr. Dallmeyer stated at the meeting that Mr. Walker, of the Eastman Co., thought that America would adopt the flanges recommended by the Convention, and that he would recommend American firms to do so.

The meeting was adjourned for the consideration of suitable dimensions for flanges of larger size.

THE PHOTOGRAPHY OF THE MORE REFRANGIBLE RAYS.*

BY V. SCHUMANN.

Spectroscopy is fortunately not exclusively dependent upon the employment of glass. Much better service is rendered by a section of quartz. Since the year 1852, in which Stokes discovered the remarkable transparency of this mineral, it has been much more used for spectroscopic researches. Its transparency for the ultra violet rays is indeed astonishing. A few seconds' exposure suffices to take a photograph containing perhaps four times as much as would be obtained with a glass having a similar dispersive power. When the limit of action of such a photograph is ascertained, it is found to be about at the wave-length 2,195; that is, as indicated by the cadmium spectrum, in the neighbourhood of the line No. 25. We have not then, however, reached the limits of the action of light. All the rays which lie on the other side of line 25 work sensibly slower. This is the case with the cadmium line 26, still more for the zinc lines 27, 28, and 29, and to a yet further degree with the 8 further lines of the same element, which required a protracted exposure in order to obtain them.

* Continued from page 361.

If the lenses of the spectrographic apparatus have a long focus (from ¾ to 1 metre) then there does not appear to be a trace of light existing beyond the zinc line No. 29. Unless extraordinary precautions are taken, one may give exposures even of several hours' duration without obtaining any result. When, however, the absorption by the air is taken into account and dealt with, then, with the aid of the aluminium spark, we may succeed in obtaining a range of lines more refrangible than the zinc line No. 29. Of the lines thus obtained, five in number, indications are obtained in the region of No. 30, 31, and 32. In my experience this is the most refrangible ray that had as yet been photographed.

The photography of these lines offers extraordinary difficulties. For years I laboured in vain to obtain the action of them upon my plates, and only in the spring of 1889 were my efforts crowned with any success. I had then at last before me in the photograph the long tried-for lines, but so weak in parts, and of so little intensity, that to insure their visibility required special care. The portion of the spectrum in which they appeared showed with diffused light no trace whatever of a line.

Are the aluminium lines above mentioned the only ones that exist on the other side of the wave length 2024 (zinc line No. 29), or is that region richer than researches up to that time had been able to prove? This question exercised me considerably, since I had made the last five lines of aluminium obedient to the rule of photography. I found myself led, by particular circumstances, to take up again my researches in this direction. A newly fitted up spectrographic apparatus, furnished with all the appliances that my experience of over ten years with the quartz apparatus could suggest—I will return to the arrangement of this instrument later on—yielded me at last, although after many disappointments, an unexpectedly happy result.

Whilst feeling my way photographically step by step along the limited region referred to, I came at last upon a new line. This showed between the pair of lines Al No. 32. Soon after I found a second, and later on a third and a fourth line emerge, and finally these were followed by a widely extended group of lines going far beyond Al No. 32, which, to the eye, appeared to contain considerably over 100 lines. Unfortunately this last-named group is extraordinarily feeble in its action. To photograph it requires an exposure of several hours' duration. Moreover, they only showed with clearness where I had suppressed, as much as possible, all diffused light in the interior of the apparatus. Whether these lines belong to aluminium itself I am not able at present to decide. Since they are so far removed in activity from the other lines, it may be supposed that these are due rather to the air than the electrodes. For me, however, this question came less into consideration. It sufficed me provisionally to ascertain that my source of light gave an almost continous spectrum extending far beyond Al No. 32, and not ceasing till the wave length 1820. Hereby, then, proof was obtained that there are rays which are much more refrangible than Al No. 32.

The unlooked-for happy success with aluminium induced me to carry on researches on the more refrangible rays with a number of other elements. I have now made experiments with many photographs of the spectra of silver, arsenic, gold, bismuth, calcium, cadmium, cobalt, chromium, copper, iron, potassium, magnesium, molybdium, sodium, nitrogen, lead, palladium, platinum, antimony, silicon, tin, tellurium, and tungsten. The wealth of lines of most of these spectra has far exceeded my expectations; at the same time, amongst the new lines are many which possess great power of light, and not a few which are of decidedly shorter wave length than that of Al No. 32. To the more powerful in light of these last-named spectra belong those of bismuth, calcium, and tellurium. The number of lines in many photographs is extraordinarily large. Tungsten, for instance, has sixty, and iron not less. Approaching this are the spectra of platinum, palladium, molybdium, and copper. Some elements give very sharply defined lines. In this particular tellurium stands forth prominently with a very characteristic group of lines close to Al No. 32. Some other photographic spectra, on account of the cloudy character of their lines, leave, for the present, much to be desired. Spectra of this kind require the utmost care if they are not to remain as quite useless for the purpose of obtaining measurements.

Although my photographs show a large number of lines beyond Al No. 32, yet I have never succeeded in obtaining any action beyond the wave length 1820.

It is known that even quartz keeps back a portion of the ultra-violet rays, and according to the paper by Soret on this subject, the most highly refrangible rays are particularly affected. Whether they are completely absorbed, or only in part, is a question which can only be decided by a medium which surpasses quartz in freedom of transmission. Such a medium we possess in fluorite. With the help of a prism and two lenses of fluorite, photographs might be obtained which, on account of the absorption of the quartz apparatus, were not with it practicable.

Patent Intelligence.

Specifications Published.

1,098. *January 21st*, 1890.—"Photographic Apparatus." Communicated from abroad by EMIL KIPPER, 361, Broadway, President of a Company, and ENOCH WOOD PERRY, junr. of 24, Easth 14th Street, Artist, both in the City and State of New York. HENRY HARRIS LAKE, of the firm of Hazeltine, Lake, and Co., Patent Agents, Southampton Buildiugs, London.

This invention relates to that type of photographic apparatus wherein a series of superimposed sensitised plates is successively exposed, and transferred from the camera-box or plate-holder into a suitable receiving chamber or box through the medium of externally operated mechanism.

The objects of this invention are to improve the construction and operation of such apparatus; to provide new and improved means for transferring the exposed plates or films into the plate-receiving chamber; to provide a novel and efficient envelope or carrier for each sensitised plate which will cut off or interrupt the transmission of the chemical or actinic rays of light to the plate or plates in rear thereof; and finally, to generally improve photographic apparatus of the type referred to.

The inventors make twenty-two claims, and their specification is accompanied by drawings.

19,896. *Dec. 10th*, 1889.—"Apparatus for the Manufacture of Photographic Films." A communication from GEORGE EASTMAN, of Rochester, in the County of Monroe, and State of New York, United States of America. ALFRED JULIUS BOULT, 323, High Holborn, London, M.I.M.E.

This invention relates to the production of flexible photographic films from a fluid solution of nitro-cellulose and camphor, and in apparatus therefor; the said apparatus being also capable of use in forming thin, uniform coatings or layers of other materials; and the said invention consists in the novel construction, arrangement, and combination of parts.

The principal elements of the complete machine, apart from the frame work, are a bed-plate having a rigid and substantially level, smooth, and perhaps polished surface; a spreading mechanism adapted and arranged to be moved longitudinally over the bed-plate, and deposit and spread a thin, uniform layer of the fluid coating material; a removable casing for enclosing the surface of the bed-plate, with exhaust apparatus for drawing off and collecting the volatile solvents, and stripping and reeling devices capable of being moved over the bed-plate, for removing therefrom and winding up the dried film or films.

The bed-plate, through preferably constructed of sheets of plate glass, may be constructed of other suitable material having either a polished or dead surface, and is properly supported and levelled, the abutting ends or edges of contiguous sections being accurately fitted to form close joints. The interstices, if any, are filled in level with the surface of the glass by the introduction of a suitable material or composition, such as cement, plaster-of-paris, wax, readily fusible metal, &c., with a view to removing all crevices and depressions into which the fluid solution might enter and thus produce ridges or other irregularities on the surface and in the thickness of the film.

The inventor claims:—

1. In a machine, such as is described, the combination of a bed-plate having a substantially flat surface and a travelling coating apparatus mounted and reciprocating upon guides parallel with the surface of the bed-plate.

2. In a machine, such as described, the combination with the depositing and spreading apparatus mounted upon guides, of a sectional bed-plate composed of sheets of glass, with the interstices between the abutting edges filled with plaster-of-paris or equivalent material level with the surface of the sheets, to form a bed-plate having a continuous surface.

3. In a machine, such as described, the combination to form the bed-plate for the reception of the film, of the frame, the vertically adjustable cross bars, sheets of glass resting upon said beds, and a filling of plastic material between the edges of adjacent sheets to form a continuation of the surface thereof.

4. In a machine, such as described, the combination with the bed-plate of a travelling coating device, provided with a receptacle for the fluid, having a discharge orifice, and a spreading blade supported in rear of said discharge orifice, and extending transversely across, and parallel with, the surface of the bed-plate.

5. In a machine, such as described, the combination of the bed-plate, a travelling hopper, or receptacle for the fluid, having a discharge orifice and spreader, and guides travelling with the hopper, and engaging the surface of the bed-plate to prevent the fluid from spreading laterally.

6. In a machine, such as described, the combination with the bed-plate, of the travelling hopper supported on guides engaging the surface of the bed-plate, said hopper having a discharge orifice, and a spreader in rear thereof.

7. In a machine, such as described, the combination with the bed-plate, and travelling carriage supported upon guides parallel with the bed-plate, of a depositing and spreading device mounted and guided upon the surface of the bed-plate, and connected to the carriage.

8. In a machine, such as described, the combination with the bed-plate, the carriage supported upon guides, and traversing longitudinally of the bed-plate and mechanism for actuating said carriage, of a coating device connected to said carriage, mounted directly upon the surface of the bed-plate; and provided with a receptacle for the reception and discharge of the fluid upon the bed-plate and a spreader blade.

9. In a machine, such as described, the combination with the stationary bed-plate and movable carriage, of the hopper detachably secure to said carriage, and provided with guides engaging the face of the bed-plate, said hopper being provided with a regulated discharge and a spreading blade.

10. In a machine, such as described, the combination with the surface upon which the film is formed, and a receptacle for containing and discharging the solution upon said surface of a flexible spreading blade, and a series of guages interposed between said blade and the surface designed to receive the solution for automatically adjusting the edge of said blade.

11. In a machine, such as described, wherein the fluid is deposited and spread upon a retaining surface, and in combination with the devices for depositing such fluid, and the surface upon which it is deposited, an automatically adjusting spreading blade, the same consisting of a series of independent sections supported upon gauges interposed between the blade sections and the surface upon which the solution is deposited, substantially as described.

12. In combination with the sectional spreader blade, and independent pressure devices applied to the sections thereof, the gauges interposed between the ends of the adjacent blade sections and the surface upon which the film is formed or spread by the blade.

13. In a machine, such as described, and in combination with the bed-plate and a hopper movable longitudinally of, and parallel with, the surface of the bed-plate, and provided with a discharge orifice for the fluid, a sectional spreader blade, supported in rear of the hopper, each blade section being provided with an independent pressure, device, and gauges engaging the surface of the bed-plate.

14. In a machine, such as described, and in combination with the sectional spreader blade supported in rear of the hopper, a pressure spring applied to each blade-section to force it towards the bed-plate, and two gauges interposed between each blade-section and the bed-plate to adjust and sustain said blade-sections with their edges removed from, and substantially parallel with, the surface of the bed-plate.

15. In a machine, such as described, the combination with the bed-plate and sectional blade co-operating therewith to form a film, or layer of the fluid; a series of gauges or supports for the blade-sections resting in contact with the surface of the bed-plate, and provided with converging or bevelled sides.

16. In a machine, such as described, and in combination with the sectional spreader blades, a series of trailing strips pivotally supported at one end, and extending beneath the blade sections, and resting in contact with the surface of the bed-plate, or supporting surface for the film.

17. In a machine, such as described, the combination with the sectional spreader blade and supports, engaging the bed-plate to hold said blade-sections removed from the latter, the bow springs engaging said blade-sections to press them towards the bed-plate.

18. In a machine, such as described, and in combination with a blade-section, a bow spring attached to a bracket at or near its centre, with its ends engaging the blade-section.

19. In a machine, such as described, the combination with the rear and end walls of the hopper, of the pivotted front wall and adjusting devices, such as cams, operating to adjust the discharged orifice.

20. In a machine, such as described, the combination of the bed-plate, the carriage travelling on guides parallel with the bed-plate, the chains or belts on opposite sides of the bed-plate driven in unison and provided with devices engaging the carriage.

21. In a machine, such as described, the combination of the bed-plate, the travelling carriage, the hopper attached to the carriage, and provided with a regulated discharge orifice, and the sectional spreader blade mounted in rear of the hopper, and provided with pressure devices and gauges for sustaining the edge of the blade substantially parallel with the surface of the bed-plate.

22. In a machine, such as described, the combination with the bed-plate, upon the surface of which the film is formed, of a removable casing for covering the film while drying, and an exhaust apparatus in communication with the interior of said casing.

23. In a machine, such as described, the combination with the frame, bed-plate, and the trunk or conduit communicating with an exhaust apparatus or device, of the removable casing provided with an inlet orifice at one end of the plate, and an outlet at the other end opening into the exhaust conduit.

24. In a machine, such as described, and in combination with the bed or plate upon which the film is formed and to which it adheres, a carriage traversing said bed and provided

with one or more cutters for dividing the film into strips while attached to the bed.

25. In a machine, such as described, the combination with the supporting surface to which the film adheres, of a traversing winding reel.

26. In a machine, such as described, the combination of a supporting surface on which the film is formed, a carriage mounted on guides, and traversing longitudinally of said supporting surface, and two or more winding reels mounted upon said carriage in different planes.

27. In a machine, such as described, the combination with the supporting surface, or bed-plate, upon which the film is formed, a travelling carriage, and rollers mounted upon said carriage in different planes, to support the strips, and draw adjacent strips at different angles from the surface.

28. In a machine, such as described, the combination of the bed-plate, the traversing carriage, and two series of winding rollers or reels mounted upon separate shafts on said carriage.

29. In a machine, such as described, the combination of the bed-plate, the traversing carriage, and two shafts mounted upon said carriage and geared together, each of said shafts being provided with a winding roll or reel.

30. In a machine, such as described, the combination with the bed-plate, or surface upon which the film is formed, and separated into strips while adhering thereto, of a travelling carriage, winding rolls or reels, and driving mechanism therefor, mounted upon said carriage, and yielding tension devices, such as springs, intermediate the reels and their driving mechanism.

31. The general combination and arrangement of parts constituting the complete film-spreading device, substantially as described and illustrated.

32. The general combination and arrangement of parts constituting the complete film detaching and winding device, substantially as described and illustrated.

33. The general combination and arrangement of parts constituting the complete machine, substantially as described and illustrated in the drawings accompanying the specification.

7,667. *May 8th*, 1889.—"Obtaining Aluminium or its Alloys." Godfrey Bamberg, 7, Holly Village, Highgate, Gentleman.

My invention relates to the production of aluminium from its chloride, or from the double chloride of aluminium and sodium, by means of zinc. It has heretofore been proposed to bring these bodies together in the solid or liquid form under heating whereby zinc chloride is formed and aluminium set free. Difficulties arise, however, in this process which have prevented its practical adoption. According to my present invention I avoid such difficulties by volatising the zinc in the first instance, and then bringing the zinc vapour together with the vapour of aluminium chloride or of the double chloride of aluminium and sodium at the temperature of a white heat under the exclusion of air, whereby the chemical affinity of the zinc for the chlorine of the chlorides is increased, and both the zinc and the chloride or chlorides are brought into intimate contact in the finest possible state of subdivision, so that a most effective reaction of the particles is established, resulting in the ready production of chloride of zinc, and the setting free of the aluminium, which condenses to metallic form.

I prefer in this process to employ an excess of zinc over and above that required for effecting the said decomposition, so that the liberated aluminium in condensing shall at once mix with the excess of zinc.

The proportions of the materials required for the above described reaction are, theoretically, 195 parts by weight of zinc to 213 parts of chloride of aluminium, but as above stated, I prefer to use an excess of zinc.

The proportion of zinc which combines mechanically with the aluminium is afterwards separated therefrom by subjecting the alloy to a temperature above a clear red heat, or about 1,040° Cent., when the zinc will distil off, while the aluminium, not being volatile at that temperature, is left behind.

The zinc vapour given off can either be directly used again in the process, or it can be condensed into the metallic form.

The zinc chloride can be converted into zinc oxide by the addition of caustic soda, and the zinc oxide can be reduced to zinc by mixing it with fine carbon in any suitable manner and raising it to white heat in the usual way of smelting zinc, and this zinc can be used over again. It will probably be advantageous to use the same zinc over again, as it will contain less impurities than the original zinc, namely, iron, arsenic, silicon, &c.

In practically carrying out my said invention I proceed as follows:—

A suitable retort is nearly filled with zinc previously melted, and of as pure a quality as practicable, and another retort is partially filled with the chloride of aluminium, or the double chloride, or materials such as would produce the vapours of the chloride upon being raised above clear red heat (1,040° C.). These retorts are connected with a third retort, or suitable mixing chamber, by pipes or channels preferably covered with a suitable non-conducting material, so that no sublimation of the chloride, or condensation of the zinc, should take place in them. The mixing chamber is maintained, under exclusion of air, as nearly as possible at a white heat towards that part thereof where the pipes from the retorts enter, while the further end should be at a lower temperature so as to allow the particles of aluminium and zinc to run together therein in the form of a liquid to be drawn off to cool. The zinc chloride will escape at the furthest least heated end as a vapour, and it can then be condensed to a liquid state by means of any of the usual cooling apparatus. The mixed zinc and aluminium is distilled, the zinc going off as a vapour which may be injected directly into the above mixing chamber again, to economise fuel, or it can be cooled down to solid form; the less volatile aluminium remaining behind in fluid metallic form, is run off and solidified.

What I claim is:—

The process for the production of aluminium, or an alloy of aluminium and zinc, from aluminium chloride, or double chloride, wherein metallic zinc and the chloride of aluminium, or double chloride of aluminium and sodium, are respectively heated in separate vessels or chambers to the point of volatilisation, the resulting vapours of zinc and of aluminium chloride, or double chloride, being then brought together in a third highly heated vessel, under exclusion of air, whereby zincic chloride and metallic aluminium will be produced, substantially as herein described.

The Royal Society.—The Royal Society was instituted in December, 1660, and is the oldest society of the kind in the world with the exception of one at Rome. From the period of the Restoration to the reign of Queen Anne, the Royal Society stood alone in this country, in which it has always been the chief scientific organization. Among its former presidents was Sir Isaac Newton, who occupied the chair from 1703 until his death in 1727. Many objects of interest, which once belonged to Newton, were on view in a glass case at the conversazione last Wednesday. Among those present at the conversazione were—Dr. John Evans (treasurer of the Royal Society), Dr. Michael Foster and Lord Rayleigh (secretaries), and Dr. A. Geikie (foreign secretary), the Archbishop of Canterbury, Sir Joseph Hooker, Sir Charles Nicholson, the Swiss Consul-General, Lord Ashbourne, Sir Patrick Colquhoun, the Earl of Rosse, Lord Sudeley, Sir Henry Roscoe, Mr. Justice Wills, Lord Arthur Russell, Sir Edward Reed, Sir D. Salomons, Lord Alfred Churchill, Lord Justice Fry, the Earl of Crawford, the Earl of Mount-Edgcumbe, Sir William Thomson, General Brackenbury, General Strachey, Sir Alfred Lyall, Sir D. Galton, Sir Lowthian Bell, Sir F. Abel, Mr. Wemyss Reid, Mr. A. J. Balfour, Sir Charles Wilson, the Astronomer-Royal, the Master of St. John's, Cambridge, Admiral Sir John Hay, the Bishop of Lichfield, Earl Stanhope, Sir Trevor Lawrence, the Austrian Consul-General, Sir Frederick Pollock, the Bishop of St. Asaph, Sir Frederic Leighton, the Provost of Oriel, the Master of Christ's, and Sir F. Bramwell. The members and visitors were received by the President of the Royal Society, Sir G. G. Stokes, Bart., more familiarly publicly known under the time-honoured name of Professor Stokes, whose discoveries in relation to fluorescence are so well known among photographers.

Correspondence.

DEVELOPMENT IN TWO SOLUTIONS.

Sir,—In reply to the letter of your correspondent "X." which appears in the last number but one of the News, I regret that there should be any difficulty in understanding the paragraph in my article in the Year-Book to which he refers. The words in italics which I now insert may perhaps help to express my meaning more clearly. "The second developer or intensifier need only consist of a similar solution *(to the first)*, with the full dose of pyro *(and alkali in proportion)*, and the addition of a soluble bromide." The quantity of pyro would be the same as recommended for the ammonia formula—viz., 8 grains to the ounce of developer, not 16 grains (as "X." puts it), which is the quantity contained in the No. 1 solution, the latter being mixed for use with an equal bulk of No. 2, which contains no pyro. The amount of bromide necessary would vary according to the alkali used; soda requires less than potash, while some samples of the latter require more than others. In either case, very much less bromide is needed than with ammonia; probably 3 to 4 grains potassium bromide to the ounce of developer will give all the restraining power necessary.

With regard to "Beach's developer," I confess I do not understand the formula as given by your correspondent, nor do I see how it can be utilized as it stands, inasmuch as the various ingredients are not soluble in anything like the proportions given; also the method recommended for using the compound is diametrically opposed to the principle I have advocated of obtaining detail first and density afterwards.

B. J. Edwards.

The Grove, Hackney, London, N.E.

PHOTOGRAPHIC EXHIBITIONS.

Sir,—It is interesting to find by your extract from the *Journal of the Photographic Society of India* that the subject of reform in the conduct of photographic exhibitions has travelled as far as Calcutta, and that our Indian brothers are already beginning to discuss the question whether present regulations are the best possible. In the course of his remarks the writer tells us that in the late Calcutta Exhibition, out of nineteen professionals exhibiting, only five were undecorated by the judges. This clearly shows that the medal craze is as bad abroad as at home. The question arises, is it possible or desirable, now that the use of medals has been so degraded, that they should be abolished altogether? If it were possible in art to decide what is absolutely good, better, or best, and any definite standard of excellence could be fixed, then some reasonable arrangements might be made for awarding to the best photographs in the show some honourable distinction. But it is quite impossible. There *is* no absolute standard of excellence in art. The best to one school—a very masterpiece—to another school may be an abomination, and so everything depends on the judges, generally honest, but seldom competent to appreciate the subtle beauties of a truly artistic production. They are thus often overpowered by the aggressiveness of size, subject, or quantity, and frequently pass over the finest work from its refined unobtrusiveness.

The exhibition promoters appear afraid to abolish medals, fearing that so doing would take away all inducement to exhibit. Well, perhaps it would act in this way to a great extent if nothing were put in their place, but it seems to me there is a satisfactory way out of the difficulty. First let me ask, why do photographers exhibit? For fame, for advertising, or to sell their exhibits, or for a combination of all these, and the *raison d'être* of an exhibition we may assume to be educational, or to demonstrate the best possibilities of the art. Now if societies holding exhibitions would start on a scale according to their means, a sort of Social Photographic National Galleries, a collection of the best work sent to their shows, they would meet the best interests of all concerned, and attain the objects of exhibitors and promoters alike, beside performing valuable historical work, preserving many beautiful productions which would otherwise in all probability drop away in a short time into obscurity. Ralph W. Robinson.

Proceedings of Societies.

Photographic Society of Great Britain.

The ordinary meeting of this Society was held on Tuesday last, the 13th inst., the President, Mr. James Glaisher, F.R.S., in the chair.

A paper by Mr. T. R. Dallmeyer on "Reflected Images in Optical Combinations, and their Effect on the Brilliancy of the Image," was read, accompanied by diagrams on the black board. In the course of the paper Mr. Dallmeyer referred to the first demonstration on the subject by his father, which had been made in conjunction with Sir John Herschel, and given to the Society in the year 1867. The subject of the flare spot was then particularly gone into, but there were other considerations which might advantageously be dealt with. Flare spot was due to the formation of the diaphragm, and could in most lenses be modified or dispersed by changing the position of the diaphragm. For the causes of want of brilliancy now to be discussed the following deductions would apply. 1. The fewer the number of reflecting surfaces, the greater the brillancy of the image. 2. The fewer of these surfaces that were concave to the plate, the greater was the brilliancy of the image. 3. The fewer of these surfaces that were behind the diaphragm, the greater the brilliancy. Flare spots and what were called ghosts had been dealt with, but a point which he believed had not been previously treated was the reflection of light by the plate itself on to the lens, and the consequent reflection back from the lens on to the plate of some of this light. A camera was shown on which, in place of lens, was a front pierced with a pattern of holes at one corner. The back of the camera was fitted in the place of the plate with a concave reflector having the same focus as the distance from the front, and images of the holes were then seen to be thrown on to the corner of the inside of the camera front opposite to that at which the holes existed. Included in the drawings on the black board were representations of the following lenses—a rapid rectilinear, a Petzval portrait lens, a Dallmeyer portrait lens, and a Dallmeyer single rapid rectilinear lens. The latter was introduced particularly because there had been a controversy between Mr. W. K. Burton, of Japan, and himself about it in the pages of the Photographic News. Mr. Burton had, however, since then, in a communication to a photographic newspaper, admitted him (Mr. Dallmeyer) to be in the right. When with this lens it was desired to obtain particularly brilliancy, and other considerations were of less importance, it would be better to use the stop behind the lens.

Capt. Abney congratulated Mr. Dallmeyer upon bringing forward a new phase of the question. One cause of want of brilliancy that had not been touched on was the fact that glass was not perfectly transparent, but acted as a source of light to the extent, indeed, of 4 per cent.

Mr. W. England thought that more care ought to be taken to shield the front of the camera from light. In his practice he never went out to photograph without a hood attached to the camera, and he thought camera makers generally ought to furnish their cameras with such an appliance.

Mr. L. Warnerke was of Mr. England's opinion, that hoods should be furnished with cameras.

Mr. V. Blanchard thought that the credit of using a hood to shade the lens was due to Mr. England, and that he had suggested it to the late Mr. J. H. Dallmeyer.

Mr. W. E. Debenham remembered seeing and using a sliding box hood, called a front camera, as long ago as 1857. It could be drawn forward so as to exclude light from the lens, except that coming from the picture to be represented. Such an arrangement was far more effective than a small hood attached to the lens itself.

Mr. T. Samuels had noticed, when photographing with Johnson's pantascopic camera many years since, that the image was more brilliant than that which he could obtain in other cameras, and found that this brilliancy was due to the fact that the camera was supplied with a front or hood to keep stray light from the lens.

Dr. G. Lindsay Johnson thought a shade for the lens very

important. He used simply a tube which just fitted freely enough on to the lens jacket to enable it to be drawn forward, as much as might be desired, for the purpose of shading the lens. He did not see the advantage over this plan of having a large hood. He would like to be informed whether the superior brilliancy noticed in photographs taken with a single lens was not due to the fact that the tube of such a lens acted itself as a hood.

Captain ABNEY could not see the advantage or difference in principle of a large hood attached to the camera over a small one attached to the lens. In illustration of his remarks, he drew a diagram upon the black board showing the sun and a lens, and, drawing a line from the one to the other, said that it did not matter where the hood was placed so long as it cut that line.

Mr. DEBENHAM thought that Captain Abney would admit that the last proposition would be correct only in the case of a lens of infinitely small magnitude, or of a pinhole photographic apparatus. Where the hood was small and close to the lens, if the bottom of the lens were to be shielded from the sun, the hood might have to be drawn down so low that the upper part of the picture which it was desired to include would only fall upon the lower portion of the lens, and so either act only with a reduced amount of light, or be altogether cut off, if, as is the case with doublets, the stop is behind the front lens.

Mr. DALLMEYER said that he agreed with Captain Abney that it did not matter where the hood was placed, and disagreed with Mr. Debenham in the matter. An optician was required to place a hood where light from any required angle, say, from where the sun was, should not pass through the diaphragm of the lens. He drew on the black board a cone extending from the front of a doublet lens, and represented a hood first, close to the lens, and then at some distance from it, and said that it was of no importance at what part of that cone the hood was placed. With regard to the desirability of allowing some reflection, he added that it gave what was called the effect of atmosphere, but whatever there might be in its favour from an artistic point of view, from a scientific point of view any loss of brilliancy should be avoided.

Mr. WARNERKE showed some strips of gelatine film such as is used for emulsion. These strips had darkened at the edges, and he thought this circumstance might help to explain the fogging of the edges of gelatine emulsion plates which was so often found to occur when they were kept for any length of time.

Dr. LINDSAY JOHNSON showed a photograph which he characterised in no very flattering terms, but which was an object of curiosity as having been taken by an automatic photographic apparatus, of which the members had doubtless heard. It was of the ferrotype kind, and measured about two inches in length.

Mr. DEBENHAM said that according to the prospectus of the company formed to introduce this machine, the chemicals used were cheaper than those at present employed in photography, and as it was proposed as part of the business to supply such chemicals to photographers, they might be led to hope for some reduction of expense from this cause. On the other hand, as it was stated the chemicals and materials for the photograph had been contracted for at the rate of a half-penny each, and as the cost of either collodion and bath, or of gelatine emulsion, for such a plate, would probably not exceed the twentieth of a penny, there might be some mistake as to the cheapness of the chemicals. The cost of ferrotype plate itself he did not know, but did not suppose that it could amount to the difference.

Mr. J. W. BEAUFORT was elected a member.

THE CAMERA CLUB.

ON Thursday, May 8th, a special lantern slide exhibition took place at the Camera Club, and photographs taken during recent tours in Egypt were shown by Messrs. Rodgers, A. Collins, and Major Nott.

Amongst the transparencies were some of excellent quality, and the collection contained a variety of interesting illustrations of present life and manners in Egypt, with original views of the pyramids and other remains and public buildings. Mr. Elder exhibited a number of photographs recently taken in Madeira and Teneriffe ; Mr. Andreae some interesting views of volcanoes in action and other subjects ; Mr. Ferrero some landscapes taken on club excursions ; and Mr. Crookes some charming pictures of Ighthan Moat-house. Other slides by Messrs. Fitz Payne, Carnell, and Sands were exhibited.

On Thursday, May 22nd, Mr. Shipton will read a paper on "Cyclo-Photography—some recent developments, including an ideal bicycle."

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

THE usual weekly meeting was held on Thursday, May 8th, Mr. J. S. TEAPE in the chair.

The HON. SEC. announced, as a result of the committee meeting held last week, that it had been arranged to have an outing once a month on the second Saturday in the month ; also that papers and demonstrations had been promised by Messrs. J. Traill Taylor, W. E. Debenham, and A. Haddon.

Messrs. H. M. Smith, A. Haddon, and T. E. Freshwater were elected delegates to represent the Association at the forthcoming meeting of the Photographic Convention at Chester.

Mr. H. M. HASTINGS passed round some prints on the new Parisian paper, prepared with chloride of iridium. He said it printed in about half the time of silver, toned very quickly, but lost considerably in the fixing. The general opinion was that, judging by the directions enclosed with the paper, and the results shown, the proportion of iridium used was exceedingly small, and that the process bore a strong family likeness to silver prints on plain paper.

Mr. HASTINGS also exhibited a series of twelve quarter-plate negatives developed with various developers—from eikonogen to pyro and ammonia. They had all received the same exposure, and were all developed for seven minutes. He considered the best result obtained with the No. 1. eikonogen developer, as prepared in the directions issued by Messrs. Marion and Co.

A circular letter was read from the Photographic Convention of the United Kingdom, asking that delegates might be sent from the Association to the Chester meeting.

Mr. P. EVERETT moved that "the circular be placed under the table, and that delegates be not sent ;" there was no seconder, and Mr. Everett withdrew the motion.

THE HACKNEY PHOTOGRAPHIC SOCIETY.

THIS Society held its annual meeting, on May 8th, at Morley Hall, under the presidency of Dr. ROLAND SMITH.

The Society has just terminated the first year of its existence, and has a roll of nearly 100 members, included in which are several well-known amateurs, prize takers at various exhibitions.

The following were elected officers for ensuing twelve months :—*President*, Dr. Gerard Smith ; *Vice-Presidents*, Dr. Ambrose Kibbler, Dr. Rolaud Smith, and Mr. J. Hubert ; *Treasurer*, Frank Jolly ; *Curator*, A. Dean ; *Secretary*, Mr. Fenton Jones, 12, King Edward's Road, N.E. ; *Council*, Messrs. H. Burton, W. L. Barker, H. J. Beasley, J. O. Grant, F. Houghton, Dr White.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

May 8th.—Alderman J. B. STONE, J.P., in the chair. Eight new members were elected.

The curator of the Municipal Art Gallery (Mr. Whitworth Wallis) sent a communication acknowledging the receipt of the National Challenge Cup (won by the Birmingham Society at the Crystal Palace Exhibition in March last), and asking for examples of the pictures which won the cup to be exhibited with it in the Art Gallery.

At the close of the ordinary business Mr. STONE announced that the present meeting had been called specially to discuss the proposed photographic survey of Warwickshire. In the course of his remarks, he said :—"There are two distinct ways in which you can deal with the matter ; one is by taking it in hand yourselves and deciding to work out the whole problem, taking credit for the result of your labours, keeping the con-

trol of the whole undertaking, and carrying it out within your own limits. If you take this view it will be your duty to set about a scheme within your own means and within your own numbers. If you take a good lead, you will be followed by others, and if you take a narrow view, and you permit jealousies to exist amongst yourselves, or in respect to other people, you will damage the whole thing. If you can decide upon broader lines, which I recommend, you will at once offer to the whole world a good idea, and appeal to the co-operation of every one interested in it to contribute towards its success. For this you must go outside your own Society. It appears to me if you do (and I hope you will) you will obtain considerable support—pecuniary and otherwise—from the county generally. You must present to the public a broader scheme, that will invite confidence and that will attract support. You cannot propose any kind of council or committee limited to yourselves; you must begin by proposing a representative council for the photographic survey, and must state frankly that you are prepared to send representative members and render every assistance. There would be, of course, elected representatives from other districts and other societies, and I suggest, also, co-optative members useful to you in many ways, and men sufficiently known to ensure the confidence of the city of Birmingham and the county generally. Then, depend upon it, your prospect will succeed, and you may almost believe that your scheme is an accomplished fact."

Mr. Jerome Harrison, F.G.S. (Vice-President) said that their President advocated the establishment of a County Council or Committee, by which the photographic survey of Warwickshire should be directed; and, considering that there were several photographic, as well as many scientific, artistic, and literary societies in the county, he agreed that such a guiding body was desirable. Such a council should consist of representatives of all the societies willing to promote the work of the photographic survey. But he (Mr. Harrison) did not think it was necessary that their own Birmingham Society should sink their own identity with the task which they had resolved to undertake. The Council of the Birmingham Photographic Society had been carefully considering the question, and they had unanimously passed the following resolution:—"That it is desirable to form a photographic survey section of the Birmingham Photographic Society, with separate officers and separate subscription, to commence and carry out a photographic survey of Warwickshire." He trusted that the meeting would endorse that resolution. The section could then invite the co-operation of other workers in the county and form the "County Council" to which Mr. Stone had alluded, by which the work done by each Society should be pointed out. As there would necessarily be certain expenses incurred, it would be needful to charge a small extra subscription to the section. He hoped they would also invite gentlemen to join the survey section who, although not photographers, felt an interest in the work; and for them the subscription should be somewhat higher. Such persons could thus join the survey and assist in its work without becoming members of the Photographic Society.

The resolution was carried unanimously.

It was then resolved, "That the subscription to the Photographic Survey Section shall be half-a-crown per annum for members of the Birmingham Photographic Society, and half-a-guinea per annum for all others."

Thirty-eight gentlemen then gave in their names as members of the new section.

The officers of the section were elected as follows:—

Chairman—Mr. J. B. Stone. *Vice-Chairman*—Mr. Jethro A. Cossius. *Curator*—Mr. B. Karleese. *Treasurer*—Mr. S. G. Mason. *Hon. Secretaries*—Messrs. J. H. Pickard and W. J. Harrison.

The question of a governing body to direct the general work of the survey was next considered. The following resolutions were then passed:—1. "That the Council should consist of representatives elected by the various photographic and scientific societies of Warwickshire, with co-optative members who may be of service in developing or aiding the work of the survey." 2. "That the photographic, artistic, and literary societies of Warwickshire be invited to send representatives to a general meeting on May 22nd, at St. Edmund's College, Edmund Street, Birmingham, for the purpose of electing a council to direct the photographic survey of Warwickshire."

Sheffield Photographic Society.

The monthly meeting was held at the Masonic Hall on Tuesday evening, when, after the routine business of the meeting, and the election of Mr. W. V. Davy as a new member, Mr. J. W. Charlesworth gave a paper on "Hand Camera Work." He began by describing one made by himself, and showed the most minute details of the same. There were also laid on the table hand cameras by Swinden and Earp, the Griffith's guinea camera, the quarter-plate Kodak and the original Kodak, two by T. G. Hibbert, viz., Turnbull and Rouch's; also the Demon, a toy.

It was announced that Mr. Chadwick, of Manchester, had promised to give a paper at an early date; also that the Britannia Company, Ilford, would give a demonstration, "How to Work Alpha Paper," at the September meeting. A copy of Dr. Emerson's book "Pictures in East Anglia," given by the author to the library, was produced, and arrangements were made for the loan of the same amongst the members.

Photographic Society of Ireland.

An ordinary meeting was held on May 9th, when the President Mr. George Mansfield, J.P., occupied the chair, and Mr. L. R. Strangways, M.A., read a paper on "Stereoscopic Work." The subject was a resumé of the past, an insight into the present, and a prophecy of the future of the stereoscope as it relates to photography.

There was a discussion which brought forth experiences of some of the older members of the Society. Mr. Strangways exhibited a number of cameras which he owned, as well as some which he obtained from the trade, to illustrate the various points he put forth.

At the conclusion of the paper and discussion Mr. Hedley exhibited a hand camera made by Messrs. Swindon and Earp, of Liverpool, which has a capacity for carrying twenty plates in the smallest space, and possesses many well-thought-out devices.

The first excursion of the season took place on May 10th to the Dargles. The morning was wet and the day very dull, which resulted in a small attendance of members.

The session is to close for indoor meetings by an exhibition of members' work in lantern slides on the 22nd inst. This meeting is to take place in the large theatre of the Royal College of Science instead of the Society's rooms.

The West Surrey Amateur Photographic Society.

On Wednesday, May 7th, Mr. Davison gave an address on "Platinotype Printing Processes," accompanied by a demonstration. Mr. Winsford occupied the chair. Several new members were nominated.

Mr. Davison, having recited the advantages of the processes, and given briefly the theory of the formation of the platinum image, explained the distinction between the hot bath, cold bath, and printing-out methods respectively, and proceeded to develop a large number of proofs showing the ordinary details of practice as well as the variations in colour obtainable by the use of the sepia papers, and by the addition of mercuric chloride (half dram to one dram per ounce of hot oxalate solution) to the developer. Cold bath prints were also developed; specimens of all the variations were handed round upon glass plates, as also mounted examples of platinum prints on fabrics and rough papers.

It was decided that the next out-door meeting of the Society should be to Carshalton and district, and that the subject for the first Wednesday in May, evening meeting, be "Gelatino-Chloride Emulsion Papers." Mr. Jaues is to treat this subject.

The Lewes Photographic Society.

A paper on "Cloud Photography" was read by Mr J. J. Hollway at the usual monthly meeting of the Lewes Photographic

Society, held on Tuesday evening. The chair was occupied by the president, Mr. J. G. Braden. A vote of thanks was passed to Dr. P. H. Emerson for the gift to the society of a copy of his work on "East Auglian Life."

Mr. J. J. HOLLWAY read his paper, and described the many beauties of cloud form and sky effects, illustrated by examples from the works of Constable and Gainsborough, showing the proper relation cloud forms should bear to the other part of the pictures. While recommending photographers to use cloud negatives to complete their pictures—for he considered nothing so offensive to the artistic eye as the broad patch of white for the sky generally seen in photographs—he cautioned them about using them iu an inartistic manner, as it was quite probable that unless clouds were inserted with taste and after careful cousideration of their appropriateness to the general effect of light and shade and general composition of the picture, they would rather detract froin what beauty might have existed before their introduction, thau bring about the desired improvemeut. Mr. Hollway exhibited specimens of his own cloud photographs, and by this means showed how greatly the general effect of a photograph could be improved by the judicious introduction of clouds.

At this meeting it was arranged to meet the Hastings Photographic Society on Wednesday, June 4th.

THE PHOTOGRAPHIC CLUB.—The subject for discussion on May 21 will be "Photo-Mechanical Processes"; May 28, "Photographic Fog."

COLOURING MATTER FROM CHLOROPHYLL.—A. Hausen (*Bot. Centralbl.*38, 632) prepares the yellow aud the green constituents of chlorophyll in what he believes to be a pure conditiou by the following process: Some leaves of grass are boiled in water from fifteen to thirty minutes, then washed many times with water, and dried iu the dark. The dry matter is extracted with boiling alcohol, and the solution saponified by boiling for three hours with a slight excess of aqueous soda; a current of carbonic anhydride is then passed through the solution, which is afterwards evaporated to dryness on the water-bath. Ether extracts from this soap the yellow colouring matter only, which is purified by evaporatiug down and crystallizing from a mixture of equal parts of ether and light petroleum. The soap, after extraction with ether, is extracted with a mixture of alcohol and ether, which dissolves only traces of the combination of the green colouring matter with soda. On adding another quantity of alcohol-ether and also phosphoric acid, the green matter is liberated and passes at once into solution, from which it is obtained by evaporation in the form of a brilliant, fragile, greenish-black solid, insoluble in water, benzene, and carbon bisulphide, sparingly soluble in pure ether, very soluble in alcohol with strong red fluorescence. The crystals of yellow colouring matter form orange-red plates insoluble in water, soluble in alcohol, ether, chloroform, and benzene to a deep yellow colour, and in carbon bisulphide to a brick red. These crystals are transformed in the light into cholesterin. The author considers this yellow substance to be identical with the yellow colouring matter of flowers and fruits in general, including that of the carrot.—*J. Chem. Soc.*

RECEIVED:—From Mr. J. R. Gotz, a bottle of special concentrated toning solution for a new Obernetter matt surfaced gelatiuo-chloride paper. The specimen prints accompanying this were free from objectionable gloss, yet contained plenty of detail. The sulphocyanide toning solution we tried upon Alpha paper which happened to be handy, and found it to give rich blacks exceedingly quickly, so that it had to be diluted more than recommended by the veudor.——Fallowfield's well-known *Photographic Annual* for 1890 has also been received. It is now a goodly volume of 432 pages, and contains a considerable quantity of literary matter, giving useful practical iuformation, in addition to the trade particulars relating to photographic applianees. Mr. Fallowfield also sends one of the sheaths which he now fits to his "Facile" hand-camera, to overcome the difficulty of the varying thicknesses of dry plates. Some notices of books and some patent intelligence we are again obliged to postpone because of press of other matter.

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

S. B.—*Mergel's Mercury Process.* The details of this process were never made perfectly clear, but you will find an account in the jouruals of April 1872. Paper was treated with ammonio-nitrate of silver, or with a gold salt, then the negative, exposed to mercury vapour, was laid down upon it, and there left, so that the mercurial fumes escaping therefrom should effect the reduction of the silver (or gold) salt, forming an amalgam on the principle of the *Arbor Dianae.* The image so produced in the paper was toned and fixed in the ordinary way, and was said to be permauent.

M. E. P.—*Gum Elemi in Photo-Lithographic Ink.* We find some particulars in the *Photo. Correspondz* relating to the employment of gum elemi in the somewhat complex mixture which is used for ink, both on stone and zinc, for the photo-mechanical processes. It is combined with suet, beeswax, asphalt, resin, and turpentiue, linseed oil varnish and lamp-black constituting, indeed, the chief ingredieut in the ink specified in a long formula therein given.

AMATEUR (Sandgate).—*New American Printing-Out Process.* Give it a trial by all ueans, and compare with your ordinary method for rapidity. No chloride is used, but equal parts of ferric oxalate, silver nitrate, and gelatine dissolved together in warm water with a sunall quantity of tartaric acid.

T. L.—*Photography in Natural Colours.* Since you wrote last week, the letters of Dr. Eder, Dr. Gunther, and M. Leon Vidal, have all appeared in the NEWS, and give as much information as seems likely to be forthcoming; but from these you will be able to glean further details.

ASSAYER (Llanelly).—*Chlorine in Hydrochloric Acid.* The best way of testing for free chlorine is to dissolve a small quantity of diphenylamine in the suspected hydrochloric acid, and look for a blue colouration. Or, the dipheuylamine may be dissolved in alcohol, and poured gently upon the surface of the acid, when the production of a blue halo at the line of junction makes itself apparent.

TECHNIC.—*The Britannia Works Premium.* It is very easy to criticise, but if prepared with a formulated scheme, the way is still open for you to submit a proposal, together with the names of those who agree to assist you in giving effect to your plans.

F. H.—*Zinc Alloys.* Unless you put in some tin, it is not possible to make zinc alloy with lead.

GOTHIC ART.—*Albert Dürer.* The current number of the *English Illustrated Magazine* devotes twenty-one pages to a notice of his works, by Albert Fleming, with some very fine engravings.

C. H. (Walsall).— Dr. W. J. Nicol's patent for "Improvements in and connectiou with Photographic Printing," is dated March 29th, 1889, No. 5,374.

F. C. S.— *New Gaseous Element.* Yes, if confirmed, the uew element damarium will quite revolutionise the present system of chemical formula according to the ruling atouic theory. Hydrogen, being no longer the lightest known element, cannot be taken as unity, but will have to give place to Damarium (D) at the bottom of our atouic series, and all the former weights will have to be doubled. Thus, hydrogen becomes 2, chloriue 71, oxygen 32, sulphur 64, &c. It is said to be the most powerful reducing agent known, instautly throwing out gold, silver, eopper, and lead from their metallic solutions, and reducing sulphurous acid to free sulphur, with production of the new oxide, D_4O. Truly this will necessite great changes, but we must wait for confirmation of this astounding discovery.

COL. WATERHOUSE.—Your interesting communication received and forwarded. Your experimeuts certainly indieate quite an original departure.

RECEIVED:—Report of the Newcastle-upon-Tyne Meeting of British Association, and Prospectus of the Automatie Photograph Company, Limited.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1655.—*May* 23, 1890.

CONTENTS.

A DAMP PROCESS.

Much is said now-a-days about the ease of the gelatino-bromide and other dry plate processes for landscape photographic work, as compared with the wet plate method of early times, with its developing tent or box, and the other heavy encumbrances it was necessary to take into the field. Perhaps the newly fledged race of photographers may be unaware that so far back as 1863 an excellent "damp" process was in use, cheaper than the present dry-plate process, whereby plates which would keep good for a day could be taken into the field just as dry plates are carried, and be brought home for development the same evening. Some practical advantages might perhaps be gained by experimentally examining the artistic and other merits of some of the best processes of the past, especially as it is well known that wet-plate methods tend to favour high quality in certain photomechanical and orthochromatic results.

The glycerine process was devised by Mr. Fysh, one of Mr. Valentine Blanchard's friends, and Mr. Blanchard published it in the YEAR-BOOK for 1863. A plate is coated with bromo-iodised collodion, then immersed in a thirty-grain nitrate of silver bath made faintly acid with acetic acid, for it is said that in this process no trace of nitric acid must be present in the solutions. The next step in the treatment is made by the use of the following solution:—Take of English honey, old and crystallized, four ounces; Price's glycerine, two ounces; nitrate of silver, thirty-grain bath, new and iodised, six ounces. When thoroughly mixed, add kaolin half an ounce and shake well, and repeat the shaking occasionally for an hour; then place the mixture in a light place, but not in sunshine, for two days. The solution above the kaolin deposit improves by keeping, and when required for use some of it is filtered into a measuring-glass for the purpose. When the plate is taken from the sensitising bath some of the glycerine mixture is poured over it, and kept moving until all oily appearances cease. The plate is then drained into the bottle, and some more of the glycerine mixture is poured over it; again the surplus is poured from the plate into the stock bottle, after which the plate is placed on edge on blotting paper to drain; when sufficiently drained it is placed in the dark slide for use. Mr. Blanchard's experience was that these plates would keep in good condition four hours in summer, and a day in winter. We used the process extensively, and about 1865 published in contemporary photographic literature some experiments made with it. By reducing the proportion of nitrate of silver in the glycerine solution, it was found that the plates could be made to keep good for a day in summer. The old protosulphate of iron developer was used to bring out the image.

The glycerine and honey mixture recommended above seems highly empirical from a scientific point of view, and no doubt the solution will bear simplification, but in general it yielded excellent results in the hands of those who gave it a trial. Mr. Carey Lea tried it on our recommendation, as mentioned in his book on photography, and spoke favourably of his experiences therewith. Those who found it a failure perhaps used impure materials, for honey is one of the most easily adulterated articles known, as the Swiss—who produce it in large quantities—are aware; then again, some samples of glycerine contain lead, and even high-class varieties sometimes contain chloride of sodium, and will not stand the nitrate of silver test. Not a bad method of applying the glycerine "preservative" is by means of a dipping bath. To those who understand the precautions necessary in working the wet-plate process successfully, the glycerine process for outdoor work within a moderate distance of home is easy, rapid, and inexpensive.

A MEETING OF OPTICIANS ABOUT LENS MOUNTS.

Perhaps the most influential meeting of photographic opticians ever held was that which took place last Wednesday night at the Mona Hotel, London, to make recommendations to the committee of the Photographic Convention about standard mounts for lenses. Mr. A. Haddon presided. Those present were Mr. T. R. Dallmeyer, Dr. James Edmunds, Mr. John Stuart (Ross and Co.), Mr. H. G. Heyburn (Ross and Co.), Mr. L. Cohen, Mr. A. Staley (Charles Reynolds and Co.), Mr. H. J. Anderson (Messrs. H. Anderson and Son), Mr. M. J. Swift, Mr. E. Clifton (the Stereoscopic Company), Mr. W. Taylor, Mr. Conrad Beck, Mr. H. Crouch, Mr. Turnbull (Messrs. Wray and Sons), Mr. T. E. Freshwater (Messrs. Newton and Son), Mr. H. W. Hobson, Mr. T. P. Watson, and Mr. H. R. Fairbanks.

As we have been requested not to publish the decisions at this series of meetings, because such publication would anticipate the report of the Committee, it would be of no use to publish the discussions which led thereto. Last Wednesday, Dr. Edmunds gave the meeting some of the benefit of his large experience relating to the construction of standard screws for scientific purposes. The resolutions about two standard flanges passed at the previous meeting were rescinded to clear the ground, because of the much larger attendance last Wednesday. Certain other resolutions as to the standards to be recommended for adoption for the flanges of lenses of all sizes were then passed, but not unanimously, for some of the larger opticians objected; the chief point of difference of opinion was as to the exact size of a standard flange approximating to 1½ inch in diameter. In the course of the meeting Mr. Taylor remarked that the opticians had but power to make recommendations to the Convention Committee, upon which Mr. Watson opined that if those present agreed to make certain standard flanges, those flanges would become the standards for the whole world; whereupon Dr. Edmunds remarked that those who would exercise most authority in the matter would be the public.

The Chairman announced that if the Committee desired to consult the opticians again, it would invite them to meet in London shortly before the opening of the Convention.

AN INTERNATIONAL PHOTOGRAPHIC EXHIBITION IN VIENNA.

An influential International Photographic Exhibition, or "Photographic Salon," will be held in Vienna in April next year, under the management of the Vienna Club of Photographic Amateurs. The regulations have not yet been formulated, but the general idea is to exhibit only first-class and comparatively recent work, and to make quality rather than quantity the predominant feature. A jury of artists and photographers will decide as to the admission, or otherwise, of each picture. The exhibition will be held in the Imperial Austrian Museum of Art and Industry. Mr. Carl Ulrich, vice-president of the Club, who is now in London, has furnished us the above particulars. The president is Mr. Carl Srna, the Club of Amateur Photographers, Wallfischgasse 4, Vienna.

In the course of his lecture last Friday at the Royal Institution, Professor Meldola said that euprous chloride is as sensitive to light as chloride of silver, and he performed an experiment in proof thereof.

ASTRONOMICAL PHOTOGRAPHY.

BY WILLIAM E. PLUMMER, M.A., F.R.A.S.

On a very superficial survey of the history of astronomy, we may easily perceive distinct epochs at which its further progress as an observational science is apparently barred, and as easily recognise the improved mechanical means whereby those barriers have been removed and a new and wider field of research opened up to patient investigation. The discovery of the telescope, coming as it did when naked eye records had accomplished their utmost accuracy, marks such an epoch; the discovery of the principle of the achromatic telescope, which happily surmounted the inconvenient difficulty presented by the enormous focal length necessary for the due performance of a single lens, marks another. And now, when we see this principle carried to such an extent in the manufacture of huge object glasses as to tax alike the powers of the optician to fashion, and of the engineer to mount, we have, in the application of photography, a possible means for the prosecution of astronomical science into regions of unexpected interest. We may, therefore, hope that astronomy as a science has not yet culminated, and that, so far from being effete, there are still awaiting solution, problems which will only be suggested by further developments in mechanics and optics.

We have alluded to the application of photography as marking an era of increased activity and further progress in astronomy. It would have perhaps been more correct to have insisted on the employment of the gelatine dry plate, as the date from which this new departure is to be reckoned; for the peculiar principle which gives importance to this method of research is its capacity for rendering available the accumulative effects of feeble light when exercised over considerable intervals of time. In the days of the wet collodion plate this valuable result could not be made effective, and consequently its application, though valuable for accuracy of delineation, secured what would have remained little more than scientific curiosities. It is not intended here to suggest that the early photographs of the moon taken by De la Rue, Rutherford, and others possess no value; but it must be remembered that they show no more detail than do our telescopes of moderate power and excellence. They do not mark any material advance in astronomical science. They exhibit the potentiality of advancement which the further progress of photography has converted into a reality. The negatives taken thirty years ago, when De la Rue and Berkowski photographed the coronal appendages of the sun during a total eclipse, taught us no more than that their shape and position could be accurately depicted for all time on a sensitised plate. It was undoubtedly in this respect a great advance over sensational hand-drawn pictures; but if the sensitiveness of the plate had not improved, and especially if the film had still to be used in a wet condition, photography would never have advanced to such a point as to be considered an engine, and a powerful engine, in astronomical research. The same remark applies to Bond, of Harvard, laboriously photographing a few of the brighter double stars in the heavens, the discussion of the measures of which showed no improvement on the micrometrical measurements of ordinary telescopes. The practical confinement of photography to such bright objects as the sun and moon, for years after the early and praiseworthy attempts of De la Rue and Bond, proves how little, in its

earlier stages, it was thought to be a serious competitor as an instrument of research with the largest made telescopes.

But as soon as the dry plate enabled us to store up the accumulated effects of the minutest points of light till they could be rendered visible on the negative, it was evident that we possessed a method of recording the aspect of the heavens with a delicacy and minuteness that were only limited by the mechanical difficulties of the operator. The exertions and experiments of photographic chemists, at first undertaken with a view of shortening the exposure, and rendering permanent very transient effects, have supplied astronomers the means of operating in a very different direction, who, by enormously increasing the exposure, have been able to perceive the traces and register the effects of constant but very minute sources of light.

In one sense it must be remembered that the photographs taken by the astronomer are pictures of very transient duration, and they are taken under exceptional difficulties which do not affect the ordinary operator. His instrument and his camera are being carried on the earth's surface with a velocity of several hundred miles an hour, while the object he is photographing does not partake of this motion. Consequently, he is often several thousand miles distant at the end of his exposure from the spot where it was commenced. This is ordinarily expressed by the motion of the heavens, and except the astronomer has some effectual means of overcoming the difficulty arising from this source, and maintaining the direction of his lens and camera unaltered in space, it is evident that he will not be able to ensure the light from a star constantly falling on the same spot of his sensitised plate. Two defects would therefore exhibit themselves on the development of the latent image: the bright stars or objects that are easily and at once photographed would trace lines on the plate indicating the direction of the earth's motion on its axis, while the fainter stars requiring long exposure to impress their images on the film would not be visible at all. The greater part of the motion necessary to counteract this difficulty is given to the instrument by means of clockwork, whose rate is so regulated as to carry the telescope with the same velocity as the earth revolves, but in an opposite direction. Consequently, if the telescope be pointed to a star and the clockwork be put into action, the instrument would theoretically remain pointed towards that star, however long the exposure was continued. But clockwork, however carefully made, and however ingeniously controlled by mechanical appliances, will never move with the perfect uniformity of the earth's rotation. Therefore it is necessary for the observer to attach a telescope to his photographic apparatus, and to keep a star seen through it accurately bisected by a wire, by slight correcting motions given to the telescope, when he perceives that the star has moved away from the wire by the smallest perceptible quantity. Nor is this his only difficulty; for owing to atmospheric refraction, which depends upon the star's altitude, and which, of course, changes during the exposure, a star will move slowly, but perceptibly, in a manner that no clockwork can adequately follow, and the continual adjustment or removal of this source of error can only be effectually remedied by minute alterations of the direction of the telescope in space. When, therefore, a plate is taken of two, three, or four hours' exposure, it means that an observer is all the time watching the behaviour and motion of a star in a connected telescope, with the view of removing or nullifying such slight deviations from regularity as the imperfections of mechanism or the physical circumstances of refraction necessarily introduce. For, without such precautions, and without a very considerable amount of care and attention, it is impossible to produce that kind of picture in which the stars are shown on development as perfectly round, hard, and small discs, various in size according to their magnitudes, the brighter the star the larger the photographic image.

The method of development is at the choice of the operator; but since accurate measurement of the distances between these minute discs is generally required, it is prudent to obtain as fine a granulation as possible. Hydrokinone gives generally very good results, but those who wish to force the utmost from their plates are rather in favour of a ferrous oxalate development.

Either of the two kinds of telescopes in use among astronomers, namely, the reflector and the refractor, is or can be made, available for photography. But there is this difference. In the former case, the reflector, all the rays, whatever be their colour or wave length, are brought to one and the same focus, and therefore such an instrument is immediately available. In the achromatic refractor as hitherto applied, the rays have necessarily suffered dispersion in passing through the object glass, and the labour of the optician is devoted to bringing the brighter rays of the visible spectrum to a common focus, while the rays about G, in the solar spectrum, the most sensitive for bromide of silver plates, are brought to a focus, or at least converge to a focus, at a point necessarily at some distance from the most suitable for visual rays. Hence in a refractor the plate is not exposed at the visual focus, and a particular form of object glass has to be selected in order to secure rapidity of action and precision of image.

The advantage appears, therefore, to lie on the side of the reflector, and it was, accordingly, with those instruments that the earliest attempts at astronomical photography on an extended scale were conducted. When we consider that a reflector is a simpler optical arrangement, that it is less costly in construction, that it is available alike for all rays of the spectrum, and can, therefore, accommodate itself to any prepared film, it is not a little surprising that most energetic efforts, finally crowned with success, have been made to adapt the refracting form to the purposes of this method of research. It is, however, a fact that, in the past, nearly all the serious astronomical observations have been made with refractors. The explanation of this rather curious fact is not hard to seek, but it would lead us too far astray to discuss the point here. The reason for noticing it is, that it was probably felt that if photography was to reap a wide and abundant harvest in the future, refractors must be constructed to play the same conspicuous part in the new astronomy as they have done in the old. And, undoubtedly, the credit for the due appreciation of this fact, and for taking the steps necessary to secure its accomplishment, belongs to French ingenuity, the ablest exponents of which, in this branch, are the brothers Henry, of the Paris Observatory. Of the permanent success which has attended their exertions it is too early to speak with confidence, but it must be admitted on all hands that they have fully appreciated the advantages to be gained, and manfully coped with the great difficulties that barred further progress.

It would extend this article to an interminable length to

attempt to give even a catalogue of the various purposes to which photography has been, and is being, applied in the region of astronomical research. To some of the more important and more interesting we shall hope to refer on a future occasion, and show how objects of which the largest telescopes had not revealed the presence, have accurately depicted themselves on a sensitised film; how variations which the eye cannot appreciate have been made easily visible; how labour has been saved, and time has been shortened. The success has been so rapid and so marvellous in the past, that it would be bold to forecast for it any ultimate failure in any direction, but there are difficulties which have not yet been wholly overcome, and of which it is not easy to see the solution.

It may be as well to point out some of these apparently unavoidable drawbacks. It is evident that if a plate be exposed for some hours in order to secure the record of the position of the faintest stars in a given district, it is inevitable but that the brighter stars must be over-exposed. Indeed, it not infrequently happens that a reversion of the negative image supervenes, and this long exposure is attended with this inconvenience, that the size of the image of the brighter stars becomes so large, that they are extremely difficult to bisect with the necessary precision, or to determine the centre of action whereat the photographic image commenced which would correspond with the position of the star in the sky. The periphery of the image is generally of so loose a texture that it is impossible to determine this point from measures made at the circumference. And further, considered as a picture it is a failure, because the brightest stars appear as points in the sky without any sensible area, and for accuracy of reproduction the negative should reveal them equally minute. The effect of brightness in the sky is translated on the negative by increased area.

This defect of over-exposure is still more strikingly shown in the photographs of bright nebulæ, where it frequently happens that when a plate has been exposed long enough to secure the detail in the fainter parts, the brighter portions show a mass of uniform density. This difficulty is partially removed by taking exposures of varying length, in some of which all the details will have received the proper exposure, and then constructing a picture of the whole, from the study of its several parts. And lastly, it may fairly be urged that a photograph has no power of discrimination to seize the momentary and best view of a celestial object. If the exposure be carried on through a short but perceptible interval, the effect registered on the sensitised film is the sum of all the varying aspects, which, owing to atmospheric tremor and many other causes, the object successively presents during that interval. The final result may be compared to the effect which would be produced by overlaying many images of the same object taken with a camera in minute but rapid vibration.

West London Photographic Association.—On the 9th the annual smoking concert took place at the Richmond Hotel, Shepherd's Bush Road, under the chairmanship of Dr. Low. The programme was in itself a work of art, having been photo-etched by Mr. Walter L. Colls from a design by J. Martin Dickens. On the 3rd about thirty members of the Society met at "Jack Straw's Castle," Hampstead, and spent an afternoon in seeking "bits" in the neighbourhood of the heath. On the 17th, twenty-eight members sought out some of the charming scenery in the vicinity of St. George's Hill. While the members were waiting for their evening repast, Mr. J. D. England exposed two whole-plate celluloid films upon them.

THE PHOTOGRAPHY OF THE MORE REFRANGIBLE RAYS.*

BY V. SCHUMANN.

Fluorite in perfect white crystals is now-a-days such a rare mineral that it is hardly to be got, even in small paltry pieces, and not at all in large ones. My optical installation certainly contains a fluorite prism, but it is, in consequence of many faults, so defective that its application to the end I had in view was not to be thought of. After having for years vainly endeavoured to obtain such a prism as I desired, my researches on the ultra-violet rays would have remained completely blocked, but that I fortunately was able to obtain, though only as a loan, a fluorite prism and lenses, both of unusual size and purity.

With this fluorite apparatus I renewed my researches, and was, thanks to its excellent definition, immediately enabled to go somewhat more closely into the question of the absorption of light by quartz.

In the first instance I confined myself to observation of the fluorescent spectrum as shown when a plate of uranium glass is brought into the path of the rays. When I, during the observation, introduced a plate of quartz between the source of lights and the slit, I found, at all events with the thicker plates, that the brightness of the image was visibly diminished, and by so much more to the eye as the quartz plate was thicker. The largest quartz plate, which was 5 c.m. in thickness, stopped the more refrangible rays entirely. The less refrangible rays, on the other hand, were but slightly similarly affected.

I am far from arguing that the total disappearance of the particular spectrum region proves the total absorption of the rays. The physiological effect stands on a different ground from the photographic effect. The whole fluorescence spectrum is, however, so badly defined in comparison with the photographic image, that I must give the preference to the latter, even when its sharpness leaves much to be desired. After the somewhat crude earlier experiment the registration of the absorption by the rays was taken in hand. On account of its energetic action I chose for this purpose the aluminium line No. 32. Although the photographs—about 100 in number—that I made for the purpose do not enable me to give an exact numerical table of absorption, yet I can state with tolerable certainty that films of quartz up to a few millimetres in thickness keep back the ultra-violet rays but very little; but on the other hand, if of 10 m.m., and still more of 20 or 30 m.m. in thickness, the quartz retards the exposure of the rays at the end of the ultra-violet in a very pronounced degree. Whether the yet more refrangible rays behave in the same manner as the aluminium line No. 32, I am unable to say. A circumstance to be mentioned later on led me to the conclusion that if there is any difference it cannot be a very considerable one.

Following these results I was able, without much difficulty, to increase the permeability to light of my spectrograph, which was fitted up with a quartz prism and quartz lenses. I reduced the thickness of the quartz through which the light had to pass by replacing the lenses hitherto used by thinner ones (2·2 m.m.) and by shifting the prism so that its edge approached more nearly the centre of the field of light of the collimator lens. In this way the thinnest portion of the prism—that is, the margin at the refracting angle—was made much more use of than

* Continued from page 382.

when the prism, as is customary, stands in the middle of the field of light. With the speetrographic apparatus thus remounted I was able to photograph all the rays, even to the most refrangible, as with fluorite. It only requires longer exposure, in order to attain to the performanee of the latter. These photographs yielded the noteworthy result that, with a sufficient lengthening of the exposure, quartz is not less well suited to the photography of the less refrangible rays than is fluorite.

When I was in the fortunate position of being able to farther prosecute my researehes by means of a fluorite apparatus, I hoped to find a quantity of new lines beyond those which my earlier researehes had diseovered. The first experiments, having this end in view, undeeeived me completely, the following ones not less, and even the last of several hundred, earried on with inereased power of the electrie spark, gave no more evidenee of a fulfilment of my desire for more light in this direetion.

Beyond the wave-length 1820 there reigned with the fluorite apparatus the same absolute darkness for the gelatine plate as in the speetra obtained with quartz. Whether there is really no aetion of light in this dark region, or whether the bodies analysed did not yield any rays in that plaee, or whether the silver moleeule on the plate so obstinately refuses to yield to rays of shorter wave-length any image that ean be developed, must provisionally be left undetermined. Of great influenee upon the sensitiveness of the plate appears to be—as my earlier researehes taught me—the enormous *impermeability of gelatine to light of all rays more refrangible than the cadmium-line* No. 18. In my experienees of later date I found that, for example, a gelatine film of only a few thousandths of a millimetre in thiekness suffieed to prevent the passage of the whole of the spectrum beyond the cadmium line No. 24, and that for the absorption of the last of the aluminium lines a yet thinner film suffices. Like gelatine, also behave eollodion and gum arabic. There now remains to me the hope that experiments with other elements—I have it in view to search for the more refrangible rays in the speetra of the elements that I have not yet tried—may enable me to diseover lines of shorter wave-lengths. With the eleetrodes of the aforementioned metals that I have already employed, further suecess may be obtained by the use of an eleetrie spark of greater energy than that of the apparatus I have hitherto applied to the purpose. Having this in view, I propose to repeat the whole of my experiments.

Hitherto, my electrieal apparatus has consisted of a chromie acid battery of four large elements, a Ruhmkorf indicator eoil for a spark of 25 em., and twenty Leyden jars 40 em. in height. For my future work I have prepared ten Grove cells of unusual size (the platinum eleetrode measures 10 by 19 em.), a Ruhmkorf induction coil for 50 em. spark (secondary coil 75,585 windings of about 54,000 metres in length, and 68,000 resistance) and a Ries battery of nine Leyden jars of 40 em. in height. Perhaps with this more powerful apparatus I may find more lines, as well as more refrangible ones, than in my former observations.

I refrain, as before stated, for the present from a more detailed description of my photographic apparatus. I propose to furnish a complete aecount as soon as I have by further experiments thoroughly proved its capability.

I will now conclude with some details of the power on light of my apparatus. My old speetrograph, even with long continued exposure, and with the slit opened wide, about ½ m.m., only onee gave me the aluminium line mentioned, and then only in weak diseontinuous streaks. With the fluorite instrument an exposure of two seeonds sufficed to obtain a photograph of the before mentioned aluminium, and that with a slit of 0·080 m.m. opening. We need go no further to diseover the extraordinary power of light of the later instrument.

The energy of the less refrangible rays of the ultra violet part of the speetrum with this instrument is so overpowering that I had never known the like. A few minntes' exposure suffieed to solarise many of the lines of this position of the region. Such lines are washed out in a eompletely exposed speetrum. Of all the speetra that I have photographed, those of sodinm, bismuth, and ehromium give the most powerful solarization; with chromium the solarisation goes to such an extent that the whole speetrum appears as light stripes, strewed with lines of slight intensity. The uneommon light power of my speetrograph has been of speeial service to me in making the extensive set of photographs of the region of the spectrum that was nndertaken.

A STANDARD METHOD OF DEVELOPMENT.*

BY C. H. BOTHAMLEY, F.I.C., F.C.S.

Method of Experiment.—Four well-known eommereial brands of plates were seleeted, of as widely diffcrent and as representative eharacters as possible, viz., Wratten and Wainwright's Ordinary, Ilford White Label, Mawson and Swan's Castle, and Thomas's Thickly Coated Landscape. They were exposed for 30 seconds behind a Warnerke screen at a distanee of 1 metre from a standard light consisting of one square centimetre of the brightest part of a Silber Argand working at full power. It was believed that a Warnerke screen would give results sufficiently accurate and coneordant for the purpose in hand, and the coneordanee betwcen the results, and the fact that there was rarely any doubt as to whieh was the eorrect number, justify this belief.

Development was eonducted in a room which had a praetically constant temperature of 16° C. (62° F.), and when finished the plates were rapidly rinsed, immersed in acidified alum to arrest development, well washed, and fixed in the usual way.

The sensitometer numbers were read off both before and after fixing. The praetiee of different experimenters differs in this respeet. Whether a number which is just visible by reflected light before fixing will be visible by transmitted light after fixing depends, of course, upon the density whieh the deposit has acquired, and sinee from a practical point of view it is efficient or printable sensitiveness that we wish to measure, to read after fixing is perhaps the better plan. In the eourse of numerons and extended series of comparative experiments in another connection, I have found that more concordant results are obtained by reading after fixing.

In order to eliminate as far as practicable the influence of air on the developer, development was in several cases eonducted in dipping baths of the old pattern, the tops of whieh were elosed by thick, flat pieees of india-rubber, cut to shape, and fastened down by india-rubber bands which passed round the bath. The bath was completely filled with developing solution.

* Continued from page 376.

The results are given in the table; B F = before fixing; A F = after fixing.

In (*a*) all the plates showed slight chemical fog, and in (*b*), with a longer time of action, the amount of fog was very considerable.

Diluting the developer with an equal volume of water, the proportions of the constituents remaining the same, practically prevented chemical fog when development was not prolonged (*c*), but the density* in all four cases was slightly less than in (*a*). With prolonged development all the plates were badly fogged (*d*).

Double the amount of bromide also practically prevents chemical fog with short development (*e*) and (*f*), although the density in (*e*) was slightly less in all four cases than in (*a*). With long development, however, there was considerable fog (*g* and *h*), though in all cases decidedly less than in (*b*).

Continual rocking of the dishes during development as opposed to occasional rocking (*e* and *f*), has no effect on the final result as regards degree of sensitiveness. In all cases the density was slightly greater with continual rocking (*f*), but the gradations were distinctly better when the dishes were only rocked three or four times in the course of five minutes.

Development in open dishes with occasional rocking gave the same numbers (*g* and *h*) as development in closed vessels, but the amount of staining was greater under the former conditions.

The discolouration of the developer is due mainly to the action of the air upon it, and only in a very slight degree to its own action on the plate. Even after development for an hour in closed vessels the liquid has only a pale sherry colour.

With regard to time, five minutes is not quite long enough to obtain the maximum effect with certainty. Prolonged development, however, tends to chemical fog, which was strongly marked in all cases where development was continued for an hour. The fact that the chemical fog was greater in (*d*) than in any other case where ammonia was used indicates that the amount of fog is a question of time quite as much as of the concentration of the developer.

Sodium carbonate, even in large quantity (*i*), acts more slowly than ammonia, the density being lower in all four cases than in the corresponding cases in (*a*) or (*e*). These plates were free from chemical fog, but in (*k*), after prolonged development, the fog was very dense. Reduction of the proportion of sodium carbonate to 10 parts in 1,000

failed to prevent fog with long development. Addition of potassium bromide in quantity equal to 2·5 parts in 1,000 prevented chemical fog, even when the plates were developed for half an hour; but the action of the developer was slower and the density less.

In presence of sodium carbonate and absence of sulphite, pyrogallol solution so rapidly becomes of a very dark colour, and stains the film so badly, that if this alkali is used in the standard developer development must always be done in closed vessels. It is also well to bear in mind that sodium carbonate has a considerable tendency to produce frilling.

Temperature is well known to exert great influence on the rate of development. If the solutions are much below 15° C. (60° F.), it is with most plates almost impossible to get density. According to Eder's experiments,† however, brom-iodide plates which gave 14° when developed for three minutes with sulpho-pyrogallol and ammonia at 2° C. (35·6° F.) only gave 15° when development was conducted at 26° C. (79° F.). It seems, therefore, that temperature has a much greater effect on the density of the image than on the degree of sensitiveness indicated by the sensitometer number. It is, however, important to fix a standard temperature at which development shall be conducted.

It is important to note that whatever the composition of the developer, *if sufficient time was given*, the maximum sensitometer number obtained was *constant for each brand of plates*. It follows that, provided that the developer is allowed to act so long that it produces its maximum effect, variations in its composition are without influence on the degree of sensitiveness registered, but affect the gradations by determining the rate at which development takes place. Mr. Lyonel Clark, as a result of his elaborate experiments with developers of all kinds, has previously arrived at the conclusion that "the action of light is absolute: that is to say, a certain quantity will effect a change in the haloid salts, and any substance capable of developing will, in a greater or less time, make this change apparent" (*Phot. News*, 1889, p. 832).

My own experiments afford independent confirmation of Mr. Clark's conclusion. In this result we have further evidence of the necessity for distinguishing clearly be-

* "Density," here and in the following paragraphs, refers to the density generally, but more especially to the density of the highest numbers.

† *Photo Corr.*, 1883 p. 87.

tween the three different stages of development, on which I insisted in my recent paper at the Camera Club Conference (*Camera Club Journal, Conf. No.*). Variations in the composition of the developer do not *limit* the formation of the primary image, but only affect the rate at which it is formed.

Upon the basis of these results, combined with general experience, I recommend the following standard developers and methods:—

I.—*Standard Pyro-Ammonia.*

5 parts pyrogallol, 5 parts ammonium-bromide, 2·5 parts of real ammonia, NH_3, in 1,000 parts by measure of the solution.

Develop for 10 minutes in an open dish or closed vessel, with *occasional* rocking, at a temperature of 15° C. (60° F.).

II.—*Standard Pyro-Soda.*

5 parts of pyrogallol, 10 parts anhydrous sodium-carbonate, Na_2CO_3, 2·5 parts potassium bromide in 1,000 parts by measure of the solution.

Develop for half-an-hour in a closed vessel at a temperature of 15° C. (60° F.).

Of the two I decidedly prefer pyro-ammonia. It acts more rapidly, and gives more uniform results with plates of various kinds. The only drawback is the necessity for determining the strength of the ammonia solution; but this operation takes very little time, and demands no more manipulative skill than will be possessed by any photographer whose work necessitates the use of a standard developer at all. Titration of the ammonia is little, if any, more trouble than the drying of sodium carbonate. A large quantity of ammonia solution can be made up at once, for at this degree of dilution its strength does not alter even in summer, provided that the bottle containing it is kept in a moderately cool place.

Some brands of plates will not stand the quantities of alkali (ammonia or sodium carbonate) recommended without giving more or less chemical fog, but it may safely be said that the quality of such plates is not of the highest desirable standard. All the plates of best repute are not fogged by the proposed standard developers.

Preparation and keeping of the Solutions.—The developer in either case must be made up in two solutions, which are mixed immediately before use. The pyrogallol should be dissolved in *distilled water*, and although it may be kept for two or three days in a well closed bottle out of contact with all traces of ammonia fumes, it is much better that it should be dissolved when it is wanted. This plan involves very little trouble, and occupies only a short time.

Standard Pyro-Ammonia.

A.—Ammonia, NH_3	... ...	5 parts
Ammonium bromide	... ...	10 ,,
Water up to	... ...	... 1,000 ,,
B.—Pyrogallol	... ...	... 10 ,,
Water up to	... ...	... 1,000 ,,

Mix in equal volumes immediately before use. It is obvious that the mixed solution will have the composition proposed for the standard developer.

The ammonia and ammonium bromide solution will remain unaltered for a long time if not kept in a very warm place, and may therefore conveniently be made up in large quantity. It is better to keep it in several bottles of moderate size than in one large bottle, partly on the score of convenience, partly because any accident happening to one of the bottles does not spoil the whole stock of solution.

In making the ammonia solution we have first to calculate how much of the "Diluted Ammonia No. 1" will be required. The titration with standard oxalic acid has given the number of centigrammes of real ammonia in 10 c.c. of the solution, or in general terms, the parts of ammonia *by weight* in 1,000 parts *by measure* of the solution. Suppose that 10 c.c. of the ammonia solution required 15·4 c.c. of standard acid, then the 10 c.c. contain 15·4 centigrammes of real ammonia, or 15·4 parts by weight in 1,000 parts of the solution by measure. We require to know how much of the solution will be required to give us 5 parts of ammonia, the quantity contained in the standard solution. Obviously—

$$\frac{5 \times 1{,}000}{15{\cdot}4} = \text{volume required,}$$

or in general terms—

$$\frac{5 \times 1{,}000}{\text{parts of ammonia in } 1{,}000} = \text{volume required.}$$

or

centigrammes in 10 c.c.

Weigh out 10 parts of ammonium bromide into a flask holding 1,000 parts by measure, add a small quantity of water, and when the bromide has dissolved, add the volume of "Diluted Solution No. 1," given by the calculation, and dilute up to 1,000 parts.

An operator accustomed to the use of the metric system will find no difficulty in making up the solutions. Any one who uses English measures will find it convenient to make up 16 ounces, *i.e.*, 7,000 fluid grains, or 10,000 fluid grains. The former quantity requires 70 grains of ammonium bromide and 35 grains of real ammonia, the latter 100 grains of bromide and 50 grains of ammonia. Measuring flasks graduated to 1,000 or 10,000 fluid grains can readily be purchased. Grains and fluid grains only should be used, and *minims should be avoided.*

Standard Pyro-Soda.

A.—Anhydrous sodium-carbonate	... ...	20 parts
Potassium bromide	... ...	5 ,,
Water up to	... ...	... 1,000 ,,
B.—Pyrogallol	... ...	... 10 ,,
Water up to	... ...	... 1,000 ,,

Mix in equal volumes immediately before use.

The sodium carbonate solution is made by dissolving the weighed quantities of the solids in water and diluting up to 1,000 parts. It may be kept for a considerable time, but the solution is very liable to attack and dissolve certain kinds of glass.

Of the proposed standards it may be said—

(1) That they agree very closely in composition with the developers used in ordinary practice.

(2) That they do not produce chemical fog on plates of good quality when allowed to act for a time sufficient to develop the maximum sensitometer number which they will give.

(3) That the proportions of the constituents are simple, the materials are easily obtained in a state of purity, and the solutions are readily prepared.

It seems, therefore, not too much to hope that they will meet with the favour of those whose work requires the use of a standard developer of general applicability.

The Photographic Club.—Subject for discussion May 28, "Photographic Fog"; June 4th, "Photo-Mechanical Processes." Bank Holiday outing at Uxbridge; train from Paddington 10.55, Westbourne Park 10.58.

GROUPS AND GROUPING.

BY C. BRANGWIN BARNES.

The photography of groups, either family, wedding, picnic, scholastic, regimental or otherwise, is a branch business in itself, and is treated as such by some firms, who manage to make a remunerative branch of it. It is a great pity that the military group business should be mainly in the hands of a foreigner; were his business premises in England I should not grumble, but the facts of the matter seem to be that up till now no English photographer has been found enterprising enough to travel round the various military centres and photograph the men of the regiments there stationed in companies, purely "on spec."

It has been left to a Frenchman to take the necessary risk, and from all appearances he seems to make a good thing of it; his operator in this country takes the negatives and the work is finished in Paris. Although I personally have strong objections to a foreigner monopolising this branch of the business, I am not prejudiced as to his work, which I must unequivocally state is uniformly good; the pictures are whole-plate size, well grouped and lighted, properly exposed, nicely retouched and printed, enamelled, and supplied in cut mounts at, I believe, two shillings per copy. As the average number of copies sold from each negative would be about fifty, this should be well worth doing, and I would here remark that the old proverb, "Anything worth doing, is worth doing well," applies strongly to taking photographic groups. If a group be well taken, every individual composing the same will purchase at least one copy, so that the better the picture, the more remunerative will it be to the photographer.

The great question in taking a group out of doors is to select a good light—direct front light is far too often used, with the result that the pictures are much too flat and poor; a side light should always be chosen, the space to be occupied by the group apportioned and focussed before the subjects are grouped.

This latter operation can be performed with the aid of one or two persons placed at the edges and centre of the space selected, and care should be taken in selecting just the necessary diaphragm; too large a stop will of course give the edges out of focus, and at the same time should too small a one be used it will unnecessarily lengthen the exposure, which is an important question when the steadiness of some thirty or forty persons has to be considered. When this part of the process has been completed, the figures should be grouped as rapidly and carefully as possible, due note being taken as to the colours of costumes, light and dark portions being so arranged as to balance properly and make a harmonious whole.

Grouping completed, a glance should be given at the composition from the front of the lens, to ensure that no one is hidden behind another, the word should be given and the exposure made, immediately followed by a second and perhaps a third. Nervousness and fussiness on the part of the operator should be avoided, as it is sure to create a lack of confidence on the part of the sitters if exhibited. In a group of any large number, there are sure to be one or two amateurs who will be free with suggestions as to what you might or ought to do; these must be quietly and at the same time politely ignored; if you let them see that you thoroughly understand what you are about, and are yourself confident of a good result, they will usually, in vulgar parlance, "dry up," and leave the arrangement in your own hands. Where the group is composed of a large number of persons, I would recommend that the size of picture taken should be at least 12 by 10, and whenever it can be managed, 15 by 12; the larger the picture the more imposing it looks, and the better the orders.

Groups look elegant when vignetted and mounted in contact with bevelled glass, so-called opalines; the only objection to this style of finish being that they look somewhat smaller than when mounted on card with a three or four inch margin, but the increased delicacy is an advantage which should outweigh the disadvantage of size.

THE PROGRESS OF THE PHOTO-MECHANICAL PRINTING PROCESSES.

BY HERMANN E. GUNTHER.

I.

Many an improvement has been made in connection with photo-mechanical printing processes since my last reports on this special branch of photography were published in these pages,* so that I think it desirable to take a brief survey of the most important advances and successes which deserve to be recorded.

Photo-zincography and Photo-lithography.—For taking prints from a prepared zinc plate in the lithographic press the bichromated albumen process is still much used in Germany, because it is about twelve times as sensitive as the asphalt method, though the latter gives finer and sharper lines. In this process the zinc plate, previously poured over with warm water, is coated with a thin film of bichromated albumen, and, after drying, exposed beneath a negative. The zinc plate is then rolled up with transfer ink, and placed in water, until it can be developed by means of a pad of cotton wool. In developing, the sensitive albumen film is sometimes rubbed rather briskly, to remove tone;† this, however, causes the lines of the image to be damaged, though only to a slight degree. But afterwards, in etching the picture, the etching fluid enters into the channel thus produced, and quickly enlarges it, so that the lines damaged during development are soon entirely broken up. This defect may be almost entirely avoided by the following method, recommended some time ago by F. O. Moerch. An asphalt solution is prepared in the well-known manner, and, after filtering, is poured over the exposed bichromated albumen film. A slight degree of heat accelerates the drying of the coating of varnish. After drying the plate is immersed in a dish of luke-warm water from half an hour to two hours, according to the amount of exposure which the albumen film has had beneath the negative. During this operation the albumen film becomes hygroscopic, but only at the parts which have been protected from the action of light, and the asphalt coating is loosened by this reaction. If now the film be slightly rubbed by means of a fine pad of cotton, the lines will come out sharply and completely. They can hardly be damaged, because the asphalt coating, if once dry, becomes exceedingly hard where it rests on a dry ground, whilst it becomes brittle and friable where the base is damp.

* See Photographic News, xxxii., page 98, 155, 197.

† It may be remembered that by the "terminus technicus" *tone* or *false tone*, that action of light is understood which extends over the parts of the film that were entirely covered by the negative, and which imparts to the impression a flat appearance.

A useful invention has been made by the firm of Wezel and Naumann, of Leipzic, who prepare zinc plates as a substitute for lithographic stones. This is done in the following manner: lithographic stone is dissolved in a mixture of sulphuric and hydrochloric acid, and to the solution is added a mixture of an asphalt solution and resin with some good oil-soap, such as sebacylic lime. After removing the superfluous acid by evaporation, the residue is dried to powder, which is now a combination of sebacylic lime and sulphate of lime. The dry powder is then mixed with a weak solution of soda, and by a steam injector sintered on the hot zinc plate, which thereby receives a coating equal to that of the natural lithographic stone. These prepared zinc plates are treated in the same manner during the transfer process as lithographic stones, only the etching is somewhat modified, inasmuch as phosphoric acid with diluted gum arabic is used instead of hydrochloric acid or aqua fortis. More than 6,000 prints may be obtained from one transfer, and the zinc plates are suitable for any kind of transfer, as well as for any lithographic pen and ink or chalk work.

An original method of photo-zincography has been adopted by a well-known German establishment. As I am told, it is the same process which is in use in the photographic department of the Belgian School of Civil Engineering for the reproduction of plans and maps. In this process, zinc of the factory of the "Vieille Montagne," in Belgium, is used, which bears the numbers 8 to 10, according to the surface of the sheets. The plate is at first cleaned in a solution of nitric acid of 8 per cent., and then polished and washed in plenty of water. The plate is then again placed in the nitric acid bath until it has acquired a uniform silver-grey appearance, when it is removed, again rubbed and thoroughly cleaned, and finally coated with a gallic solution. In the above-mentioned establishment this solution is prepared as follows: 75 grammes of nut-galls are broken and dissolved in 1,500 c.c. of water. The solution is reduced to one-third its volume by boiling; next it is mixed with 125 grammes of gum arabic, 25 c.c. of hydrochloric acid, and 12 c.c. of nitric acid, and then filtered. The zinc plate is coated with this solution by means of a flat brush. When the coating is dry, the plate is washed, dried, and coated with the following sensitive solution:—

Asphalt	...	...	...	20 grammes
Oil of lemon	...	...	...	15 ,,
Benzine	...	...	...	500 c.c.

which should be filtered after solution. The exposure necessary is from 30 to 40 minutes in the sun, and 2 to 3 hours in diffused light. The development of the plate is effected with essence of turpentine, or, if this does not exercise the necessary dissolving power, with a mixture of this essence with benzine. After development, the plate is immersed in a bath of diluted acetic acid (5 per cent.) to remove the nut-gall and to uncover the lines of the image. In order to transform the image into one which can be machined like a lithographic stone, it is coated with a solution of 100 grammes of absolute alcohol and 5 grammes of gum-lac, by means of a brush, dried, and treated with essence of turpentine, by which the asphalt is dissolved. By this treatment the portions of the zinc plate beneath the lines of the image are uncovered, and the plate can then be rolled up by the use of an aqueous gallic solution, and printed in the well-known manner.

A rapid photo-lithographic process has of late been invented by M. Balagny. A gelatino-bromide plate is placed for a few minutes in a solution of bichromate of potash, when it is removed, dried, and exposed beneath a photographic negative. It is then exposed for a few seconds to light at its back, and then thoroughly washed. The plate is now fixed on the table of a photo-lithographic press, rolled up with fatty ink, and printed in the customary way. Balagny uses gelatino-bromide films, specially prepared for this purpose by M. Lumière, the gelatine coating of which is attached to its pellicular support by a silicated solution. In using ordinary gelatine plates, the film would probably be pulled off in rolling up the plate. By this process a number of photo-lithographic prints can be procured an hour after the negative to be reproduced has been made.

The same process has been for several years in practical use in the Imperial Printing Establishment at Berlin, with the difference that the prints are not taken directly from the negative, but that after rolling up the negative, a transfer is made from it on to a zinc plate.

An excellent method of preserving drawings and photo-engravings on lithographic stones, so that they may be reproduced after a lapse of many years, has quite recently been published by Fr. Sandtner, of Copenhagen. From a stone bearing an engraving, or a photographic transfer, a print is taken, with a solid black ink, on transfer paper, and this print is at once transferred to a sheet of white gelatine, or to parchment paper, which has been coated with a gelatine solution. This transfer is mounted on a drawing board, and by the aid of a flat and soft brush covered with a solution of aniline brown, taking care that no streaks are produced. After drying, it is coated once more, and, when dry, again; the printing ink is washed off with a few drops of turpentine by means of a small pad of cotton. The gelatine transfer is then removed from the drawing board, when it shows a beautifully clear negative, which is perfect to the smallest details. Imperfect transfers can be at once washed off gelatine sheets by means of essence of turpentine, and the sheets may be used again. Negatives of this kind can be preserved for many years if they are varnished with a white turpentine varnish to which some siccative has been added. The picture side is varnished first; then the back of the sheet. This coating of varnish not only protects the negative from moisture, but it prevents folds and wrinkles. Prints from such negatives are taken on transfer paper which has been prepared, in the well-known manner, with a solution of bichromate of potash, and the impressions are then transferred to the stone.

PHOTOGRAPHY IN COLOURS.—In the *Photographic Globe's* editorial notes, the writer says:—"To express an opinion that photography in colours is impossible, or to discredit the announcement that somebody has succeeded in it, is something photographers ought not do. The French did not believe in Daguerre's success until a famous savant introduced his discovery for him, and if anybody claims to have succeeded in colour photography, give him a chance and listen to his statement. It is bound to come, but whether in the form now agitated in Austria, Germany, or on the lines of Mr. Bierstadt of New York, it is impossible to say. Mr. Bierstadt evidently knows more about the subject as connected with process work than any other photographer, and an examination of some of his work in coloured prints, the plates of which were made with chromatic screens, equivalent to the coloured prints, would lead one to believe that chromophotography is not far off.

Notes.

The *Court Journal* is well advanced with its photographic intelligence. It gravely announced in a recent issue that the Photographic Exhibition now being organized by the London Chamber of Commerce was opened on the previous Wednesday week. Our contemporary evidently has got a little mixed between photographs and the plans of the Watkin tower which have been on view in the hall of the Drapers' Company, where, also, the Photographic Exhibition will be held. *Apropos* of the Drapers' Hall, it may be said that no such gorgeous surroundings have ever accompanied an exhibition of photographs. Probably the hanging committee will have some trouble in arranging the pictures so that all shall be equally well lighted, as most of the four or five halls are illuminated only from the sides.

The enterprising people who have been offering a confiding public a "two-pound pastel portrait free" on the condition that it shall be "framed suitably so that the work shall show to advantage," have not thought it worth while to take any notice of the rather damaging correspondence which has been published, and which throws a light on their curious method of doing business. Two persons have related their experience in the *Globe*. This experience is identical. Each sent a photograph, and received an answer requesting the remittance of ten shillings for a frame, as it was to their "mutual interest to have the picture framed by a first-class house." If, the writer went on to say, the purchaser was not perfectly satisfied in every respect with the pastel and frame, the remaining nine shillings need not be sent. In the two cases mentioned, neither thought it worth while to send ten shillings for a frame which had not been seen, and declined the tempting offer, and the coincidence concludes by the inability of both to get back their photographs from the advertisers. What is wanted now to make the story complete is the experience of some person who has complied with the conditions of the advertisers.

Lady William Lennox, who is doing a good business as a milliner, doubtless writes from experience when she says, "some women invariably hate a new gown or bonnet the instant it has been sent home. 'I wish I hadn't bought it; so stupid of me not to remember that I look hideous in that colour always'; or, 'of course, I ought to have known that these sleeves would make me too frightful for words.'" This is the experience all over of the photographer. Some ladies invariably hate their new photographs. Perhaps they discover (a discovery, by the way, not always made known to the photographer) that the dress they were photographed in does not suit them, or that some little peculiarity in the gown has been made manifest by the camera, and so they do not like the photograph. Not a few regard being photographed as they regard shopping—an occupation which demands a great variety to be shown them before they can make up their minds. The idea of having but a single photograph to approve, or the reverse, is a species of Hobson's choice which is almost repulsive. All this makes the photographing of some ladies a nervous undertaking, not to be regarded lightly by the photographer.

Quite an unique collection of photographs is in progress of arrangement at Moscow. The idea has originated with the Baroness Klara von der Deckler, of Tiflis, who has sent a circular letter to the beautiful women of the world, asking them to forward their photographs to her. These photographs will be examined by a committee of artists, and those approved of will be placed in an album to be entitled, "Types of Female Beauty of the last years of the Nineteenth Century," and deposited in a museum at Moscow for preservation. All this is interesting, but one would like to know what plan the Baroness has adopted to find out the beautiful women. She must have names and addresses, because a letter simply addressed, for instance, to the most beautiful woman in London, would have sufficient claimants to puzzle the Post Office.

The Royal Geographical Society has taken a step in the right direction. It is now alive to the fact that there are not only such persons in the world as amateur photographers, but that now-a-days there is scarcely a man who travels who has not a photographic kit stowed away somewhere in his luggage. The Council of the Society has therefore issued a request to all the Fellows to forward copies of any photographs they may have taken during their travels, to the map curator of the Society. Should the donor have purchased the photographs, he is desired to give the name and address of the photographer for reference. If this idea be well supported by the numerous travellers who belong to the Society, a valuable collection will be accumulated.

Epping Forest is becoming one of the happy hunting grounds of the amateur photographer. A stroll through its woodland glades the other day revealed the fact that not one, but dozens, had selected the place for photographic study. Somebody recently complained that when setting up his camera he was stopped by one of the keepers, but surely this must be a mistake. The only explanation possible is that the amateur intended to photograph a group of friends, and that the keeper mistook him for one of the peripatetic professionals who, we presume, either pay for the privilege of making a living out of the visitors, or have a licence from the Common Council.

The occupation of the peripatetic photographer, by the way, must have been seriously interfered with by the amateur. Save on such places as Hampstead Heath, Epping Forest, and Clapham Common on popular holidays, he cannot have much to do. Even among the working classes cameras are becoming common enough, and in hosts of little suburban back gardens on Sundays they may be seen at work.

THE ROYAL ACADEMY OF ARTS, 1890.

BY THE REV. F. C. LAMBERT, M.A.

GALLERY No. 3.—No. 186 ("Onwards," Sir John Gilbert, R.A). Our first feeling is that the frame is too small for the picture, and that the horse will shatter the whole thing to atoms, and dash out the brains of the unfortunate rider. No one can say that there is not plenty of "go" here.

In No. 190 ("Departing Day," Peter Graham, R.A.) we miss the cattle, and feel the rose-red mountain crowns are what the street-hawkers describe as "'ighly coloured"; but, in spite of the vivid tint, the scene is a beautiful one.

No. 195 ("A Smithy," W. C. Symons). This is coming nearer home—*i.e.*, nearer the photographer's pasturage—and is well worth careful examination, both for pose, arrangement, tint, and tone. The *realities* of life are the *natural* food for the camera.

Two pictures by Walter J. Shaw, No. 200 ("Off Bolt Head"), and 206 ("A November Day"), are such grey and green seas as have been seen (and tried for) on many a focussing screen.

The large and central picture of this end, No. 203 ("Redemption of Tannhäuser," Frank Dicksee, A.), the work of an Associate, put in this place of honour for the first time, speaks for itself. It is almost superfluous to say that it is altogether a masterpiece. Note the earnest expressions of the youthful acolytes; the central massing and grouping of the "whites," and of the "blacks," at side; the sacerdotal, inflexible dignity of the priest—movement of the messenger bringing the symbol of absolution; sympathy of the pilgrim band; the emotion in that *one* hand of the utterly broken Tannhäuser; the unity throughout, and general convergence towards the leading theme; breadth of treatment, and warm glow of declining day. All go to befit it for its place of honour.

There are two portrait studies near here, pointing a lesson to the portrait photographer—Nos. 204 (by James Sant, R.A.) and 211 (by H. T. Wells, R.A). Note carefully the open lips. There are very few people who can keep their mouth shut, either literally or metaphorically; fewer still who can do this gracefully; and still fewer when before the lens, especially when *told* to "close the lips and look cheerful." Therefore, do not make everyone close his lips when before the lens, if he seldom or ever closes them away from that cannon's mouth.

In portraiture, note again No. 212 (by E. J. Poynter, R.A.), how a lovely face may be detracted from by a distressing background.

No. 215 ("Low Tide," Peter Graham, R.A.) pleases one more by his figures and the bit of rock they are on, than the rest of that picture.

In No. 224 ("Rus in Urbe," Briton Riviere, R.A.) we take to the "collie" rather than to the boy; and again, in No. 225 ("The Anxious Look-Out," Thomas Faed, R.A.), the faces are not to our liking—quite.

No. 234 ("Thames, Dorchester," Vicat Cole, R.A). Here is some fine cloud drawing, and the "swirl" of the eddying waters is good to look upon, but the trees—a larger stop . . .!

No. 235 ("Portraits," W. O. Orchardson, R.A.) contains many a hint to the taker of groups.

Let us now consider together: No. 241 ("Outward Bound"), No. 248 ("Stand by"), and No. 76 ("All hands shorten sail," in room 1, all by Frank Brangwyn). No need to refer to catalogue to know that these three are off the same palette; almost monochrome—in cool tint and low in tone—broad, and simply, relying on drawing with true values, and lo! the picture grows. In No. 76, that unruly bucket, rolling from the lurch of the ship, seems somewhat "too sharp" to give a satisfactory idea of its erratic motion; possibly its entire omission might have been an advantage. This is a debatable point, of course; but, anyhow, the residuum of success goes far to support the dictum frequently attributed to Turner, viz., "it is the *greys* which make the picture."

Now look below at No. 243 ("Bath of Psyche," by Sir F. Leighton, P.R.A.), call to mind No. 166, and see opposite, No. 310 ("The Tragic Poetess"), by the same master, and each in their severe, yet befitting classic frame-surroundings. Psyche, the beloved of Eros (Cupid), and rival of Aphrodite (Venus), the personification of the human soul purified by passion and misfortune, and so prepared for perfect purity and happiness; the Dawn in search of the life-giving sun, &c. One needs such exquisitely beautiful manifestations as these to enable the ordinary mind to participate in the rich, boundless imagery of ancient Greece. Such creatures—*i.e.*, creations as these—we at once feel are not made of ordinary human clay. Nor are they, I take it, ever intended to be looked upon in that light. Art is as manifold, not only as nature herself, but also as many sided as the creatures which a cultured imagination can conceive, or create, upon a basis of idealised nature. And, although just for the moment it is not easy to fully grasp the foreshortening of the left arm of the Tragic Poetess, nevertheless the creation, idealisation of her care-burdened beauty, the inexorable sweetness of the face, gives one a fuller meaning to the conception, *Nemesis*. The deities of classic times were a reality then, such as but few can now realise, and those few alone can reveal them to us. Each of the three pictures helps one to realise that poetry is not for the ear alone. That they are not to be thought of as made of human clay, one has but to glance to the next frame, No. 249 ("A Jib for the New Smack," J. C. Hook, R.A.), where the hardy toilers of the deep are further hardened by their toil.

In No. 258 ("The Terrace," G. D. Leslie, R.A.), one's sympathy goes out towards the young lady, who, with justice, might repudiate being so utterly ignored in the title, and, as a matter of arrangement, we should have preferred the basket of flowers being almost anywhere else rather than where it is

No. 266 ("Brixham Trawlers," C. Stoney) is an old and familiar, beloved and valued, photographic friend.

No. 270 ("The Sculptor," J. B. Burgess, R.A.) is a fine work. The sculptor is the sort of man who lives for his art, and yet is not unworthy of the loving adoration of his wife. The "Church militant" called in to pass opinion on "the clay" evidently feels *his* responsibility concerning Pia Mater, Alma Mater. Note the echo of the theme, the repetition, re-duplication of the mother and child "in the flesh," as well as "in the clay," the picture on the wall, the subdued background and surroundings, contrast of the old and the young, the relief of contrast in darks and lights, general unity throughout, and the harmony of tint and tone. Altogether, a picture to study and learn much from.

No. 271 ("Loch Katrine," J. MacWhirter, A). An instructive study for the camera-man; shows the value of a subordinate figure. Note its position, relative size, and balance, the simple scale, and soft warmth of colour.

* Continued from page 374.

Also, in No. 279 ("Old Sherwood") by the same artist. Again, note the broad and simple treatment, true in tone and warmth of the after-glow; how the grouping of the bits of "life" all lead up to "that bold captain of a fearless band."

In No. 285 ("Highland Tramp Crossing a Headland," Thomas Faed, R.A.), although there is a feeling of the frame being too small for the size of the figures, and rather cramping their space to move in, yet the man's face is just simply *grand*—a bit of real life—a face with a history behind it, and worth all the rest of the picture put together.

No. 296 (Portrait, F. Goodall, R.A.), with a plain background of a rather unusual tint, which tells well against the face, and also the black and rose-coloured silk; and yet, possibly, it might have been still better had the green been of a somewhat lower tone; perhaps the hands are not quite satisfactory, but certainly the balance of the head is admirable.

No. 294 ("By the Committee Boat," W. H. Bartlett). Boys about to start for swimming race. The variation of pose is noteworthy, but we do not ever remember seeing boys (or men) racing in bathing caps.

No. 311 ("Grey Day at Newlyn," Anna Nordgren). We should very much like to have seen this picture put in a more see-able position. It is undoubtedly a carefully wrought work, in cool, low tone, nothing "painty" or shrill, but ably carrying out the feeling of a grey day: calm, sombre, quiet.

In No. 318 (Portrait), Professor Herkomer shows us his well-known skill in portraiture, and, in No. 319 ("Poverty and Progress," A. H. Y. Titcomb), shows the power of "reality" treated with simplicity, truth, and breadth, the "common-place" conveying true pathos. The world is full enough of *subject*; it only wants *seeing*.

No. 324 ("Frigidarium," L. Alma-Tadema, R.A). The interior of a Roman bath, where, at the time represented, it was customary to begin with a Calidarium (hot bath) or Tepidarium (tepid), and take the Frigidarium (cold) afterwards. The cold bath was in great repute after Antonius Musa recovered Augustus from a dangerous disease by the use of it, but fell into discredit after the death of Marcellus, which was attributed to the injudicious use of this remedy. Of course the marble and draperies are all that this painter has taught us to expect, yet, nevertheless, we have seen several of his larger works which have pleased us much more.

Of the two diploma pictures, No. 337 ("Freedom of the Press," J. B. Burgess, R.A.), and No. 338 ("On the North Foreland, W. O. Orchardson, R.A.), the "censors of the press" will probably appeal most strongly to the photographic instinct. Several notes may here be made—in pose, general arrangement of subject, and chiaroscuro.

In No. 328 ("Garden Flowers," Marcus Stone, R.A.), the garden steps and girlish beauty call to mind similar pictures (and backgrounds), yet the youthful grace of the figure, the flower of the "posie," is restful for the eye to dwell upon. The title, "The world went very well" (No. 302, by John Pettie, R.A.) calls up "All in a garden fair."

While at this end of the room, take a distant view of two large portrait studies—No. 269 (C. Calthrop), and No. 292 (P. R. Morris, A.R.A). Both bring to mind the effect produced by using a too short focus lens—not "(wide-angle)-wisely, but too well"—(revised edition). Is this effect contributed to by being hung aloft?

PHOTOGRAPHIC LENSES.*

BY THOMAS R. DALLMEYER.

FROM the general formula deduced from the three investigations above, applied to a case to find the distance of the diaphragm and the radii of the surfaces most favourable to the formation of a distinct image, it is found that it is

not possible to form an image perfectly distinct on a plane, although a distinct image can be formed on a curved spherical surface, the curvature of which is dependent on the refractive index and the focal length; in fact, its radius is μ F.

In these two cases (shown on black board), the diaphragm in one case is situated behind the lens at a distance

$$\frac{\mu - 1}{\mu^2 + \mu + 1} f.$$

Radius $R = \frac{\mu - 1}{\mu^2} f.$ Radius $S = -\frac{1}{\mu - 1} f.$

The other case is in the plano-convex lens, where the distance of the diaphragm

$$= \frac{\mu - 1}{\mu} f$$

$$r = \infty$$

$$s = (\mu - 1) f.$$

And as the curvature of field is dependent on μ, the higher the refractive index, the less curved will the field become. The effect of the diaphragm has a most important bearing on astigmatism, curvature of field, and distortion. In connection with astigmatism, the use of the diaphragm is the only means, in a single lens or system of lenses, of diminishing it if it should exist. On curvature of field and distortion it acts in exactly opposite directions in single lenses or single cemented combinations of more than one lens.

Take the case of the plano-convex lens above with a small diaphragm in contact. The curvature of field here will be very considerable, but the distortion practically *nil*. Now the further the diaphragm is removed from the lens the greater becomes the distortion, but the less the curvature.

It will be seen that by limiting the aperture the image-forming rays for each small pencil are closer together, and are not interfered with by those that have shorter foci, and would meet the lens at far greater refracting angles if the full aperture were employed. The further the diaphragm is removed, the flatter does the field become, but more distortion is introduced.

(*d.*) Distortion. The usual and simplest manner to describe this is to find the appearance after refraction of a square grating when the diaphragm, supposed small, is placed in front of the lens, and the field "flat" or cured of curvature. Where the refracting angle is greatest, viz., furthest away from the axis, the pencils are more refracted towards the axis than they are as they approach the axis, the axis itself suffering no displacement. The single rays of course may be taken as the axes of pencils. You

* Continued from p. 372.

will thus see that the pencils representing the lines become convergent towards the axis. This distortion is known as "barrel-shape" distortion. The opposite distortion, called pin-cushion, occurs if the diaphragm be placed behind the lens. The "barrel-shape" distortion is generally considered the less disagreeable of the two, and hence the diaphragm is usually placed in front of the single lenses.

Being now familiar with the effects of spherical aberration as produced by single lenses, and the general principles adopted to eliminate these errors, we will proceed to investigate how combinations of lenses may still further and better tend to annihilate the errors of form.

The various applications of lenses to different purposes will indicate the most appropriate directions in which to work to accomplish this. For very rapid lenses, such as are used in portraiture, it is necessary to pay strict attention to the aplanatism of the central pencil, and choosing such forms as are best suited to eliminate curvature of field, astigmatism, and distortion, but these latter are made subservient, in the main, to those of rapidity. When, however, aperture may be sacrificed, we are enabled to lay greater stress on the three latter considerations, but in every case the skill of the optician consists in the best compromise among the effects of aberration.

We have seen that a single glass lens can neither be achromatic nor aplanatic for parallel rays, but we have found that a single lens can be made achromatic by combining it with another lens of different dispersive power; the condition for axial achromatism being merely one of the correct relation between the focal length of the lenses or their powers. Let us now examine the condition for aplanatism by combination with another lens.

In the first approximation combining two lenses we have—

$$\frac{1}{v_1} = \frac{1}{f_1} - \frac{1}{u}$$
$$\frac{1}{v_2} = \frac{1}{f_2} + \frac{1}{v_1}$$
$$= \frac{1}{f_1} + \frac{1}{f_2} - \frac{1}{u}$$

so that if the lenses are in contact, the effect is the same as one lens equal to the *algebraical sum* of the *powers* of each; if the second lens was negative, for example, we should get—

$$\frac{1}{v_2} = \frac{1}{f_1} - \frac{1}{f_2} - \frac{1}{u};$$

and with any number lenses—

$$\frac{1}{v_n} = \frac{1}{f_1} + \frac{1}{f_2} + \ldots + \frac{1}{fu} - \frac{1}{u}.$$

We have found a second approximation for a single lens showing the aberration, and for our purposes here this may be put under a more convenient form.

Since $\frac{1}{u} + \frac{1}{v} = \frac{1}{f}$, and $\frac{1}{r} + \frac{1}{s} = \frac{1}{\mu - 1}\frac{1}{f}$;

Let $\frac{1}{u} = \frac{1}{2f}(1 + a)$, $\frac{1}{r} = \frac{1}{2(\mu - 1)f}(1 + x)$,

$\frac{1}{v} = \frac{1}{2f}(1 - a)$, $\frac{1}{s} = \frac{1}{2(\mu - 1)f}(1 - x)$,

If we then find the values of

$$\left\{\frac{1}{r} + \frac{1}{u}\right\}^2 \text{ and } \left\{\frac{1}{s} + \frac{1}{v}\right\}^2$$

we obtain the second approximation in a more convenient form after the necessary reductions, viz.:—

We have at the first lens,

$$\frac{1}{v_1} = \frac{1}{f} - \frac{1}{u} + \frac{1}{\mu(\mu - 1)}\left\{\frac{\mu + 2}{\mu - 1}x^2 + 4(\mu + 1)ax + (3\mu + 2)(\mu - 1)a^2 + \frac{\mu^3}{\mu - 1}\right\}\frac{y^2}{8f^3}$$

This may be written

$$\frac{1}{v_1} = \frac{1}{f_1} - \frac{1}{u} + \omega_1 y^2,$$

and on passing to the second lens

$$\frac{1}{v_2} = \frac{1}{f} - \frac{1}{u} + \omega_1 y^2$$
$$= \frac{1}{f_1} + \frac{1}{f_2} - \frac{1}{u} + (\omega_1 + \omega_2)y^2$$

and in general—

$$\frac{1}{v_2} = \frac{1}{f_1} + \frac{1}{f_2} + \frac{1}{f_3} + \ldots \frac{1}{f_n} - \frac{1}{u} + (\omega_1 + \omega_2 + \ldots \omega_n)y^2.$$

The object then for aplanatism is to make

$$\Sigma\, \omega = 0.$$

Now this can always be done by assuming a definite ratio between the radii of one lens and finding the ratio between the radii of the second that shall destroy the first aberration.

Now if we call r_1 s_1 the radii of the first lens, and r_2 s_2 the radii of the second lens, and take a form of aplanatic combination, such as the rapid rectilinear, in which both front and back combinations are identical with cemented and identical contracts.

Here s_1 and r_2 are identical except in sign, and if the glasses chosen are suited, there is only one form for the best correction for spherical aberration. The ratio of the powers is a constant, and therefore by a proper substitution in the above equations, this construction becomes a simple matter. The question evolves itself into a simple quadratic, one root of which is usually imaginary. Should both be imaginary, the glasses are unsuited to the purpose, and a symmetrical system cannot obtain.

The front combination alone, with its convexity towards the object for the oblique pencils, has a powerful coma-*in*, and the back combination alone, with its concavity outward, a powerful coma-*out*. The two in the combination have the effect of counterbalancing one another, more or less, according to the selection of suitable material; the residuum effect of aberration for the oblique pencils being visible as astigmatism or curvature of field, but distortion is destroyed. A proper selection of the new glasses certainly enables improvements in both these respects with larger apertures than was formerly possible.

For the elucidation of the possibilities of producing combinations of large aperture suited to portrait work, at a period, too, when rapidity was of the utmost importance, we owe a great debt of gratitude to the prince of mathematical opticians, Professor Petzval. His portrait combination, known to you all, was a triumph, and the result of pure analytical investigation. He proved to working opticians the possibilities of vast improvements in the instruments then made, and also confirmed them in many of their geometrical and practical deductions.

For your interest I have made a drawing, tracing the course of the rays through a Petzval combination for the oblique as well as the central pencil, and it serves to show how perfectly the mathematical elegance—perhaps I should say labour—brought to bear on this subject corresponds with the general principles then known and

worked upon for the best relation to exist between the incidence and emergence of the various pencils to form a distinct image.

I think I may be allowed to mention here, with pardonable pride, my late father's improvements in lenses generally since that period, and particularly with respect to his portrait combination. It was a great advance on that of Petzval, not only for greater covering power, but for strict mathematical capabilities. You are well aware that a lens that is free from spherical aberration for parallel rays is not so for nearer objects, but becomes what is called over-corrected for spherical aberration. Now, in addition to better optical perfection, the form of the back combination, by a mechanical contrivance of separating the back flint from the crown, will correct or counterbalance the over-correction for nearer objects if necessary, or may, on the other hand, be so far removed as to introduce, according to taste, a considerable amount of positive spherical aberration, that was first asked for by the late Mr. T. R. Williams, to soften the biting sharpness of lenses when required to produce more artistic results.

In slower lenses, where rapidity is sacrificed, a judicious selection of the powers of the elements in the combination or combinations, and arranging their curvature so that, as in the case of achromatism, the pencils at incidence and emergence are similarly treated for every part of the lens, so do we arrive at better perfection of the image, until the maintenance is so perfect that it becomes a parallel with an imaginary pinhole (without diffraction), the aperture or intensity being as great as possible consistent with this perfection.

To conclude, as photography for utilitarian purposes in the sciences and commerce require our lenses to attain the highest mathematical precision, no less does art—and photography is rapidly gaining ground as an art—require the optician to handle the subject in an equally intelligent manner, to give to those instruments wider capabilities.

Photographic Society of Great Britain.—Technical meeting, Tuesday, May 27th, at 8 p.m., 5A, Pall Mall East, when "Stereoscopic Work" will be discussed.

Colonel Stuart Wortley.—We regret to have to announce the death of Colonel Stuart Wortley, who occupied a leading place in London photographic circles some years ago. His large landscape photographs and his sea views, in which the camera often faced the sun, were many of them of a highly artistic character. Not long since he went on a voyage round the world for the benefit of his health.

A Varnish Vehicle in Painting.—In a circular issued by the Aston Chemical Company of Birmingham, it is stated that an article in the *Daily Telegraph* has said:—"The late Frank Holl used as a vehicle, amber varnish, diluted may be with a little nut or purified linseed oil, to make it run more freely, and though amber varnish is found difficult to work with, it has proved to be the only durable preparation of its kind extant. Mr. Herkomer, Mr. Sant, Mr. William Hughes, and other prominent painters 'swear by amber varnish,' and the freshness of their productions of several years ago sufficiently testifies to the merits of that valuable vehicle." The circular adds that the one great drawback to the use of a varnish vehicle in painting is its rapid drying quality, causing the brush to drag, and preventing its being worked freely; and again, if an oil be mixed with amber varnish, the incorporation of the two is not complete enough to form a reliable stable mixture. Mr. Standage has overcome both these drawbacks; his medium is neither a varnish nor a simple oil, but a peculiar combination of the purest linseed oil with the finest quality of carefully hand-picked amber. No other ingredient whatever enters into its composition.

THE ROYAL INSTITUTION.

Professor Meldola on "The Invisible Photographic Image."

Last Friday night Professor R. Meldola delivered a lecture at the Royal Institution upon "The Invisible Photographic Image." Dr. Edward Frankland, F.R.S., presided. Among those present were Captain W. de W. Abney, Professor Alexander Herschel, Mr. Paul Waterlow, Mr. Geddes, Mr. J. W. Swan, Mr. H. Trueman Wood, Lord Rayleigh, Mr. C. V. Boys, Mr. Walter Coffin, Professor Dewar, Professor Hughes, Mr. F. Goldby, Dr. J. H. Gladstone, Mr. Shelford Bidwell, and Dr. James Edmunds.

Professor Meldola began by giving an outline of the history of photography, beginning with the photographic design produced by Schultze in 1727. The next step was the considerable advance made by Wedgwood, and first made known at the Royal Institution, of spreading the sensitive compound over a surface instead of using it in mass; this was done in 1802. He told how Fox Talbot, in 1835, produced photographs on paper by means of chloride of silver, and how later on some of these photographs were brought under the notice of the Institution by Faraday. Sir John Herschel coated glass with chloride of silver by subsidence, and one of his early photographs produced in that way was exhibited. The discoveries of Niépce de Chalons and Daguerre were described, and their likenesses, together with that of Fox Talbot, were projected on the screen by means of the electric lantern. As to Dr. Thomas Young's photograph of Newton's rings, taken in 1803, Professor Dewar by search had found on the premises what was believed to be the appliance made by him for producing the rings, and, as they could see, some of the rings were distinctly visible. The lecturer spoke of the discovery of the action of light on bichromate of potash by Mungo Ponton, then entered into historical details of later date.

The speaker pointed out how silver chloride becomes discoloured under the action of light and at the same time gives off chlorine, or, under some circumstances, hypochlorous acid. Bromine acts in analagous manner under the action of light, and silver iodide does so only when a halogen absorbent is present. The amount of darkening produced has no relation to the relative sensitiveness of the three haloids; it only means that some of the products are more highly coloured than others. Evidently the action is one of photo-chemical decomposition, and is not a mechanical change. Substances which absorb the liberated halogen accelerate the decomposition; oxidising substances act as retarding agents. Captain Abney has made this his own special subject, and it is evident that a ray of light falling on a silver haloid is doing chemical work. The chemical nature of the coloured product resulting from decomposition by light is still shrouded in mystery; all that is known is, that it contains less of the halogen; it is never formed except as a mere trace, mixed with a relatively vast mass of unaltered haloid. Carey Lea has called such products photo-salts, meaning thereby a combination of each dark product with unchanged haloid. He (Professor Meldola) thought that the free metal theory of the deposit hardly holds good, because chloride of silver will darken in the light under strong nitric acid, and the latter acid would dissolve the dark product if it were silver. The sub-haloid theory may be true, but still it has not been established in such a way as the chemist has the right to demand.

The oxychloride theory is also without vigorous proof. He had put most carefully dried silver chloride under dried liquid hydrocarbons, and in every instance it had darkened under the action of light; such results, however, merely raise the question, what are the kinds of products due to the medium in which the decomposition takes place? When chloride of silver darkens under water, an oxychloride may be formed.

Mr. Carey Lea has recently formed some beautifully coloured compounds of silver, which he thinks to be identical with those which form the photographic image. In 1859, a committee of the British Association described something of the same kind, and how to form red silver chloride.

The invisible photographic image is now formed in a minute fraction of a second, but there is good reason to believe that it is analagous in composition to the photo-salt, although it would be premature to say that it is the same. It was at one time held that the invisible image is due to a molecular and not a chemical change, an idea which he believed to still survive. Reducing and oxidising agents act in the same way upon the visible and upon the invisible image, and halogen absorbents make modern films more sensitive still, which facts tend to show that the image is of the same nature in both cases.

Carey Lea, Eder, and Abney have shown that mechanical pressure will produce the same effect upon a sensitive film as that which is produced by light, but a halogen absorbent must be present; and, if the result of the action of stress or light were merely mechanical, he could not see the necessity for the presence of the halogen absorbent. That this absorbent must be present is a fact strongly in favour of the chemical theory of the invisible image. The experiments of Mr. Spring, of Liége, show that in some instances when great pressure is brought to bear upon certain dry salts, chemical reactions are set up; something of the same kind seems to take place when light acts upon a silver haloid. In conclusion, he thought that the scientific foundations of the problem of the nature of the invisible image must be laid by the chemist; but the problem is a difficult one, because the photo-salts of Lea are not of such a definite nature as those with which the chemist is in the habit of dealing.

We postpone a criticism of this lecture until the full text has been published.

North Middlesex Photographic Club.—An outing of this Club will take place on Monday, May 26th; the members will meet at Paddington Station at 10 a.m., and proceed to Cookham and work to Maidenhead. Friends and visitors are invited to join.

The Late Mr. W. H. Geddes. — In the course of an obituary notice the *Arbroath Guide* says:—"Mr Geddes is best known from his connection with photography in Arbroath, and in that connection he is known far and wide. He was the oldest photographer in the town, and indeed it was his brother Thomas who introduced the art into Arbroath. Mr. Thomas Geddes had his joinery shop in North Grimsby, and somewhere about the year 1848, while continuing to carry on that business, he opened a photographic studio in High Street. At that time the Daguerrotype was the common form of photography, but shortly after starting the business Mr. Geddes began to take portraits on glass, and he continued long enough in practice in Arbroath to introduce also the taking of photographs on prepared paper as at present. In 1851 Mr. Thomas Geddes emigrated to Australia, and his brother William took up the photographer's business, doing good work. Since then the business has been much developed by his son, who will carry it on under the same title as before.

FICTION IN PHOTOGRAPHY.

The story of a Strange Sitter, also told by an American of Americans, has a wholly unexpected finale, and so possesses one of the most interesting features in historical narrative—that, namely, of surprise. It is Christmas Eve; the hour is within a few minutes of midnight; outside the closely-fastened shutters the wind is howling, driving the blinding snow into the eyes of a few solitary wayfarers who are luckless enough to be out of doors at such a season and at such a time. The photographer's little parlour is rendered still more cosy by the charms of contrast. All is comfortable here. Cigars are lighted, fresh glasses of toddy, with the due quantum of lemon peel, are supplied; chairs are drawn closer round the roaring fire—the matter of drawing closer of chairs is *de rigueur*—and the American artist and host begins his tale, a long one, of which the following is a short summary.

I lived at that time, says the narrator, next door to a boarding house, which supplied me with frequent customers. One afternoon, about a week before Christmas, a certain Captain Adolphus Smith called to have his portrait taken. He was a remarkably handsome man, "clustering curls waved round his chiselled brow," and so on. He was also very particular about the appearance of his necktie. Two days after his visit, while I was working at his portrait, I was started by a voice immediately behind my chair. I turned and saw a young girl of a pale ghastly appearance, dressed entirely in white, with a single red rose in her bosom. "I wish," she said, "for a carte-de-visite, to be given, when finished, to Captain Smith." In a state of extreme excitement, I took the necessary negative without the slightest trouble. The girl remained motionless, and in a good position. When I returned with the plate she was gone, and I should have thought the whole matter a dream, had there not been a material greenback, which was not there before, lying on my table. In due time I gave the Captain his own portrait and that of the mysterious young woman. "What!" he cried, in a voice hoarse and almost inarticulate with rage, "what is this?" and fell to the floor in a fainting fit. It was afterwards explained to me that the portrait was that of a Miss Susan Robinson, who had fallen in love with the Captain, had been treated by him with much unkindness after kindness; had received, in short, her *coup de grace* from the Captain's cruelty, and had died some twelve months before she appeared in my studio. So far, says the photographer, it seems evident that I had taken the photograph of a ghost; but there is more to come. Some months afterwards, a lady from the boarding-house chanced, in looking at my scrap-book, to light upon the portrait of my strange sitter. "Ah!" she said, "I see you have taken Miss Sarah Robinson." "Pardon me," said I, "Susan." "No, no, Sarah," replied the lady; "Susan died over a year ago. This is the portrait of her twin sister, who was staying in our boarding-house last Christmas." I then learnt, says the photographer, that Miss Sarah was subject to epilepsy, and had been treated with nitrate of silver, which, lodging in the tissues of her skin, had imparted to it a permanent livid colour, fully accounting for my spectral sitter's ghastly appearance. She had probably seen the Captain enter my studio, and being acquainted with the whole story of her sister's unhappy love, had determined to give that gay soldier a lesson. Not, I fear, to any good purpose, concludes

* Continued from page 337.

the story teller, since the last I heard of him was that he was one of the most notorious male flirts in New York.

Another story of several pages professes to show what may be done by a photograph. "Only a Photograph," is the title, but from a photograph arises—not probably for the first or the last time—a wedding. The reader is introduced to the Picture Gallery at Antwerp, where a visitor, Mr. Brown, has received another man's hat in exchange for his own, which he had left in the charge of the proper official. Now, Mr. Brown's hat had the distinction of holding a lady's photograph fastened to the top lining. The gentleman who has received this hat for his own sees the picture, becomes enamoured of the shadow, and seeks the substance. For some time his efforts are fruitless. The tale gives an amusing description of his obtaining, after much toil, an introduction to a lady who, alas! though similar to his ideal, differs from it on a nearer view in some important particulars. After numerous difficulties, upon which the story dilates at large, he meets with the object of his aspiration, tells her all about the photograph, without showing it to her, and asks her advice on the subject. The lady, who loves him at first sight, finds her position a hard one. She is unwilling to assist him in discovering the girl who, she naturally supposes, is her rival. That, indeed, would be in her opinion, crowding the mourners. No: she declines to advise him. "Will you, then, see the picture?" asks the lover. "That would not be right," replies the unconscious beloved. However, being a woman—and so not entirely devoid of curiosity—she at last consents to look at it. A handsome case is handed to her, which she opens, and discovers her own portrait. The conclusion, so far as these two are concerned, may be confidently left to the reader's imagination. Only one difficulty remains for after-consideration. How did this lady's photograph find its way to the hat of the gentleman who visited the Picture Gallery at Antwerp? Mr. Brown had a sister, a friend of this lady, and the owner of her photograph. When Mr. Brown left his sister for Antwerp, she, wishing to remind him of her, pinned, on the night he left, what she thought was her own picture, in his hat. The picture was really that of her friend. And this little mistake of Miss Brown's was the cause of the marriage. Nor must the photographer be forgotten, for had the portrait been a bad one, that marriage would probably never have taken place.

In the next tale, a photograph, so far from producing a marriage, nearly produces a divorce. The interest of this story of a tragi-comic character turns on an error in a number affixed to a negative. It is told by a rising photographer, who begins by numbering his negatives as people sometimes number their cheques—with thousands for units. The dramatis personæ are a young man with an old and jealous wife, and a middle-aged friend who has formerly been a suitor for her hand. The old lady, of course, has money. One day this former suitor comes to bid her farewell. He is compelled, he says, in a sad and mysterious tone, to leave England for ever. The old lady receives this intimation with calm composure. "You are one of my husband's most intimate friends," she observes: "can you tell me anything about him—I mean as to what he does when away from me—before you go?" "Nothing," he replies; "yet stay! last Wednesday he visited a photographer's with me. Go to that photographer's and ask for No. 99,999. When you obtain the unfortunate's portrait, it will explain all"; and without a word more he was gone. The unfortunate! Horror-struck, the wife, already in her imagination abandoned, visits the photographer who tells the story—the photographer indicated by her former suitor—and asks for the fatal number. She receives it, utters a shriek, and faints. The husband returns home unsuspicious to his meat tea. The kettle is boiling on the hob, the cat lies in her accustomed place on the hearth-rug, but his wife—ah! his wife—has become a fury. "Look," she cries with vindictive emphasis, "at this," and thrusts No. 99,999 before his astonished eyes. "Well," says her husband, "what of it?" It is a pretty face, in a dress very fashionable and very low cut. "It is," says the wife, "a brazen hussy, and you ought to be ashamed of yourself." "Why on earth should I?" asks the innocent husband; "I never saw the woman in my life." "Oh, the perfidy of mankind!" she groans in reply, and threatens the divorce court. At this juncture the former suitor comes in radiant. He learns what is the matter, and asks to see No. 99,999. "Good gracious!" he exclaims, "here is some mistake. No. 99,999 is the number of my own portrait, and it has been affixed to the portrait of—well, somebody else." "Your sister," he continues, turning to the lady, "had refused me, I had determined to leave for America, and I was anxious to let you have my own portrait which I had taken for her. However, she and I have made it all up now, and you must do the same." "The mistake," says the photographer, "was owing to the negligence of a careless boy, whom I was unwise enough to employ as a clerk. It very nearly made me a witness in proceedings in the Divorce Court.

(*To be continued*).

PHOTOGRAPHIC MOUNTS.

The *Liverpool Daily Courier* of Saturday and Monday last contains a report of a case which came before Mr. Justice Lawrence and a special jury at the Nisi Prius Court, Liverpool spring assizes.

The *Courier* of Monday last says:—"This was a part heard action by Aaron Vandyke, photographer, Bold Street, to recover damages for breach of contract from Marion and Co., wholesale dealers in fancy and photographic goods, London and Paris. Mr. J. C. Bigham, Q.C., with Mr. T. S. Little (instructed by Mr. Walter H. Cowl), appeared for the plaintiff; and Mr. W. R. Kennedy, Q.C., with Mr. Pickford (instructed by Mr. Henry White, of London), for the defendants. The plaintiff purchased from the defendants, about the end of 1886, 50,000 enamelled cabinet mounts, which were alleged to be defective, photographs mounted on them exhibiting signs of streakiness after the lapse of a few months. This, the plaintiff contended, was due to the presence in the mounts of hyposulphites, caused by insufficient washing during the process of manufacture. On the other hand, the defence was that the streaks in the photographs were to be attributed to lactic acid, produced by fermentation of the germs in the solution of starch used by the plaintiff in mounting the photographs. Further evidence was given for the defendants, among the witnesses examined being Mr. Thomas Bolas, F.C.S., Mr. Frank Bishop, a partner in the firm of Marion and Co., Mr. Cowan, photographic specialist, Mr. George Taylor, Mr. W. Downey, and Mr. Mowll, photographers. After considering their verdict for three-quarters of an hour, the jury returned into court, the foreman announcing that there was no possibility of their agreeing. His Lordship, however, said they must make another effort to arrive at a definite decision. In reply to the jury the plaintiff expressed his willingness to take the verdict of the majority, but to this the defendants refused to assent. The jury again retired, but as after two hours' further deliberation they were unable to agree, they were discharged."

Specifications Published.

9,358. *June 5th*, 1889.—"The Production of Alloys of Aluminium." Robert Ellis Green, late of No. 41, Sandringham Road, Hackney, now of No. 5, St. John's Terrace, Southall, Merchant.

This invention relates to the production of alloys of aluminium with any other alloy-forming metal; its object is to produce such alloys, not by combining metallic aluminium, which has already been produced, with a metal, but directly by decomposing the fluorides of aluminium or the double fluorides of aluminium and potassium or sodium in the presence of the metal with which it is desired to form an alloy.

To illustrate the manner of carrying out the invention, I proceed to describe the details of the process when the object is to form an alloy of aluminium and iron.

I use a crucible or retort or any suitable furnace which will bear the heat at which iron becomes fused; at the lower part of the crucible or furnace I fix a tuyère or inlet pipe, connected to a supply of carburetted hydrogen or hydrogen gas. I place in the crucible or furnace iron, and fluoride of aluminium, or the double fluoride of aluminium, and sodium or potassium, and sometimes white sand (silica) or silicate of soda, or potash, or other compound of silicon if it be necessary; that is to say, that inasmuch as many qualities of iron contain silicon, I am guided by the amount of it that is contained in the iron which I am about to use. Thus, if the iron be free from silicon, and when desiring to produce an alloy of aluminium and iron which shall contain one per cent. of the former, to every 100 lbs. of such iron which I put into the crucible or furnace, I add 8 lbs. cryolite (double fluoride of aluminium and sodium), and 35 ounces silicate of soda, or 40 ounces silicate of potash, or 32 ounces silicon disulphide, or 26 ounces of white sand, and I lessen the quantity of silicon compound which must be placed in the crucible or furnace in proportion to the amount of silicon contained in the iron in accordance with the chemical combining proportion.

Having made these calculations and put the necessary quantities of each material into the crucible or furnace, and turned on the supply of gas through the tuyère, I gradually raise the temperature of the crucible or furnace till the whole contents have become fused. I keep up this heat for about thirty minutes, when the fluoride having decomposed, its aluminium is absorbed by the iron and the alloy formed, and is ready to be drawn off into moulds.

When forming alloys of aluminium with other metals I proceed in the same manner, and use the same materials, except that I substitute the other metal with which I wish to alloy the aluminium in place of the iron as above.

What I claim is:—

1st. The production of alloys of aluminium in the manner described.

2nd. The production of alloys of aluminium direct from the fluorides of aluminium, or the double fluorides of aluminium, and sodium or potassium, and silica, or compounds of silicon reacting upon each other in the presence of a metal.

10,594. *July 1st*, 1889.—"Shutters for Photographic Cameras." John Kershaw, 47, Spring Gardens, Buxton, Derbyshire, Photographer.

The improvements which are the subject of this invention relate to the means employed for closing the spring blind in the shutter of a photographic camera, and the object of this invention is to construct a shutter that may be used either as an instantaneous shutter or as a time shutter, when an interval of time for exposure is required in lieu of instantaneous exposure.

I construct a shutter in which is a spring blind with an aperture for exposure of light to the sensitive plate. By means of a gravitation lever in combination with a ratchet wheel on the end of liberating roller of spring blind, as described in the specification of my invention, for which letters patent for Great Britain were granted to me bearing date the 21st day of April, A.D. 1885, and numbered 5,014, the spring blind in the shutter may be closed instantaneously.

For the purpose of obtaining an interval of time for exposure when instantaneous exposure is not required, I employ a secondary lever of an angular shape in combination with the aforesaid gravitation lever. I suspend this secondary lever to a stud formed on a spring plate, which I attach to the side of the shutter in proximity to the gravitation lever. I form an angular slot or cam groove in this secondary lever, through which I pass a stud which is attached to the gravitation lever. On the end of the liberating roller of spring blind I attach a worm which, when the said liberating roller is revolved by the operator in order to wind the blind on, the said roller, preparatory to exposure, actuates a worm wheel affixed to the side of the shutter. I form this worm wheel with a hole in the face thereof, into which a stud attached to the aforesaid spring plate is caused to enter by the action of the spring plate, when the ratchet wheel is revolved and the before-mentioned hole comes opposite the stud in spring plate. I attach a pawl to the aforesaid spring plate, which engages with and prevents rotation of the ratchet wheel affixed to the end of the blind roller immediately the said stud enters the hole in the face of the worm wheel, but not at any other time.

When it is required to close the spring blind instantaneously, the herein-above-described secondary lever remains inactive, and the spring blind in the shutter is instantaneously closed by one compression of the air bulb which is attached to the pneumatic tube acting on the gravitation lever; but when it is preferred to obtain an interval of time for exposure, the said secondary lever, in which is a cam groove, is set at an angle which necessitates a second compression of the air bulb in order to close the blind or shutter, the first compression causing the blind to open and remain open until the second compression of the air bulb, which releases the pawl from the ratchet wheel by the return of secondary lever to its original position, and thus permits the spring blind to close.

To obviate concussion in checking the blind when the said blind is required to be kept open to obtain a longer exposure,

I place in the liberating roller a coil spring with a resistance which is insufficient to neutralise the action of the spring contained in the bottom or receiving roller for the blind, but is sufficient to prevent concussion.

When it is required to give more exposure to the foreground than to the sky, I cause the aperture in the blind to open from the bottom of the shutter by placing the coil spring in the receiving roller in the upper part of the shutter, by which means the blind is caused to pass from the liberating roller contained in the upper part of the shutter, over the tension roller at the bottom of the shutter, and, returning upwards, is wound on the receiving roller.

10,504. *June 28th*, 1889.—"Deciding the Correct Exposure in Platinotype Printing." CHARLES ROBERT CRAWFORD, 10, Monmouth Road, Bayswater, London, Gentleman.

I take a negative of a number or series of letters, or figures, or signs, and when this negative has been duly developed and properly treated for printing, I cover the first letter, or figure, or sign with one layer of fine tracing paper or other suitable material, and the second letter, or figure, or sign with two layers of paper or material, and the third letter, or figure, or sign with three layers of paper or material, and so on, providing as many letters, or figures, or signs as may be desired, and covering the same, if necessary, with glass, and under this negative so treated I place a piece of ordinary sensitised paper, enclosing the whole in a suitable printing frame. In the same frame, or in another by its side, I place the platinotype paper under its negative, which has also been properly treated, and I give these two prints the same exposure until the platinotype print has been correctly exposed, when I note the letter, or figure, or sign that is just visible in the first mentioned or deciding print. The next prints are arranged for and from both the negatives in the same way, and when the letter, or figure, or sign noted as above is again just visible in the deciding print, the correct exposure has again been given to the platinotype print, and in this manner all these platinotype prints will be exactly alike when they are finished off in the usual manner, care being taken that the bath is kept at about the same temperature. When the trial exposure has not been quite exactly correct, it will be easy to make a due allowance therefor, and note a letter, or figure, or sign before or behind that which is just visible as aforesaid.

9,403 *June 6th*, 1889.—"Apparatus for Copying by Photography." ARCHIBALD BARR, Professor of Engineering, and WILLIAM STROUD, Professor of Physics, both of the Yorkshire College, Leeds.

Our invention has reference to the copying by means of photography of pictures, drawings, book illustrations, and the like, more especially for cases in which it is desirable to have the reproductions or negatives of all one size, or restricted to a very few definite sizes. Now the object of our invention is to provide an apparatus by means of which such copying may be effected with ease, rapidity, and accuracy.

Such an apparatus should provide or consist of means, (1) for properly supporting the book or picture; and (2) for supporting the camera, and adjusting the same at the proper height and distance, and in the proper position with reference to the picture, and also for focussing the same. One of the most useful cases to which our invention may be applied is the production for lecture use of lantern slides of illustrations from books, and we shall describe our invention with reference to such use, as this, perhaps, best illustrates and ascertains the nature of our invention.

An apparatus constructed in accordance with our invention consists in the first place, of a holder or support for the book. Such holder may conveniently consist of a box-shaped frame, open at the front, and provided at the back with two sliding boards arranged so that they can be simultaneously and to an equal extent moved towards or from a central vertical line. The upper edges of the boards may be arranged to move in a narrow groove in the under side of the top board of the frame close to the back edge thereof. The lower edges of the sliding boards may be similarly fitted to slide in grooves in the bottom of the frame, or provided with lugs or bosses fitting on a tubular or plain slide or guide bar. The two sliding boards are so connected together that they are constrained to move simultaneously and to an equal extent towards or from the centre vertical line (in which their inner edges would meet if closed up). This may be effected by suitable link mechanism, but is perhaps most conveniently carried out by providing each sliding board at its lower end with a tapped or screwed boss or socket, fitting respectively on opposite (*i.e.*, the right and left hand) side portions of a quick pitched right and left handed screw. In this case a guide for the lower edges of the sliding boards as above mentioned is unnecessary. The book, opened to the page containing the illustration to be copied, is placed with this page against the back sliding boards, which have been opened the necessary distance so as to expose the illustration to be copied. The opposite page of the book is laid on the top board of the frame at the back thereof, and a pointer or index attached to one or other of the sliding boards facilitates the adjustment of the boards to give the proper opening, the size of which may have been previously ascertained by measurement from the illustration. A couple of Argand gas burners, or other source of light, placed one towards each side, and towards the front of the frame, supply the necessary illumination for the picture; the front of the frame being, of course, covered in so much at each side, as to exclude the direct light from the lens of the camera. Instead of using artificial light, the frame may be arranged and placed so as to expose the illustration to be copied in daylight.

The second part of our invention relates to the means for supporting, adjusting, and focussing the camera. The camera is supported by mechanism for adjusting it to the proper height (to be afterwards described) from a frame or carriage capable of being moved on a railway or longitudinal guide, so that the centre line of the camera may be moved to and fro in a direction at right angles to the back of the frame or book-holder, *i.e.*, to the illustration to be copied. An index or pointer attached to the carriage or frame, and a scale of equal parts fixed on the side of the railway or longitudinal guide, enables the camera to be at once adjusted at the proper distance from the book holder to produce a negative of the desired size.

The scale is most conveniently graduated and marked according to the longest dimension of the picture to be copied, so that when the camera is placed with the index opposite this division, the image of the picture in the camera will be of the desired effect.

The camera is supported from the carriage or frame by means of a parallel motion, so constructed as to keep the camera in a perfectly horizontal position both longitudinally and transversely, and preferably so as to constrain the camera to move in a vertical line, so that its up and down motion may not affect its distance from the book-holder. Such a parallel motion may consist of two pairs of hinged boards (or equivalent link connections), the angular or radial movement of the one pair being at right angles to the angular or radial movement of the other pair. Or the two pairs may be arranged with their angular or radial movements in the same sense or direction, in which case a vertical guide and a connecting board or rods joining the middle hinge is required in order to keep the camera perfectly horizontal in a longitudinal direction. The lower boards hinged to the carriage or frame may further be prolonged below the point or axes at which they are hinged to the frame or carriage, and carry a balance weight or weights to facilitate the raising and lowering of the camera; or a spring may be introduced so as to balance or partially balance the weight of the camera. Such spring may be conveniently introduced at the hinge connecting a pair of radial boards or frames. A pointer attached to the camera, and a vertical scale of equal parts fixed to the carriage or frame, facilitate the adjustment of the camera to the proper height, a scale of equal parts being also attached to the inner edge of one or both of the sliding boards of the book-holder, for reading off the requisite height of the camera. The movable or negative end of the camera is provided with a pointer or index, and the base of the camera with a scale of reciprocals for facilitating the focussing of the camera; the graduations and markings of

this scale being made to correspond with those of the scale indicating the distance of the camera from the book-holder. By the arrangement of scales described, if a picture, for example, having twelve inches as its longest dimensions is to be reproduced, the camera is to be removed to the mark twelve on the railway, and the back end of the camera to the mark twelve on the base board of the camera.

Provision may be made for securing the camera in any position in which it may have been adjusted.

In order to facilitate the use of the apparatus for the production of positives from negatives, provision may be made for supporting the negative in the same position as that described for the book-holder; or provision may be made to alter the position, and a second pointer or index attached to the camera carriage at a distance from the other equal to the distance between the front and back of the book-holder.

To support loose drawings, photographs, pictures, we may provide a board to which they may be fixed, such board being furnished with a ledge or brackets at right angles thereto, so as to rest upon the top board of the frame.

7,983. *May 14th*, 1889.—"Making Lantern Slides for Copying." Walter Griffiths, Highgate Square, Mosley Road, Birmingham, Manufacturer.

My invention consists of a new and more convenient arrangement for holding photographic negatives or positives—lenses and sensitive plates for the production of lantern slides, transparencies, or other copies of the aforesaid photographic negatives or positives—in such a way that the instrument is always ready fixed as regards the required size, the required position, and the required focus of the said photographic picture, and without the necessity of any preparing whatever, as distinguished from the ordinary methods and necessities in producing lantern slides and transpareneies.

I carry out my invention as follows:—

The focus of the lens to be used having been discovered or determined, I prepare a tube, preferably square, and of the length to suit the said focus. This tube may be of any suitable material, such as wood, metal, mill-board, or straw-board, &c., or a combination of these materials; as an instance I use wood, straw-board, and cloth combined. Into one end of this tube, which I will call the "front," I fix a grooved frame, into which to slide the photographic negative or other plate, and which is thereby held in the required position.

These grooves are made to fit any one size of plate, such as the standard photographic sizes—6½ by 4¾ inch, 8½ by 6½ inch, &c.

Immediately in front of this groove I place, if required, a second groove, into which may be inserted a ground glass, for the better diffusion of the light passing through the negative or photographic plate, this being often desirable.

At the opposite end of the tube, or at any required distance up it, I fix a frame with an aperture in the centre, in which aperture is to be placed the sensitive plate, before-mentioned, and which may be held in position by a spring, or any of the usual devices. Between these arrangements, at each end, I insert a third frame in the aforesaid tube, this third frame carrying the lens, which is to project the picture upon the sensitive plate mentioned, and placed in the aperture mentioned.

I provide a double cap or lid, which fits over what I call the back end of the tube, its function being to protect the aforesaid sensitive plate from all light except that passing through the lens mentioned, and which light contains the image from the negative or photographic plate situated in the grooves at the front end of the tube. Small handles, or such like, may be placed on the lid or cap or other parts, for convenience in handling.

I complete the apparatus ready for use by setting the aforementioned frames in such relative positions that an image of the negative or photographic plate is projected upon any sensitive plate in the back end of the tube, with all the requisite sharpness of focus, and correct size and position, that once being fixed, all further setting may be dispensed with, and the instrument rendered always ready for immediate use.

10,092. *June 20th*, 1889.—"Improvements in the Construction of Lanterns." John Farmer Chapman, of the firm of Farmer and Chapman, of Caledonian Works, Bilston, Staffordshire. Tin-plate Workers, and Japanners and Wrought Iron Hollow-ware Manufacturers.

The object of this invention is to so construct the articles that the tops and bottoms may readily be packed as detached from the bodies, and the bodies themselves be opened out, so that they may be packed flat-wise, or approximately so, one upon the other, and the parts be readily put together and fixed in place on arrival at their destination.

The inventor claims:—

1. A lantern, or lamp, or lamp head, which is similar in character to a lantern, having the top and bottom made separately from the other portion of the body, so that they may be packed detached therefrom, and the sides, including the door (or vertically divided portions of the cylindrical part of a round lantern, lamp, or lamp head, of the character described), hinged together with hinges of which the pins may be used also to fix the top and bottom to the sides.

2. A lantern, or lamp, or lamp head, which is similar in character to a lantern, having the top and bottom made separately from the other portion of the body, so that they may be packed detached therefrom, and the sides, including the door, (or vertically divided portions of the cylindrical part of a round lantern, lamp, or lamp head, of the character described), hinged together with hinges of which the pins may be used also to fix the top and bottom to the sides, said top and bottom being provided respectively with turned-down and turned-up edges (or, in the case of a round lantern, lamp, or lamp head, of the character described, with a turned-down and turned-up portion respectively of its edge).

3. A lantern, or lamp, or lamp head, which is similar in character to a lantern, constructed substantially as described with reference to drawings.

Proceedings of Societies.

London and Provincial Photographic Association.

At the weekly meeting on the 15th inst., Mr. P. Everitt occupied the chair.

Mr. Pask passed round some silver prints showing red patches. The prints were on paper sensitised by himself; he had not experienced markings of this kind before.

Mr. W. E. Debenham thought it arose from weakness of the silver bath.

The Hon. Secretary believed the markings to be due to the paper having been kept in a damp place.

Mr. W. H. Prestwich said that he had several reams of albumenised paper toned a blue colour which he wished to decolourise; he found that a little nitrate of potash added to the fixing bath had the desired effect. He enquired if the use of the fixing bath was likely to prove detrimental to prints.

Mr. W. E. Debenham suggested the use of a chloride of lime toning bath in preference.

The Chairman showed some sheets of blotting paper made from cotton waste; it was smooth, tough, and absorbent, and well adapted for blotting off sensitised paper.

A question from the box—"Is the stability of a print increased by using an alum bath after fixing?"

Mr. W. E. Debenham believed that it was. The results of his experiments in this direction had been published.

The Chairman said that he had noticed that the tone of prints turned more purple a few days after toning, fixing, and drying.

Mr. J. S. Teape said that he had noticed the same thing.

Bristol and West of England Amateur Photographic Association.

The monthly meeting for May was held in the Queen's Hotel on the 2nd inst., Colonel Playfair in the chair, when an exhibition of slides entered by members for the Society's lantern competition took place. The slides entered were few, comparatively, but made up for the most part in quality what

was lacking in quantity. They were entered in three classes, under the heads of landscape, architecture, and figure subjects, and in sets of six or more, numbered. Members present voted during the exhibition of the several lots, and the result was declared later, Mr. E. Brightman being found ahead in all three classes.

A special feature of the evening was the use with the lime-light apparatus of the patent saturator, invented by A. W. Scott, of Weston-super-Mare. For the purpose of comparison, the ordinary mixture of oxygen and coal gas was first employed, some slides outside the competition being passed through. On the employment of the saturator, however, so marked a superiority in the illumination was at once perceptible, that all present were of opinion that the light was more than doubled. The saturator consists of a spiral worm or perforated tube, coiling through a cylinder packed with asbestos, or some similar material, and soaked in gasoline previous to use. This arrangement is encased in an outer cylindrical body of tin or brass, having a small box in conjunction with one of its sides, in which burns a wax night-light, which gives off just enough heat to vaporise the gasoline about as fast as is necessary. The tube from the oxygen cylinder being connected with the lower end of the spiral worm, a current of oxygen gas is allowed to pass through, and it "saturates" itself on its way with the gasoline vapour liberated by the warmth in the interior cylinder. Thence passing directly to the jet, it is employed precisely as the mixed gases are in the oxyhydrogen limelight, and the result is probably as good.

Professor SCOTT, the father of the inventor, conducted the demonstration, and shortly recounted the various advantages of the saturator.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

A MEETING of the Society was held in the Mayor's Parlour, Old Town Hall, on the 14th inst., Mr. GEO. BANKART in the chair. Two members were elected. The report of the excursions committee was brought up, and the following recommendations as to excursions were accepted:—June 19—To Stratford-on-Avon; July 17—Forest District; August 14—Miller's Dale, half-day; September 11—Maxstoke Priory.

The medals were then presented to the successful competitors in the print competition, held April 15, as follows:—Society's medals (for prints over whole-plate)—Silver medal, Mr. Geo. Bankart; bronze medal, Mr. F. Pierpoint. Past President's medals, presented by Mr. Geo. Bankart (for prints under whole-plate)—Silver medal, Mr. A. W. Wilson; bronze medal, Mr. W. Jolliffe.

Mr. Sculthorp having resigned his position as treasurer to the Society, the hon. sec. was requested to convey the hearty thanks of the Society to him for his past services, and Mr. A. W. Wilson was unanimously elected to the post.

THE SOCIETY OF ARTS *conversazione* will take place at the Natural History Museum, Cromwell Road, S.W., by permission of the Trustees of the British Museum, on Friday, 27th June. The reception by the Duke of Abercorn (Chairman) and the members of the Council of the Society will commence at 9.0 p.m. The bands of the Grenadier Guards and the Scots Guards will perform during the evening.

RECEIVED.—From Mr. Alfred Jubb, Huddersfield, "The Art and Practice of Interior Photography," by F. W. Mills. The book is divided into two parts, the first comprising apparatus, exposure, orthochromatic photography, the dark room, and various matters involved in making the negative. Part II. treats of the various printing processes; and this is followed by appendices giving the tables usually inserted in photographic manuals. The negatives from which the illustrations are produced were specially prepared, the author states, to illustrate the text by examples of different styles of work.——From Wilhelm Knapp, Halle A.S., the third edition of "Anleitung zur Photographie für Anfanger," edited by G. Pizzighelli. This book for beginners consists of 200 pages, and has 101 illustrations.——From Messrs. F. E. Becker and Co., illustrated and descriptive cata-logue of photographic apparatus and material; a book of nearly 200 pages, with a comprehensive index.

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

"APPLES."—*Discolouration.* The yellow marks on your print seem to be caused by atmospheric sulphuration or an escape of gas getting into the frame, for you notice that the margin, where pressure is applied, is free from yellow stain. The mount is not at fault, for all the covered parts are perfect; neither is the starch wrong. In short, unless you have recently been throwing down your silver residues, or working with sulphuretted hydrogen too near the house, we should be inclined to suppose that a leakage of coal gas, or of foul air, had tinged the whites of your print. Try a paper smeared with acetate of lead to discover the origin of these foul gases, which are evidently doing you some damage at the present time.

J. W. M. (Stroud Green).—Wants to hear of a good white light for copying purpose without resorting to electric illumination. Mr James Downey, of Eldon Street, South Shields, will give you an account of the Ligroine lamp; or, you might enquire of Messrs. T. Fletcher and Co., of Warrington.

LANE.—*Back Numbers.* If complete, or nearly so, you might offer them for sale by advertisement. Otherwise they are only valued as waste paper.

A. W. L. (Finsbury Park).—*Slow Toning of Albumen Prints.* The method of ammonia fuming ought to meet your case, and this would neutralise the excess of acid which causes you so much trouble. *Lens for Groups and Buildings.* A rapid rectilinear for 12 by 10 would be suitable, or a wide angle if you are often required to work in cramped positions.

J. A. D.—The hearing lasted three days, and many interesting points were touched upon. The jury were unable to agree, but we were told that the majority was in favour of a verdict for the defendants.

COL. WATERHOUSE.—Owing to a full programme for the May meeting, your valued communication could not be read. The date will secure priority, although it may have to stand over until June; or, very likely, it may be published in the *Journal*, if taken as read.

J. E. B. — *Bromide Prints and Platinotypes.* 1. You may readily distinguish between them by touching the prints with a drop of corrosive sublimate solution, $HgCl_2$, which has no power of acting upon platinum, whilst silver prints of any kind would be instantly bleached. 2. Quite true, the price of platinum has been very considerably advanced, being now about 54s. per ounce.

PAT.—*Leather Photographs.* Why select leather as the basis, when you can so readily obtain more uniform materials or layers on which to work? This is going back to the earliest and crudest phases of photography, such as practised by Davy and Wedgwood.

CHEMIC. — *Boride of Silver.* There need be no fear of carbon reducing boracic acid or borax in the presence of silver; the experiment referred to necessitates the employment of magnesium along with the borate of silver.

W. L. P.—We have not heard of any such forthcoming exhibition. Let us hear further particulars, if you have any definite information.

R. B. B. (Glasgow).—*Photo-Engraving.* A very good account of the photogravure process was recently given, with a practical demonstration, at the Camera Club Conference by Mr. W. T. Wilkinson. See the NEWS of March 28th, p. 237.

PHOTO-LITHO.—*New Albert Transfer Paper.* This was not procurable a few weeks ago, when we had occasion to enquire on behalf of another correspondent.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1656.—*May* 30, 1890.

CONTENTS.

PAINTERS AS JUDGES OF PHOTOGRAPHS.

IT has for a long time been the custom at photographic exhibitions to invite an artist or two—sometimes more than two—to join with photographic experts as judges of the works sent in for competition, their province being to examine the pictures, and to award medals or other prizes to those which, in their opinion, are best entitled to distinction. That they exercise this power with honesty of purpose and with great good nature—for time with them means money—no one can for a moment deny, and it would, indeed, seem ungrateful and unnecessary for anyone to raise an enquiry as to that phase of the question. But it has more than once been asked—not, we may say, in parenthesis, by disappointed exhibitors—whether painters are qualified judges of what a photograph should be.

At first sight, it would perhaps appear to many that the question can be dismissed in a very easy manner. An artist's business is to make pictures, and surely no one else can be a better judge of what a picture ought to be. This would certainly be a correct way of regarding the subject if all pictures were produced by the same process and in the same medium; but we know that this is not the case, and that the means by which a photograph is rendered possible are very different to those adopted by the artist, who causes his very thoughts to grow upon the canvas.

By a long course of study, involving intense application and observation of things around him, he has mastered the art of creating, with a few apparently magical strokes of his brush, images which have either been first impressed upon his retina, or which he has evolved out of his inner consciousness. The roughest sketch of a skilled artist is often a masterpiece, and will afford more pleasure to the earnest student than will the most finished picture. It may be a landscape, a seascape, or perhaps a rapidly executed study of the human face. It is quite rough in texture, and the lines of the brush are evident; perhaps even the paint stands up in ridges where the palette knife has been. It is not intended for, nor will it bear, the closest examination, but we must retire from it a short distance, and then we shall see how excellent it is. Now let us try an experiment with this rough sketch in oil. Cut a hole the size of a penny piece in a square of cardboard, and cover it over the canvas so that only part of the picture enclosed within that little circle is visible. It is meaningless; it is a patch of paint, and nothing more. The painting, we at once acknowledge, must be studied as a whole, and at a certain distance, or its beauties will never unfold themselves; but, seen thus, we cannot fail to admire the skill of the artist, and wonder how it is that he is able to express so much by so little.

But how different is this picture to a photograph. Its very roughness, which constitutes one of its chief charms, exhibiting as it does the power of mind over matter, would not be even tolerable in a photograph. Its want of detail, its lack of sharpness, would at once condemn it in the eyes of a man whose art education had been confined to photography. Such a man would, however, be able to tell us that by certain devices he could mimic these effects which are so dear to the artist. He would say that by purposely throwing his lens a little out of focus, so as to soften the outlines of his picture, and by other little devices during the printing operation, he could make his photograph appear not unlike a painting in monochrome. He might also truly say, that sometimes by accident—by an error in development, for instance—a negative will give a peculiarly soft misty effect when printed, which will at once attract the eye of a painter. Let us suppose that such a picture finds its way to an exhibition where an artist is among the judges. The painter at once recognises an effect that he would fain produce on canvas with his brush. His practised eye insensibly clothes it with colour, and he admires it as something which he has never before seen in a photograph. To his mind, therefore, it stands out distinguished by an indefinable beauty from its fellows. It more nearly approaches in its nature a painting than anything else

on the walls around him, and to it, in his honest opinion the medal ought to go. If this view be supported by the other judges present, who will perhaps hardly like to set up their opinion against that of an R.A., the prize will go, not to the best photograph, but to the one which most resembles in appearance and general treatment a painting.

It is a recognised canon of art that a worker dealing with a particular material shall not hide its identity, and attempt to make it imitate something else. The æsthetic craze of a year or two back—laughed at as it rightly was for many of its extravagances—at least did good in teaching people that a plain coating of honest paint was better than graining to badly imitate something else, and that red brick is not improved by stucco to make it appear like stone. The woodcarver must remember that he is working with wood which by its nature lends itself to a certain treatment, and that he must not produce from it the solid ornament more fitted for stone. The worker in iron must follow the path laid down for him by Quentin Matsys and others, and must not trespass upon the domain of Grinling Gibbons, or attempt to reproduce the delicate filagree work of those who work in gold, silver, or ivory. A painter in oils would at once acknowledge the foolishness of attempting to imitate the work of his brother in water-colours, and the pastellist will, if he be wise, steer clear of both, knowing that his coloured chalks have a field all their own. We consider that the same thing should hold good with photography. It has its own particular merits and demerits, and it should not be bent and tortured to resemble that which it is not, and with which it has little in common. Those who juggle with it, and try to get certain effects from it by purposely putting lenses out of focus, and otherwise abusing their apparatus, would do well to throw up photography altogether, and take to some branch of art where the hand can be made obedient to the eye, and where the will rules both.

But to return to our question, "Are painters qualified judges of a photograph?" We humbly think not, and have set forth our reasons for this opinion. At the same time we trust that we have also made plain our high admiration for an artist's work. His opinion would be invaluable were it confined to pointing out errors of composition, or indicating faults which might have been remedied by a more judicious position of the camera. But if he be ignorant of the many difficulties with which a photographer has to contend—and has not had himself some practice with the camera—he is hardly qualified to pronounce judgment upon a photograph placed before him. He is, indeed, in much the same position as a photographer would be if called to pass judgment upon a number of paintings. The photographer, like the artist, would be trammelled by preconceived notions of nature which he had gathered from his own daily practice. He would at once discard all excellencies due to subtle contrasts of colour, for they would be beyond his ken, and if he were called upon to pass an opinion upon, say, one of Turner's pictures, he would probably assert that it was most outrageously out of focus, and would suggest that the artist would do well to insert in the picture the details which were lacking.

GLASS SCREENS FOR DEVELOPING-ROOM LAMPS.

From current literature it appears that some confusion prevails in the minds of a considerable number of photographers as to the best kind of light to use in the developing-room, and its relative amount of safety. The only way out of this maze is to consider each item upon scientific principles, and the one selected for consideration now is that of the glass screens of developing-room lamps.

Sometimes it is said that such-and-such a sample of red or other glass is not safe, and it is condemned accordingly, after being tested somehow, either by means of photographic plates or by the spectroscope. The circumstance should be borne in mind, however, that all transparent coloured glasses are white, or, rather, practically colourless, if made in sufficiently thin films, and that only as the thickness of the glass increases, does its power of selective absorption of particular rays of the spectrum become apparent. Hence, a sheet of ruby or other glass which has been condemned, might have been accepted by the person who rejected it had he tried two thicknesses instead of one. The second sheet of the same average ruby glass scarcely reduces the light visually more than if it had it been a sheet of common window glass, because the first piece cuts off nearly all the rays it naturally absorbs, and the small fraction remaining has alone to be cut off by the second sheet of glass. If, however, the sample of glass be really bad for the purpose, because it naturally freely transmits a band of rays injurious in developing, such rays may more or less pass through the second sheet as well as the first. Once, in an instance in which a photographer had, after employing his mode of testing, rejected one sheet of red glass in favour of another, we recommended him to try two thicknesses of the first glass, and it proved to be better for his purpose than the single sheet of glass which he had originally accepted.

In all experiments of this kind the light should be practically constant; that given by any particular make of candles—which candles are turned out commercially in tolerable uniformity—is near enough for utilitarian purposes. The flame should always be at exactly the same distance behind the screen. The man who uses variable daylight as his source of illumination, and then arranges his screen to make the light inside the room fairly safe under all circumstances, is acting against first principles, and straining his eyesight considerably and unnecessarily, taking the average of a whole year's work.

Why is an ordinary sheet of ruby glass transparent, and a sheet of iron opaque? The theory is that the molecules of the glass are all in a state of vibration, and that waves of light of different wave-lengths beat upon the vibrating molecules. Those waves of light

which coincide in time of vibration with the period of swing of the molecules, are absorbed by the latter, and increase the motion of the molecules; such increased motion is made evident in the form of heat. The glass grows warmer by cancelling such rays, for power is never lost; it can only be transformed. The waves not of the same period as the molecules have not their energy taken up by the latter, so pass round them, and come out at the other side of the sheet of glass. A sheet of iron contains atoms or molecules which respond to all the waves of the luminous spectrum, hence none of them pass through. Ice absorbs the invisible rays of the sun freely, but transmits the visible rays, so whilst the former rays will gradually melt a lens made of ice, the visible rays will pass through the ice lens freely, and can then be made to ignite gunpowder.

CURIOUS EXPERIMENTS WITH LIGHT.

The following is an abbreviation of a letter from Mr. G. M. Minchin, of the Royal Engineering College, Cooper's Hill, which appeared in last week's *Nature*:—

Before publishing in detail the results of many experiments on the generation of electricity by the action of light falling on certain sensitive substances, I wish to make known a result which seems to be of a most remarkable character.

The photo-electric cell which I employ consists of a small glass tube, filled with an alcohol; two metallic plates are immersed in the liquid; each plate is connected with a platinum wire which may either be *soldered to the plate* or passed through a small hole in the plate and *pinched tightly to it*: these wires pass through the ends of the glass tube and are sealed into it. The poles of the cell are connected with the poles of a quadrant electrometer.

The plate is sensitised by a peculiar process, the mere publication of the details of which would not enable a reader to make it successfully. The publication of the process is therefore reserved for a future occasion. One plate is quite clean—not sensitive to light. The cell is fixed vertically in a clamp. When the cell is of the "impulsion" kind, what happens is as follows: Daylight being allowed to fall on the sensitive plate, the spot on the scale of the electrometer moves, and after a few seconds comes to rest, indicating an electromotive force varying with the intensity of the light, its amount for such diffused daylight as we have at present (May 10) at noon being between $\frac{1}{2}$ a volt and $\frac{3}{4}$ of a volt—which is, I submit, a surprisingly great magnitude. On the withdrawal of the light, the deflection falls, and there are means of rapidly getting rid of the deflection without injury to the cell. Either before or after this deflection caused by light ceases, let a slight tap (sometimes inaudible) be given to the base or clamp in which the cell rests, and then results a remarkable change in the cell. *It is no longer sensitive to light.* The insensitive state is indicated by a rapid return motion of the spot on the scale; it is merely *indicated* by this motion, there being no necessary connection between this motion and the insensitive state, for if the cell were now left for some time (perhaps an hour or so) in the dark, the disturbing E.M.F. of the cell would vanish, and there would be nothing to tell us that the cell remains insensitive; but that it is really still in the insensitive state we find at once on again exposing it to light. Another gentle tap given to the clamp, or the stone table on which the whole apparatus rests, will restore the sensitive state; and so on indefinitely, the sensitive and insensitive states following each other and being produced, in the case of many such cells, with great ease.

These results I found a long time ago, and they have been seen by, or communicated to, several scientific friends. From the first, I maintained that the results are due to an alteration of the molecular state of the sensitive surface, or of the layer of contact of this surface with the liquid, and that in one arrangement of the molecules the light energy can be taken up electrically, while it cannot be so taken up in the other.

I now come to the special point which is the occasion of this communication. A few days ago I was investigating the effect of static charges communicated to the plates on the sensitive and insensitive states, and in the course of these experiments I found that if a Voss machine, not in any way connected with the cell or the electrometer, was worked in the room while the cell was in the insensitive state, *the moment a spark passed between the poles of the Voss, the insensitive state was altered to the sensitive*, whether the cell was connected with the electrometer or not. Finally, I found that the best method of showing the inductive effect of the spark is to connect an insulated wire, apparently of any length, to either pole of the cell, and to place the poles of the Voss near the wire (a distance of several feet will do with a spark about half-an-inch long).

If the cause to which I have assigned the change from the photo-electrically insensitive to the photo-electrically sensitive state of the cell is the true one, it is impossible to avoid the speculation that impulsion results of this kind may be very common in the economy of nature; and that the mode in which solar energy is taken up by plants may be effected, and even altered in kind, by sudden electromagnetic disturbances. The effect of a Hertz oscillation is, indeed, not confined to an alteration of a plate from the insensitive to the sensitive state; for I have cells in which if the sensitive plate is, on exposure to light, electrically negative to the back plate, a Hertz oscillator at a distance will reverse the relation when the plate is again exposed to light.

While the above communication was going through the press, I made an experiment which renders it almost certain that in the impulsion cells the results are due to the formation of some *oscillating layer* at the surface of the sensitive plate. Being anxious to keep the alcohol in the cell (which in this instance was closed by a ground-glass cap), I sealed the cell into a glass tube through the extremities of which the wires of the cell passed. The effect of the disturbance thus resulting was that no amount of tapping the support of the cell would change it from the sensitive to the insensitive state, although before being thus treated it was sensitive to the most minute disturbance. I suspected, however, that after some hours the liquid and the plate would again enter into the peculiar relation on which the impulsion results depend, and so it turned out; after three hours the cell could be rendered insensitive by taps, and sensitive by the inductive effect of a Voss machine.

Eikonogen.—It will be seen, from an article by Julius F. Saehse, quoted on page 414 of our present issue, that eikonogen is the favourite developer with professional photographers of Germany, whose opinions were recently asked by circular.

ETHICS OF PHOTOGRAPHY AND PHOTOGRAPHERS.*

BY J. TRAILL TAYLOR.

Some are unkind enough to allege that there is no system of ethics applicable to photographers and photography, unless in the inverse application of the term, and they adduce examples in favour of this negation, to some of which I shall have occasion to allude.

Can photography lie? it has been asked. Can photographers lie? or, to put it more plainly, Do photographers lie, and why, or under what circumstances, do they lie? Is it necessary they should, and is it expedient that the strict and severe Temple of Truth be erected in its midst? In the social world strict ethics are largely ostracised; ethics and politeness, popularly so called and practised, are not invariably in harmony.

In what I say, I am not supposed to have reference to photographers as social, private individuals, but merely to them *as* photographers. In itself photography is but a plastic tool in the hands of those who know how to employ it, and it may be made to subserve good or evil. My present purpose will be served by pointing out certain directions in which deviations from pure ethics are occasionally made by those who handle the camera. In doing so, I take no cognisance of departures from accuracy of statement made to serve the exigencies of trade or commerce. Deliberately false or misleading representations do not enter into the topic before me, this being simply *falsehood* open and palpable. Neither do the tradesman's arguments to his innocent purchaser that such and such a piece of apparatus is the thing for him to have, because such an one uses none else, and he has obtained a plethora of medals at exhibitions; this is *humbug*. Nor does my category include the one who assures me a lens is ten inches in focus, while, measured properly, instead of from the posterior end of the brass work, it is twelve; this is *ignorance*. Nor the tramp who, pointing his camera at a house under pretence of photographing it, secures the money in advance, without having any intention of developing his plate, if plate there was in his camera; this is *fraud*. Nor the young Daguerreotypist who, having succeeded in taking one or two fairly good Daguerreotypes, handed his camera over to a more experienced man, after having, unseen, smeared iodine on the shutter of the dark slide, by which his rival failed *in toto* in producing a picture; this is *trickery*, and, under some circumstances, pardonable. Nor the one who rubs powdered nitrate of silver inside the front of the dude's hat at a picnic with ladies when the thermometer is in the nineties; this is *mischief*. These, and numerous examples of like nature of departure from the straight path which might be adduced, scarcely come under the heading of *mal* ethics, although they are not ethical. And yet the line of demarcation is hard to draw.

Nice distinctions may even be drawn between artifice, deception, fraud, charlatanry, empiricism, delusion, white lies, and black lies, but they all belong to the same family.

Photography is in itself so absolutely truthful that it is accepted as evidence of realism. The camera merely depicts what is placed before it. But realism is not necessarily, and does not necessarily convey, truth. The large lump of coal placed on a cloth-covered table with a few miniature shrubs and twigs around its base, and then photographed on a large scale to do duty as a scene in the Rocky Mountains, or anywhere else, cannot be said to be in accord with ethics if such be done with intent to deceive, even although the trick cannot be discovered by the experienced geologist who examines the perfect strata through his magnifying glass.

A point of sight may be selected for a view which, when aided by a lens of short focus, shall give as a result a photograph true as a piece of realism, but conveying the false idea that the duck-pond in the foreground is a large lake, and that the shrubs or trees of six foot height almost rival the giants in the Maraposa Grove in California. A realistic photograph, while thus geometrically true, may not only fail in conveying a truthful expression, but one the every reverse.

Stepping from nature outside to inside the studio, who has not heard of the two sets of solid furniture—one being in miniature, to be had in use solely when men of Zaccheus-like stature desire that their circumscribed longitude should be elevated into that of mid-stature by contrast with the surrounding tables and chairs. I touch only lightly upon one of the most prevalent of *mal* ethics in the studio, because it is the outcome of the ignorance of the photographer; I refer to the two entirely different kinds of perspective to be so often found in one picture—that of the background and side scenes on the one hand, and that of the figure on the other. In a portrait—a standing figure of a lady full length—which was seemingly much admired at a recent exhibition, the point of view of the background was below the knee, that of the figure itself was about opposite her eyes. But some background painters and photographic artists so-called do not appear to think that perspective has anything to do with their art. The amateur who takes his portraits out of doors with natural surroundings never encounters this anomaly; the perspective of his figure and background necessarily harmonise, and is it to be wondered at if the educated artist or observer of nature is found to give preference to one over the other?

Artists seem to arrogate to themselves a prescriptive right to improve upon nature. I have heard the late Sir George Harvey, President Royal Scottish Society Academy, speak in approving terms of a local artist who always enlarged the eyes of his subjects when working them up by the brush or pencil; photographs, in the estimation of this gentleman, always made the eyes too small—for artistic taste, I presume. But æsthetic truth and ethical truth are not the same thing, although there are cases in which one may with advantage be made subservient to the other. I heard a famous New York photographer giving directions to his managing printer, who was one morning submitting to him rough proofs from the negatives of the preceding day. "Take a big slice off that lady's belly (indicating with a pencil) and place it on behind. It will much improve her appearance." And it did so. "But that is not like ———," I remarked of a new portrait of a famous actress, since extensively published; "she is rather sour and scraggy, while this one is amiable and somewhat fleshy." "Oh," remarked the photographer, "a retoucher has been working a whole day on that face in order to obtain this effect. She doesn't care whether it is a good likeness or not, so long as we make her good looking.

Retouchers! O, what ethical sins have you not to answer for! You supply all the crudities and deficiencies of nature. At your magic touch strabismus vanishes. Where nature has been unkind in the matter of eyes, 'tis

* A lecturette at the London and Provincial Photographic Association.

yours to supply the required number, and convert minocular into binocular vision; to round the sharp angles of the features by the transference of adipose tissue from where it is not wanted to where it is needed; to fill up the furrows dug by time; to enact the chiropodist upon facial excrescences: and the dentist, in case the taker of the negative has forgotten to stuff cotton wadding pads inside the mouth to ensure a pleasant rotundity to the wan cheeks—a thing a New York photographer never omits. *You* do not believe that the man or woman exists who, in his or her heart, endorses the sentiment of Oliver Cromwell about being painted with his wrinkles and warts. And you are right. They may assert as much as they like, but you well know such phrase and fact do not coincide, and accordingly you dress your ewe in lamb fashion, taking shelter behind Luther's dictum, that a great artist portrays a man as he should be, and not necessarily as he is.

Perhaps it is in the West States of America where retouching has its highest development. A reporter in California interviewed a photographer and conversed on retouching.

"What do you think of that?" said the artist, showing a cabinet portrait. It was simply the likeness of a mild, motherly, middle-aged lady, and the reporter said he could see nothing remarkable about it.

"I suppose not. How do you like this?"

"Good Lord, what a fury!" exclaimed the reporter, as he looked on the deeply seamed face of an old woman, with lowering brows, thick, cruel lips, and a brutal chin.

"Same subject," explained the photographer, putting the two pictures side by side. "Shows what retouching can do."

"But the retouched one does not look a bit like the woman who sat for it."

"Of course not; that's the beauty of it. The old woman wouldn't have taken the picture if it did. A photographer these days has to be barber, surgeon, and dentist. Look at this."

It presented a man with a bald head and a twisted eye. In the finished picture the eye was straight and the baldness gone.

"For friends of his youth in the West, you know. Here's another."

This time a young man with two of his upper teeth protruding repulsively was shown. The tusks had been extracted by the artist's brush.

"Corresponding with a Boston girl he had never seen, but that he wanted to come out and marry him."

The reporter looked over piles of negatives, and compared them with the pictures made up from them, and sent out unblushingly by the sitters as likenesses. Plain women were made pretty, pretty ones given beauty, and in all cases the looks had been vastly improved. No woman seems to want to have herself shown just as she is, and the men are quite as vain. Very young men are frequently amazed at finding how much heavier their moustaches and downy siders are when photographed. The camera makes lean women plump and fat ones slimmer, knocks off ten years at least from the age of the mature, and in ninety cases out of a hundred lies shamelessly. Of course, it is the camera, not the photographer, who is to blame.

(To be continued.)

The Photographic Club.—The subject for discussion on June 4th will be "Photo-Mechanical Processes."

HIGH ART.

The following, from last week's *Referee*, is not altogether complimentary to the photographic profession:—

They coaxed me up a hundred stairs,
  They lured me to their den,
For me they laid their artful snares—
  Those photographing men.
They dragged me to a room of glass
  Beneath a blazing sun,
I thought I should have died. Alas!
  I'm nearly fourteen stone!

They saw their victim pant and blow,
  They heard him cry, "I melt!"
But ne'er a one for all my woe
  One grain of pity felt.
They seized my head and screwed it round,
  And fixed it in a vice,
And simpered when they had me bound,
  "That pose is very nice!

"Look up—look up, and wear a smile,
  Look pleasant, if you please.
You must keep still a little while;
  Just straighten up your knees."
'Tis thus they jeer and jibe at me
  As, faint and hot, I try
An inch before my nose to see
  With sunstroke in my eye.

I think of all the bitter wrongs
  My later life has known;
I writhe beneath Fate's cruel thongs,
  I knit my brow and groan.
And still, with many a smile and smirk,
  The artist trips about,
And gives my chin a little jerk
  And sticks my elbows out.

Ye gods, am I a grinning ape
  To pose and posture thus?
Am I a man in human shape,
  Or turkey that they truss?
My head is free; with fiendish mirth
  I raise a vengeful hand,
And dash the camera to earth,
  And fell the iron stand.

I take the artist by the throat
  And pin him to the wall,
And jerk his chin and tear his coat,
  And hold his head in thrall.
I bid the trembling victim smile,
  I cry, "Be gay and laugh,
And in the very latest style
  I'll take *your* photograph!"

I twisted till I broke his neck,
  I baked him in the sun;
I left the room an awful wreck,
  And then the deed was done.
They held an inquest on the bits;
  Ye photographing crew,
Before to you the writer sits
  Just read that inquest through.

The opening soirée of the City Photographic Exhibition, under the auspices of the Photographic Trades Section of the London Chamber of Commerce, will take place in the Drapers' Hall, Throgmorton Street, this evening, at nine o'clock.

One of Mr. W. M. Ashman's photographs—which he showed us yesterday—of the interior of Bath Abbey, has a large stained-glass window in front of the lens rendered in all its details with unusual perfection and sharpness, and this without under-exposing the interior of the building; it forms a good sample of this difficult class of work.

DEVELOPERS USED BY GERMAN PROFESSIONAL PHOTOGRAPHERS.*

BY JULIUS F. SACHSE.

EARLY in the present year the publishers of *Liesegang's Photographisches Archiv*, in Dusseldorf, Germany, prepared a circular to be sent to the most celebrated professional photographers within the German realm, for the purpose of thoroughly settling the question as to what special developer, formulated for gelatine dry plates, was in most general use with professional artists who make portraiture their speciality, further asking information how their special formula works in every-day practice. As a test whether the scheme would meet with a favourable reception, and bring forth free responses, it was concluded to send out at first but half a hundred of these circulars as a feeler. To the surprise of the projectors of the scheme, twenty-eight replies were received within a few days.

The editor of the *Archiv* prefixes the list with the explanation that they do not wish it to appear as if they believed the success of photographic portraiture to depend solely upon the composition of the developer. We reproduce the list entire for the benefit of our readers, both amateur and professional, that they may gather such facts and hints as have proved of value in the practice and experience of the most successful artists in the far-off Fatherland.

The circular contained the following four leading questions, viz.:—(1) What developer do you use in your portrait studio? (2) What special properties or qualifications do you claim for your developer? (3) Give combination of solutions used in cases of normal exposure? (4) Do you use a preliminary bath (Vorbad), and what of?

Herr von Ayx, Mainz.—Developer—Eikonogen. Properties—The brilliant action on the half-tones and highlights during reduction, with proper manipulation. Composition (No. 1).—Sulphite of soda, 200 g.; distilled water, 3,000 g.; eikonogen, 50 g. First pulverize the sulphite, then dissolve in the water; to this solution add the eikonogen in crystals; place the whole in a water bath until the latter is wholly dissolved. (No. 2).—Carbonate of soda, 150 g.; distilled water, 1,000 g. For use, 3 parts No. 1, 2 parts No. 2. No preliminary bath.

Carl Bornträger, Hofphotograph Wiesbaden.—Developer—Eikonogen. Properties—It permits of a shorter exposure than any other developer known to me; works out fine detail, neither monotone nor too hard, with great rapidity. Composition (A)—Distilled water, 1,500 c.cm.; sulphite of soda, c.p., 100 g.; eikonogen, 50 g. Dissolve the sulphite and eikonogen in hot water. Keep this solution in a dark bottle with ground-glass stopper, in dark closet away from all contact with ammonia or acids. (B)—Distilled water, 500 c.cm.; carbonate of potassium, c.p., 75 g. For use, three parts A to one part B immediately before using. When plates are developed far enough, wash well under tap, then place in 5 per cent. alum bath for one minute, again wash thoroughly, and fix in bath: Water, 800 c.cm.; hypo, 200 g.; bicarbonate of soda, c.p., 40 g. No accelerator.

Heinrich Fritz, Hofphotograph-Greiz.—Developer—Eikonogen. Properties—Advantages over the oxalate developer formerly in exclusive use: 1. Shortening time of exposure by one-half, so that slower and better plates can be used; 2. Use of developer until exhausted, therefore much cheaper and convenient. Composition—Sulphite of soda, 100 g.; carbonate of potassium, 40 g.; eikonogen, 20 g.; to which is added a few drops of hypo, 1 : 50. (Note in the original the volume of water is not given.) By addition of water and bromide of potassium, over-exposed plates may be easily corrected. Accelerator—Unnecessary with above developer.

Arno Cersten, Hofphotograph, Altenburg 1 S.—Developer—At present only eikonogen (since six months), prior to that, oxalate and iron exclusively. Properties—The local water supply is strongly impregnated with limestone, and great difficulty was experienced in cleaning the hands and utensils while iron was used; therefore, eikonogen is now exclusively used. In addition, I value the rapidity of development, the softness and clearness of the shadows, in spite of which they still have enough strength. I use my own dry plates, made after Obernetter's modified formula. Composition—I rub 12 g. eikonogen crystals to powder in a small wedgewood mortar; pour this into a funnel; after closing the opening with cotton, I then add 50 g. pulverized sulphite of soda, then fill the funnel with 750 c.cm. distilled water; stir with glass rod until filtered. To this add 8-10 c.cm. concentrated solution of bisulphite of soda, at 38° R., which almost destroys the colour of the filtered solution. Then pour 38 g. of calcined soda (c. p.) in the same funnel with 250 c.cm. of distilled water; filter when dissolved; then pour both solutions together, and shake well. Thus I make 1 litre of developer in 15 minutes without using boiling water. Accelerator—Not necessary in normal cases; when necessary, take 1 part hypo to 3-10,000 parts of water; soak the plate a minute, then develop without washing. Fixing Bath—1 part hypo to 5 parts water; to 3 litres of this solution add 50 c.cm. of concentrated solution of bisulphite of soda.

Julius Schaar, Dusseldorf.—Developer—Eikonogen. Properties—Quick and strong action; the negative being very soft yet strong, without having to resort to intensification; with attentive manipulation the picture appears in three to four minutes beautifully modulated. Composition (A)—Distilled water, 1 litre; sulphite of soda, 10 g.; eikonogen, 10 g. (B) Carbonate of potasssium, 150 g.; distilled water, 1 litre; hypo, ½ g. Take equal parts.

L. Springer, Hirshberg in Schlesien.—Developer—During the past six months eikonogen, with great advantage, in place of all others. Properties—Magnificent, clear, yet strong negatives, when developed until the deepest shadows show through; results not to be obtained with any other developer. Composition (A)—Sulphite of soda, 200 g.; distilled water, 3,000 g.; eikonogen, 50 g. (B) Carbonate of soda (cr.), 150 g.; distilled water, 1,000 g. For use, A, 1 part; B, 2 parts. Fixing bath—Hypo, 250 g.; sulphite of soda, 50 g.; water, 1,000 g.; sulphuric acid, 8-10 g. In developing a plate, old developer is first used until the image appears; this is then poured off and completed with fresh developer until the negative is very strong, as the negative is apt to reduce in the fixing bath. In copying poor photographs the oxalate developer is used, as the eikonogen brings out the grain of the paper in too great relief. This fact in itself is a proof that greater results are obtained with eikonogen than any other developer.

I. H. Voight, Hofphotograph Homburg, v.d. Hohe.—Developer—Eikonogen for negatives as well as contact

* A digest of the useful information about developers, collected by the Dusseldorf publishers, appeared recently in these pages in a letter from our German correspondent. The present article of Mr. Sachse, from the *American Journal of Photography*, contains the details.—ED.

prints and enlargements on chloride and bromide paper. Properties—the image appears rapidly, and develops gradually until the required density is reached, when it may be immediately checked. If proper attention is paid to the work, neither intensification nor reduction is necessary with my developer. A clear picture is obtained, perfect in all detail. Water, 500 g.; sulphite of soda, 25 g.; carbonate of potassa, 5 g.; carbonate of soda, 15 g.; eikonogen, 5 g. Eikonogen must be pulverised in a mortar to thoroughly dissolve.

P. Barth, in Elberfeld.—Developer—Iron oxalate. Properties—Simplicity, greater capabilities of development, especially in the case where a large number of plates are to be developed consecutively. Composition—Saturated solution. Just so much iron is to be added to the oxalate as the latter will stand without becoming turbid. I wish to mention it is, on the whole, immaterial what developer is used. The whole difficulty in portrait photography consists in properly lighting the subject.

Emil Becher Dillenburg.—Developer—Iron oxalate. Properties—With this developer I always obtain the same results. It is easy and simple in its manipulation, and gives negatives such as are only obtained with hydroquinone or eikonogen under extraordinary favourable circumstances. It also allows, in my experience, shorter exposure. Composition—Sulphate of iron and oxalate of potash are dissolved in distilled water. For cabinet plates I take 12 g. iron to 40 g. oxalate, by normal exposure. When the light was weak, increase the volume of developer one-half. In over-exposure, reduce the volume of developer and add water. The chemicals must be pure. [Note.—I prepare my own dry plates.]

A. Blankhorn, Hofphotograph Offenbach a. m.—Developer—Iron oxalate; tried hydrochinon; plates fogged, time too long, preparation too complicated, also too dear. Properties—Simplicity of manipulation, absolute safety, and cheapness. Composition (A)—Sulphate of iron, 1 part; distilled water, 3 parts. (B)—Oxalate of potash, 1 part; distilled water, 3½ parts. Dissolve warm. Just before using, mix 1 part A to 2 parts B. For under-exposure add 1 drop soda (to -15-45 solution) when partly developed. In case of over-exposure 2-3 drops bromide potassium. Accelerator—For short exposures 1-2 minutes in hypo bath, 1-1,000 for instantaneous pictures of children invaluable.

(To be continued.)

THE LIVERPOOL PHOTOGRAPHIC EXHIBITION.

The Liverpool Amateur Photographic Association will next year hold an International Photographic Exhibition, and by permission of the Liverpool Corporation, in the Walker Art Gallery there.

The Exhibition will open on Friday, 6th of March, 1891, and close on Saturday, 4th of April, 1891. The intention is to keep the Exhibition open for four weeks only, but no frames can be removed until the "final close" of the Exhibition.

The Executive, being anxious to elevate the standard of public competitions in every way, intends to restrict its efforts to triennial public exhibitions; also, as far as practicable, to reduce the number of awards, the intrinsic value of a medal being, of course, a secondary consideration. It trusts that other associations and photographers will assist its efforts to limit public exhibitions, their frequency being somewhat fatal to originality and good work, as well as a severe tax on exhibitors.

Among the numerous conditions are the following:—Pictures from exhibitors abroad—*i.e.*, outside the United Kingdom—may be sent unframed, packed in boards. They will receive every care, and be framed temporarily, free of cost. The executive undertakes, free of cost to exhibitors, to unpack, repack, and deliver to the carriers at the close of the exhibition all exhibits, but will not hold itself responsible for any accidents. The best professional assistance will be engaged, and every possible care exercised.

The names of the judges will be announced in January, 1891, prior to the date fixed for entry of exhibits. The board of judges will consist of men of recognised artistic and technical ability, with whom the executive is satisfied that merit, and merit only, will be their guide in giving the awards. The name of the exhibitor and title of the picture must appear plainly on the front of the picture, mount, or frame.

The number of awards will be practically left to the judges, they having discretion to withhold entirely awards in any of the classes where more than ordinary merit does not exist, or the number of competitors is not considered sufficient. The judges have also power to award extra medals for work of special merit. The award of the judges shall in all cases be final. No medals will be awarded except those struck off the dies of the Liverpool Amateur Photographic Association, and no prizes or awards will be accepted from any other source. Except in the champion class, no picture of any description shall be entered or allowed to compete which has been previously exhibited at any public competition in the United Kingdom, an exception being made in favour of the Photographic Society of Great Britain as regards its 1890 Pall Mall Exhibition. Private exhibitions confined to members of photographic associations not to count as public competitions or exhibitions.

Properly printed, unmounted, duplicate copies of the winning pictures are to be supplied to the Liverpool Amateur Photographic Association, which will be preserved in a suitable album, to remain on view in the Club Rooms of the Association, as a memorial, and record of the prize winners of the 1891 Exhibition.

THE PHOTOGRAPHIC CONVENTION AT CHESTER.

The excursions connected with the Photographic Convention have been arranged as follows:—

Excursion A.—Conway Valley, Tuesday, 24th June, Conway and Bettws-y-Coed; leaders, Messrs. C. H. Bothamley and W. Tomkinson; leave Chester by train for Llandudno Junction. Two parties will be formed—one for Conway, the other will proceed by train to Bettws-y-coed. (1) Conway.—Leader, Mr. C. H. Bothamley. Conway Castle, exterior and interior—Plas Mawr, an old Elizabethan Mansion—Town Wall and Gates—Beach—Shipping. A return journey to Llandudno can be made from the Junction at various times during the day. Tal-y-Cefn, a very picturesque village up the valley, can also be reached by rail, leaving by Llandudno Junction, and returning from Tal-y-Cafn. (2) Bettws-y-coed.—Leader, Mr. W. Tomkinson; by train from Llandudno Junction. Swallow Falls—Miners' Bridge—Fairy Glen—Conway Mill and Falls—if time, Ponty Pant and Ledr Valley. Those who intend to go on to Bettws, and wish to break the journey at Conway, must take return tickets for Bettws.

Excursion B.—Moreton Old Hall. Train *via* Crewe, to Mow Cop. Members must obtain of the local Secretary tickets of admission to the Hall and its surroundings. Only twenty can be issued for each day. This also applies to Thursday's excursion.

Excursion C.—Eaton Hall, Wednesday, 25th June; leader, Mr. G. Watmough Webster; by steamer from the Groves at 1.15; return fare, 6d. A Convention Group will be taken.

Excursion D.—Vale of Llangollen, Thursday, 26th June; leader, Mr. J. L. Mackrell. (1) On arriving at Llangollen the party will make for the Vale Crusis Abbey—Morning Light; (2) Cross over mountains to Chain Bridge and Berwyn, then down the Canal; (3) The Old Maid's residence.

Excursion E.—Moreton Old Hall; leader, Mr. F. Evans; train *via* Crewe, to Mow Cop. (1) The Royal Mersey Yacht Regatta, Friday, 27th June; leader, Mr. Paul Lange; (2) Hawarden. Train from Northgate Station. The Old and New Castle—The Park—Church and Village.

For the convenience of members wishing to visit Eaton Hall during the week, time tables will be published of the sailings of the s.s. *Ormonde*, the new twin-screw steamer specially designed and constructed for passenger traffic on the River Dee (under Board of Trade supervision), for the safety and comfort of passengers. Eaton Hall is six minutes walk from Eccleston Ferry. The return fare to Iron Bridge or Eccleston, upon production of membership ticket. The best view of the Hall is to be obtained from the river bank, near the Iron Bridge, in the morning before 10.30.

Permission has been given to photograph the following places, at any time during the week, upon production of a membership ticket—By the Dean, for Cathedral and precincts; by the Rev. S. Cooper Scott, for St. John's Church and Ruins; by the Duke of Westminster, for interior and exterior of Eaton Hall and Park; by Mr. W. H. Gladstone, for Hawarden Castle and Park.

RETOUCHING IN THE NEAR FUTURE.

BY REV. F. C. LAMBERT.

THE question, "Is retouching moral?" is one which certainly presents one aspect of the question, but the old adage, "Any fool can ask a question which may puzzle a wise man to answer," comes to my mind. For I may at once confess that this question is not altogether unlike the older one, "Is it permissible to use poison?" And like many such questions, can only be answered by asking other questions.

There is more similarity than may appear at first sight between the retouching and poison problems. We may reply that a poison in the hands of a competent person, familiar with its limits and uses, ceases to become a poison in the ordinary sense, and becomes an invaluable means of producing a much desired result. Everyone now-a-days knows that many of our most valuable medicinal remedies were for a time regarded simply as poisons, and marked "dangerous" in mental capitals. The reckless and ignorant use of them would have kept them on that formidable platform, had not kindly science turned these tyrants into faithful servants.

The liberal abuse and abundant contempt with which it seems just now in certain quarters a matter of habit to besprinkle the art of retouching, is certainly a matter for some consideration.

The question I would place before the consideration of practical workers is this: Is retouching being used with that care with which we should handle a most powerful drug, or with the freehanded lavishness with which our forefathers administered the cure-all black draught?

It is worse than foolish on the part of the professional worker to nurture ill-will against that part of the younger generation which is being told and taught by its artistic friends that professional portraiture is a burlesque on art, and reply that the public "will have it;" that they pay for the "glass-marble" surface, and expect to get it; for the question remains: Who taught them to expect them?

History repeats itself often enough, as we all well enough know. The introduction of this new power of course was followed by its liberal abuse. There is some connection, too, between the sharpness of detail and characterless smoothness of surface.

But the pressure of cultivated taste is slowly but surely making itself felt in a growing demand for a general softness of outline—less glitter and polish—and a not altogether unreasonable demand that a portrait should contain *some*, if small, resemblance to the original.

Therefore a word of friendly warning and suggestion may be offered to the professional worker—viz., "Progress, reform, change is in the air. The novelty of the egg-shell or billiard-ball surface is fading. The time-honoured glassy stare, with the two catch lights in the eyes, is losing its mesmeric effect. The discriminative sitter does not value sharpness-all-over (or anywhere, for matter of that) so much as many a negative maker would suppose. With less of this sharpness there is less need for retouching. Broad and simple lighting again will render that little still less. A characteristic pose, well caught, will make the sitter and his friends prefer *that* particular print with possibly faulty technique, to a more 'highly finished' show case specimen."

Voluntary reform from within is surely better than enforced reform from without.

The motto is "less and better;" less of indiscriminate smoothing this and sharpening that; and *what little* is wanted, let it be in the *right place*.

We may for convenience of expression say that so-called retouching of negatives is of two kinds.

1. *Remedial.—i.e.*, endeavouring to remove those results produced on the print which are not, under normal conditions, observed in the sitter—freckles, colour blotches, deep-seated scars, and all such differences which the plate emphasises in a way not usually observable.

2. *Constructive* (and often Destructive).—Removing wrinkles, straightening noses, and "improving!" nature generally.

It is with this latter sort that I would say, with the coming generation, "We'll have none of it."

That a certain amount—but not so much as many think—of No. 1 is not only legitimate, but necessary in our present state of knowledge, it is altogether idle to deny.

But the best doctor is the one who cures us with the least physic, and so the best retoucher is he who can *do* the most *with* the least. Quality, and not quantity. To touch without some knowledge of drawing, &c., is to prescribe without knowing the symptoms of the case or the properties of the drugs.

As the chemical and optical side of our art grows, the need for the retoucher will decrease in inverse ratio; but meanwhile, the man who hopes to gather approval and support must assuredly, in the very near future, diminish the quantity and increase the quality of the retouching part of his work. As to the education of the retoucher, and the duration of his work in the future, I must defer my remarks; concluding with one most significant fact—viz., the phenomenal growth of matt-surface—black and white printing processes, which very considerably reduce the quantity of remedial retouching required to produce prints, which commend themselves more to trained artists than any other, be they never so highly finished specimens.

MR. GLADSTONE AND THE AMATEUR PHOTOGRAPHER.—Says the *Daily News*:—"A story told at Hawarden about the amateur photographer stopping Mr. Gladstone in the village, and appealing to him just to stand one second till 'a snap picture' of him was taken, is quite correct; but our Chester correspondent says there is a sequel which has not been recorded. Mr. Gladstone shook his head, smiled pleasantly, and walked on towards the new station. Returning later, he found the enthusiastic amateur still standing near the same spot, and looking extremely unhappy at his failure. To a second appeal in these circumstances, Mr. Gladstone, good-humouredly entering into the situation, yielded, and stood in the village street until the camera was adjusted and he had been 'taken' by the now delighted artist, who, after profuse thanks, went on his way rejoicing."

THE ROYAL ACADEMY OF ARTS, 1890.

BY REV. F. C. LAMBERT, M.A.

GALLERY No. 4.—As no photographic exhibition is complete without a view of Conway or Windsor Castle, so, also, is it almost axiomatic that no collection of portraits is complete without Mr. W. E. Gladstone, No. 361 (by Sir J. E. Millais, R.A.). The monotony, however, is relieved in this case by a grandson being added. "Grandpa" has his eye on the speaker, or rather the spectator, "as usual." Monotony is again relieved by having a view *from* Windsor Castle, 366 (F. Goodall, R.A.; for a view *of* the Castle *vide* 484), and certainly the bit of foreground wall is not the least attractive part of the canvas. The general light seems somewhat cold, and not inviting of prolonged study. Nor is our old friend the Conway utterly forgotten, *vide* 353 (D. Watson). No. 396 ("Puritans' First Winter," G. H. Boughton, A.) has all the subject and sentiment for a strong picture, but somehow, the distant figures do not look as distant from the foreground figures as their relative size would imply. No. 405 ("A Difficult Passage," E. W. Grier) presents an elderly gentleman—with a ruby nose—deliberating how he may best "shift" so as to "how" a difficult passage of "crotchets and quavers" on his "cello"—a simple, homely subject, without the usual superfluous studio properties (N.B., an unobtrusive background), and, taken altogether, a picture well worth a few mental notes.

No. 420 ("The Haven under the Hill," Sidney S. Morish) makes one think of the delightful fresh air of our coast line—say Luccombe Chine, or some of the Denes in Yorkshire. Study this picture carefully. The portrait study, No. 441 ("Lady Betty," P. H. Calderon, R.A.), is interesting, inasmuch as it presents a by no means unpleasing rendering of a tint of hair not generally admired. Poets have sung of tresses and locks of tints without number, almost without name, but one fails to recall any poetic epithet for this tint except we have licence to call it "golden." However that problem may find issue, it is a most admirable and masterly piece of painting. Note the graceful pose of the head, disposal of the hands, and simple lines of drapery—some valuable hints here. Before quitting this room, observe No. 398 ("An episode of the Deluge," C. E. Butler). No. 386 (Ditto, Mr. W. Blackden), and last, but not least, No. 499 (Ditto, ditto, H. J. Draper) in the next room (Gallery V.). These three would have gained rather than lost in the public eye had they been placed side by side.

GALLERY No. V.—The first thing which catches our eye on entering Gallery V. is No. 449 (Portrait, W. B. Richmond, A.), and almost involuntarily we say, Oh, what a splendid frame! and then pass on to No. 457 ("Harvest Festival in Cornish Fishing Village," W. B. Fortescue), a natural realistic gathering "of the people," who have brought their offering of fish and fruit. Note the effect of the back lighting of figures in the gallery. Is it a desirable or satisfactory thing to represent people with their mouths open as though singing? (On this point compare No. 774.) Close by is No. 458 ("Where Sea and River meet," B. W. Leader, A.); perhaps somewhat gaudy in foreground, nevertheless full of sunlight. Observe there is abundant definition without great extremes of small detail.

No. 462 ("A pound a leg," Leghe Suthers). An evening effect admirably rendered in subdued and harmonious tones and tints. The itinerant horse dealer offering "a pound a leg" for a doubtful nag from a still more doubtful gipsy owner. The arrangement of the parts is instructive and note worth.

No. 470 ("Conversion of St. Hubert," A. Lemon), showing Hubert, who, engaged in the pleasures of the chase to the exclusion of his religious duties, until a stag with a spectral crucifix presented itself and converted this merry huntsman from the chase to the cloister, where he "lived happy ever after," finally becoming Bishop of Liège, and bequeathing to all members of his race the power of curing the bite of mad dogs (query M. Pasteur). Altogether a dramatic composition, yet not unpleasing, excepting in the rawness of its sky, perhaps.

No. 473 ("Echoes of a far-off Storm," J. Brett, A.R.A.), a "stormy" letter to the plate maker demanding an explanation of that streak of thin emulsion or fog mark across the plate?

No. 485 ("The only Survivor," F. Bourdillon). The pose of kneeling figure is admirable, full of suggested strength and pathos.

No. 487 ("A Summer Night," A. Moore) calls to mind the word "stipple." The formal interlacing of the flowers is rather distressing. Some of the figures are well worth study as regards pose and balance.

No. 501 ("Yarmouth, I.W.," Henry Moore, A.). Note the "echo" of the two foreground cows "in focus," and the more distant ones less so, and how it gives depth of planes, gradation of distance, the simplicity of the lines of composition, general treatment and handling, full of light and air.

No. 507 ("Oliver Twist," James Sant, R.A.). A scene from the boundless store-house of Dickens. Who can forget his first impressions and sympathy with Oliver? "He had a crust of bread, a coarse shirt, and two pair of stockings in his bundle. He had a penny too—a gift of Sowerberry's after some funeral in which he had acquitted himself more than ordinarily well—in his pocket. 'A clean shirt,' thought Oliver, 'is a very comfortable thing; and so are two pair of darned stockings; and so is a penny; but they are small helps to a sixty-five mile walk in winter time.' . . . So after a good deal of thinking to no particular purpose, he changed his little bundle over to the other shoulder and trudged on." (Ch. viii.) Oliver before us seems a bit too fresh, may-be? Are the dog and sheep an artistic license? The shepherd in distance is not the least interesting part of the picture.

No. 519 ("Paris and Œnone," G. A. Storey). The red cap worn by Paris does not seem to quite harmonise with the red parts of Mrs. Paris' garments, nor does the youthful figure of Paris give one an idea of the sort of person to carry off Helen of Troy. Was it a case of Troy, Troy again?

The question proposed by C. Seton, No. 512 ("A doubtful Strad."), seems to find some sort of answer in No. 1050 ("A genuine Stradivarius," W. Gay). A pity these two frames are so far apart.

SIR H. TRUEMAN WOOD.—Sir Frederick Bramwell announced last week at the Society of Arts that Mr. H. Trueman Wood is about to be knighted, and added that this was "a mark of honour from our Sovereign which I am sure no man has more thoroughly deserved than he has. The way in which he has carried out the duties of secretary since the death of Mr. Le Neve Foster must, I am sure, have been appreciated by our thousands of members, and the way in which he carried on those duties which he undertook of looking after British industries at the late Paris Exhibition deserves praise at all hands."

Notes.

Military authorities seem to be suspicious of photography. On no other ground can the curious fact of the entire absence of photographs of the interior of the Tower of London be explained. A few days ago we strolled through the interesting building, and on arriving at the Beauchamp Tower enquired whether any photographs could be obtained. The answer was in the negative. In justice to the sturdy yeoman of the guard who was in charge, we are bound to say that he was rather hazy on the subject, as he seemed to think that the etchings he had on sale would answer our purpose as well as photographs. But this was excusable, as it was impossible for him to express an opinion on what he had never seen, and, so far as we could discover, the interior of the room in the Tower so full of pathetic records has never been photographed.

This seems a strange piece of indifference or neglect. On the walls, carved by their own hands, are the names of prisoners whose lives—or, to put the matter correctly, whose deaths—are part of the history of England. Surely no more interesting memento could a visitor carry away than such a *fac simile* as photography could give. Even as a question of profit, the walls are worth photographing. If a description of the writings on the walls can be sold, why not also photographs? There is not an American visitor—and they can be numbered by scores—who would not purchase a photograph of the word "Jane," so deeply indented by the unfortunate ten days Queen of England. As for the other objects of historical interest in the various parts of the Tower, their name is legion, and yet not a photograph is purchasable. It sounds incredible, yet it is the fact. We do not know who is the responsible authority, but if it rests with the Constable, perhaps the newly appointed official, Sir Daniel Lysons, will take the matter into consideration.

Whatever the result may be, what is known as a "boom" has set in with regard to penny photographs. The parent Automatic Photograph Company has the capital it asked for, and on the strength of its success has floated a more extended scheme for the purchase of its foreign patents, for which it modestly asks a quarter of a million. Meanwhile one of those ingenious persons always ready to follow somebody else's lead, has spotted a weak point in the original undertaking—the omission to make any mention of artificial light, without which the use of the machine is restricted to the daytime—and has brought out a rival company, one of the features of which is that provision has been made under the patents to apply the electric light automatically. This company estimates the number of its customers at fifty per day, whereas the other one put the possible number at thirty. No doubt one estimate is as trustworthy as the other, but as both companies have taken great care not to invite photographers to give an opinion on the merits of the rival schemes, we do not know that we need trouble ourselves about the matter. If the public must speculate, they may as well speculate in photography as in anything else.

The highest price ever offered for a photograph was probably that which was mentioned in vain some weeks ago for the photograph of the plaintiff in a certain action. The theory of the defendant was that the plaintiff was the same person who achieved notoriety on the Continent some time since, but to sustain the theory, proof of identification was necessary. A hundred pounds was offered for a photograph, but the person who had one in possession refused to sell. An artist was then employed, and attended the court during the hearing of an appeal on some point of law. Unfortunately, he could only catch a glimpse of the plaintiff, and his sketch was a failure. Up to now sensitive plates are not equal to the subdued light of our law courts, or a detective camera would have been called into requisition.

The Americans are extremely fertile in their invention of photographic "notions." The latest freak of fashion is for a gentleman to send to the lady he admires a handsome box, which, when opened, shows a photograph of an aristocratic pair of ears, the back button-hole of an abnormally high collar supporting a closely cropped head, and a view from behind of a well-cut coat. Indignation is, of course, the first emotion raised by the receipt of such a portrait, and the young lady naturally seizes a piece of ribbon attached to the box with the intention of rending the unwelcome gift to pieces, when, at the first tug, the picture slides out of the box, disclosing another which shows the proper features of the young man, smiling, after the manner of his kind, at his mollified sweetheart.

It is not every sitter who is so indifferent to his personal appearance as represented in a picture as is the King of the Belgians. He was recently sitting to an artist, and, getting somewhat tired, expressed a hope that the work would be speedily completed. The artist replied that he was afraid he should be obliged to detain him a little longer. The King sighed and remarked, "You might finish me off in a couple of seconds or so." "How?" exclaimed the amazed artist." "By just drawing a large man with a big nose." This was undoubtedly an abbreviated way of describing his appearance, yet, judging by the Belgian postage stamps and the Belgian coins, it was sufficiently accurate.

But monarchs must, after a long course of photographers and artists, grow somewhat callous as to how they look. As each photographer and each painter gives a different rendering of the royal features, the only interest the sitter must have in the subject is how he or she will be turned out at the hands of the new man. In fact, crowned heads at times must get a little mixed as to what is their exact appearance and expression.

The West-End photographers have been exceptionally busy on the occasion of the recent Drawing-Rooms in photographing the *debutantes*. It would be exceedingly convenient if the Queen would have a studio fitted up at Buckingham Palace, so that ladies could be photographed in all their freshness as they arrive. To array oneself for the ceremony, and to put on one's dress, train, and feathers for the photographer the next day, is not quite the same thing. Somehow, all the spirit and "go" of the affair evaporate. Her Majesty is a great collector of photographs, and why not add to her interminable list of albums a "Drawing-Room Album," to contain such portraits of the ladies presented to her as might be available? It would probably mean an extensive studio and a large staff of artists, but it need not cost the Queen a single farthing. There are plenty of enterprising firms who would undertake the task, provided they were not hampered by Court routine or restrictions.

In more than one instance we have recently noticed with satisfaction that ethnographical science is finding out the value of photography. At the Stanley Exhibition are several pictures which give a good idea of the natives of different tribes—what manner of men they are, and how they occupy themselves. We have all read much about Africa and its inhabitants of late months, but these photographs tell us at a glance much more than we can glean from any written description. One photograph, showing how the huge tusks of ivory are carried from the interior of the country to the coast, is especially interesting. The poor natives have evidently yet to learn how to keep still and look pleasant, for they have done neither the one nor the other, some of the figures being very indistinct in outline; but as they are somewhat deficient in clothing, a little fuzziness is not a matter for regret.

But at our more permanent ethnographical collection at the British Museum the value of photography is also recognized, for several fine enlargements from pictures taken at New Guinea by Lindt, of Melbourne, have recently been hung on screens. These pictures measure about 42 by 36 inches, and if we remember rightly the originals of some of them were shown a few years back at one of the Pall Mall exhibitions. One picture of a chief's house, supported on rough piles above water, is most interesting, as showing a lake dwelling of to-day, resembling those of ancient times, the remains of which have been so often found in Europe. A group of children—little black imps—is huddled together on a platform in front of the house, just as we see the small monkeys at the Zoo crowding together on a cold day.

Some other photographs in the same gallery seem, by their yellow tint, to be of older date. These are portraits of Kaffirs, some of which exhibit a remarkable form of head-dress, which looks like a tall cap covered with astrachan and with a plate on the top. But this is, in reality, no cap at all, but is formed by the natural growth of the hair, or rather wool, which is clipped all round like a well-kept hedge, and is crowned by a ring made of palm leaves, which is covered with vegetable wax and polished up with charcoal until it rivals in the splendour of its shine the domestic fireplace of civilisation. There is an old saying that "one half the world does not know how the other half lives." It would seem that photography is destined to be of great service in supplying part of the required information.

Those who still make oxygen gas—and their number must have been greatly reduced since the Brin Company have supplied it in cylinders at such a cheap rate—will be interested in a letter which appears in the *Scientific American*, in which the writer asserts that he has for some time discarded the use of manganese for admixture with the potassic chlorate, and has substituted for it carbonate of iron. There is probably some confusion here, for carbonate of iron is the crude iron ore, occurring either as spathose, or, in a more impure form, as clay ironstone. This, under the action of heat, is changed to ferric oxide. The red oxide has long been used in association with potassic chlorate for oxygen making, and if this substance is intended, there is nothing new in the suggestion. If, on the other hand, the clay ironstone is meant, impurities would be likely to be introduced into the retort, which might lead to serious accident.

It is evident, from reports reaching us from many sources, that eikonogen as a developer is fast finding friends among both professional and amateur workers. From our own trials of it we believe it to be more valuable for portraiture than for any other branch of photography, and for the reasons that the contrasts which it affords are soft, and that the colour of the deposit lends itself admirably to the inevitable retouching pencil. Amateur workers who have been used to obtaining vigorous landscape negatives with pyro and ammonia generally fail in their first attempts at portraiture, because they aim at a density which blots out all the finer lines and expressive markings of the face. With eikonogen they can hardly fall into this error. It gives an image like a ferrous oxalate developed plate at its best, and works with far greater certainty of result. We all know that on the Continent almost exclusively, and in some of the principal studios in this country, the ferrous oxalate method has for a long time been the standard system of development for portraiture. Eikonogen seems likely to usurp its place.

The French Exhibition, like most other large exhibitions now-a-days, was far from complete on the opening day, and half consisted of packing cases. In about another week it will be in a fairly advanced state. The Exhibition consists largely of fancy articles, in which the French display their acknowledged high level of artistic excellence and refined taste.

FICTION IN PHOTOGRAPHY.

A PRETTY and pathetic story was told many years ago—at a time, indeed, when photography was a mere infant—in the *Family Herald*. A certain honest peasant woman, known as "La Veuve Yvonne," living in a little secluded village in Brittany, having heard of the marvellous powers of photography, determined to visit Paris to test its merits after a fashion of her own. Arriving at the capital, she inquired for a photographer, and visited his studio. "I wish," she said, "for a portrait of my child." "Certainly, madam; have you brought the child with you, or shall I call upon you?" "Neither," replied La Veuve Yvonne: "they tell me you are very clever in making children's portraits." "I succeed pretty well," said the photographer; "but when they are exceptionally restless."—"My child will not trouble you with his restlessness." "Ah! then," replied the photographer smiling. "I am pretty sure to do well." "My child," she continued, "is dead." The photographer ceased to smile. "You want a picture of him before he is buried." "He has been dead and buried for five years." "What!" said the surprised artist; "you have, then, a picture of him." "If I had," replied the widow, "I should not be here." The photographer told her kindly that what she requested was impossible. "Impossible!"—and the widow's countenance fell—"they told me that photography could work miracles." A sudden thought sprung from the kind heart of the photographer, and illuminated his brow. "You have still your child's clothes, madam?" "Yes. I made them for him myself." "How old was he?" "Six years." "The colour of his hair?" "Golden." "He was a good boy?—you will forgive my inquiries." "He said his prayers every night at my knee." "Pardon me for asking all this," said the photographer to the weeping mother. "You shall—yes, by the help of heaven—you shall have his portrait. In a couple of days come to me again." The widow came, and received the first proof. "It is he!" she cried with a mother's happy love, "it is my son. He wears the little boots I got for him from neighbour Dubois. This is his little coat with the pearl buttons, which I sewed on with my own hand. Ah! and that is his long, bright, golden hair. Oh! monsieur, what shall I pay you for this?" "Madame," replied the photographer, "photography, you have been told, can work miracles, and miracles are never paid for."

Dame Yvonne returned to Brittany, and remained till the day of her death convinced that the portrait she had placed over her cottage bedstead was the portrait of her dead child.

The good photographer had dressed a small child of his own in the boy's Breton costume, and had represented him in a kneeling attitude, his head bent, and his face hidden by his hands, clasped together in the humble attitude of prayer. On a deceit of this kind, as on the celebrated oath of Uncle Toby, the recording angel, while inscribing it in the book of human actions, surely dropped a tear, blotting it out for ever. That celestial being, indeed, seems to have inspired the mother with a reply to all the doubts and cavils of inquisitive neighbours. "Why," said one of these, "does your son hide his face thus in his hands?" "Ah!" replied La Veuve Yvonne, "you must be a bad Christian indeed to ask that. The little angel in heaven is praying for me, his poor old mother, who is left in the world alone."

Even religious stories have been suggested by photography. But they seem not to have been a commercial success. A little volume containing them, entitled the "Photographer," was discontinued after the second number. These stories present a melancholy reflection of Bunyan. The camera appears not to lend itself kindly to the purposes of conversion. In one tale we are told that the three brightest features in the Christian's countenance are Faith, Hope, and Charity. So far, indeed, as faith is the evidence of things not seen, the photographic comparison is happy. The protagonist of another tale is asked, "Do you perceive your faithful likeness? Does your countenance appear hopeful? Is your charity sufficiently in shadow? Is your body full of light? Is the light which falls on you unsteady? Are you endeavouring to look cheerful, or are your features rigid and harsh?" Dismayed by these enquiries the protagonist endeavours to escape, but the photographer adjures him not to run away, to let him look again at his general appearance, and finally adjourns the sitting to a time of increased light.

The preceding stories were all told in prose. The following was originally composed in rhyme. A young officer, cornet Fitz Sparrow, in the Aldershot Blues, "stood four feet six in his shoes," and his diminutive stature was to him a source of enduring shame and sorrow. He forgot, or never knew, apparently, the moderate statures of those military heroes, those thunderbolts of war, Nelson and Napoleon. It was in vain that he mixed raw eggs and brandy and drank the compound: it was in vain that he wore the tallest top hats he could find; it was in vain that his bootmaker, by the aid of cork heels carefully concealed in his boots, thought to accomplish the unaccomplishable. No man, we have it on the best authority, can by taking thought add a cubit to his stature, and that was exactly what cornet Fitz Sparrow attempted to do. The brandy gave colour to his nose instead of length to his legs; the tall hat made him look top heavy; the high heels went before a fall. And cornet Fitz Sparrow was so anxious to marry, but every maiden said him nay. At last he resolved to advertise. "Wanted, a Wife."

A dozen answers were sent to his advertisement, but every one of the applicants desired his carte-de-visite. This request, which would betray the smallness of his stature, he felt to be a death-blow to his hopes. However, he went to a photographer—a cunning artist—who assured him he could give him the appearance of a giant. Fitz Sparrow was in raptures when the photographer, by the aid of a child's table and chair placed close to the cornet, gave him the size of a modern Goliath. He immediately forwarded a dozen copies of his carte to the dozen applicants, and they appointed a dozen meetings at a dozen different times and places. Alas! one by one they came, saw, and, disgusted by the lowness of his bodily frame, left him; all save one, the twelfth, a little fairy, who whispered in his ear, "Oh, I am so glad; I was so afraid you were too tall." It is needless to give much more of this rhymed story. They married, and, being both short, kept each other in countenance in more senses than one, and were happy; and ever afterwards, Cornet Fitz Sparrow, though he only "stood four feet six in his shoes," stood, in his own estimation, five feet ten at the very least.

MR. F. P. CEMBRANO and Mr. J. B. B. Wellington are now in Stockholm, after a hand-camera excursion up the Rhine, down the Danube to Vienna, then to Oberammergau and the Passion Play, thence to Copenhagen.

REMARKABLE NOVELTIES IN PHOTOGRAPHIC INSTRUMENTS.

Last Wednesday night, Mr. J. A. Rudge, a scientific instrument maker of Bath, exhibited to the Bath Photographic Society a new optical lantern, with mechanism attached, to represent, by means of a series of photographic slides, men and other animals moving as in life. The first instrument of this kind was exhibited a few years ago to the Photographic Society in London by Mr. Friese Greene, who informed the meeting that it was invented by Mr Rudge, of Bath. It consisted of a lantern with one condenser, and four small projection lenses, each receiving light from the lamp through a separate part of the condenser. A rotating opaque disc was so shaped that before one image—say of a face—was entirely cut off from the white screen, the next image was imposed upon it, so that the one gradually melted into the other. In this way the face could be seen changing from grave to gay, and so on, and the very twitching of the skin of the face could be seen. Mr. Greene heightened the effect by painting the gelatine negative with cobaltic and other salts, so that, as the slide grew warm from the heat of the lantern, colour gradually appeared in the face and dress. The effects were, from an entertainment point of view, vastly superior to those produced by Mr. Muybridge and others by application of the thaumatrope principle, the unpleasant jerkiness of which is well known. Mr. Rudge's lantern was defective in several ways, and, among others, in the small sizes and numbers of photographs it could take in one series.

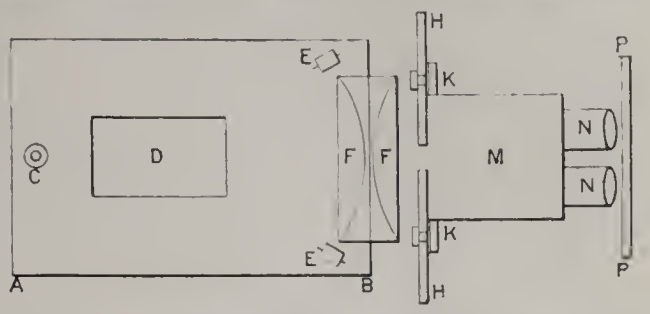
Later on Mr. Greene brought out an invention upon the same lines, and had an instrument constructed consisting of three lanterns, by which means he was able to bring the full power of one condenser to bear upon each slide exhibited; the instrument also included some costly mechanism for automatically bringing a long series of twenty or more slides into play. Practically, like most new inventions, it was defective, and, for want of sufficient adjustment beforehand, was far from doing its best work when exhibited before the Photographic Society. Since then considerable improvements have been made in the instrument, but at present they are not for publication. Mr. Chang, the Secretary to the Chinese Embassy, had a private view of the whole machine at work a few days ago, and was much interested therein.

Lanterns of this class necessitated the taking of photographs in rapid succession—that is to say, several in the course of one second of time—and that led to the invention by Mr. Greene and Mr. Mortimer Evans of the camera for giving ten or even more exposures a second.

Quite recently, as published in these pages, Mr. C. V. Boys has invented and used a machine for taking one hundred or less of photographs per second, when the object is sufficiently self-luminous, or illuminated.

The next public step in this eventful history took place last Wednesday night at Bath, when Mr. Rudge exhibited to the Photographic Society there a new instrument, which may be explained by the aid of the accompanying diagram.

In this diagram AB is the lantern, pivoted at C to permit a small front motion, of which C is the centre; D represents the position of the lamp and chimney; EE are rollers to facilitate a little right and left motion of the front of the body of the lantern, from which the parts in front of the condenser FF are detached; HH are two discs, on each of which six photographic portraits of the same person are printed; the discs rotate upon their respective pivots KK. The large tube M carries two smaller tubes NN, in which are mounted lenses which



swivel in any direction, and can then be clamped. PP is a moving shutter.

When this machine is in action, the front of the lamp, and the condenser thereupon, are constantly moving either to the right or to the left; this enables a smaller condenser to be used than would otherwise be necessary, and tends to equalise the illumination on the screen during the changes in the image. The discs and photographs resemble those obtained with Stirn's camera, but are of larger size; the apparatus used with the lantern is also employed when taking the negatives, so that when the latter are printed as positives on another circular sheet of glass, they are certain to be in true register. The greatest difficulty in making this class of instruments consists in obtaining perfect registration everywhere, so the mechanism must be perfect. The next greatest difficulty is in obtaining equal illumination of the projected images during their changes. The machine exhibited by Mr. Rudge last Wednesday night was not quite finished, and as the positives were not ready, he had to employ negatives instead; it served, however, to explain the principles involved. He is making this machine for Mr. Greene.

The instruments already mentioned are probably the heralds of the dawn of a new branch of photography, the ramifications of which no one can foresee. We once published that the power of taking and of printing negatives with immense rapidity brings us several steps nearer the greater use of photography as a means of publishing news and of bringing out of books. Mr. Boys has already found such appliances necessary in one branch of scientific research. Mr. P. Braham told the meeting on Wednesday night that crystals in the incipient stage of their formation do not grow slowly, but shoot out all at once, consequently such instruments may possibly reveal the details of this scientific phenomenon, and show how crystals grow in their primary stages. Of the value for historical purposes of such instruments, when perfected, Mr. Friese Greene wrote in the last Year-Book.

Yesterday morning we called, with Mr. Friese Greene, upon Mr. W. M. Ashman, whose skill in practical photographic work is well known. His studio faces the south, so is glazed with ground-glass, and in hot weather, by turning a tap, he can let a thin sheet of water flow down the whole surface of the roof; this, he says, makes the whole studio beautifully cool in about ten minutes. Of course the evaporation of water has a powerful cooling effect. He uses homely furniture as accessories in photographic work, and has striped tinted blinds, instead of white ones, so that the whole studio has a little more than usual the appearance of an ordinary room.

THE PHOTOGRAPHIC SURVEY OF WARWICKSHIRE.

A MEETING of those interested in the Warwickshire Survey was held at St. Edmund's College, Birmingham, on Thursday, May 22nd, the Mayor of Sutton Coldfield, with Mr. J. B. Stone, F.G.S., in the chair. There was a numerous attendance of the members of the Birmingham Photographic Society, together with representatives from the Vesey Club, the Municipal School of Art, the Coventry Photographic Society (Mr. F. W. Dew), the Philosophical Society, and others. Letters of apology were read from Messrs. S. Timmins, Richard Tangye, Surgeon-General Ranking (President of the Leamington Photographic Society), H. W. Jones, F.C.S. (Vice-President of the Coventry Photographic Society), A. E. Donkin (Rugby School), H. R. Lloyd (Birmingham Archæological Society), Professor Poynting (Mason Lodge), and others, all giving their approval to the survey, and promising to help in the work.

Mr. Stone said that the object of the meeting was to organise a County Survey Council which should take charge of, organise, and carry out a survey of every object of public interest in the county of Warwickshire. The survey would include photographs of buildings—ancient and modern—of ancient manuscripts, of paintings, of objects of geological and botanical interest; it would, in fact, form a record which would enable future generations to have some idea of the state of the county as it existed in the latter part of the nineteenth century. He referred to a letter which had been received from the secretary of the Birkenhead Photographic Association, claiming originality for the idea of making a photographic survey. There could be no originality in the idea, for it had been carried out—after a fashion—many times. He had himself made what he supposed the Birkenhead Society would call a photographic survey, by photographing all the old buildings in the hundred of Hemlingford, quite a quarter of a century ago. But the survey which Mr. Jerome Harrison had proposed, and which they were prepared to carry out, was something of an altogether different nature. He proposed "That a County Photo-Survey Council be created for the purpose of organising a complete photographic survey of Warwickshire; such council to consist of elected representatives from the various photographic societies in the county, in the proportion of five per cent. of the members of each society, together with two representatives from each of the scientific, literary, and artistic societies in the county; that the council shall have power to elect co-optative members, and shall appoint public trustees for taking charge of the records obtained."

The motion was seconded by Mr. W. Jerome Harrison, F.G.S., who said that he heartily welcomed the presence on the survey of the scientific and artistic workers whom he saw present. They could lend great aid in drawing up lists of noteworthy objects to be photographed. He trusted that Mr. Bagnall, whose "Flora of Warwickshire" was on the eve of publication, would at once supply them, for example, with a list of famous trees within the county. Mr. Jethro Cossins, the eminent architect, had promised help with the churches. It would be part of their first work to obtain information as to the thousands of valuable negatives which were already in existence.

Mr. W. Buncher (School of Art) hoped the council would take into early consideration the question of publication of a selection of the results obtained. He thought that a thousand subscribers to such a work could be obtained with ease.

Mr. F. W. Dew (Coventry) promised hearty co-operation in the work, and spoke of the great alterations which had been made within the last few years in the churches of Coventry. He had many valuable negatives of those churches before their restoration.

The motion was carried unanimously.

The Chairman proposed, Mr. S. G. Mason seconded, and it was carried unanimously, "That the first co-operative members should be appointed at that meeting; that they should retire at the end of the current year, when the council shall proceed to elect other members to fill the vacancies, the retiring members to be eligible for re-election."

The last resolution, which was put from the chair, seconded by Mr. Jethro Cossins, and carried unanimously, was "That the photographic and other societies of the county be requested to at once elect their representatives, and that the first meeting of the new council be called for June 12th."

Notices of Books.

THE AMATEUR PHOTOGRAPHER'S LIBRARY, Nos. 2, 3, and 4. (*Hazell, Watson, and Viney, London*, 1890.)

THESE are three recently issued little volumes, each dealing with special subjects of interest and use to photographers, especially to beginners.

CAMERAS, LENSES, AND SHUTTERS.

"Cameras, Lenses, Shutters, &c." is the title of No. 2 of the series, and consists of a number of articles by different authors who have given special attention to the subject. The first article in the book is on "Cameras," by Mr. W. V. Corbet, who, after a few practically useful remarks about tripods, says:—"A plain screw and a flat camera bottom offer a ready means of revolving instrument, at same time abolishing horizontal front, and lessening weight and complication. It will now be seen that revolving heads and horizontal fronts are not wanted." This is an example of the slipshod composition pervading the article of often leaving out the word "the" where it ought to have been inserted, and contains error as to a matter of fact. No revolution of the camera on its axis will bring an imaginary line, passing through the centre of the lens, away from the centre of the plate and nearer to one or other of its edges; the horizontal front enables this to be done, and with certain subjects, and when using lenses with a not very flat field, gives optical advantages not otherwise obtainable. When using a portrait lens, to take instantaneous photographs in places where the light is not good enough to permit the use of a doublet, sometimes the view may be such as to cause a horizontal front to become a welcome appliance. The rest of the article contains some useful suggestions.

Another article on the same subject is by Mr. John Powell, who deals with the subject of camera-legs with considerable critical ability, showing that the legs of cameras deserve more scientific attention than they have hitherto received. At present they are made too much by rule of thumb, so far as obtaining the maximum rigidity with the minimum weight of wood is concerned, so that the photographer is often carrying more wood than is necessary to obtain the same amount of rigidity. Some of Mr. Powell's valuable utterances on this subject are here quoted:—

> There is one important factor which seems to have been entire overlooked, viz., that with the same cubical dimensions—in other words, the same weight of timber—we can obtain greater rigidity. Viewing the ends of most tripods, we note that the pieces are approximately square, that the breadth and depth are nearly similar, instead of being *long rectangles*. Let us take two examples, one of the former and one of the latter, and consider their respective comparative strengths:—
>
> | | Breadth. | | Depth. | | Content. |
> |---|---|---|---|---|---|
> | No. 1. Approximately square section, in eighths of an inch | = 5 | × | 6 | = | 30 |
> | No. 2. Long rectangular section, do. | = 3 | × | 10 | = | 30 |
>
> In the first case, the breadth is assumed as $\frac{5}{8}$ in., and in the second case as $\frac{3}{8}$ in. Now, under a cross strain the strength is proportional to the breadth, so that No. 1 : No 2 : : 5 : 3, that is, No. 2 is only $\frac{3}{5}$ of the strength of No. 1. Next, in the first case we have taken $\frac{6}{8}$ as the depth, and in the second case $\frac{10}{8}$. Now the depth is most important. The strength varies as the square of the depth, so that in this respect No. 1 : No. 2 : : 36 : 100, or in other words, No. 2 is nearly

three times as strong. Lastly, combining the former and latter calculations, it will be found that No. 1 : No. 2 : : 180 : 300, or that No. 2 is nearly double the strength.

Further, as already stated, the ratio of length to depth in No. 1 would be 64 to 1, whereas in No. 2 it would be 38·4 to 1, a considerable advantage.

Again, the clear space between the joints would be, say, 15 ins. Hence the ratio of length to breadth, that is, 15 to $\frac{3}{8}$ in., would be 40 to 1. Further, as this only applies to one part, and that part could not buckle under ordinary circumstances without the pair being similarly affected, it is manifest that it is fully equal to the other proportions, the only disadvantage being the formation of a rectangle with the joint pins, which would be somewhat dependent on a sound, well-finished joint. To this, however, both are comparatively dependent for rigidity.

Mr. Powell also considers the first principles of construction to secure the rigidity in the camera, which in theory should be so affixed to the tripod that the centre of gravity of the camera is below its support. He suggests a camera constructed upon these principles, and describes it by means of diagrams, but as the diagrams do not appear in the book, having been omitted apparently by accident, readers are not in a position to criticise the details. Apparently the camera is fixed below the head of the stand. The author says :—

> The advantages, briefly, may be summed up as follows :—
> 1. The legs practically meet at a point.
> 1. The camera is in stable equilibrium.
> 3. It dispenses with the use of a level.
> 4. The line of sight is always normal to the plate.
> 5. It presents the least equivalent area of pressure to the wind, which, other things being equal, is a decided advantage in form over the pyramidal, as the latter is over the square or rectangular form.

Mr. Powell, in dealing with the subject of conical *versus* square bellows for cameras, gives his verdict absolutely in favour of conical bellows, chiefly because, when open, they present less wind surface. This is the most questionable part of his excellent article. When the camera is of long range, which is the case with the most serviceable instruments, conical bellows are apt, under certain circumstances, to cut off a part of the image when the operator is using the rising or falling front ; various devices exist for overcoming this defect by gathering together and fixing some of the folds of the bellows, but it would be more convenient were no such devices necessary.

A third article on "Cameras" is by Mr. J. H. Taylor, who says that he prefers plumb levels to spirit levels for cameras : the former, however, are more in the way of the operator. A level of any kind is scarcely necessary, where buildings are in the field of view, to give truly perpendicular lines as a guide in focussing, but in some mountainous regions, with no vertical straight line in view, and the legs of the camera erected on a bank sloping like the roof of a house, the photographer soon discovers the value of levels for special purposes. A fault in many of the levels now sold for photographic purposes is that they are too sensitive ; were they less so, within certain limits, they would be easier to use, and no practical disadvantage would creep in. Mr. Taylor speaks of the large per centage of defective photographs obtained from one cause or another in the use of hand-cameras, and recommends that whenever possible they should be used on the top of a light stand. This advice is good for those who care for quality rather than quantity.

Next come some papers on lenses. The first, by the Rev. T. Perkins, gives some of the optical principles at the root of the construction of lenses. Towards the close the author says :—

> Half a doublet forms a landscape lens which will work with about $f/23$ or $f/32$; in many of Ross's rapid symmetricals, the two combinations are of different foci, and as either will screw on the back of the lens tube, two different singles may be obtained. A doublet of intermediate focus may be obtained by removing the back combination, and replacing it by the back combination of a doublet of longer focus. Ross's portables may be thus used. It is well to have a cap to fit each end of the lens tube. Dust is thus excluded, and the lens protected from injury. But, despite all care, dust will find its way to the glasses ; to remove it, dust with a camel's hair brush, then wipe with chamois leather, or a soft silk handkerchief kept, when not in use, in a broad-mouthed stoppered bottle. A little pure alcohol may be used to remove stains that the dry leather will not remove. The lenses, when not in use, should be kept in a case with a division for each, or put away in a box, each lens being placed in a bag of chamois leather.

Mr. J. H. Hargrave gives a paper on the same subject, so also does Mr. J. H. Taylor. The latter, on page 31, gives an elaborate description of a diagram, which diagram is not in the book. It is a good memoir.

The next article is by Mr. W. Groves on "Shutters." The roller blind shutter next the plate is theoretically the best for giving the largest amount of light in a given time. Mr. Groves says that its bulk is objectionable. This would not matter so much, especially as it forms part of the camera ; but its weight, as at present generally made, is against its general use. A remedy would be to substitute aluminium for brass in some of its parts. Mr. Groves says of this shutter :—

> Shutters used immediately in front of the plate permit the full power of the lens to act on each portion of the plate during the whole time the said portion is uncovered. By using a drop shutter or roller-blind shutter with a narrow aperture the width of the plate, it is probably possible to give shorter exposures and obtain sharper images of objects than with shutters in other positions. In the case of rapidly-moving objects the images obtained by these shutters are slightly bent or distorted, as will readily be seen when it is considered that the image is exposed bit by bit as it travels along the plate. This distortion may be reduced to a minimum by causing the shutter to travel in a direction opposed to that of the image. Variation in the exposure given to the foreground and sky may be affected as in shutters immediately behind the lens. Shutters in this position become very bulky for the larger sizes of cameras ; their exposure apertures have to travel over a large amount of space, and, as in the case of shutters immediately behind the lens, they require to be especially fitted to the camera. Shutters behind the lens are particularly adapted for hand or detective cameras.

The next article on "Shutters" is by Mr. J. H. Taylor, and the third by Mr. Louis Meldon, whose objection to the roller blind shutter next the plate we think to be stated in too strong terms, and that its utility is far above his estimate. Mr. Meldon gives the following table of the rapidities of different shutters, but does not state who made the experiments, nor how the measurements were made, and the latter is a point of vital importance :—

> The following is a list of the rapidities shown by certain shutters, which may be of some little use in affording an approximate idea of what may be expected from them :—

	Second.	
Drop Shutter	$\frac{1}{15}$	Aperture, $2\frac{1}{4}$ sec.
„ „	$\frac{1}{50}$	„ $\frac{1}{4}$ sec.
Newman's	$\frac{1}{15}$	Whole-plate.
The Plunge	$\frac{1}{5}$	Quarter-plate
„ „	$\frac{1}{11}$	„ „

Watson's Double Snap ...	$\frac{1}{20}$	Whole-plate.
Phantom	$\frac{1}{12}$ to $\frac{1}{33}$	„ „
„ sky	$\frac{1}{100}$	Quarter-plate, double bands.
„ foregrouud ...	$\frac{1}{40}$	
Cadett's Lightning : sky ...	$\frac{1}{33}$	Whole-plate.
„ „ foreground ...	$\frac{1}{25}$	
Wollaston's Diaphragmatic ..	$\frac{1}{25}$	Whole-plate.
Robinson and Son's (go and return) foreground	$\frac{1}{15}$	Half-plate.
„ „ sky	$\frac{1}{22}$	
Lancaster Instantograph ...	$\frac{1}{15}$	Half-plate medium band.
Kershaw	$\frac{1}{17}$ to $\frac{1}{60}$	Whole-plate.
Grimston ... ... up to	$\frac{1}{23}$	Aperture $1\frac{3}{4}$ ins.
Meldon (as made by Perken) „	$\frac{1}{300}$	„ $1\frac{1}{4}$ „
Caldwell (as made by Wray) „	$\frac{1}{200}$	„ „ „
Thurey and Amey ... „	$\frac{1}{300}$	„ „ „
Mr. P. Lange's	$\frac{1}{77}$	„ $1\frac{1}{2}$ „

The next article is by Mr. L. A. Burrow on "The Sensitive Medium," in which the author deals with emulsion making. He says that with iodide of silver alone in emulsion the image is dense, but there is little detail in the shadows or high-lights. But has the best method of preparation, or vehicle, or mode of development for iodide emulsions yet been discovered? It may be remembered that Sutton and a few others stated that iodide of silver is more sensitive than the bromide in the wet collodion process, but necessitates greater attention to the purity and condition of the nitrate bath.

Mr. W. P. H. Foster contributes an article on the same subject, so also does Mr. J. A. Randall. The latter puts forward the following pleas for the use of slow plates, except where quick ones are a necessity :—

Before preparing an emulsion, it must be decided whether it is to give rapid or slow plates. The difficulty of making a good emulsion increases as means are taken to gain rapidity ; whereas to prepare a slow emulsion is a certain and comparatively easy matter. The film of a plate coated with a slow emulsion is of an orange colour, and much denser than the film of a quick plate ; for this reason halation is not so likely to impair the quality of the finished negative. With a slow plate a degree of richness can be obtained that is not so often seen in a rapid plate. There is a certainty connected with slow plates, and an amount of comfort in working, which cannot be equalled with rapid plates. They can be developed in a light which adds considerably to this comfort and certainty of result : the plates being more manageable, whilst developing the latitude of exposure is much greater. For fleeting effects in landscapes, instantaneous views, and moving subjects, a rapid plate is, of course, necessary, but when it is not a matter of time in exposure, no advantage can be gained by using an extra rapid plate.

The Rev. T. Perkins, M.A., contributes an article on "Exposure," at the close of which he says :—

Many photographers find a difficulty in timing exposures. Wishing to keep their eyes on the subject during the exposure, in order that they may re-cap the lens even before the full intended exposure has been given should anything suddenly move and so irretrievably ruin the picture, they cannot keep their eyes on the second hand of their watches ; but I always count seconds in the following manner, and by it I can count even a minute with an error of not more than one or two seconds : I repeat as fast as I can as many letters of the alphabet as I find from experience I can say in a second, thus, "a b c d e f, one ;" "a b c d e f, two ;" and so on up to ten seconds ; then I begin a second set until the requisite number of seconds is completed. A little practice is all that is required to gain great accuracy by this method, the first idea of which I gained from Professor A. S. Herschell, who used a somewhat similar plan to count the time of the flight of meteors across the sky ; and I should advise its use for exposures not exceeding twenty or thirty seconds—for longer exposures a watch is more convenient.

Mr. W. A. Watts, M.A., also contributes an article on "Exposure."

Finally, the book closes with three articles on "Development," by Messrs. H. E. Murchison, F. T. Bennett, and W. A. Watts. Subjects which should meet with more attention in a future edition of this useful little work are finders, focussing-glasses, focussing screens, and something about eikonogen, for, although the book is dated 1890, there is nothing in it about the latter developer.

For the notices of the other two books of the series, space cannot be found this week.

Anleitung zur Photographie fur Anfanger. Von G. Pizzighelli. (1890. *Knapp, Halle a S.*)

This work, which is not bulky, although containing 200 pages illustrated with over 100 woodcuts, professes modestly enough to be an introduction to photography for the use of beginners. It will certainly serve this purpose, as each subject is taken from the beginning, and explained in a way that is calculated to make it understood by those who have not had previous instruction in photography. It is, however, so thorough in the treatment of the subjects included in its scope that it may well take place as a manual not for beginners merely, but for reference on the part of the amateur, and even of the professional photographer. We have seldom met with such a trustworthy and, so far as it goes, complete handbook in so small a compass as is presented in the present volume by the well-known writer and experimentalist, Captain Pizzighelli.

Specifications Published.

9,312. *June* 5th, 1889.— "Photographic Box Cameras." George Charles Inkpen, Architect and Surveyor, 12, Havelock Road, Southsea.

The construction of box cameras, the means of releasing the exposed plates, bringing forward fresh plates and storing them after being exposed, also the construction of the lens shutter and means for opening and closing same.

The camera consists of an oblong box with raised platform each end. On the back platform the plates are placed in vulcanite sheaths and held in position by india-rubber bands, and are pressed up to the front by means of a coil spring. The lower edge of the sheath is caught in a catch and the upper part by a lever worked from the outside of the box, which, on being moved alternately to the left or right, correspondingly passes over notches in the vulcanite sheaths, and releases the

plates, which fall upon a roller covered with india-rubber, and are afterwards passed and collected together beneath the platforms at each end of camera. The front platform carries the lens of the ordiuary type, and the focus can be regulated from the outside. The shutter consists of two vulcanite discs, fixed on a centre, attached to a base board, and haviug a drum with two cords wouud upon it. The pulling of the cords alternately causes a corresponding movement of the discs, which, in passing over the lens aperture, opens and closes the lens.

The inventor claims :—

1st. The ueans by which a plurality of plates, films, or other sensitised media, arranged one behind the other in a camera, are released in succession, removed from the field of the lens, passed into a depository chamber, and retained there in such a manner as to prevent them falling forward so as to obstruct the field of the lens, as substantially set forth.

2nd. In providing a back of thin vulcanite, or other suitable material, with projecting edges, as a carrier behind the plates or films, and securing the two together by means of elastic bands, preferably placed towards the ends of the carrier, which also prevents the sensitised surfaces being damaged, as substantially set forth.

3rd. In cutting notches in the projecting edges of the carriers above-mentioned in such a manner as to be alternately placed when a number of carriers are arrauged in succession one behind the other, and a sliding bolt or other similar ueans which, by engaging with the projecting edges of the carriers, causes the catch or catches of the bolt to release its hold on passing the notches or slots in the upper edge of the carrier, and allows one carrier with the plate or film to be expelled from the platform, whilst the plate immediately behind it is secured by the bolt and carrier, as substantially set forth.

4th. The arrangement of the sliding bolt and the lever which imparts a movement to it actuated from the external case of camera ; also the capability of the lever being connected to the mechanism of a lens shutter so as to set it and reset it, as substantially set forth.

5th. One movement alone is required to reset the shutter and release a carrier with plate ; the action being simultaneous, it follows that it is impossible to take two views on one plate, as substantially set forth.

6th. Exhibiting the number of the carrier by a sliding register visible from the outside of camera of a corresponding number to that placed on carrier, as substantially set forth.

7th. In providing a platform in the body of the camera, on which are placed one or more rollers, covered with india-rubber, to break the fall of the carrier with glass plate or film when expelled from the platform, protect the sensitised surface, and conduct the carrier to the depository chamber, as substantially set forth.

7,522. *November 4th*, 1889. — "Photographic Apparatus." VICTOR JULES EMILE DAMOIZEAU, 17, Rue St. Ambroise, Paris, Gentleman.

This invention relates to the construction of photographic apparatus which is capable of taking in any desired angle or even the entire horizon, for producing panoramic views for plans, landscapes, and the like.

The inventor claims :—

1. The construction of a carriage with two racks worked by a common pinion, which permits the use of a lens of any focus, and insures an equal and simultaneous displacement of the camera and of the front.

2. The general arrangement and construction of the camera forming a magazine coutaining folded bellows, and capable of being taken off in one piece.

3. In the camera proper, the arrangement and use of cylinders and rollers aud lever which secure the regular rolling up and unrolling of the sensitive material, as well as the ueans for driving them from the motor which actuates the carriage at the same time.

4. In the camera described, the employment of two quadrants for determining the aperture of the diaphragm and regulating the time of exposure.

5. The combination with the camera described of a spring pricker for making the register-marks on the sensitive material, and of the counter constantly indicating the amount of the sensitive material that has been used.

6. The means for working the shutter simultaneously with the other parts, and for closing the same automatically when the carriage stops.

7. The construction of the front with slides for obtaining a horizontal and vertical displacement with a wide range of motion.

8. The special construction of the lens mounting, which forms one with the sliding front, and which is furnished with an opening to permit the lenses to be changed.

9. The synchronous moving of the optical centre of the lens, and the roll of sensitive material which is unwound at the back of the lens.

10. The addition to the extremities of the sensitive roll of black paper or fabric, or the like, which covers the sensitive material when rolled up, so that it may be withdrawn from the camera or placed in position therein in open daylight.

11. The general arrangements and combinations of parts constituting the improvements in photographic apparatus, substantially as described and illustrated by drawings accompanying the specification.

7,347. *May 2nd*, 1889.—"Photographic Cameras." RICHARD WILLIAMS THOMAS, 121, Cheapside, London, Artist.

My invention is principally designed for cameras for taking instantaneous photographs. I construct my improved camera with two lenses, and preferably in the shape of an ordinary field or opera glass—one side beiug fitted with a lens and focussing glass, and the other side being provided with a lens and also suitable arrangements for the dark slide and shutter. The two sides are joined together and worked backwards and forwards by means of a screw, as in an ordinary field glass, and the lenses in each side are so arranged that by movement of the screw both are focussed at the same time ; the shutter is connected with a catch or spring fixed or projecting to or near the wheel or thumbscrew, by which the screw is worked. By means of my invention the operator is able to see the object at the time he takes the photograph, and the risk of failure is thereby minimised.

10,319. *June 25th*, 1889.—"Supports for Photographs." HENRY JOHN MANSELL, 57 and 59, Golden Lane, London, Wholesale Stationer, and EUSTACE FRITH, of the firm of Frith and Co., Wray Park, Reigate, Surrey, Wholesale Photographic Publisher.

The object of the invention is to provide a cheap and readily applicable stand for photographs, cards, and other articles. The stand consists of a back-board to which is attached a shorter or lesser front-board, the two being hinged together. The extent of movement of the shorter board or limb is controlled by means of a band, cord, or attachment, which may conveniently consist of a doubled ribbon, the fold enclosing a ring at one end, which ring rests against a hole in the back of the board whilst the ribbon passes through it, but the ring cannot pass, on account of its greater size. The other end of the ribbon passes through a hole in, and is attached to, the shorter hinged portion. The photograph, card, or other article to be exhibited is cemented or otherwise secured to the short limb, and the back-board serves with the photograph or other article—such as opaline cabinet or other sized photograph—to which the shorter leaf may be attached, to form a steady support for the whole, and serving to hold the photograph up in a convenient position for exhibition.

19,897. *December 10th*, 1890.—"The Manufacture of Photographic Films." A communication from GEORGE EASTMAN, of Rochester, in the County of Monroe, and State of New York, United States. ALFRED JULIUS BOULT, 323, High Holborn, London, M.I.M.E.

Specification in our next.

THE June number of *Scribner's Magazine* contains an article on the "Emin Pasha Relief Expedition," which is illustrated with reproductions from photographs taken by members of the expedition.

Correspondence.

"UNHAPPY COLONIALS."

Sir,—Though I spent a good many years in England in graduating at Cambridge, and going to the Bar, I am a native of Tasmania. In my early days, I well remember the quality of wares imported into several of our Australian colonies. Anything was good enough for us, and if the articles imported were not up to the mark—well, the diameter of the world separated the English manufacturer from our wrath. In later times we have been better treated; but I want to tell you of a recent experience of mine with a box of —— whole-plates. As I cannot blame the local vendor, I may say that I got them from a well-known Melbourne firm—Messrs. J. W. Small and Co. I have long confined myself to this one make of plates; but in one of the boxes no less than five plates had a line clearly and cleanly cut through the film, which ran a photographic telegraph wire across my picture. I would enclose a print, did not the description appear plain enough. After two plates in succession treating me in this way, I expended the rest on views of the magnificent Derwent River at Hobart, taken from the garden of my brother, the Chief Justice of that colony.

Now, how about the next box of this make, which I place in my slides? As I take in and *read*, not only your paper, but another English one, as well as American, French, and German, and occasionally an Italian book, such as "Bettini's Fotographia Moderna," I deem it prudent to place my plates in their slides in absolute darkness. If it does no good, it can do no harm, and you can dust and insert without much trouble in the dark. But then these —— "lines" cannot be detected. I am familiar with the "D" line in the solar spectrum, but I felt seriously inclined to designate these happily unfamiliar ones as "D—d."

Now, I simply ask you, would this box of plates have been placed on the market in England? And was it not sold out here simply because we are helpless in the matter?

I would not have mentioned the name of the firm were not its wares so well established in the market that my complaints are necessarily and intentionally harmless. Moreover, the managers of the —— Company are probably unaware that defective plates left their establishment; nor do I want that company to forward me a box of their best manufacture to replace the defective box. I imported some of —— films from America; they developed with many spots. On writing to them to ask how to get rid of them, that firm admitted that many complaints had been received of a similar nature, and said that they were anxious to replace the faulty sample with others. I wrote thanking them, but declining the replacement. All I ask for is a little more care in exporting goods to the Antipodes.

F. Stanley Dobson, LL.D., M.L.C.

Melbourne, 5th March, 1890.

[We have omitted names of firms in this letter, to deal only with general principles. Mr. Dobson's remedy over one box of bad plates is not through newspaper channels.—Ed.]

THE HACKNEY PHOTOGRAPHIC SOCIETY.

Sir,—Below is our programme for June, 1890, at the Morley Hall, Hackney, Room No. 4 :—

Wednesday, 4th—Excursion to Loughton; trains leave Liverpool Street for Loughton at 10.6 and from Fenchurch Street at 10.13. Dine at "King's Head," Loughton, at 7; social evening. Saturday, 7th—Excursion to Wanstead Park; meet at Leytonstone Station at 3.8. Thursday, 12th—"Hand Cameras," Mr. A. R. Dresser. Thursday, 26th—"Selection and use of Lenses," Mr. H. Crouch. "Selection, use of Camera, parts, and apparatus advisable," Mr. J. O. Grant.

W. Fenton Jones, Hon. Sec.

12, *King Edward Road, Hackney, London.*

It is really astonishing what immense progress the art of photography has made these last few years. Why, you don't really know your friends' likenesses when you see them.—*Fliegende Blatter.*

Proceedings of Societies.

The Photographic Society of Great Britain.

At the technical meeting of this Society held on Tuesday evening last, the 27th inst., Mr. G. L. Addenbrooke occupied the chair.

The subject of stereoscopic photographs and apparatus having been previously announced as matter for the evening's discussion,

Mr. T. Sebastian Davis showed a stereoscopic camera fitted with a sliding shutter resembling a drop shutter, with two openings, but working laterally by pushing with the finger, or by an elastic band instead of falling by gravity. The openings in the moving board were made as long as practicable, and by this means it was not necessary to adjust it to a great nicety when used for time exposures. As to the distance at which the two halves of slides should be mounted, they ought not to be more than about $2\frac{5}{8}$ inches, which might be considered as a full average of the distance of the human eye from centre to centre; otherwise the pictures did not properly coalesce in the stereoscope. He thought, too, that the size and proportion generally chosen were not the best. He believed that many amateurs had given up stereoscopic photography on account of the smallness of the angle of view included in the pictures. He would get over this by the use of a lens of short focus—3 inches. The picture should be $2\frac{3}{4}$ inches in length; but, for landscapes, he thought a more artistic and satisfactory proportion would be to have them only $2\frac{1}{4}$ inches in height. The surface for printing on should, he thought, be as fine and free from grain as possible. Albumen paper he did not consider fine enough, and glass transparencies were not suitable for all subjects.

Mr. Arnold Spiller considered that paper prepared with chloride of silver in gelatine was better than albumen paper for the purpose. There was a fine enamel as a basis for the emulsion, and there was more detail in the shadows than with albumen paper.

Mr. Friese Greene said that it was his impression that celluloid was better than paper as a basis for stereoscopic prints.

Mr. Atkinson showed a stereoscopic print upon gelatino-chloride of silver paper, which supported Mr. Spiller's view. He also showed a stereoscope fitted with achromatic lenses.

Mr. Valentine Blanchard thought it was an objection to the dimensions proposed by Mr. Davis, that the foreground would be so much cut off. It was just the foreground in landscape pictures generally that gave such value to the stereoscopic effect of the photograph. In order to utilise the foreground to a greater extent than would otherwise be the case, Mr. Wilson, of Aberdeen, would frequently place his camera within two feet of the ground.

Mr. W. E. Debenham said that the necessity for limiting the distance at which the two halves of a stereoscopic photograph should be mounted, depended upon the eyepieces used. These might be so arranged as to unite two photographs of, say, whole-plate size. In any case it was desirable to have the eyepieces so mounted that they could be separated more or less. By this means they could be adjusted for eyes that were either farther apart or nearer than the average, and adjustment could also be made for photographs that were mounted at a greater or less distance apart than ordinary.

Mr. T. Samuels thought that it was more correct in principle to use a single lens in a Latimer Clark camera rather than a pair of lenses. The axis could then be directed to the centre of the pictures.

Other members did not hold the same view.

Mr. W. England had sometimes, when photographing statuary, used a lens of twenty inches focus. This was to prevent exaggerated perspective caused by coming too near to the subject. He also showed photographs of large size, mounted as stereoscopic pictures. They required a special stereoscope in which the pictures were necessarily farther apart, and farther from the eyepieces than in the usual form of instrument.

Mr. L. Warnerke showed some specimens of a gelatine film

which had been prepared as a basis for a second coating with silver emulsion. It never had been coated, but was nevertheless covered along the exposed edges with a stain like that seen on plates that have been kept for some time. He thought, therefore, that this stain, which has been so often noticed, does not belong to the silver emulsion, but to the gelatine itself.

Mr. Chapman Jones said that the edges, which looked dark on the plates, came out clear in the developed picture.

Mr. Arnold Spiller said that the films shown were not comparable with the gelatine in an emulsion, as in these films there was a large quantity of carbolic acid, the action of which must be taken into account.

Mr. L. Warnerke showed a block that had been made upon a zinc plate previously coated with copper. The plate was so hard, that five thousand impressions might be worked off it.

The Camera Club.

May 22nd.—Sir George R. Prescott in the chair.

The Chairman exhibited a hand camera which he said that he cousidered to be the simplest that he had ever seen; the plates were mounted in sheaths in a kind of a book, and each plate, after exposure, fell down on hinge, leaving the next to be exposed after it was moved into true focus; and this was done by one movement.

The Hon. Sec. exhibited a Watkins exposure meter and one of Fallowfield's sheaths for plates.

Mr. E. R. Shipton read a paper entitled "Cycle Photography and its Recent Developments, including an Ideal Cycle," and said that by means of a tricycle the photographer rolled his kit instead of walking with it, so economised energy and gained the power of going farther afield; in fact, on a tricycle he could conveniently carry a 15 by 12 inch camera and appurtenances. He exhibited a tricycle with wheels fitted with the new pneumatic tyre, and described various spring carriers for attachment to any tricycle to protect the photographic apparatus from vibration. The pneumatic tyre had given him an average of two miles per hour increase in speed, and had proved most luxurious in use, but added £6, or thereabouts, to the cost of the vehicle; he could go eight or ten miles an hour with it, carrying 100 lbs. weight of luggage; the weight of his machine was about 95 lbs. He could go over every kind of road, including sharp flints. For the first few days he was nervous about going over stones with the new tyre, but gradually gained confidence, until he took every kind of road which came in his way, and altogether he had been about 300 miles with the new tyre. The tyre must not be allowed to get flabby, but must be kept blown out; he had had to blow out his tyres three times, and lapse of time, more than of work, seemed to render this necessary.* He described the construction of the pneumatic tyre, how to blow it out with a little forcing syringe, and how to repair it should it get accidentally or wantonly punctured. So far, his tyre had not become even marked, and seemed as good as at first.

Mr. H. Sturmey remarked that one objection to the pneumatic tyre was, that if it were driven at a large obstacle, such as a brick, it gave a rebound, and "up went the whole lot." The great bugbear in cycling with photographic apparatus was dust, especially that caused by the jolting of the plates in the slides. Sometimes with the new tyre he had driven two miles an hour faster, but on the average had not gained much in speed over that obtainable with the old one; with the new tyre, going down hill, the machine went flying.

Dr. Patterson had found the resistance of the air to be of more importance than weight when tricycling, and liked the baggage to be so packed as to present as narrow a surface as possible towards the front of the machine.

Mr. Enrico Ferrero had been a cyclist for twelve years, and did not believe in carrying so great a weight of luggage. An expert like Mr. Shipton could do more in the carrying of luggage than could an ordinary cyclist. He (the speaker) did not believe in tricycles in photography; they were always an encumbrance; with them the photographer had chiefly to keep to the road, and not to enter paths and fields to get views he frequently required. A safety bicycle and half-plate apparatus would be found to be as convenient as anything. The best place for carrying photographic luggage was on the back of the cyclist.

Mr. George Davison had also found a tricycle to be always in the way when used on a photographic expedition.

Mr. Shipton, in the course of his reply, said that he wished that opticians would make casket lenses with a shutter forming part of the lens tube, and not burden purchasers with so great a weight of brass as at present, when lenses of different kinds are carried.

* Certain gases will slowly pass through india-rubber, and the oxygen of common air passes more rapidly than the nitrogen.—Ed.

The Hackney Photographic Society.

The ordinary meeting of this Society was held on Thursday, Dr. Roland Smith (vice-president) in the chair. Mr. E. J. Wall's paper on "Photographic Chemistry" was read. Mr. Wall preferred giving an elementary paper, as there were many amateurs who only took up photography for the purpose of getting pictures without the particular study and value of each of the chemicals used. He described the manufacturing of plates and the compounds used, and gave the uses of chemicals in other photographic operations. In the discussion which followed, Messrs. Dean, Grant, Reynolds, and others took part. Mr. Dean showed a simple stereoscope made by Pumphrey. He had found it effective. Various books were given to the Society by Messrs. Dean, Reynolds, Grant, and the Secretary.

On the motion of Mr. Reynolds, a vote of thanks was passed to the officers of the Society for their efforts during the past year, and he complimented the Secretary for the manner in which he had conducted the affairs of the Society.

Mr. Bruce Capel was elected a member.

The excursion on June 4th will be to Loughton, and on the 7th to Wanstead.

London and Provincial Photographic Association.

At the meeting on the 22nd inst., Mr. A. Cowan occupied the chair.

Mr. H. M. Hastings exhibited some prints on the new chloride of iridium paper. Some pieces also of this paper were distributed among the members for trial.

Mr. J. Traill Taylor read a paper on the "Ethics of Photography" (see page 412).

In the course of the discussion that followed the reading of the paper—

Mr. W. E. Debenham disagreed with the idea that amateurs interfered detrimentally with professionals. The great strides that photography had made were due, in a great measure, to amateur workers.

Mr. T. E. Freshwater spoke of the anomalies that were sometimes seen in photographs on the market. He referred, as an instance, to a photograph of a brook, which had a very large sale. A stork had been printed-in not in proportion to the surroundings; the stork was about three times the size it ought to be. He knew a case where a gentleman sent some negatives of Florence to have some prints made; when he received the prints he found some clouds had been introduced into the pictures. The prints were all returned with the remark, that clouds were not usually seen in Florence.

The Chairman said that it was sometimes not borne in mind, when printing-in clouds, that they should be reversed in the water; he had seen photographs with clouds printed in the sky which were conspicuous by their absence in the water. The reflection of clouds in water was easily done by printing through the glass.

Mr. W. E. Debenham, speaking of stereoscopic vision, said that, in addition to the microscope and stereoscope, there was an instrument which, he thought, might prove useful in warfare; he referred to the telestereoscope, by which the solidity of an object at a distance could be judged. Some years ago he constructed a telestereoscope, using a pair of field glasses for the purpose. To one of the object glasses a mirror was fixed, which received the reflection from a second mirror fastened at the end of a rod fixed at right

angles to the field glass; by this means distant objects could be viewed stereoscopically. Mr. Debenham explained the construction of the telestereoscope by diagrams on the blackboard.

Mr. T. WALTENBERG asked whether he could restrain anyone from copying a photograph he had taken some years ago; he had been paid in the usual way of business by the sitter, who was now dead. It was the opinion of the members that, having been paid for the negative at the time of sitting, he had no publishing rights whatever in the possession of the negative.

THE PHOTOGRAPHIC SOCIETY OF IRELAND.

THE last meeting for the season of this Society was held on Thursday evening, 22nd inst., by permission, in the Lecture Theatre of the Royal College of Science, Stephen's Green, Dublin, and took the form of a public exhibition of lantern slides. There was a large attendance of members and their friends, and upwards of 200 slides, principally contributed by members, were passed through the lanterns. In the absence of Dr. J. Alfred Scott (vice-president) the slides were described by the hon. sec., Mr. J. H. Hargrave, C.E. The lanterns were worked efficiently by Mr. James Carson, C.E. Amongst the slides deserving special notice were those of Miss White, the only lady member of the Society, and the "slumming" hand-camera work of Mr. C. R. Strangways, Dr. J. A. Scott, and Dr. Cosgrave.

EYE-PIECE FOR THE LICK TELESCOPE.—It is said that the Lick Telescope will, in a few weeks, be supplemented by a remarkable piece of mechanism. This is an eye-piece which has just been completed at Rochester, N.Y. No other eye-piece of anythiug like equal dimensions has ever been made. The largest now in use is not over two inches in diameter, while the new piece measures over three inches. The eye-piece is constructed on a perfect theory. There are two lenses, six inches apart. The larger one is called the field lens, and is six and one-half iuches in diameter. The other leus is the eye-glass proper. It is composed of three lenses, a double concave, double convex and meniscus, cemented together. The field lens is of crown glass. The meniscus, or correcting lens, is of flint glass. The light from the heavenly bodies, seen through the Lick Telescope and this new eye-piece, will be 2,000 times as bright as that seen with the naked eye.

ARTIFICIAL ILLUMINATION.—Prof. Langley, says the *Detroit Free Press*, read a paper at Washington on the subject of artificial illumination, in which he advanced a novel idea. He says that all existing systems in a varying degree sacrifice economy, because a very large per centage of the energy used is diverted from the production of light to the useless generation of heat. This is not only a direct waste, but the production of heat is a positive disadvantage. He shows how much better nature does this work in the case of the firefly, and of the luminous infusoria which are seen upon the surface of the sea, aud are so numerous especially in the British Channel, as to have a practical effect in lighting the course of the vessels. He says that the light which distinguishes these insects is produced by a chemical, not by a physical process, and is unattended by any perceptible development of heat. He expresses the belief that a careful scientific study of these insects may lead to the discovery of a means by which the same effect can be artificially produced upon such a scale as to have an industrial value.

RECEIVED.—The monthly part for May, of "Traité Encyclopédique de Photographie," by Charles Fabre, published in Paris by Gauthier-Villars and Son. The present issue embraces, among other subjects of interest, a chapter on platinotype, and is, like its predecessors, freely illustrated.——From Ed. Liesegang, Dusseldorf, "Photographischer Zeitvertreib," by J. Schnauss. It contains a number of interesting applications of photography, old and new, collated from various sources, and is freely illustrated. A more extended notice will be given of the book in due course.——Watson's exposure meter, a criticism of which is postponed.

Answers to Correspondents.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

L. E.—*Horny Dryness of Sensitized Albumen Paper.* During the prevalence of unusually hot or dry weather you may find it advantageous to add nitrate of soda to the silver bath. The addition of ten or fifteen grains to each ounce of sensitizing bath makes a considerable difference, but be careful not to exceed this amount, for there may be danger of staining your gelatine negatives. Sugar is sometimes employed for the same purpose.

M. P. S.—*Photo-Chemical Investigations.* An extremely important paper, embodying the results of many years of research, was read by Dr. Ferdinand Hunter, at the recent meeting of the Liverpool Section of the Society of Chemical Industry. The subjects treated of were the density or opacity of the negative, modes of measurements, development of plates under varying conditions, gradation secured by different developers, the intensification and reduction of negatives, unit of exposure, rapidity of sensitive plates, and instruments for actinometry. The whole matter is treated in a thoroughly scientific spirit, and we hope to give you shortly a résumé of the author's valuable communication. At the same meeting Mr. E. G. Ballard exhibited a new actinometer, in which Balmain's luminous paint is employed, but in a different way to that suggested by Mr. Warnerke.

TYRO.—*Action of Chromic Acid upon Alcohol.* The substance you obtained was aldehyde, which is always formed when alcohol is heated with sulphuric acid and a bichromate, or with chromic acid itself. Chrome alum could not give rise to its formation. Aldehyde has a very peculiar aromatic odour, aud in composition stands midway between alcohol aud acetic acid.

W. M.—*Backing for Drying Plates.* The common method is to paint with a mixture of raw sienna and dilute gum water or dextrine, but Dr. Fol's plan is better. It is to moisten a piece of carbon tissue cut to the size of the plate with equal parts of glycerine and water, and apply it like a sticking plaster to the back surface, pulling it off before developing the negative. The same piece of black tissue may be used many times. *Photo-Engraving.* See Answers to R. B. B., of Glasgow, last week. Mr. W. T. Wilkinson's book is not yet reprinted, but it contains much useful information.

A. SMITHSON (Dublin).—*Magnesium Chloride as a Fixing Agent.* Dr. Liesegang proposes the use of this salt as a solvent for chloride of silver, aud urges its superiority over hyposulphite on the ground of its being more readily got rid of by washing. It is equally applicable to plates and prints.

T. F.—*Lime Light.* Your letters received. The hand-bellows would be considered a disadvantage, and probably lead to inequality in the lighting. A powerful Bunsen burner, surmounted by a ball of platinized asbestos, or zirconia lime, might possibly give a steady light of sufficient intensity for copying purposes.

R. S. L.—*Cyanide Fixing of Gelatine Plates.* As a ready means of getting rid of free caustic potash in the cyanide, you might mix with it a certain quantity of sal-ammoniac, which would have the effect of turning this impurity into the harmless free ammonia, and then it could not soften the gelatine.

ENQUIRER.—*The Opera-Glass Camera.* The statement is probably true. A very similar, if not identical, arrangement was brought out many years ago by MM. Geymet and Alker.

A. M. M.—*The Journal of the Photographic Society of India* contains, as you say, amongst other matters of great interest, the identical paper which formed the subject of our correspondence. No injustice will be done by taking the proposed course, as the communication bears date April 22nd.

Received: CLAPHAM and W. H. S.; WM. HARBUTT, replied by post.

VOL. XXXIV. No. 1657.—*June* 6, 1890.

CONTENTS.

TRANSLUCENT SCREENS FOR DEVELOPING-ROOM LAMPS.

LAST week the subject of transparent coloured screens for developing-room lamps was considered. Next in order come translucent screens, such as those of opal or ground glass, or fabrics like paper or cloth.

A translucent screen may act in two ways, namely, by its colour, if it have any, and by its translucency. By means of its latter function it diffuses the light from the flame, preventing the rays from the latter falling direct upon the plate; it also, to a limited extent, quenches some of the blue and violet rays. Particles in suspension, such as mist or dirt in the air, or solid particles in translucent screens, tend to cut off the blue and violet rays more than the yellow and red; this is why street gas flames, seen through a fog, appear redder and redder the farther they are from the eye of the spectator, and why most samples of opal glass have a yellowish hue when viewed by transmitted daylight. For this reason a sheet of opal glass, used with a sheet of unsafe ruby glass in a developing-room lamp, will probably at once make the light practically safe, not alone by lowering the intensity of the light by diffusion, but by cutting off more or less of the feeble band of blue rays which found its way through the imperfect sheet of ruby glass. As, however, two sheets of ruby glass scarcely reduce the amount of light in the room more than does one sheet, two sheets of ruby glass and one of opal glass in each window of the lantern tend to give an exceedingly safe light, all other conditions being equal. Opal glass has such power of quenching and diffusing any feeble blue radiations which may find their way through an imperfect sample of ruby glass, that any spectroscopic testing of the triple screen described is practically unnecessary. Opal glass is the best diffuser of white light known obtainable in mass, but it quenches such a large per centage of the light that gas globes made of it prove excessively costly in use, unless the light required to be utilised falls where it is wanted through a large orifice in the bottom of the globe. Ground glass, which consists of plain glass with a surface of minute abrasions, cracks, and scratches produced by grinding, is not so good a diffuser as opal glass.

For the perfect diffusion of white light, it is necessary that the particles producing the diffusion should be exceedingly clean. One more perfect means of diffusing light than by opal glass is known, but cannot be utilised in photography, namely, by means of smoke consisting of particles of phosphoric acid. Phosphorus burnt in oxygen gas throws off this smoke, and when the smoke gets thick enough to hide the flame of the burning phosphorus, a light is obtained surrounded by the best and cleanest diffusing medium known.

Cloth, paper, and such like fabrics for developing-room lamps now demand attention, and at first sight it seems strange that such coarse substances should be so useful when dealing with such minute agencies as waves of light. Put a piece of coloured cloth or tissue paper under the microscope, and, with a strong white light on the other side of the fabric, it will be seen to be full of minute holes, letting through white light in abundance, and brighter light will be seen coming through some parts of the fibres themselves than through other parts. If, now, two thicknesses of the fabric be used, almost all the white light is cut off, because a hole in one thickness will rarely so come before a hole in the next thickness that a ray of white light can pass through both. Three thicknesses of red cloth make an excellent screen, the total amount of colour and translucency being large, and all pure white light cut off. Telegraph cables are made on the same principle; there might be a fault in one layer of gutta-percha, but if the cable have a second layer, it is hardly likely that a fault will occur in both at the same place; three layers of gutta-percha make everything practically safe.

Sometimes it is recommended in print to make a developing-lamp window with one large sheet of red cloth, and those who make the recommendation have doubtless found it to answer in their own experience; yet this single screen lets some white light pass through

its numerous minute holes. The explanation is, that the exposure of the plates of such operators has been long enough to enable a good image to be developed before the fogging power of their light has had time to act injuriously. On the same principle, by suitable manipulations, an instantaneous exposure on one scene may be given to a plate by means of a shutter, and afterwards a longer exposure of the same plate to another scene, and in the developing bath the latter will come up all right, with no trace of the former. As regards developing-room lamps, it is as easy to make good as bad screens, so it is as well not to employ imperfect means, which have to be compensated in other ways, when good results have to be obtained therewith.

There is reason to suppose that dead white bodies, such as opal glass, are entirely built up of transparent particles. The foam of the sea is white, yet it is formed entirely of transparent drops of water; the light getting into the midst of the myriads of drops is refracted and reflected in all directions, and becomes so scattered as to produce the effect which is called "white." The same thing occurs with ground glass. The glass is as transparent as ever it was, but the numberless minute cracks, scratches, peaks, and valleys upon its surface scatter the incident light and produce the dead white effect to the eye. The whiteness of paper is due to the way in which it scatters light, but let its interstices be filled up with varnish, it scatters the light less, and the transparency of the cellulose fibres becomes more manifest.

PHOTOGRAPHS OF LONDON.

The day is approaching when the man who does not use a camera will be looked upon as quite a remarkable character, and his biography and portrait will appear in those publications which keep the memory green of those who have deserved well of their country. But before that day comes the Continent, and places generally where holiday seekers most do congregate, will photographically be used up. There will be then no spot which has not been haunted by the photographic worker, and "taken" by everybody. Perhaps, however, London itself will escape this general photographic scourge, for it is a remarkable circumstance that every dweller therein runs away from the "big village" before he deigns to unlimber his camera and tripod. Why this should be so we cannot guess, unless it be a kind of perversion of the text which tells us that no man is a prophet in his own country. Certain it is that most photographers do not see in their own city anything worth photographing; otherwise they would not be in such a hurry to turn their backs upon it in favour of places not possessing one tithe of its beauty or interest.

Although we hold that in London can be found a wealth of pictures by those who have eyes to see and minds to appreciate, we must confess that London people are far from picturesque. To begin with, we have no distinctive national costume. Next we have the influence of fashion, which plays mad tricks with the human form divine, and which does its best to correct or destroy the graceful design upon which our first parents were built. If we turn to western London, and stray into Kensington Gardens, we are among these fashionable folk. They are what is called well dressed; but they are all alike to the photographer, who must perforce neglect the charms of colour. One lady is to him adorned very much like another, the tailor-made girl being predominant; and as to the men, there is still less variety, for the coats are all of one pattern, and the chimney-pot hat does not lend itself to artistic treatment. If we go east we have a difference, but little variation. The starched collar is replaced by the dirty spotted neckerchief; the black coat by one which was once black, but which, like the average lodging house keeper, "has seen better days;" and the shiny hat of respectability is deposed in favour of the "billycock." But look at them as we may, no one is picturesque. One class is trim, clean, and neat, and the other slovenly and dirty, but they do not make good pictures.

The streets themselves are, some of them, in spite of the march of improvement, full of beauty. Of course there are miles and miles of ugly thoroughfares, with rows of houses exactly alike. There is the Belgravia pattern, the Bloomsbury pattern, the Pimlico pattern, and any number of other patterns peculiar to the districts in which they occur, and which owe their design to the fertile imagination of some jobbing builder, who has often been, more successfully, the architect of his own fortune. Then there is the suburban villa, which can only be described by that truly dreadful word, "genteel." All these the searcher after the picturesque will studiously avoid. He can, if he will only seek them out, find plenty of old world nooks in and about the city. Crooked lanes, containing rickety houses, and ending often with a peep at some old church tower, or spire, which completes a perfect little picture. Then there is the noble river Thames, which affords an endless field for pictorial possibilities. The river has plenty of photographic worshippers, but they all confine themselves to its upper reaches, and everyone takes the same views. There is, for instance, that eternal cottage on the bank near Cookham, Boulter's Lock, and many other spots which have been so often photographed that, if the wet process had continued to hold its own, the taking of these pictures would have run the Thames dry. But it is in the city part of the river that the real pictures are to be had, and one artist—Wylhe—has been quick to see this, as his noble masterpiece, now hung at South Kensington, and many of his other works, declare. Photographs of barge life, of merchantmen, and of the Dutch-built boats which still find their way to London Bridge, form in themselves materials for much study.

The extreme ugliness of the London houses is in many places relieved by the beauty of the trees. It is too much the fashion to talk of the smoke, the dirt, and the noise of London streets, as if there were no beauty, no cleanliness, and no quiet to be had anywhere

within its walls. All lovers of the metropolis will resent this as a gross libel, for there are not only many quiet spots, but there are plenty of beautiful trees. And especially beautiful are these trees just now in the early summer, when they have but lately unfolded their leaves. Some of our suburban streets, too, just lately have been brilliant with laburnum, lilac, and white and red may, the colours of which have delighted the eyes of those who seldom see a country lane, while their scent has reminded them—as only a scent can—of long-forgotten days among fields and hedgerows.

But what may be called the permanent trees of London are full of beauty, and especially is this true of the noble plane tree, which flourishes with such unwonted luxuriance that it would almost seem as if it preferred to suck in the carbonaceous matter necessary to all vegetable growth in the form of soot and fog. Walk by the side of some of those old squares in Bloomsbury, from which fashion has long ago fled, and where many of the houses are let out in apartments, or are filled with boarders. The trees there are above the dictates of fashion, and continue to thrive and afford a grateful shade to those who pass by. In Bedford Square, Mecklenburg Square, and many other similar localities these plane trees are in lovely condition, and throw out their twenty-five or thirty foot branches, crowded with graceful foliage, over the footpaths, and they wave lazily in the gentle breeze as the afternoon sun steals through their leaves. But even in the city itself trees are not unknown. In one or two of the old city churchyards there are fine specimens. Note those, for instance, hard by Billingsgate, just opposite the Custom House, where thousands of sparrows congregate in the evening, and make a veritable Babel with their ceaseless twittering. Nor must we forget that famous tree in Cheapside which has been immortalised by Wordsworth. It is now, unfortunately, walled-in in such a manner that its top only is visible from the main thoroughfare, and it is a matter for wonder that it continues to live under such conditions. But we believe that it is a fact that, within the past twenty years, rooks have been known to build in that tree, until, perhaps, the long journey necessary to them before they could obtain their natural food, made them give up the struggle.

If proof were wanted that London is capable of affording fine opportunities for the picture maker, we might refer to an exhibition of water-colour drawings, by Mr. Herbert Marshall, R.W.S., which was lately opened in Bond Street. Here we had no fewer than one hundred sketches in colour by one artist, many of them being perfect little gems. If one painter can do so much, surely there is much to be done with a camera.

The Devon and Cornwall Camera Club forwards a programme of summer outings; among them we notice the Royal Plymouth Yacht Club Regatta, to which the Photographic Club will be conveyed by its aquatic *confrères* in the s.s. *Sir Francis Drake*.

GUAIACOL AS A DEVELOPER FOR DRY PLATES.*

BY COLONEL J. WATERHOUSE, B.S.C., ASSIST.-SURVEYOR GENERAL OF INDIA.

In connection with the use of the pyrocatechin, or catechol, as a developer for dry plates, it struck me that guaiacol, or methycatechol, which is a very much cheaper product, being only about 1s. 6d. an ounce, instead of 4s. a drachm, might possibly be of use in the same way. On trial I find it is so, and it may, therefore, be interesting to the Photographic Society to know of it, in order that further trials may be made by anyone interested in the matter. I cannot find any record of its having been tried before.

Guaiacol is a colourless, oily liquid, with a rather pungent smell. It is obtained by dry distillation of guaiac resin, and in other ways. It is only slightly soluble in water, but readily so in alcohol, ether, acetic acid, and alkalies. I find it dissolves easily in solutions of caustic soda or the carbonate of soda, the solution having a slight green tint.

I have not yet had time to ascertain the best proportions for developing purposes, but 20 minims of it in 2 ounces of a solution of carbonate of soda crystals at 4 per cent., well stirred till dissolved, gave a solution which, though somewhat slow in action, possessed very fair developing powers. A similar solution of 30 minims of it in 2 ounces of a solution of caustic soda (1 part solution used with Thomas' hydroquinone developer, diluted with 3 of water) developed rather quicker, but otherwise seemed no better. The negatives are not nearly so dense as those obtained with a similar solution of pyrocatechin, but are more harmonious. The deposit is even and fine grained, and of a yellowish-brown tint, which seems to have fairly good printing powers. I enclose some film negatives, with prints. There is no tendency to stain or fog, nor to the superficial veil common with hydroquinone. The developing solution, after use, takes a much stronger colour, and also has a strong empyreumatic smell, which is somewhat persistent, and sticks to the hands for some time afterwards.

So far as I can see at present, guaiacol is not likely to supplant ferrous oxalate, pyrogallol, or other recognised and well-tried developers, but the use of a liquid developing agent is new and interesting; and, if the material itself can be kept indefinitely without decomposition, it might be useful for travellers in place of the more readily decomposable dry developers, like pyrogallic acid and hydroquinone, which easily spoil by exposure in corked bottles. The smell will be somewhat against the new developer, though it is really not unpleasant, and is probably wholesome, as guaiacol has recently been recommended as a remedy for consumption.

According to Watts,† guaiacol forms crystalline salts with the alkalies and alkaline earths, which appear, as might have been expected, to be readily decomposed and turned black by exposure to air and moisture. Otherwise they might form very efficient developing salts, and be more convenient to use than the guaiacol itself. To have the alkali and developing agent together in a single crystalline salt would be most useful for travellers. The further development of this phase of the question I must leave to more experienced chemists.

---

* The above paper was received too late to be read at "the May meeting of the Photographic Society." Any discussion that may arise on its publication will be taken at the June meeting.

† *Dictionary of Chemistry*, Vol. II., p. 946.

THE CITY PHOTOGRAPHIC EXHIBITION.

The above exhibition was opened to the public last Saturday at the Drapers' Hall, Throgmorton Street, London, and on the preceding evening its promoters, the Photographic Section of the London Chamber of Commerce, invited a number of their friends to a *conversazione* in the hall. Among those present were Alderman Sir H. and Lady Knight, Sir Charles Clifford, Sir Frederick Young, Mr. Carl Ulrich, Vice-President of the Amateur Photographic Association of Vienna, Mr. John Spiller, Mr. Leon Warnerke, Miss Warnerke, Sir Charles Mills, Mr. Alderman and Sheriff Stuart Knill and Mrs. Knill, Mr. Under-Sheriff Beard, Mr. Alderman Cowan, Mr. J. S. Balfour, M.P., Mr. Howard, M.P., Mr. W. F. Lawrence, M.P., Mr. D. W. Coates-Hardley, Mr. Benjamin Scott (City Chamberlain), Mr. J. S. C. Heywood (Master of the Drapers' Company) and Mrs. Heywood, Mr. and Mrs. S. Hope Morley, Mr. and Mrs. T. Tyrer, Mr. W. S. Bird (Chairman of the Photographic Section), Mr. F. Bishop (Deputy-Chairman), Mr. K. B. Murray (Secretary), Sir G. Chambers, Mr. E. N. C. Braddon, Sir James Garrick, Senor de Olano, Mr. A. S. Pollard, M.A., Mr. J. A. Brand (City Comptroller), and Mr. W. Leaf.

In formally declaring the exhibition open, Sir Albert K. Rollit, M.P. (Chairman of the Council of the London Chamber of Commerce), delivered a short address, in the course of which he spoke of the great development of photographic art, as shown in the exhibition, and emphasised the wisdom of making the art familiar to as many minds as possible, thus leading the public to appreciate and cultivate it. Looking at it from another point of view, he said that they must not forget what photography had done for cognate sciences. The recording and measuring instruments connected with photography gave the opportunity of fixing questions of time and space beyond the possibility of human error, and in connection with astronomy and physical science the assistance of photography had been invaluable. They were deeply indebted to those who had taken so much trouble to bring this exhibition about, and he felt it a personal privilege to be able to declare it formally open. A vote of thanks having been accorded to the Drapers' Company for the use of their hall, Mr. Alderman and Sheriff Knill briefly apologised for the absence of the Lord Mayor, who had only that evening returned from Yorkshire, in, he was glad to say, much better health.

The exhibition included a fine show of apparatus and photographs, but in the collection were few things of novelty; the object of the exhibition was to show the public something of the present position of photography and its appliances, and in this it succeeded well. Day by day the attendance of the general public increased, probably because the rumour spread from month to mouth that in the Drapers' Hall was a photographic picture gallery worth seeing, and should the exhibition become an annual institution, the benefit will be felt of having broken the ice of public apathy this week.

Mr. Walter Tyler, of London, exhibited lanterns and cameras; Mr. W. F. Slater, frame mouldings and apparatus; Mr. Gotz, apparatus and lenses; Mr. Abrahams, apparatus; Messrs. Houghton and Co., the French pantascopic camera, already described in these pages; Mr. F. W. Hart, varieties of apparatus and a portable stand of bamboo, which, when disjointed, can be readily carried under the arm, and can be fixed so as to hold backgrounds and reflectors for use in private houses with the flash-light; it can also be used to hold a magic lantern screen; at the exhibition it was used with curtains, so as to form a kind of canopy over Mr. Hart's stall; this portable stand is a new invention. Mr. Dallmeyer exhibited lenses; the Stereoscopic Company, apparatus; Messrs. Sands and Hunter, apparatus; Messrs. R. and J. Beck, apparatus; Mr. Schölzig, albumenised papers, and a few German cameras and stands; Mr. Morley, apparatus; Mr. Crouch, apparatus; Messrs. Marion and Co., appparatus, and an illustrated book issued this week by Mr. Robert Slingsby, on photography by the flash light. Mr. B. J. Edwards, specimens of work in orthochromatic photography; Messrs. Watson and Son, apparatus; they exhibited one of their "Acme" cameras fitted with an extra-wide front for stereoscopic work, and it is useful to be able to apply a light modern camera in this way. Messrs. Wray and Sons exhibited lenses; Messrs. Newton and Co., elaborate oxyhydrogen and electric microscopes; Messrs. J. Lewis and Co., apparatus; Messrs. Pearson and Denham, apparatus; Mr. E. G. Platt, brass work for photographic apparatus; Mr. J. D. England, celluloid negatives and films; Mr. England says:—"The instantaneous views were taken by my father and myself on a trip to Bushey Park on Whit Monday, and although the apparatus was jolted on a tricycle over a dusty road, there is scarcely a single pinhole on any of the negatives." Messrs. Perken, Son, and Rayment exhibit apparatus. Mrs. George Smith exhibited some transparencies mounted as table lamp screens and fire screens; Mr. George Smith exhibited his sciopticon camera and other apparatus; Messrs. Mawson and Swan, apparatus.

"Walks in the Grand Duchy of Luxemburg," will form a new illustrated section to the forthcoming issue of Mr. Percy Lindley's "Walks in the Ardennes."

Hydroxylamine Developers.—There is a new reducing salt, also a reducing solution sold by the Badischen Aniline and Soda Fabric Company, which contain hydroxylamine. The former compound is a white substance with an acid reaction, soluble in ten parts of water. It contains sulphate of hydroxylamine and some organic substance. Analysis showed that 100 grammes of it contained an amount of hydroxylamine corresponding to 16·5 grammes of the hydrochloride, while 100 grammes of the solution contained a quantity equivalent to 10 grammes. Hydroxylamine is a very suitable developer for gelatino-chloride plates,—A. Lainer, in *Phot. Mitt.*

Doubly Albumenised Papers.—M. L. Van Neck gives the following formulæ for sensitizing and toning doubly albumenised and very brilliant papers. 1. Add magnesium carbonate to the silver bath in the proportion of two grammes to a litre of the bath; this will prevent the formation of a red colour in the bath. 2. The strength of the sensitising bath should not be more concentrated than from 8 to 10 per cent. It may be strengthened from time to time by the addition of a 12 per cent. solution of silver nitrate. 3. The washing before fixing should be done with tap water, rain water being frequently very impure. 4. Toning bath:—

1.—Sodium acetate, pure fused ...	15 grammes
,, ,, crystallised ...	15 ,,
,, biborate	8 ,,
Distilled water	2 litres
2.—Gold chloride (brown)	1 gramme
Distilled water	50 c.c.

An hour before use mix the two solutions, shake well, and place in the flask in a strong light. The toning action is very rapid. In winter the solutions must be kept at a temperature of 20° C. —*Bulletin Belge.*

PHOTOGRAPHS ON VIEW AT THE DRAPERS' HALL, THROGMORTON STREET.

BY REV. F. C. LAMBERT, M.A.

The number of pictorial exhibits is not so large as one would expect, for, although most of the well-known large firms are represented, yet one rather expected to see a stronger contingent of the less known workers sending one or two frames of their best work.

Passing up the spiral staircase, and entering the room nearest the top of the stairs, the visitor finds himself in what, for convenience sake, may be called Gallery I. As there are no numbers on the frames, it may save time by saying at the outset that the order of these notes runs from right to left round the walls, and then the screens are taken in order.

Close to the left of the door on entering are several frames sent by Messrs. Waterlow and Son, illustrating those processes of reproduction for which this firm is so well known. It is instructive to notice, not only the various effects produced by different methods, but also how both surface and tint bear influence in the general effect. Messrs. Frith come next with two frames—one chiefly landscape, executed in the manner familiar to all who know their name, and a second, devoted to architectural studies; some of the interiors are remarkably fine. Then come Messrs. Lambert Weston and Sons with several frames: that at the bottom in the left-hand corner, seems to outstrip the others—at any rate, for pose and ease of expression, and unconsciousness of the operator. Above is "Our Village," produced by Mr. Thurston. Perhaps one might venture to say that this is *not* Bushey; the clouds seem rather heavy for the lighting of the roadway. To the right of this is "A Misty Morning," and very misty it looks—a picture well worth careful study.

The inevitable "Eiffel Tower," with Wray's rapid rect., is not far off, and in company with several yacht studies by Messrs. West and Son, all of which are admirable specimens of that well-known firm's work. At the other end of the room, and near the door, are found several of Mr. Payne Jennings' pictures, many of them so well known to travellers over the Great Eastern Railway. A very small one in the middle of the frame nearest to the doorway should be noticed.

Passing to the screens, the first frame likely to interest is that containing the two poets, Tennyson and Browning, by Cameron and Smith. Messrs. Elliot and Fry send a large show in various styles, the most pleasing, as a study, being a portrait of a little lady in red carbon—the smooth, bright, clear, surface of the so-called opal being fitted for the rendering of such young and tender skin, the bloom of maidenhood. Mr. F. Dower sends a collection of very interesting studies, chiefly of Professor Herkomer, R.A., as "Filippo," in the poetic comedy performed at the Bushey Theatre in April last. These admirable studies would have been still more interesting had a little care been given to the background; or at least, to avoiding the dark band behind the legs. Near here is an instructive photogravure, after Blair Leighton, by the Typo Etching Company; also, close by, are several flash-light productions, which will interest experimentalists in this direction. Messrs. Window and Grove, and also Morgan and Kidd, are fully represented on the screens in this room.

On entering Gallery II. the Stereoscopic Company demand attention by their numerous productions in various styles, and here may be seen several portraits of well-known public characters. Then comes an admirable portrait of Professor Huxley, and also another, nearly as good, of Dr. Joachim; both are well worth careful study, and reflect great credit on Messrs. Downey. Messrs. Fry (Brighton) show a frame of camp life studies which will be of interest to the Volunteer "camper." The Autotype Company exhibit a large screen of carbon pictures in various styles of frame and shade of tint. Many old friends turn up again, but are none the less worth re-study. The Parthenon Frieze must on no account be passed withou due attention.

On the other side may be seen a collection of curious and deeply interesting early fans, produced at a time when it was *not* necessary to say, as it seems now-a-days, "painted by hand" (as though it was more general to use the feet for that purpose). The antiquary will be interested in seeing a reproduction of a page of the Magna Charta. Messrs. Bedford Lemere and also Mayall send numerous examples of their portrait and other work.

The third gallery (or exit passage) is not very happily lighted, there being rather too much glare and glint on the glass to enable seeing the pictures to full advantage. Mr. Flather sends specimens of the "dry point or needle finished" enlargements, which produce an effect somewhat out of the usual enlargement groove. Next come two fine portraits by Robt. Faulkner, and various specimens of his proverbial skill with children. High up—too high up, in fact, for comfortable survey—are two large opal studies of "Sun and Cloud," by Friese Greene, interesting in more ways than one, and decidedly reflecting credit on their producer.

Several portraits of Mr. Thomson recall the Gainsborough style of background, and are suggestive of various hints in that respect. Three or four portrait studies by H. S. Mendelsohn, and Messrs. Doulton & Co., reproductions of those never-to-be-forgotten Tinworth bas-reliefs, bring our survey to an end.

A small gathering of lantern-slides by Messrs. Fincham, York, & Son, and "last but not least," Mr. G. Smith (trading as the Sciop tican Co.), also a collection of coloured ones by Newton & Co., are to be seen in some of the windows.

On the whole, although not being particularly impressed with any great proportion of new work, there are several pictures worth study, even if seen before. It is not a very rash prophecy to prognosticate that if an exhibition be held on similar lines, say in ten years' time, there will be seen a decided change in some respects at least—the direction will be, perhaps, rougher surfaces and less retouching.

On Monday next, June 9th, Mr. G. J. Clarke will give a lecture on "Photographic Optics" before the North Middlesex Photographic Club, Jubilee House, Hornsey Road.

Can it be true that the historically interesting initials, devices, and mottoes on the walls of the old prisons in the Tower of London have never been photographed? A writer in the Photographic News assures us that he made inquiry on the spot, and received a negative answer. This of course does not mean that the "beefeater" produced a "negative," but, on the contrary, that this simple and only trustworthy mode of reproducing these pathetic records of captivity had not been adopted. In their place some etchings were offered; but these are obviously very different things. The camera should at once be brought to bear upon the inner walls of the Beauchamp Tower.—*Daily News.*

PHOTOGRAPHY IN ROME.

The *Bollettino*, a journal published every two months in Rome, and the chief organ of those interested in photography in that city, gives the result of the last election of members of its Photographic Society as follows: Adler, Dottor Vittoria; Intrigilo, Avv. Benedetto; Tenerani, Cav. Carlo; and of the correspondent members—Calvaria, Cav. Avv. Giuseppe, of Castellamare di Stabia; Daniele, Oreste, of Catania; Garzia, Oronzo, of Maglie; Hermans, Charles, of Brussels; and Orsini, Marchese Antonio, of Solmona.

The opening of the Second Annual Exhibition of Photography took place in the Palazzo di Belle Arti on the 2nd of May, when a large number of members took part.

The display included landscapes and interiors, portraits, instantaneous views, film negatives, photo-micrographs, enlargements, flash-light pictures, architectural views, and representations of costumes taken in Morocco and in Sweden.

An excellent article on "The Duration of the Pose" begins thus:—"Formerly, when collodion occupied the whole field of photography, the first difficulty in the art was the preparation of the sensitive surface. Now that the preparation has undergone a radical change, passing into a branch of industry, that first difficulty has vanished, and there has succeeded to its place the duration of the pose, the exact determination of which has over the resulting picture an influence as great, and possibly greater than formerly, seeing that in the very short poses of the present time even a little error has a value of relatively greater importance." The article goes on to say that the duration depends (1) on the sensitive preparation, (2) on the actinic power of the light, (3) on the object, (4) on the diaphragm, and (5) on the distance. Thus, if it were required to represent by an algebraic formula the conditions governing the pose t'', we should have—

$$t'' = k.\ P.\ L.\ O.\ d.\ D.$$

where k is the invariable constant.

The article, which is too long to translate, is written by A. Roncalli. It is succeeded by a short notice of the effects of the Schippang varnish upon collodion enlargements. This article, written by Ab. F. Castracane, makes mention of some unhappy results of the use of this varnish on some of his own pictures. After this comes a letter from Sac. D. Ratti, on halation, or *aureole*, as the Italians call it. Then a paper on the development of instantaneous negatives and on the toning of aristotype paper, by Bne. T. Melazzo. Various notes and receipts, with a bibliography and a short notice of the illustrated supplement, complete this interesting number. The illustration is that of a moonlight effect, the negative by A. Ducros, the phototype by Danesi, of Rome. "To obtain this picture," says the letter-press note, "it was sufficient to set the machine against the setting"—pardon the indiscretion; I was about to add sun—"and to remove the cap. But, before this is done, that certain fifth* sense has to be taken into account," without which,

'Non licet adire Corintum!'†

and Signor Ducros, profound and advanced artist and photographer as he is, possesses this fifth sense, and uses it in a masterly manner."

Prof. O. N. Rood says that the retina of the human eye is so sensitive to the action of light that a flash lasting only one forty-billionth of a second is sufficient to make an impression upon it.

* "Sixth, or do the Italians reckon only four senses?"—Pr. Dev.

† Corinthum.

THE ROYAL ACADEMY OF ARTS, 1890.

BY THE REV. F. C. LAMBERT, M.A.

Gallery No. VI.—Close to the doorway is No. 523 ("When the Flowing Tide comes in," W. Rainey); a jolly lot of little sandboys dabbling their feet in the tide-water, calling to mind some of friend Sutcliffe's delightful Whitby studies, and opens the question of how *he* would have arranged a row of "little lads" just like that? Many a photographer, on seeing such a scene as No. 539 ("The History of many a Winter's Storm," F. Walton), would have said, "there's nothing in it," but Mr. Walton has contrived to "knock a picture out of it." N.B., No. 540 ("Viaticum," J. M. Price) just at first glance reminds one of the photographs one sees of the much-talked-of "Angelus," by J. F. Millet. The picture before us represents some two or three peasants, presumably French, kneeling and watching the "Priest" passing in the distance on some errand of mercy—perhaps conveying the last sacrament to some departing member of his flock. It is a work in a low key, cool in grey, subdued tint, and worthy of careful study.

No. 543 ("A Stranger," N. Garstin). Pose of the two children is note-worthy, but the picture reminds one somewhat of the "two-negatives'" effect.

No. 551 ("The Death of Cleopatra," Hon. John Collier) is quite the big thing of the gallery—should be seen from a considerable distance—in fact, is best seen from just without the opposite doorway. The texture and cold surface polish of the two colossal gods of dark green granite or syenite, is admirably rendered; perhaps the colouring of the pillars is somewhat raw, the general parallel trend of the seated figure, and the dead one on the floor catches the eye; also the elevation of sternum of the dead Cleopatra, over whom is spread a delicate diaphanous drapery, showing the modelling of the figure in a very masterly way; altogether a fine picture, and one from which much may be learned.

Close by the door (and also near the floor) are three small pictures, well worth looking at, viz., No. 583 ("The Edge of the Quarry," T. T. Rowe); No. 584 ("Windsor Castle," W. Fitz); No. 585 ("A quiet pool," A. Lawson).

No. 582 ("Thunder Clouds," A. W. Williams) is also a very creditable rendering of a by no means easy subject.

No. 604 ("A Grey Day," A. Hulk), might well have been greyer still.

No. 632 ("In old Kent," R. W. A. Rouse), is well worth the attention of the photographic eye. Note the admirable rendering of that bit of chalk or clunch quarry.

No. 646 ("A Lantern Manufacturer," E. Docker); a clean faced urchin manufacturing that ever-favourite ghost producer—a turnip lantern. A picture showing good, honest, straightforward painting, and of which, perhaps, the too clean face of the "manufacturer" is the least satisfactory. Before leaving this room, Nos. 524, 542, 553, 560, 562, 571, 599 may be looked at, and several hints gathered, and, as Captain Cuttle would advise, "when found make a note on."

Gallery VII.—No. 658 ("Resurgam," H. Swanwick). A lone dead body of a toiler of the sea, washed up by the tide. Truly a gruesome subject, not the sort of picture many people would select as a daily companion at the dining-table; yet, withal, not without some charm in its rendering of air and soft morning dawn-glow.

No. 672 ("The Silent Evening Hour," B. W. Leader, A.). Here is an answer to the familiar question, "What's in a name?" Who can deny that a first impression is often

(though, perhaps, unjustly and unconsciously) influenced by a name? The title (often enough very misleading) tempts many a one to buy a book. Here is a poetical title of a poetry-yielding subject. The old homestead of red brick and thatch, surrounded by uncultured patches of gorse, affording glorious shelter for the rabbits out to feed at the "evening hour," the crows returning home, the sky all a-glow with warm, rich golden light; all put together with "Leader-esque" skill, and conveying much in the way of hint and suggestion.

Above is an utter contrast, No. 671 ("The Dock Strike," D. Hardy). A vivid reality of life, and a creditable rendering.

No. 695 ("Highlands and Islands," Keeley Halswelle). The title reminds one of "spelling-bees" and Peter Piper of pepper-corn fame. The rainbow seems much nearer than is usually seen, and so also do the clouds. This picture comes rather as a puzzle, and bewilders one in trying to find a satisfactory place to start from.

No. 699 ("A Gem worth polishing," C. Calthrop). The gem is a country lad with a turn for "fiddling," discovered by "The Squire" in a humble cottage. There are several points worth observing and remembering, both in the matter of pose and lighting, although the four figures placed at the four corners of a "lozenge" is somewhat formal; and there is, perhaps, a more than pleasant scattering of the lights and darks.

No. 701 ("Golden Autumn," G. N. Langlands), No. 706 ("Pulling Turnips, &c.," M. R. Jones), and No. 723 ("Turnip Field," J. H. Inskip), are all most suggestive to the camera-artist, well worth careful study for hints in the general arrangement of subject and tone, whereby homely subjects are made attractive by the way in which they are treated.

No. 726 ("Undine," R. Lehmann). This calls to mind 81, and if, after seeing that picture, there lingered any doubt, this (726) is quite conclusive that there are "*many* more fish in the sea, &c."

No. 708 ("Mount Etna from Taormina," John Mac Whirter, A.) must not be passed by without careful study. Stand back a couple of yards or so and observe how the feeling of distance is given by the gradual suppression of minute "f-64 detail"—how the contrast of values is subdued in the receding distance, as the shadows are filled more and more with diffused light, and observe, too, how certain parts (planes) in the middle distance are more sharply defined than some of the nearer or more distant ones. Note the high key in which the scale of tones is pitched, and how the azure waters melt into the prismatic purples and greys of distance. All of which go to show that there are "many ways to choke a dog"—pardon—to paint *a picture* without tying the mill-stone-like tenets of *any* school about one's neck. Before quitting this room, No. 719 ("Dawn," S. E. Waller) must be inspected, although lying somewhat out of the photographer's range, yet it is most desirable that he should contemplate good work of any and every kind. The picture carries us back a century or so to a country garden at early dawn, and the guests, who have "kept it up" till "daylight doth appear," are departing in the combined light of carriage-lamps and dawn. A couple of lovers in the foreground "linger in sweet moments." There is much admirable work to repay careful study, even to the delicate gossamer, "as fresh as morning dew distilled."

Gallery VIII.—The first picture on entering Gallery viii. is No. 758 ("The last Blessing," C. Tayler). Stricken unto death lies a wasted form, tendered by a trouble-worn mother, a hardy-handed, tender-hearted father, and the priest in absolution conveying the last blessing of Mother Church, conjuring up a fearfully, awfully real scene of love and sorrow; the whole, painted in a low key, in harmony throughout both in tint and tone with the sentiment, producing a picture of great power. The face of the father—honest fellow—is a fine study.

No. 775 ("How Lisa loved the King," E. B. Leighton). See previous note on open mouths, as though to represent singing without the sound. The pose of the listeners is more listener-like. The texture of the marble is not quite satisfactory.

No. 781 ("The Angry Sunset, &c.," R. Jobling) is a nice, simple, airy picture, broadly painted in pleasing harmony—sunny yet not gaudy, conveying the feeling of open space rather than specific detail.

No. 792 ("Tired Out," P. E. Stretton). It is not often, perhaps not often enough, that one sees pictures of this "interior dimly lighted" kind, and this one comes as a relief, inviting and also repaying careful examination. An anxious mother watching beside the bed of a fever-worn, tired-out sleeping child, in a room but dimly lighted by a glowing fire and candle, in the small hours of dark night. There is no oppressive detail, but everything is seen when looked for, yet nothing catching the eye to carry it away from the leading theme.

No. 794 ("Rifle Match," E. Crowe, R.), brings to mind the hand-camera-out-for-a-bank-holiday; at first sight a little anxiety arises as to whether the "shootist" is aiming at a blade of grass about six feet away.

No. 821 ("First Snow," F. W. Meyer). A town dweller might be disposed to condemn this picture as too raw, but it is not by any means an out of the way effect as seen by those who live in the country all the winter round.

No. 744 ("Seeking Sanctuary," R. Hedley) must be seen from a distance—across the room—and all diffused light shaded off from the eyes, when the moon-lit Norman doorway and iron work of later period comes up well, but the man's face seems somewhat over lighted.

Gallery No. IX.—No. 830 ("River Camel," W. Llewellyn) points the moral of the too great squareness of a 10 by 8 plate, and the patch of thin emulsion towards the middle is an unpleasant reminder, but the clouds are nice and soft, not painty, but airy as clouds should be.

No. 842 ("Bathers," E. Stott), brings up again to mind the old conundrum "How big should the wafer be on the negative to represent the size of the sun?"

No. 846 ("Frosty Morning," F. Whitehead). A capital version of what is seen (and felt) often enough in the fens.

No. 857. ("Net barking," F. S. Richardson). Excepting the sky, this picture is one to please and instruct.

No. 866 ("On the Temple steps," E. J. Poynter, R.A.). This, at first glance, suggests the question, Was the painter here trying to see how many different patches of differing colours it would be possible to work in together? Pink, red, lake, crimson, yellow, greens, blues, purples, &c., and flesh tints. The part which seems to come out of the encounter best is the legs below the knee, and the inscription-bearing marble slab behind them.

No. 888 ("Twilight," C. W. Wyllie) is a nice, quiet, cool, grey moonrise, with the "blue band" of a distant fog, with which the fire-smoke and fire-lights blend pleasantly.

No. 895 ("Washing Day, Newlyn," H. L. Norris)

seems to run somewhat too far into the low-toned end of the colour octave. It does not require any great effort of the imagination to fancy a brighter, whiter, and lighter froth of soap-lather, for instance.

No. 890 ("Lava mea ab iniquitate mea," A. Lonza) is a jolly picture, a "tale well told." An old monk drawing an obstinate cork from a wine flask. The expression on his feature-drawn face may suggest more than one "wrinkle."

The "hangmen" were, perhaps, "cruel to be kind" in hanging No. 913 ("Water Meadows," J. L. Bernard) and No. 914 ("Malvern," J. Ehrke) one above the other. We have here and almost "in a nutshell" the "focus *versus* fuzzy" question. It is well worth while for photographers of both or any "school" to look at these two from a little distance, and also as near as he can get, and then think a bit for himself and see if he cannot see some recommendation in the writer's favourite motto, "via media, via tuta."

No. 972 ("Fresh from the Altar," J. Hayllar). A very remarkable piece of fine detail painting, representing more painstaking skill than some of the big brush school would credit, and instances admirably the lesson that one subject may find fitting expression in a method which would be utterly fatal to one *partially* similar.

Gallery X.—In this room the pictures which are most likely to repay the observant visitor are No. 996 ("Portrait," M. C. W. Flower), *vide* also No. 635 by same artist; No. 1,016 ("Waiting for the Train," J. H. F. Bacon), a sweet, thoughtful face painted with great sympathy; No. 1,009 ("Brunswick," V. P. Yglesias), a quiet bit of N. Yorkshire; No. 1,042 ("Three miles to the Fair," C. Hayes), perhaps the most truthful rendering of snow in this year's collection; and No. 1,028 ("The 9th of November," W. Logsdail), a picture which makes one say Oh!

Gallery XI.—No. 1,090 ("The Young Wheat," David Murray) will certainly repay careful study, and is the kind of subject open to the country photographer. Observe how perspective of the parallel lines gives feeling of distance, and how the lines of the clouds assist in giving also the feeling of space—the open air effect so seldom sufficiently conveyed.

No. 1,146 ("By order of the Court," S. A. Forbes). One of the leading pictures of the year; contains *many* hints which space does not permit being given at length, but must not be passed over without careful study. There are also several other pictures to be carefully examined, viz., No. 1,076 ("Perseus and Andromeda," H. S. Tuke), No. 1,104 ("October Glow," A. East), No. 1,111 ("Last Load," B. Gast), No. 1,112 ("Chip of the old block," W. B. Fortescue), No. 1,113 ("The Ferry," W. Osborne), and No. 1,140 ("Roman Holiday," F. M. Skipworth).

The Architectural Room calls up numerous interesting questions both as to interior and exterior work, and therefore will repay a visit. The "Black and White" and also Water-colour galleries are obviously abounding with lessons and hints, which space does not permit one to enter upon; and the question of the bearing of photography towards the revival of miniature painting and growing attention recently given to "burnt-in enamels," must all be reserved; but most reluctantly do we relinquish our study of, perhaps, the most difficult branch of art, viz., sculpture, but a branch which no real serious and truth-seeking art student can afford to neglect.

HERR H. F. R. VOIGTLANDER, of the firm of Voigtlander and Son, has, it is reported, been knighted by the Emperor of Austria.

ETHICS OF PHOTOGRAPHY AND PHOTOGRAPHERS.*

BY J. TRAILL TAYLOR.

A FUNNY instance of slightly unethical behaviour comes to my recollection. The once well-known Marcus Sparling was intent upon taking a stereoscopic view of an old house in the Edinburgh Cowgate, but, when the light suited, the street was usually full of boys just out of school, who invariably persisted in standing in front of his camera. In this dilemma he applied to me for advice, and, as a consequence, the next day found him with a huge, highly-polished French portrait lens attached to the *back* of his camera, and pointing in the direction opposite to that where stood the coveted old house. This time the boys, true to their instincts, posed in front of the showy lens in the rear, and stood still patiently during the three or four minutes (these were the days of long exposures) required to get the building photographed. This may be off-colour from the ethical standard, but what was one to do under the circumstances?

Here is a view, fully exposed, taken of a railway carriage when the train is certified by the engineer as having been going at thirty-five miles an hour, and yet every one of the occupants of the compartment is sharp and distinct. As the story stands it is simply a marvel, but "seeing is believing." Where the ethics come in is the withholding the explanation that it was taken from the window of a carriage in another train, which, on a parallel track, was moving at the same rate of speed, and when, consequently, one was motionless as regards the other—a phenomenon that can be witnessed every morning, about nine o'clock, between Finsbury Park and Holloway Stations, on the Great Northern Railway.

Double printing, when practised by one imperfectly skilled, may prove a fertile cause of departure from truth. Clouds of a nature totally inadequate to the character of the scene may be introduced. The foreground of a picture may be Indian, and in the distance may be seen the Crystal Palace with its Sydenham surroundings. One of our members has, by way of joke, introduced in a view in Epping Forest an alligator disporting himself by the bank of one of its pools; but many things equally non-natural are sometimes to be discovered in a combination photograph. Thus, we have the incongruities arising from the attempts to combine, in one picture, pieces of landscape or incidents taken with lenses the foci of which are widely different. Not only so, but we have in one inharmonious whole parts of views lighted differently from each other, and as many kinds of perspective as there are elementary parts in the finished result. I have seen in a pseudo-moonlight photograph the orb of night printed the size of a threepenny piece, when that of even a split pea would have proved too great. Nay, I have, and you all have, seen moonlight photographs in which the dominant light fell upon the objects from a point thirty or forty degrees to one side of the position of the full moon by which the scene was supposed to be illumined.

The mere mention of photography in the law courts will recall an incident narrated by one of our members a few years ago. It was a case of ancient lights, and in the morning he, as a well-known professional, undertook the task, in the interests of the plaintiff, to show by truthful photography that the erection of a building then in progress would most certainly cause a serious obstruction of

* Continued from page 376.

the light. He did his work to the satisfaction of the solicitor, and received his well-earned fee. But next morning the solicitor for the defendant employed him to establish the fact by truthful photography that by the erection of the building in question no light whatever would be obstructed. He effected this, as in the previous case, in a satisfactory manner, and received his fee. He, doubtless, reasons that there is no more immorality in this than is reputed to be found in the daily practice of legal or patent experts, and other counsel, who give "opinions" usually favourable to those by whom their advice is sought. Nor is there.

A humorous application of *mal* ethics in photography is to be found in the photographer in an agricultural district, who had often occasion to take negatives of cattle and horses. He overcame the difficulty so often experienced of the animals whisking their tails and spoiling the exposure, by the ingenious expedient of keeping a large and various assortment of negatives of cows' and horses' tails, from which he selected one that matched that of any given specimen, and printed it in, having previously stopped out the original that was blurred by motion. This suggests the practice of the photographer in the military town, who kept a stock of well-taken figures in uniforms, but minus the heads, which he supplied from those of the gallant patrons of his studio. And this in turn suggests mention of a practice, horrible in its abomination, which, more than twenty years ago, was—happily not frequently—adopted by some foreign photographers, of printing the heads of respectable ladies on the undraped bodies of some of the same sex to whom this qualifying term could not possibly be applied. Of all ethical sins in photography this one was the vilest, as the junction of head and figure was so perfectly effected as to deceive even photographers themselves.

And dry-plate manufacturers, what of them? Are they ever guilty of practices contrary to ethics? Honestly I believe they are not. The day has long gone by since any manufacturer sought to utilise his waste or "shady" plates by inserting two or three of them in every dozen package of good plates. Happily, this system, being suicidal, quickly effected its own cure, so it no longer exists.

"Borrowed plumes" is a term which covers several departures from the strict ethical path. I allude particularly under this heading to professional photographers who display in their show cases as their own work that which has been executed by others; and also to amateurs who, buying their plates ready prepared, get their developing, printing, mounting, and finishing done by others more skilled, and then exhibit, and possibly obtain medals for it, as their own work. A case is on record in which this was carried to an extreme, for not only was all the foregoing done, but it was done with a borrowed camera, and an artist present had indicated the spot on which to erect it, and the exposure to be given. Well might the narrator ask *who* of all these should have got the medal that was awarded the picture made under these circumstances?

I have mentioned an amateur of one type; there is another, viz., the one who, posing as an amateur, yet enters in some respects into pecuniary competition with the professional, doing work for his friends and such of the public as apply, at so-called prime cost—that is, cost of material—thereby in many cases depriving the man who has to subsist by the exercise of his profession of his means of living. On the unfairness of such a proceeding it is not necessary I should dilate, especially as it is not unethical, and does not come properly within the scope of my subject.

Photographic authors and writers do not usually lend themselves to the encouragement of departures from ethics, but Elbert Anderson, in his book, "The Skylight and the Dark Room," is not so fastidious. He advises that, even "if your sitter sits still and has a good expression, but upon developing the negative you find you have committed a blunder, rush out of the dark room, and tell him with a bold face that he *moved!* *You* must never be in the wrong; it must always be *his* fault."

Over a month ago I was discoursing on stereoscopic photography at another Metropolitan society, and after speaking of the expedient that had to be resorted to when photographing the moon, namely, taking advantage of her librations, and thus increasing the stereoscopic base from the two and a half inches between the eyes to many thousands of miles in order to show her in the stereoscope as the spherical ball we know her to be, and by parity of reasoning I adduced my own experience in photographing a coast line from the deck of a yacht, allowing a space of a few hundred yards between the shots in order by such abnormal displacement to show every creek and jutting headland as they existed in nature, although undecipherable in the monotonously straight coast line as seen by the eye. It was objected that this was not truth. Not, perhaps, as a representation of what the eye saw at the moment, but literal truth all the same. This expedient is an aid to vision on the same principle as looking through a telescope to see an object at a range too great for normal vision, or photographing by microscopic aid an object otherwise altogether invisible.

But mention of the stereoscope suggests malpractices with it which are altogether contrary to ethics. For instance, trimming pictures so as to impart a fictitious acclivity to a railway ascending a mountain which is already fairly steep in itself, as practised by a well-known photographer; or making a stereoscopic pair of pictures from one and the same negative, by which they undoubtedly coalesce when viewed in the stereoscope, but which are devoid of relief.

"Dodges" are not necessarily antagonistic to ethics. They are generally expedients for expediting the means to the end. Many of them could be mentioned were it desirable or necessary.

Do not look upon me as hypercritical in regard to the latitude permissible to photographers. All things are or may be lawful; the expediency thereof must be determined by circumstances. Let photographers practise every conceivable dodge that they can think of, and no offence against the strictest code of ethics will be perpetrated, so long as it is not done, to quote Truthful James, "The same with intent to deceive."

DEVELOPING FLASH-LIGHT NEGATIVES.—A word as to the developing of flash-light pictures. As nine out of ten are hard, the best method, in my experience, is to give them as little pyro or eikonogen as possible, so that the detail will have time to appear, and after detail comes up, and the high-lights are thin and translucent, apply full strength developer until the negative is strong. In this respect a flash-light picture is like a snow scene, easy to take, but difficult to develop.—C. M. COHEN.

Notes.

The French police are nothing if not methodical. When the May-Day demonstrations were feared in Paris, several of the leading capitalists and financiers received threatening letters. These letters were all photographed carefully, and submitted to experts for the purpose of ascertaining if they had been all forwarded by the same person, or "group" of agitators. Why these letters should have been photographed, instead of the originals being submitted to the experts, we do not understand; but doubtless the police know why. Perhaps it was necessary that the official photographer should be kept employed.

Our reference to the absence of photographs of the interior of the Tower, and especially the Beauchamp Tower, has attracted the notice of the daily press. The *Daily News* quotes with approval; the *Globe* with a reservation. The *Globe* agrees with us that the cause is partly due to the "array of ceremonial" with which the Tower is hedged round, but urges also that "in the first place the light in such places is very bad, and the position of prisoners' inscriptions is often very awkward." But the badness of the light is, in these days of magnesium powder and sensitive dry plates, no obstacle at all, while there are no inscriptions save those in the passage—the most interesting of which is that of Robert Dudley, Earl of Guildford—which present any difficulty. "It is, besides," adds our contemporary, "possible to attach too much importance to such relics of old days. Some of the inscriptions are, beyond doubt, genuine, and are often deeply pathetic. But it is not quite certain that imaginative custodians have not fathered them upon imaginary authors." This may or may not be, but the question of authenticity is not one which the photographer is called upon to decide. Meanwhile it is pleasant to see that the subject is deemed of sufficient importance to draw comments from two of the leading London papers.

It is now, we read, the fashion for barristers' chambers in the Temple to be ornamented with pictures of various "bits" of the Inn, both interior and exterior; while it is almost *de rigueur* that on the walls should be hung portraits of judges and other legal celebrities. This possibly explains why the photographs of the luminaries of the bench and bar can be so readily purchased; otherwise, one would think the sale of such pictures was so small, it would hardly pay for the trouble of keeping a variety. In regard to the pictures of the buildings, these, it appears, are mostly water-colour sketches and etchings, a series of the latter being now in process of completion. It is curious that photography has been made use of to such a small extent as it has in regard to photographing the Inns of Court. The briefless barrister—and his name is legion—might do worse than employ his idle hours in photography. Yet, so far as we know, few of them have taken up the art.

Even those who have, appear to have done so in a perfunctory spirit. Witness Mr. Stavely Hill's experience. Mr. Hill paid a visit to Canada some time ago, and took with him a camera and a number of double backs. In crossing the Atlantic, the ship encountered some icebergs, and Mr. Hill promptly brought out his camera and made six exposures on the frigid monsters. On his return home, the backs, with their contents, were handed over for treatment to a professional photographer, who, on opening the slides which it was supposed contained the precious negatives of the icebergs, made the unpleasant discovery that the whole six were empty. Instead of filling the slides himself, as a genuine amateur would have done, Mr. Hill trusted to the dealer of whom he had bought his apparatus, and, by some carelessness, the assistant had omitted to fill some of the slides. It was exceedingly unfortunate that Mr. Hill should have picked out the empty slides, because he was particularly anxious to obtain a picture of an iceberg; but in photography 'twas ever thus. It is always the cherished picture which comes to grief.

Not enough notice has been taken of the phenomena which found publicity, not in the photographic but in the daily press, of the efficacy, photographically speaking, of thunderstorms. We were told of two instances of photographs in natural colours. One occurred during a photographic lecture at the Polytechnic, when a violent thunderstorm arose, with the result that a coloured image was imprinted, not upon the plate, but upon the lens. In the other case, a lady clothed in a black dress checked with green, red, and a narrow yellow stripe, was sitting for her portrait. When the thunderclap had burst, and the lady had scampered away in fright, the operator developed, and found, to his astonishment, "a beautifully delicate, naturally-coloured Daguerreotype." We do not like to doubt the veracity of anyone, and least of all the veracity of a photographer; therefore, although we have not seen either the "lens" or the "Daguerreotype," we would not say such things have not been.

The point we would like to enforce upon photographers is the desirability of not allowing a thunderstorm to slip without trying to utilize it. Warm weather has now been with us for some time, and the probability is that thunderstorms will follow. The proper thing, therefore, to do is, directly thunder and lightning make their appearance, to rush to the studio with a sitter who is not nervous, and begin taking photographs one after the other. Benjamin Franklin got a good deal out of a flash of lightning with a homely umbrella, and we do not see why the photographer should be less successful with a camera.

Architects' drawings look very pretty, but do not gain by being photographed. Photography has a knack of exposing their weak points, and, as a rule, make them ridiculous. An American paper having published the photograph of the architect's drawing of

an hotel to be erected in Mexico, a Mexican journal favours its readers with the report of its special artist upon the photograph in question. The expert, after severely criticising the building, says:—"The only redeeming feature I was able to discover in the photograph are three mops on the right hand side of the building, and two on the left-hand side. I suspect they are meant to signify palm trees, as a homage to the tropical character of Mexico." Severe, but, we doubt not, truthful criticism.

Now that the optical lantern is taking such a prominent place in all sorts and conditions of work, it will not be out of place if we refer to a possible application of it which may not have occurred to those chiefly concerned. We refer to the aid which it might render to the theatrical scene painter. The usual course in painting a scene is to first of all make a small sketch of the composition, and then to rule lines across it so as to divide it into squares. Similar squares are then "struck" by charcoaled string on the large primed canvas as a guide to the artist, who then reproduces the sketch in its enlarged form. Now, of course, all this work would be greatly hastened and simplified by photographing the original sketch, and throwing the image of the negative on the whitened canvas, so that the scene painter could follow the outlines with charcoal or brush. With a lens of good definition, and with a simple form of lime light—always available in a theatre—the thing could thus be easily done. In painting-rooms of limited area, there might be a difficulty in finding sufficient space for the lantern; but there would even then be the alternative of making the enlarged sketch on the stage itself.

In the old wet-plate days, developing dishes were unknown. The liquid was thrown over the glass as it was held by one corner between the fingers, and the image showed itself almost immediately. But now a dish is necessary, and, with many developers, rocking that dish becomes a necessity if we wish to avoid unequal action on the film. We can of course rock the dish by simple manipulation; but those good people, the dealers, whose province it is to save us all trouble, and who will, if we wish, do everything for us save exposing the plate to the action of the lens, have devised several ingenious rockers. The pendulum has until now been the usual principle of this arrangement; but Mr. Hinton showed us the other day an extremely neat contrivance, by which the rocking is done by clockwork. The apparatus consists of a neat box, with the clockwork inside, acting, like a watch, by means of a coiled spring. It gives movement to a metal platform above, upon which a developing dish may be placed. After being wound up, the platform will execute a see-saw movement for about five and twenty minutes.

Although the season for flash-light photographs is now past for the present, we may call attention to a new form of light of this description which lately formed the subject of a communication to the Washington Chemical Society. Dr. Thomas Taylor, of the United States Department of Agriculture, was the originator and exhibitor of this new aid to photographic work. The magnesium powder is associated with charcoal made from the silky down of the milk weed—a form of carbon so pure, that it leaves no ash. A little of this composition placed on tissue paper, and fired, produced a flash which was so instantaneous, that enough heat was not developed to scorch the paper upon which the powder rested. We well know that this is not the case with several of the more or less dangerous mixtures which have been recommended for flash-light purposes. Many of these not only set fire to the surface upon which they rest, but scatter burning particles around, and behave generally like a small volcano.

If there be such a man as a photographer who is puffed up with an inordinate opinion of himself, he can very easily get the conceit taken out of him by studying one of the boards placed by the London County Council at the entrance to all parks and open spaces under their control. Inspection of one of the regulations will speedily convince the reader that the L.C.C. does not think much of camera-bearers in general, for they are classed with itinerant showmen, gypsies, and other hangers-on of open air existence. The particular regulation to which we refer prohibits all kinds of amusements dear to holiday folk, and numbers among them the innocent tripod stand and its belongings. The section is thus worded:—"Erecting or placing in the Park any post, rail, fence, photographic apparatus, cocoanut, stand, swing, or any building, erection, or obstruction of any kind whatsoever."

Shades of Daguerre, Niepce, and other departed ones, who laid the foundations of our art science, hear how your followers are treated by officialism in this year of grace 1890! They are classed with cocoanut throwers at "three shies a penny," with Aunt Sally, with round-abouts, with erectors of swings, and with all that wandering class of irresponsible persons who, in the old days of fairs, used to live in an atmosphere of gilt gingerbread and flaming naphtha lamps. But perhaps, after all, this is a little joke on the part of the newly elected Council, for certain it is that if proper application be made to their Secretary, he will recognize the claims of the ubiquitous photographer, and will grant him the necessary "open sesame."

A single permit to photograph, issued by the County Council, holds good for all the parks and open spaces under its control. In Battersea Park will be found a few scenes which make excellent photographic pictures, since there the authorities have been to some little expense in the production of artificial rockwork and waterfalls; the rocks are now so mellowed with age, and covered with vegetation, that nature unadorned seems to rule throughout. Some of the trees in the park are sub-tropical; they are moved and kept under glass during the winter months.

PHOTOGRAPHIC EXHIBITIONS.—No. I.

BY GEORGE DAVISON.

Exhibitions are taking a prominent place in photographic history. The causes of this growth and extension are not far to seek, and their influence may be readily traced. Just at present there is a revolt against the greater part of the system in vogue, and what were a few years ago regarded as unpopular and fanciful reforms now promise to be taken up and generally adopted. This ready surrender is probably attributable to the vast increase in the number of exhibitions and to the frequent absurdities and inequalities which have resulted from the application of an unsuitable code of regulations.

Recently I happened to hear a photographer of long standing complain that there was nothing but exhibitions talked about and reported, so much so that he did not care to read the journals. He was a worker of the older school; one whose delight was in processes and the mechanical practices of photography, and, probably, it would be impossible for such an one to appreciate the highest objects of such exhibitions, or the motives which actuate those whose anxiety to place the whole system on a higher level finds such frequent and earnest expression. The chief interest which has been taken from the first by photographers in the work of these exhibitions has been as to what new wonder or scientific excellence they brought before the public. The whole was looked upon and judged by scientific standards and conventions. It has taken a considerable time and experience to teach the lesson that there must be a wide separation of artistic and scientific applications and results by photography. An understanding of this distinction is essential as a foundation for the framing of what will probably be the future regulations for photographic exhibitions.

Photographers have been misled by the conventions, or absorbed and distracted by the business of photography. They have been faithless and disloyal to their art, and have distrusted its power for anything beyond what they had themselves done. But there has been growing a belief in higher art possibilities for photography, and, in spite of some strenuous attempts to impose unnecessary limitations, there are a good many photographers who are enthusiastic in assisting whatever may prove or extend the capabilities of photography as a means of artistic expression. It is this latter influence which is responsible for much of the desire for exhibition reform which is now so prominent.

The question to be considered is what regulations and conditions are required for an art exhibition. The general characteristics and requirements of pictorial art must be considered and made the test. If this be done without prejudice, the difficulties concerning regulations very greatly vanish. The way is clear. Where struggles concerning detail arise, they may be traced to an attempt to compromise with old prejudices, the domination of standards, or the exigencies of popular vulgar taste and craving for excitement. So far in general terms. In subsequent articles this test will be applied to some of the difficulties which arise and are very generally discussed.

There are some interesting points in connection with early exhibitions which may well be referred to, as naturally leading up to a consideration of affairs as we find them to-day. Exhibitions are responsible for the prosperity and even for the existence of some photographic societies. The foundation of the Photographic Society in 1853 is greatly attributed to the influence of the Great Exhibition of 1851, for the *Athenæum* of March 13th, 1852, refers to a proposal which was before them for the formation of a Photographical Society, which, they state, originated in the "meeting of the professional and amateur photographers from various countries whose pictures were shown at the Great Industrial Exhibition of 1851." This proposition had for some time been "hung up" on account of the difficulties attending Fox Talbot's patent rights. More directly, too, the exhibition of photographs "by the most notable professionals and amateurs" at the Society of Arts, in December, in 1852, as described in "Notes and Queries" of that year, had an influence in stimulating the enthusiasm and warming up the sympathy which pressed forward the movement, which had in 1851 received so much impetus by the showing of Dr. Diamond's specimens at Lord Rosse's *soirees*. At the exhibition held at the Society of Arts, it may be noted that the admittance was 6d. each, and that certain ladies greatly distinguished themselves by their exhibits.

From the first the Exhibition of the Photographic Society took leading place. Some of the early regulations of the exhibition of January, 1854, are given in that Society's Journal. These were very simple and general, the most interesting being a grandmotherly restriction as to amount of margin desirable and allowable for the photographs, and a rule that "prints from touched or painted negatives must be described accordingly." These exhibitions were well supported. It was announced that 1,000 pictures were included, and this is about as many as are received to-day. Further, the gallery was open to the working classes in the evening at a charge of 3d. each. In February, 1854, the Devon and Cornwall Photographic Society had its first meeting at St. George's Hall, Stonehouse, in connection with a small exhibition and *soiree*, which was "attended by all the most distinguished people in the neighbourhood," and at which "photographs were taken by artificial light in the presence of the company." This may be taken as typical of the frequent local societies' inaugurations of recent days, though more prosperous sounding than the reports of these latter meetings.

As the societies multiplied, so did exhibitions increase. There was mutual action and reaction. A writer at the date remarks that the exhibitions mostly take place at the same time, and the bewildered exhibitor scarcely knows where to astonish the public gaze with his "pet productions"—a very exact anticipation of the remarks which have been so freely heard of late. Manchester had its first annual exhibition in May, 1856. The Bombay Society, with over one hundred members prior to April, 1855, had its exhibition and Journal, and a class in the Elphinstone Institution for instruction in photography. Brussels, also, had an exhibition in 1856, and we find the International Photographic Society at Amsterdam giving medals about the same period. With the institution of such societies as Liverpool, Dublin, Birmingham, Norwich, Brighton and Sussex, Maulmain, Bengal, the Société Française, and the Photographic Society of Scotland, exhibitions very naturally grew and extended. As might be expected, it it was not, however, until the dry plate became established, that the multiplication of societies and exhibitions became phenomenal. These exhibitions are found to popularize photography, and to advertise and give a stimulus to the societies organizing them. Sympathy, emulation, and business enterprise, all combine to ensure large and prosperous shows. In the multitude of rival exhibitions, those responsible for their management have thought it

necessary to devise fresh allurements every time to attract a large body of exhibitors. The result of this has been, in this age of absurd competitions, a multiplication of prizes and an exclusive consideration of what would ensure a large crop of frames and a commercial success. The spirit of competition has for a time affected photographic exhibitions in an astonishing manner. Exhibitors have been led to give themselves entirely away in the scramble after prizes which could carry no real honour. Even the judges have been too anxious to accept what seemed to be the superior distinction of deciding upon the respective merits of well-known competitors. Now, however, there is a strong tendency to scrutinize regulations before consenting to be associated therewith, and there is also a fair prospect of exhibitors, judges, and exhibition authorities combining to better the present state of things. There are already satisfactory signs in the announced regulations or proposals for forthcoming exhibitions at home and abroad, to which reference will be made in further discussion of this subject.

PHOTOGRAPHY IN FLORENCE.

The *Camera Obscura*, a monthly review connected with the progress of the art of photography, and published under the able direction of Professor L. Borlinetto, with Germano Salvi as editor, and an efficient staff of collaborators, contains, besides articles on the development of the latent image, and on the formation of composite pictures, a notice of the Italian Photographic Society, which holds its meetings in Florence.

The last general meeting, on the 11th of May, was presided over by Professor Golfarelli, on account of the lamented indisposition of the president. Thirty new associates were admitted. After the transaction of the usual necessary business,

The President gave a demonstration of the perfection gained by Italian makers of gelatino-bromide plates, such as Melazzo, of Naples, Cappelli, of Milan, and the recently established house of Semplicini, in Florence.

Signor Paganori then spoke, in a few moving periods, of the death of the late able and well-known member of the Society, Giuseppe Alinari. The great loss experienced by the photographic world in the decease of this accomplished artist is further touched upon in the necrology at the conclusion of the *Camera*. It is there stated that Alinari, who gained for the establishment over which he was the technical director numerous national and international prizes, was born on the 29th April, 1836. He was a pupil in the Infant Asylum founded by Guicciardini, and entered while yet extremely young the house of Falcini to study the art of inlaying and mosaic. His brother Leopoldo, having taken it into his head to become a photographer, made some successful early attempts, and was encouraged by Giuseppe Bardi, who had chanced to see his work, to continue his labour, and ultimately opened a small establishment on the ground floor of a house in the Via Cornina, taking as his assistant his brother Giuseppe. This happened in 1853. By degrees he was induced, through his increasing business, and by the advice of his friends, to add to his little shop a chamber for taking portraits. But this was in its turn found insufficient, and Leopoldo having acquired some ground in what is now called the Via Nazionale, there erected a large and imposing building, which was not completed till 1862.

The photographic labours of the brothers Alinari were soon so highly appreciated, not only in Italy but in other countries, that amongst the many important commissions with which they were entrusted about this time, must be reckoned that of the Archduke Alberto, who, in addition to requiring a reproduction of a part of the designs in the Royal Gallery of the Uffizi, also desired that the brothers Alinari should betake themselves to Venice, and after that to Vienna, in order to execute some designs which he had chosen there for photographic representation.

On the 9th November, 1865, little more than two years after the inauguration of his new establishment, Leopoldo ceased to occupy himself therewith, leaving the care of his two infant orphans to his brothers Romualdo and Giuseppe, giving the former the general administration, and the latter the technical direction of his well-established house. It was then that the earnest activity, the noble unselfishness, and the artistic intelligence of Giuseppe Alinari made themselves chiefly conspicuous.

Ever ready to work, always at his post at the proper time, apparently unwearied by labour's fatigue, he effected in a few years by his own unassisted endeavour more than the result of the united forces of many excellent photographers in Italy and elsewhere.

The frescoes of Santa Croce, executed for the Duca di Luynes, those of San Miniato, executed for the same patron, the chapel of Brancacci al Carmine, the frescoes of S. M. Novella, and those of the Palazzo Riccardi, of the Sistine Chapel at Rome, and a thousand other works, all of extreme difficulty, were undertaken and completed by Giuseppe Alinari by means relatively weak and poor, seeing that at that epoch the great universal panacea, the gelatino-bromide of silver, which has transformed countless "fools" into photographers, was not known, but recourse must then have been had to wet collodion, in the use of which so many modern photographers have encountered almost insuperable difficulties.

Being such a man as has been described, Alinari was at the same time excessively modest, and rather sought to avoid than to encounter all that might produce for him honour and prizes; nay, he went so far on several occasions as to refuse both when they had been offered to him. It was with no little difficulty that he was at last induced to become a member of the committee for the promotion of the photographic exhibition held in Florence, and of the photographic society, in which he would never accept any mark of exceptional honour or any post of unusual distinction.

The later years of his life were spent on the illustrations of a work on architecture, published by Professor Steigmann. To this work he brought so much passion and so great intelligence that Steigmann, in the letter of condolence which he sent to his nephew Vittorio, thus expresses himself:—

"I have just heard of the death of Signor Giuseppe Alinari. What a grief for me! What a loss for art!

"In him I miss a friend, not only to myself, but to my work.

"But all the world may mourn for one who has brought into the hearts of so many a love for the photographic art."

Giuseppe Alinari died the 24th April, 1890.

The Photographic Club.—The subject for discussion on June 11th will be "Paintings as Art Examples to Photographers"; June 18th, "Mounting and Finishing Photographs."

A PHOTOGRAPHIC EXHIBITION AT HEXHAM.

BY JAMES BROWN AND EDGAR G. LEE.

PERHAPS the most remarkable "one man" exhibition ever held is now on view in the Town Hall of the quaint old market town of Hexham, commonly known as "the heart of all England." The show consists of over 400 photographs by Mr. J. P. Gibson, of Northumbrian scenery and antiquities, ranging from whole-plate to 15 by 12, and mostly by the platinum toning process, which, in Mr. Gibson's hands, lends itself admirably to artistic effect.

Mr. Gibson is an ardent antiquarian, whilst as a landscape photographer he has stood in the front rank for many years. The standard of the exhibition is high, and the work shows evidence of thought and tender care throughout. The technique, as might be expected from such a careful worker, is good, except in a few of the architectural subjects, in which the effect of the "harmless" yet necessary wide-angle lens is somewhat unpleasantly manifest.

Whilst some of the subjects possess only a local and archæological interest, they are treated in the same careful artistic manner as his well-known landscapes. Entering the Town Hall, we find photographs illustrating Northumbrian architecture from pre-historic down to modern times, instantaneous street scenes, views of bleak moorlands, and of the sylvan and romantic scenery of the Tyne and its tributaries, which Mr. Gibson has made peculiarly his own. With so many pictures on view, it would be difficult to attempt a lengthened criticism, but we propose to single out a few for special comment.

The 15 by 12 first claim our attention, and a long way ahead stands No. 269, "Autumn Haze," a charming view on the South Tyne, with the distance beautifully softened by a perfectly rendered haze. Another feature of this picture is a choice bit of reeds and rocks, with figure judiciously introduced. Next is No. 267, "Under the Haycock Fast Asleep," in which the foliage in the middle distance is exceptionally fine, and the figures from which the picture takes its title are placed naturally without any straining after effect. In No. 268, "September," we have a reach on the South Tyne, a piece of pure landscape art, with gleams of sunshine playing over the water at the bend of the stream, and a gnarled old oak standing out in bold relief. Coming to the whole-plate series, the task of selection becomes more difficult. Our own feeling is that No. 82, "At Ladle Wells," is the choicest and most artistic *pure* landscape in the whole exhibition. It represents with startling realism a desolate, barren moorland; rushes and burnt heather make up the foreground; two trees, bare and bleak as the surrounding heather, stand out weird against the wintry sky; the whole forming one of the finest and withal simplest pictures we have ever seen. No. 36, "By the Brooklet," is of its kind a gem, which shows how a simple subject may be aided by artistic feeling in placing figures as aids to the composition. In No. 65, "Out for a Holiday," an otherwise fine work is slightly marred by too much white road, which exercises a disturbing effect. In No. 69, "The Beautiful River," the subject does not belie the title; a splendidly balanced picture, with an artistic foreground. No. 159, "The Wind that Stirs the Mere," is another scene of loveliness—a small Northumbrian lake. Here, again, the materials are simple—a crag and a sunlit expanse of water broken up into ripples by the wind, with the foreground and sky—two of Mr. Gibson's strong points—alike admirably treated, so treated, indeed, as to make the picture.

Space does not admit of further individual notice, although many pictures merit it. In this catagory may be included No. 39, "Old Ridley Bridge"; No. 55, "Coastley Burnfoot"; No. 57, "The Lonely Moor"; No. 76, "Hindley Burn"; No. 99, "Tickling the Trout"; No. 342, "Waiting," and No. 222, "The Thief's Tyke." This last is a vigorous subject vigorously treated, larch trees against the sky with a finely-broken up foreground.

The architectural subjects, as subjects, do not call for special comment, but locally, of course, are interesting. The salient feature of the series is the fact that by proper handling, the careful study of lighting, and judicious selection of clouds, what in many cases would have been ordinary photographs are transformed into works of art.

Summing up, the effect produced upon our minds by this unique show is one of unmixed pleasure, and admiration of the thoughtful adaptation of means towards ends displayed in many of the works. We suggest that the Camera Club authorities should at an early date endeavour to secure some of the gems of this collection for one of their "one man" exhibitions.

Notices of Books.

THE Amateur Photographer's Library, Nos. 3 and 4. (*Hazell, Watson, and Viney, London*, 1890.)

EXPERIMENTAL PHOTOGRAPHY.

THIS little book, Number 3 of the series, is written by Mr. C. J. Leaper, a Fellow of the Chemical Society, and contains much elementary information about photographic chemistry likely to be of use to those beginners who have not studied the latter subject. As regards developing room illumination, he is right in recommending a large window, eighteen inches square, for the lantern, but says that it should be of one thickness of ruby cloth; if he examines such cloth under the microscope by means of a strong light on the other side of the fabric, as recommended in another column, he will see reason to alter this advice, and to advocate the use of at least two thicknesses.

Much of the book deals so much with elementary photography, that any criticism of it would be of little interest to our readers; suffice it say, the instructions given to learners are, generally speaking, sound.

Mr. Leaper gives the following instructions for the production of prints of different colours by iron processes:—

If we do not admire the blue colour of these prints, we can readily change it to a very beautiful green by immersing the finished print for a few minutes in very dilute sulphuric acid, about two drops of the strong acid to the ounce of water. Views of breaking waves printed in this manner make striking pictures.

A dark-brown tint can be secured by making use of the well-known reaction between the salts of iron and tannin, a reaction to which the colour of ordinary writing ink is due. To obtain such a brown colour we float the blue print for five minutes on a solution of tannin containing 10 grs. of the substance in an ounce of water, then transfer it to a solution of ordinary washing soda of the same strength, and lastly retransfer it to the original tannin solution, after having washed the print for ten minutes in running water.

A black print can, lastly, be obtained from a blue one by floating the blue print on a solution of silver nitrate containing one grain of the salt to the ounce of distilled water, leaving it there for five minutes, washing the print for about half-an-hour to get rid of every trace of free silver nitrate, and then immersing it in the usual ferrous-oxalate developer, the same, in fact, as we employed with the Eastman paper.

In the preceding processes we have produced blue prints on a white ground, *i.e.*, the unexposed parts remain white, and the exposed portions become blue. The salts of iron can, however, be also made to yield prints of the reverse character, viz., ones in which the exposed portions remain white and the unexposed portions become blue. To understand how this is brought about, we again take some ferrous sulphate and ferric chloride, and add to each a small quantity of a solution of potassium ferrocyanide or yellow prussiate of potash. We shall find that the ferrous salt will yield a light-blue precipitate, changing rapidly to dark blue, whilst the ferric salt will yield an immediate dark-blue precipitate.

If we could exclude from the ferrous salt every trace of the

ferric compound, we should obtain a white precipitate. We can now understand how, by employing potassium ferrocyanide as a developer, we can obtain a print in which the exposed (ferrous) portions remain white, whilst the unexposed (ferric) portions become blue. The solution previously used is not very suitable for this purpose, but the following will yield good prints :—

Citric acid	...	...	...	40 grs.
Ferric chloride	...	...	...	18 ,,
Gum arabic	...	...	...	42 ,,
Water	...	...	...	11 ounces

Soak the gum arabic for a couple of hours in half the quantity of water, and then dissolve it by placing the vessel in a warm place. Meanwhile, dissolve the citric acid and ferric chloride in the other half, and mix the two solutions. The paper is floated on the solution for a couple of minutes, then dried and exposed, and the prints developed by floating them on a solution of potassium ferrocyanide containing twenty grains of the salt in an ounce of water. Development completed, the prints are immersed in weak sulphuric acid (six drops to the ounce of water), and finally washed for ten minutes or so.

The "cyanotype" in this form is only, of course, a curiosity when employed with negatives, but it is a very valuable process indeed when the object is to reproduce engineers' drawings on tracing paper. Evidently in such a case the black lines will, if the paper is exposed under the drawing, be rendered as blue ones, whilst the ground through which the light has passed will remain white, the sensitive substance having been changed there from the ferric to the ferrous condition.

Ordinary note-paper is good enough for experimenting upon with these processes, but some of our readers might wish to secure blue prints possessing the brilliancy which characterises those made on sensitised silver paper. To do this, ordinary albumenised (*not sensitised*) paper is first washed in running water for half-an-hour to free it from the ammonium chloride with which it is impregnated, then dried, and treated with the sensitising solution, making use of a pledget of cotton wool to *brush* the solution on the surface, instead of floating the paper. And if a still greater amount of brilliancy be desired, the albumenised paper can be first of all floated on *boiling* water to coagulate the albumen, then washed and sensitised as before. Washing the paper in cold water removes the greater part of the albumen as well as the ammonium chloride, but this is avoided by coagulating it by heat.

The action of light upon ferric oxalate is the basis of the deservedly popular platinotype process, in which the image consists of metallic platinum, one of the most unalterable substances known.

The author gives information about the wet collodion process, and how to make lantern slides thereby by superposition. This may prove useful to some of the new race of photographers not versed in the processes of the past. The wet plate process is still somewhat extensively used by professional photographers for special purposes.

Art Photography.

Number 4 of the series, "Art Photography," is written by Mr. H. P. Robinson, and contains several engravings, all of which have been carefully printed. The work is readable, and is written in Mr. Robinson's usual analytical and interesting manner. On page 37 the author says :—

Although I have said I should prefer a beautiful untruth to an ugly fact, I cannot deny that more truth, within its limits, is expected of photography than of any other method of representation, and we must give all the truth we possibly can. If we cannot give the truth, the whole truth, and nothing but the truth, then we must lie like truth, which, after all, is perhaps as good a definition of art as we have.

The little book contains some practical instructions about combination printing, of which art Mr. Robinson stands undeniably at the head. As the whole system of combination printing has been vigorously attacked during the last year or two, the following utterances of Mr. Robinson in its defence may not be without interest:—

It was a maxim with the Spartans that if your sword was short you should add a step to it. It being, I think, sufficiently proved that our present optical resources do not enable us to represent properly some of the simplest scenes around us which we ought, as artists, to reasonably expect to be able to obtain, we must try some other way that will help us to succeed. The obvious step that we must add to our short sword, until something better is invented, is combination printing. I have now had more than thirty years' experience of this method, and still think it not only the best, but the only way of getting many subjects which should not be lost to our art. It is of all others the process for the amateur ; it will enable him to spend many pleasant hours, and haply achieve distinction. The method takes time and patience, no doubt, but you "get your own out of it."

Specifications Published.

18,897. *December 10th*, 1890.—"The Manufacture of Photographic Films." A communication from George Eastman, of Rochester, in the County of Monroe, and State of New York, United States. Alfred Julius Boult, 323, High Holborn, London, M.I.M.E.

This invention relates to the manufacture of the improved flexible film produced in the manner and having the characteristics hereinafter described.

In practising this invention, a clear fluid solution of nitro-cellulose, or gun-cotton and camphor, is first made by dissolving said materials in one or more of the known liquid solvents, such, for example, as methyl-alcohol, which is preferably used because of its active solvent properties. To remove all unconverted or imperfectly dissolved substances from, and to clarify the solution, it is preferred to filter it through fine cotton cloth, the object being to obtain a solution which will be perfectly clear, and which can be readily spread in a thin layer or film upon the surface of a level glass plate or other rigid supporting surface, and which, when dry, will be photographically structureless. Such a fluid solution may be produced by dissolving 9,000 grains of soluble gun-cotton, or nitro-cellulose, and 5,400 grains of camphor in 112 ounces of methyl-alcohol.

It has been found that when such solution is spread out in the form of a film, and dried as the process of drying is accompanied with the evaporation of the more volatile constituents, the mass shrinks, and its exposed surface is liable to become pitted or covered more or less with small depressions, and that it is otherwise liable to prove objectionable. To obviate this it is preferable to add to the solution made according to the above formula, say 28 ounces of fusil oil, and also preferably, though not necessarily, 7 ounces of amyl-acetate, or any equivalent agent which produces the same effect.

The proportions above given for the solid and liquid constituents of the solution may be varied, as well as the proportions of fusil oil and amyl-acetate according to circumstances, but those which are above given have been found to give satisfactory results.

The dissolving of the solids may be hastened and the products rendered more uniform by the application of gentle heat with occasional agitation, the process being conducted in a

closed vessel to prevent loss by the evaporation of the volatile constituents.

Having made the clear liquid solution mentioned, the next proceeding is to obtain a thin layer or film of the same by depositing and spreading the solution upon a rigid supporting surface. For this purpose it is preferred to use a flat table or bed plate of plate-glass or other material having either a polished or dead surface, and on the surface of which the solution may be spread by means of a suitable spreader moving longitudinally over the said table.

It has, however, been found that when the fluid solution is applied directly to and dried on the clean surface of the table or bed-plate, it adheres so firmly to the said table that the subsequently formed complete photographic film can be removed only by the application of considerable force, which sometimes results in the tearing of it or in its being stretched unequally so that it will buckle, and be unfitted for use in roll holders and for negative making. To overcome this difficulty the surface of the glass or other rigid supporting surface, before the fluid solution is spread thereon, is rubbed over or coated with a weak solution of mineral wax in benzine, or other suitable solvent, or a weak solution of beeswax, or with any other equivalent agent to produce the same result. After the bed-plate or table has been so prepared, a thin layer of film of the fluid solution of nitro-cellulose and camphor in methyl-alcohol is spread evenly upon it.

The preliminary coating of wax solution should be of a character to weaken without preventing the adhesion to the glass surface of the supporting film, as it is very desirable that this supporting film, when dry, should adhere throughout its whole under surface to the rigid supporting surface until the photographic film is to be removed.

The next operation, which must be performed in a photographic dark room, is to apply to the surface of the supporting film a suitable sensitised medium such as fluid gelatino argentic emulsion in the form of a thin uniform layer or film, but experience has shown that unless special provision is made against such a contingency this sensitised film will not adhere at all points to the supporting film, but will be detached or separated at parts, and thus form blisters in the photographic film.

This, it has been ascertained, is due in part at least to the greasy character of the surface of the supporting film, to remove which such surface is washed preferably with clear water, to which has been added from 2 per cent. or 3 per cent. of a binding agent such as silicate of potash or silicate of soda. After the surface of the film support is again dry the layer or film of gelatino argentic emulsion is spread evenly upon the washed surface, and will be found to adhere uniformly The spreading of the sensitised film may be effected by the same apparatus as is used for spreading the supporting film.

The supporting film and sensitised film which, combined together, are herein termed the photographic film, are retained in place upon the rigid supporting surface until the sensitised film has dried, when the photographic film may, if desired, be cut into strips of suitable width, and it is then ready to be removed or stripped from the said rigid supporting surface, which may be effected by means of a traversing roller.

The film for supporting the sensitised film is necessarily made quite thin, ordinarily from 3 to 5 one-thousandths of an inch in thickness, or about the thickness of the paper supports heretofore generally employed in ordinary roll holders.

A photographic film produced as described, is of such thickness and flexibility that it can readily be wound upon the spools of ordinary roll holders, such as the Eastman-Walker roll holders, and manipulated for exposure in the latter. The supporting film or backing for the sensitised film is of a material unaffected by moisture, of uniform density, free from striae and buckles, and photographically structureless, and the photographic film as a whole is capable of being used for all those photographic purposes for which can be used glass plates with sensitised films in ordinary cameras or paper, with similar films in roll holding cameras.

Having now particularly described and ascertained the nature of this said invention, and in what manner the same is to be performed, as communicated to me by my foreign correspondent, I declare that what I claim is:—

1. The herein-before described improvement in the art of producing flexible photographic films, which consists in first applying a fluid solution of nitro-cellulose and camphor in a layer or film upon a rigid supporting surface, then drying the same, said film being photographically structureless when dry, and of sufficient strength and stiffness to properly support and sustain a suitable sensitised film through all the operations of negative making and printing positives therefrom; then spreading thereon, while still upon said rigid supporting surface, a thin layer or film of gelatino argentic emulsion; then drying the same while still on said rigid supporting surface; then stripping the photographic film from said support; such photographic film when dried and stripped being of such a thickness as to be flexible enough to be wound upon the rollers of, and used in, ordinary roll holders.

2. The herein-before described improvement in the art of producing flexible photographic films, the same consisting in depositing upon a rigid supporting surface a fluid solution of nitro-cellulose and camphor, spreading the same into a film of substantially uniform thickness, but having the surface in a flat plane, drying said film while still in contact with said rigid supporting surface, thereby producing its uniformity of surface and causing it to adhere closely to said rigid supporting surface, said supporting film being photographically structureless when dry; applying a thin layer or film of fluid gelatino argentic emulsion to the said dried and adherent supporting film by spreading said emulsion progressively from end to end of the previously dried supporting film, drying said film of emulsion while the supporting film is still adhering closely to the rigid supporting surface, and finally detaching or stripping the photographic film from the rigid supporting surface preparatory to winding the same upon spools; said photographic films being sufficiently flexible when dried to be wound upon the rollers of and used in ordinary roll holders, and to be manipulated in the latter for exposure.

3. The herein-before described improvement in the art of forming flexible photographic films, which consists in first making a fluid solution of nitro-cellulose and camphor; second, filtering such solution; third, depositing and spreading the same in a film upon a rigid supporting surface and allowing the volatile constituents to evaporate while the supporting film is adhering to the said rigid supporting surface, said supporting film being photographically structureless when dry; then applying an even layer or film of fluid sensitised emulsion to the surface of the supporting film, while still adhering to the rigid supporting surface, and finally drying said sensitised film and stripping the photographic film from its support.

4. The herein-before described improvement in the art of forming flexible photographic films, which consists in first making a fluid solution of nitro-cellulose and camphor; second, filtering such solution; third, depositing and spreading the same in a film upon a rigid supporting surface and allowing the volatile constituents to evaporate while the supporting film is adhering to the said rigid supporting surface, said supporting film being photographically structureless when dry; then applying an even layer or film or fluid of sensitised emulsion to the surface of the supporting film while still adhering to the rigid supporting surface, and finally drying said sensitised film and stripping the photographic film from its support by means of a traversing roller.

5. The herein-before described improvement in the art of forming flexible film supports, which consists in adding fusil oil to a fluid solution of nitro-cellulose and camphor, and subsequently depositing and spreading such solution upon a rigid supporting surface and drying it.

6. The herein-before described improvement in the art of forming flexible film supports, which consists in combining methyl-alcohol, camphor, nitro-cellulose, and fusil oil to form a fluid solution, and then depositing and spreading the latter upon a supporting surface and drying the same.

7. As an improvement in the art of producing flexible film supports, the herein-before described improved step in the process, which consists in forming the fluid solution, of a mixture

of methyl-alcohol, fusil oil, nitro-cellulose, and camphor, to form a fluid solution for spreading in a thin film upon a support.

8. As an improvement in the art of producing flexible film supports, the addition of amyl-acetate to a fluid solution of nitro-cellulose and camphor in a liquid solvent, and the subsequent depositing and spreading of said solution in a film upon a supporting surface and drying the film upon the latter.

9. As an improvement in the art of producing flexible film supports with smooth surfaces, the same consisting in combining fusil oil and amyl-acetate with nitro-cellulose, camphor, and and a fluid solvent, and subsequently spreading the fluid solution in a thin layer or film upon a supporting surface and drying the said film, preliminary to the application of a film of gelatino-argentic emulsion.

10. The herein-before described improvement in the art of forming flexible photographic films from a fluid solution of nitro-cellulose and camphor, the same consisting in first applying a solution of wax to the supporting surface; depositing and spreading the fluid solution in a thin layer or film upon said surface; drying the supporting film thus formed; spreading a thin layer of gelatino-argentic emulsion upon the dried supporting film and drying the same; and finally stripping the photographic film from the support upon which it was formed.

11. The herein-before described improvement in the art of forming flexible photographic films, which consists in applying an even layer or film of a fluid solution of nitro-cellulose and camphor to a flat surface by means of a spreader moving longitudinally of the same, evaporating the volatile constituents to dry said layer or film, and subsequently, while said film is adhering to the flat surface upon which it was first deposited, applying a fluid sensitised emulsion to its exposed surface by means of a travelling spreader, drying said sensitised film, and finally stripping the photographic film from the flat surface.

12. The herein-before described improvement in the art of forming flexible photographic films, the same consisting in first forming a layer or film of a solution of nitro-cellulose and camphor by spreading such solution upon the flat and rigid support, evaporating the volatile constituents to dry said film and cause the same to adhere firmly to said flat support, applying a film of sensitised emulsion upon the exposed surface of said film support and drying said film of emulsion, dividing the photographic film into strips while still attached to its flat support, and then winding said strips upon a roller or rollers to strip said photographic film from its support.

13. The herein-before described improvement in the art of forming flexible photographic films, the same consisting in depositing and spreading a fluid solution of nitro-cellulose and camphor upon a supporting surface in the form of a thin layer or film, and drying the same; then washing the face of the dried film support; then spreading upon the surface of said film support a film of fluid gelatino-argentic emulsion and drying the same; and finally stripping the photographic film from its support.

14. The herein-before described improvement in the art of forming flexible photographic films, the same consisting in depositing and spreading a fluid solution of nitro-cellulose and camphor in a thin layer or film upon a plate or surface previously coated with a solution of wax; drying said film support; washing the exposed surface of said film support; then spreading a thin layer or film of fluid gelatino-argentic emulsion upon said film support and drying the same; and finally stripping the photographic film from its support.

15. The manufacture of photographic films substantially as specified.

304. *January 7th*, 1890.—"Apparatus for Coating Photographic Plates." Frank Bishop, of the firm of Marion and Company, 22 and 23, Soho Square, London, Dealers in Photographic Materials, and Alexander Cowan, Chase Side, Southgate, London, Manager of Marion's Photo-Works, Southgate, London.

This invention relates to improved apparatus for coating photographic plates with sensitive emulsion.

The invention relates first, to the construction and mode of mounting of the coating trough, and has for its object to ensure the even distribution of the sensitive emulsion, and enable the thickness of the deposit to be easily regulated.

The trough is V-shaped in cross section, and is constructed of two strips or plates of glass, or other suitable material, the one, forming the inclined bottom side of the trough, being bedded upon a hot water circulation chamber, and the other, forming the upright side of the trough, being clamped in position with regard to the first-mentioned plate, its lower edge being truly ground at a suitable angle, and set at such a distance from the surface of the bottom plate as to regulate the escape of the emulsion, and allow it to flow in an even stream down the lower projecting part of the bottom plate. The ends of the trough are closed by blocks which assist to hold the two plates or strips in proper relative angular position. The hot water chamber extends the whole length of the trough, and to it are fixed at intervals clamps having set screws adapted to hold the plates forming the two sides of the trough in their proper relative position at all points of their length. The trough is supported by the ends of the hot water chamber being seated on balanced levers mounted to oscillate at the sides of the coating table, over which the trough extends, the lower edge of the inclined side of the trough resting lightly on the plates to be coated as they are carried beneath it upon the coating table.

In the case of a long trough, a lip formed by a strip of flexible material interposed between the bottom plate and the hot water chamber would be used to compensate for inequalities in the glass, and would rest upon the plates to be coated instead of the lower side of the trough itself.

The invention further relates to the means of supporting and guiding the plates whilst and after being coated, so as to avoid defects in the film due to local differences of temperature consequent on the contact with the under sides of the freshly-coated plates of their carrier-rollers or other supports. It also relates to means of receiving waste emulsion from the plates, so as to avoid the soiling of the under face of the plates with emulsion.

For this purpose, the plates are supported at their extreme edges only by knife-edged rails, and run between guiding rollers or pins mounted alongside the knife-edged rails, the edges of the plates overhanging gutters formed to receive superfluous emulsion, the guttered rails being arranged above a hot water tank, by which an even temperature is maintained.

5,046. *April 1st*, 1890.—"Photographic Camera." William Blake Luce, Boston, Suffolk, State of Massachusetts, United States of America, Draughtsman.

The inventor claims:—

1. The combination of a vertically elongated camera-box, having upright grooves and an aperture in the lower part of its front, and a lens-tube open at its inner end, and longitudinally movable in the said aperture, the said parts being so arranged that when the lens-tube is within the camera-box, sensitive plates placed in the grooves of the latter are supported by the lens-tube, and, as it is withdrawn, the plates drop one by one into the field of the lens carried by the lens-tube.

2. A camera-box having vertical grooves and apertured front, the said aperture being circular and internally threaded, in combination with a cylindrical, threaded lens-tube removable in the said aperture, substantially as set forth.

Royal Institution.—At the monthly meeting on June 2nd (Sir James Crichton Browne, M.D., LL.D., F.R.S., treasurer and vice-president, in the chair), Messrs. C. J. Cullingworth, M.D., F.R.C.P.; Jonathan Hutchinson, F.R.S., F.R.C.S.; Rudolph Messel, Ph.D., F.C.S.; Henry Charles Mylne; and Dan Rylands, were elected members.

Aluminium.—Every common brick contains two to three pounds of metallic aluminium. The raw material containing this capricious metal forms one of the chief constituents of the earth's crust, so that, next to oxygen and silicon, and perhaps calcium, aluminium may be considered the most abundant of the elements; yet the difficulties in the way of extraction are still so great as to call for a comparatively high selling price.—*Aluminium, its Uses and Alloys.*

Correspondence.

THE KIMBERLEY CAMERA CLUB.

SIR,—I am pleased to inform you that a Camera Club has been started out here. The following is a newspaper report dated May 10th :—

"A meeting of the principal amateur photographers in Kimberley was held last night at the Gresham Hotel, there being present Messrs. Macfarlane (in the chair), Trimble, Harrison, Chappell, Wallace, Ablett, Harden, Pringle, Skead, Moriarty, Titmas, Bousfield, Gassen, and the Rev. Ogle.

"The Chairman, in a few remarks, explained the object of the meeting, which was to form a club for the mutual improvement of members in photography. He had much pleasure in stating that eighteen members had already been enrolled.

"The following gentlemen were elected office-bearers :—*President*—Rev. Ogle ; *Vice-President*—Mr. M. Macfarlane ; *Hon. Secretary*—Mr. F. O. Wallace ; *Committee*—Messrs. F. Skead, T. Titmas, H. Moriarty, and J. T. Harrison.

"It was resolved that another meeting be held in a fortnight's time for the purpose of drawing up a set of rules ; a vote of thanks to the Chairman terminated the business."

F. O. WALLACE, HON. SECRETARY.

Kimberley, S. Africa, May 10th.

NEW OBERNETTER PAPER.

SIR,—I wish to call your attention to the new issue of Obernetter gelatino-chloride of silver paper for matt surface, exhibited at the Drapers' Hall in two prints. The toues obtained are beautiful and finer than platinotype or bromide, and though in black and white, preserve just that tint of half tones which is distiuctive of a photographic image. J. R. GOTZ.

19, *Buckingham Street, Strand, June 2nd*, 1890.

THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—AN APPEAL.

SIR,—Will you kindly afford me space to appeal to your readers on behalf of the P.B.A. ? At the annual meeting the fuuctions of the Association were so largely extended, by enabling the committee to deal with any well-authenticated cases of distress brought to their notice, that we are anticipating a considerable increase in the number of calls on our limited funds. In fact, the grants already made this year largely exceed the average. Under the new rules, contributions of former subscribers to the funds to the extent of £250 have been set aside as a nucleus around which to form an annuity fund, and this sum cannot be drawn upon for the purpose of grauting temporary relief. I wish to impress on your readers the fact that this is the only charity which exists with the object of assisting persons connected with photography who are in necessitous circumstances arising from misfortune ; and many who have been reduced to this necessity, including more than one name once distinguished in the profession, could testify with gratitude to welcome aid received from the P.B.A. in the time of need. The minimum subscription has been fixed at 2s. 6d., and I appeal to the benevolence of your readers to induce them, if I can, to subscribe to the funds according to their ability, with the confident assurance that the committee will deal with any money entrusted to them with discretiou and economy.

Subscriptions and donations will be thankfully acknowledged, and a copy of the rules forwarded, by the honorary secretary, Mr. H. J. Beasley, 65 aud 66, Chancery Lane, W.C.

Thanking you for your kind support in the past,

WILLIAM BEDFORD, *Chairman of Committee.*

EAST DULWICH PHOTOGRAPHIC SOCIETY.—The following are tho excursions proposed for the dates named :—June 21, Windsor ; July 19, Boxmoor, Hemel Hempstead, and neighbourhood ; August 4, Arundel ; August 16, Burnham Beeches ; September 20, Chingford and Epping Forest. The place and time of assembly are to be arrauged on the night immediately preceding the excursion.

Proceedings of Societies.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting on the 29th ult., Mr. T. E. FRESHWATER occupied the chair.

Mr. C. H. COOKE passed round three plates he had exposed on some flowers. No. 1 had been dipped in a bath of erythrosin and ammonia ; No. 2 in erythrosin without ammonia ; No. 3 was an ordinary plate. A yellow screen had been used in all cases. No. 2 gave the best results. The strength of the erythrosin solution was 1 in 35,000.

Mr. P. EVERETT asked the particulars as to Tailfer's patent, and Mr. W. E. Debenham explained them as far as his memory permitted.

Mr. J. S. TEAPE passed round some prints on the iridium paper distributed at the previous meeting ; he corroborated the statement made on that occasion, viz., that the printing was very rapid, but the loss in toning and fixing was very great. In answer to a question, he said that he used the toning bath as soon as made, and it was considered that had he used an old toning bath the reduction would not have been so great.

Mr. DEBENHAM said that many years ago Messrs. Hennah and Kent, of Brighton, produced a number of pictures on plain paper which were much admired. When Mr. Hennah published his formula it was found that he used a small quantity of chloride of gold in the salting solution.

Question—"In using a pinhole camera, how is the distance between the hole and sensitive plate determined ?"

The questioner was referred to the tables published in the Journal, giving the size of hole and distance by which best results had been obtained. The image is in focus at different distances from the piuhole.

Mr. A. COWAN said if the pinhole were a suitable size, all that had to be determined was the size of picture, roughly speaking. If a 6-inch focus lens would give the object the size required, the plate should be placed about that distance from the pinhole.

The Saturday outing for June 14th is to Epping Forest. Members to meet at Hale End Station (G.E.R.) from 3 to 3.30.

THE LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

AT the meeting on the 29th May at 3, Lord Street, Mr. PAUL LANGE presided.

The following were elected members of the Association : Messrs. R. Rawlinson, F. Hope Jones, Edgar Storey, R. L. Rawlins, H. Bebbington, and James Nelson, jun.

Mr. WILLIAM TOMKINSON reported on the excursion to Burton on 3rd May, when about forty members took part in photographing this picturesque Cheshire village, and 163 pictures were taken.

Mr. J. MACDONALD BELL exhibited a patent plate rocker, wound up and set going with a clock-work arrangement.

The PRESIDENT announced that the next excursion would be to Rossett and Cresford on Saturday, the 7th June ; and that the next practical demonstration would take place on the 11th June, the subject to be "The Intensification aud Reduction of Negatives ;" demonstrator, Mr. T. L. Mackrell. After this the series will be discontiuued until September, when it will recommence with "Lantern Slide Making."

The Eastman Company (representative Mr. H. M. SMITH), then exhibited and explained the Kodak No. 4, 5 by 4 camera, and promised to come to the next meeting on June 19th, and give a practical demonstration with the films.

The evening concluded with the exhibition of the Boston (U.S.A.) new set, entitled "The White Mountains of New Hampshire," prepared by members of the Boston Camera Club, and lent to the Liverpool Association in trust, for exhibition to any photographic society in the United Kingdom on application to Mr. E. M. Tunstall, hon. sec. of the Liverpool Association.

Mr. PAUL LANGE read the descriptive lecture which accompanies this set, mounted in type on large cards, with the photo-

graph of each slide on the back, so that the lecturer is able to keep a check on the lanternist by referring to the back of his card. The slides were shown by the aid of Messrs. Archer's oxyhydrogen lime-light lantern. It may be interesting to notice that our American friends have had their slides made by the wet collodion process, and this set is considered far superior to the former one on "Boston."

The Bath Photographic Society.

May 28th.—Mr. George F. Powell in the chair.

Delegates were appointed to represent the Society at Chester. Dr. Preston King, Messrs. E. J. Appleby, and G. J. Turvey, were elected members.

Watkins' exposure meter, sent for exhibition, was shown.

Mr. C. Cloakley exhibited a new tripod stand, constructed with double parts at the bottom; also an instantaneous drop shutter, rigged on a shifting platform, by which means the shutter is pushed aside when desired for focussing or other purposes. The points referred to he claims as new.

Mr P. Braham, F.C.S., F.R.M.S., then delivered an address on the subject of "Photo-Micrography," which he fully illustrated. Mr. Braham commenced by saying photography is a powerful aid to science and truth, and in each branch of investigation its uses are increasing, and also arts and manufactures are benefitted by it. What its future developments may be, it is hardly competent for human intellect more than dimly to surmise. In astronomical investigation it has already done great service, and objects unseen by the human eye have been developed by the sensitive film and, assisted by spectroscopy, given information concerning systems hitherto unknown. In microscopic investigations, permanent and truthful records can be retained of transitory subjects, and successive periods in formation and development printed on the film for future reference. The small bijou lime light was shown to be, next to sunlight, the best for producing sharp images, as the rays emanate from a spot of light, while with other lights a portion of a sheet of flame is used, and cannot give a perfect image. The diminutive lime light is fitted on a condenser stand, or on the microscope in place of the mirror, and has an adjustable lens in front consisting of a microscopic objective, a convergent, divergent, or parallel beam being alone used with no eye-piece, as every additional lens interferes with the accuracy of the image. If different objectives are used, with sufficient distance between them and the sensitive plate, photographs of any required size can be taken. There may be a slight adjustment required from the visually perfect image to the photographic; this can only be accurately ascertained by experiment, as this distance varies with different objectives.

Photographs were taken of a microscopic photograph to graphically illustrate the difference between photo-micrography and micro-photography, and also of an opaque object, which were very successful. With regard to objectives generally, the lecturer said that in the telescope the effective or useful area should be clearly specified, and the angular aperture or effective area in microscopic objectives, and in photographic lenses the largest stop with which a sharp picture can be obtained should be known.

A discussion followed, in which Messrs. Wheatcroft, Wells, Bristow, Williams, C. G. R. Wood, Cloakley, Dr. King, and the Chairman took part. Several questions were put and replied to, and a hearty vote of thanks was accorded to the lecturer.

Mr. J. A. Rudge exhibited in action the machine which he has invented, and named "The Bi-Phantascope." The object of the inventor is to take photographs which can, by the same lens, be reproduced with sufficient exactitude to represent animation. Thus, facial expressions, under any circumstances, may be shown by means of transparencies from suitable negatives, with all the muscular action noticeable in life, and free from jerkiness attendent upon the "wheel of life" method adopted by Muybridge and others.

The Chairman showed a series of pictures made by means of the No. 2 Kodak, charged with a band of sensitive celluloid. Some of the prints were among the best that have been seen of this class of work.

Mr. E. E. Peacock handed round samples of combination printing of a creditable character.

Two fine studies of cloudland, reproduced on bromide opal, 24 by 18, were sent for exhibition by Mr. Friese Greene.

The Photographic Society of Philadelphia.

A meeting was held on May 7th, president John G. Bullock in the chair.

The committee appointed to prepare a memorial of the late president of the Society, Mr. Frederick Graff, presented their report, from which we extract the following:—"Perhaps one of the greatest sources of consolation to those who are called upon to mourn the loss of a friend and leader, is the review of his past life as connected with themselves and the interests over which he presided, particularly when those recollections fill us with love, admiration, and respect for the character of our lost friend; we think this will be found pre-eminently the case in regard to our late lamented president, Frederick Graff. We have been accustomed to see him in our midst so ong a time, presiding over our councils, encouraging us by his example and advice, exciting our zeal in the race by his own untiring interest in our work, and his great desire that our noble art should be more than a casual amusement for the passing hour. His own love for it was genuine—amongst the very first to take it up as an amateur, and to apply to it all the energy and resources of his well-trained mind, his interest never flagged, nor did his enthusiasm diminish during his life. The social side of his character was not less remarkable. He was always ready to assist with his advice and counsel those standing in need."

Mr. Frederick E. Ives sent to the meeting a package of photo-micrographs. In a note accompanying the prints he stated that they were made with comparatively low-priced objectives, which were not intended for photographic work, and not selected with a view to such use. Some of the plates used were Carbutt "orthochromatic," others Seed plates treated with erythrosine, and all exposed through yellow colour-screens. A small pencil of light was used for amplifications up to forty times, a bull's-eye condenser for medium powers, and condenser of seventy degrees for high powers.

Mr. Cheney, referring to the matter of incrustations on cover glasses of lantern-slides, stated that having had occasion to remount two old silver prints which had been framed for many years, he found the same incrusation on the glass which had covered the pictures. In this case the cause could not be looked for in any chemicals emanating from the glass plate. He attributed the incrustation in some way to acetic acid.

Mr. Stirling read a letter from Mr. York, the English slide-maker, stating that the incrustation was due to the use of French or German glass, which contains an excess of alkali which is acted upon by moisture. With English flatted crown glass the trouble could not occur.

Mr. Coates, who had a large collection of slides made by Mr. York, stated that he had never found the defect on any of these slides.

Mr. Fellows stated that he had experienced the trouble with English flatted crown, as well as with the French glass.

Mr. Sartain had frequently seen the deposit on the inner side of the cover glass of Daguerreotypes. In this case it was thought that the chemicals used in forming the picture caused the deposit on the glass.

Mr. Stirling, referring to the recent Photographic Exhibition at Newcastle-on-Tyne, thought the Society had reason to congratulate itself very much on the achievements of three of its members, no less than four medals having been won by them. Mr. Pancoast won a silver medal for architectual subjects, Mr. Bullock a bronze medal for landscape work, and Mr. Redfield a silver medal for figure subjects, and also one for lantern slides. The best English professional and amateur workers met on equal ground in these competitions, making the result all the more gratifying.

Mr. Francis Burrows showed a French hand-camera, in the form of a pistol. It contained a roll of Kodak films, making a square picture the full width of the film. The exposure

was made by pulliug a trigger, as with an ordiuary pistol. About one hundred exposures had been made, but, owing to some fault in in the shutter, which was rather heavy, it had not quite produced a sharp negative, the shutter invariably jarriug the camera at the instant of exposure. A register showed the number of exposures made, and two short legs could be turned down in front, forming with the pistol butt a tripod stand for use with time exposures.

Mr. EARLE showed a camera made by R. and J. Beck, the mountings of which, as well as the lens, were of aluminiuun. The reduction in weight as compared with brass, as usually used, was about one half. A rack and pinion movement operated the back portion of the camera in focussing, enabling a short focus lens to be used as readily as one of long focus. The front board could be extended by hand to any desired point, within moderate limits.

Mr. WALMSLEY showed a camera he had devised for microscopic work. The box was but about four inches square, mounted on an adjustable rim stand, with bellows for attaching to the microscope in any position. Authony's Lilliput plate-holders were used, carryiug either plates or films. He had used powers rangiug one and one-half to one-fifteenth with equally good results.

Mr. REDFIELD showed a tripod stand made by Ashford, of Birmingham, England. It was made of teak wood, and so constructed as to be very strong and rigid, and at the same time quite light. The lower leg, by a convenient arrangement, could be drawn up between two of the four upper pieces entirely to the top, shortening the legs one-half, and making the adjustment for uneven ground or to various heights very convenient.

Mr. HANAWELT showed an exposing-shutter of his own invention, in which the slide moved horizontally in front of the lens. The opening being narrower at the top than at bottom, gave one-half the exposure to the sky as compared with the foreground. By an ingenious mechanism, a sort of crauk motion operated the slide, avoiding any jar at opening and closing, aud regulating the movement of the slide so that its speed was slowest at the instant of full opening, and quickest at the begiuning and close of its action.

Mr. J. E. DAWSON writes that the story quoted in our last from a daily paper, about Mr. Gladstoue and the Photographer, is not quite accurate, and encloses us an iuteresting extract from the *Huddersfield Examiner*, for which there is not space this week.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The last meeting of the session will be held at 5A, Pall Mall East, ou Tuesday, June 10th, at 8 p.m., when papers will be read on "The Estimation of the Efficacy of Plate Backing," by W. E. Debenham; on "The Staining and Clearing of Gelatine Films," by Chapman Jones, F.I.C., F.C.S.; and on "Photographing the Induction Spark," by Sir H. Trueman Wood, M.A.

HE KNEW HIS BOY.—Father (to Photo Artist): "I would like you to give my son a chance in your studio." Photo Artist: "What can the lad do?" Father: "Well, at first he couldn't do anything more than take charge of all the operating, retouching, and printing departments; but later on, when he has more experience, he will be right handy to do the sweeping, clean the windows, and sift the ashes."

CAMERA CLUB NOTICES.—Thursday, Juue 12th, 8 p.m.—Informal Meeting. Friday to Monday or Tuesday, June 13th to 16th or 17th.—Excursion to Norwich and the Norfolk Broads; Leader, Dr. D. G. Thompson. Meunbers intending to join are requested to notify same, and the time they will remain of the party. See notice of particulars in Club, or write for same. Thursday, June 19th, 8 p.m.—Informal Meeting. Thursday, June 26th, 8 p.m.—Informal Meeting. Saturday, June 28th.—Excursion on River Thames, from Reading downward. Ladies invited. Leaders, Mr. W. Clarke and Mr. J. F. Collins. Full particulars will be sent to those desiring them.

H.—The ladder by which you are ascending to the Temple of Fame, candidly we do not think to be poetry.

M.—The less said about the matter the better.

Owing to the pressure on our space, articles by Dr. Morton, Hermann Gunther, and others in type, are held over till our next.

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

W. M. (Clapham).—*Oiled and Crumpled Paper Negatives.* The best way would be to remove the oil or vaseline first by repeated treatment with fresh benzol, theu dry, and iron the negatives between leaves of blotting paper. This will make them clean and flat again, and then perhaps you can intensify; but great care must be taken first to remove every trace of fatty matter. This done, grease them again with vaseline oil on the wrong side, bake them well in the sun until all opaque spots have disappeared, aud finally remove the superfiuous grease with cotton wool.

M. P. S.—*A New Method of Determining the Sensitiveness of Photographic Plates.* The research to which we briefly referred last week should have been attributed to Dr. F. Hurter and Mr. V. C. Driffield coujointly, iustead of being put down as the work of the first-named gentleman alone.

COL. WATERHOUSE.—*Guaiacol as a Developer.* Your paper was received in time to be printed in the May *Photographic Journal*. All other particulars were given in our private letter of the 28th ult.

W. H. S.—*Judges, 1890 Exhibition.* Your views have to a considerable extent been endorsed by the writer of the leading article in last week's NEWS. Although several painters have been nominated to serve ou the jury, it is hardly likely that more than two or three will be elected, and these would strengthen the body of judges on the art side, so that great benefit may be expected from their association with the photographers as in former years. Your second remark is answered by the official notification that the ballot was not to close until June 4th, thus giviug ample time for the voting papers to be returned.

A. G. (Brighton) — *The City Exhibition at Drapers' Hall* is well worth a visit, and remains open a week longer. In addition to the framed specimens and isochromatic work, there is a goodly show of apparatus, including the Moessard cylindrograph camera.

E. P. (Bangor)—*Strength of Acetic Acid.* The hydrometer furnishes no reliable indication, for the specific gravities are altogether anomalous. You may test with standard alkali (dilute caustic soda) added until litmus paper shows it to be exactly neutralised. For the glacial acid, a very good proof is to boil it in a test tube, and see whether the vapour is inflammable.

A. M. M.—We thank you for your kind offices in the Indian matter.

L. E. D.—*Stereoscopic Photography.* Of late there is quite a revival in this branch of our art-science, several English and many foreign amateurs having been working with twin lenses during the last and present seasons. The Belgian *Bulletin* has an article on the subject, and the last technical meeting of the Photographic Society was devoted to it. Although Wheatstone announced the instrument in 1838, it was not until photography had come to his aid by furnishing satisfactory diagrams, and Brewster had popularised the matter by the invention of the lenticular stereoscope, that much progress was made; then Wheatstone gave his Bakerian lecture on January 15th, 1852, to put the finishing touch to this important branch of scientific work. The earlier attempts failed by reason of employing too wide an angle.

J. W. W. (Burnley).—*Brown Stains on Dry Plate Negatives.* The plates seem to have been kept too long; try the effect of prolonged immersion in a clearing bath of citric acid and alum. See YEAR-BOOK, p. 197; or, for fresh trial, use Bedford's developer, p. 195.

W. V. MORRIS, H. F., J. M., and A. T., received.

CONTENTS.

PHOTOGRAPHY IN NATURAL COLOURS.

Much stress has been laid by Dr. Eder and Dr. Vogel about the amount of permanency of the photographs in natural colours sent to them by Herr Veress, unaccompanied by a description of his process. As yet, there is no published evidence of any advance having been made by Herr Veress over those who have preceded him in the work, and the testimony as to the durability of the results may be founded upon incomplete information as to what has been done previously in this matter. The photographs in natural colours, in their earliest days, faded rapidly, but after a time it was found that they could be to some extent fixed by a weak solution of ammonia of carefully regulated strength; little or nothing is on public record as to the time of immersion in this bath. The fixing at last arrived at such a degree of perfection that Mr. Traill Taylor, who had some of these photographs sent to him for delivery to Sir David Brewster, found that they were not visibly affected by two weeks' exposure to daylight. To the day of his death Mr. Warren De La Rue had one of Becquerel's partially fixed silver-plate photographs in natural colours in his possession. We first saw it about twenty years ago at his private observatory at Cranford, where he photographed the moon, and again quite recently, but a few months before his death. In the twenty years it was practically unchanged, so far as memory can be trusted, but it must be remembered that when it was not required for inspection Mr. De La Rue kept it carefully protected from light in a leather case.

Some of the early photographs of this class being thus permanent, what becomes of the only testimony adduced that Herr Veress has made a new departure? He candidly says that "too much bustle" has been made about his experiments, a remark which is amply justified so far as any information at present before the public is concerned. Dr. Vogel has found that twenty minutes' exposure at four o'clock in the afternoon to slightly veiled sunlight, or seven minutes' exposure to an unspecified kind of electric light at a distance of fifteen centimetres, deepens the ground tint of the photographs sent to him by Herr Veress.

In all photographs of this class hitherto produced, those on paper have not been so pronounced or so pleasing as those upon glass, partly, perhaps, because the ground colour seems to show up more strongly upon paper.

The latest information upon photography in natural colours relates to pictures on paper, and is published in the number of *Le Moniteur de la Photographie* just to hand. The *Moniteur* sets forth that at the last meeting of the General Photographic Syndicate in Paris, M. E. Vallot exhibited a good photograph in natural colours, printed directly from a coloured picture upon glass, and it was produced in this way:—

Thick photographic paper is floated for three minutes upon—

Water	100 grammes
Chloride of sodium	20 ,,

It is essential that the paper shall then be dried quickly.

Next it is sensitised for five minutes upon the following bath:—

Water	100 grammes
Silver nitrate	10 ,,

After draining for a few moments, it is washed in running water for ten minutes.

Then, to get rid of all traces of nitrate of silver, it is placed for five minutes in—

Water	100 grammes
Sodium chloride	20 ,,

It is then washed for several instants.

The violet argentic chloride of silver is then formed by exposing the paper to light in a bath containing five hundred centigrammes of water to which twenty centigrammes of the following solution have been added:—

Distilled water	100 grammes
Protochloride of tin	3 ,,
Sulphuric acid...	10 drops

When the film has taken a deep violet colour, it is washed for five minutes and allowed to dry.

When dry, it is washed for two minutes in a mixture of equal parts of the two solutions given below :—

Solution A.

Water	...	...	...	100 grammes
Bichromate of potash	...	...	5	,,

Solution B.

Saturated solution of copper sulphate.

After being dried, the paper is in a condition suitable to give colours. Under a coloured painting on glass, an exposure to full sunlight for three-quarters of an hour is necessary.

When removed from the printing frame the colours are seen on the paper, but as if fogged, but come out more brilliantly after the print is put in the following bath :—

Water	...	...	...	100 grammes
Sulphuric acid	...	...	20	,,

The prints must not be left too long in this bath, because it at first improves, and afterwards destroys the colours.

After abundantly washing these prints, M. Vallot albumenises them to give *eclât* to the different tones. The *Moniteur* says nothing about any fixing operation.

Full information as to the production upon silver plates of photographs in natural colours will be found in the last PHOTOGRAPHIC NEWS YEAR-BOOK, and to bring information on helioehromy down to the latest date, we now quote a letter from the *American Journal of Photography* just to hand, which letter is written by Herr Veress himself, who therein also does a valiant battle royal with the English language, in which the language has come off the victor :—

DEAR SIR,—Please accept my thanks, dear sir, for your kindness as to continue sending your journal to me, although you knew that my journal, the *Fenykepészeti Lapok*, had ceased to appear. I assure you, it has been always an enjoyment for me to receive your paper, so excellently edited, and I would truly be very glad if the little sortiment of my photos upon paper and glass in natural colours, I send you by the same mail, would prove you how much I esteem the favour you do me. Please, dear sir, to select some of the photos, and deliver it, as well as the enclosure, to Mr. Carey Lee, his lodging being unknown to me. I shall be very thankful to you, because I want to say him myself, how much I value his arduous labours. He goes quite another way than I do, but if he be ready to unite his experience with mine, I am persuaded we would triumph in a very short time. You see, dear sir, that I succeeded to fix the colours ; its for the preparation upon glass, it is in gelatine, upon paper in collodion. The exposure of the photos upon glass was of 3-5 hours, upon paper 2-3 days. Since I succeeded to make such photos upon smooth plates of thickened (condensed) petroleum in 10-30 minutes.

The plate is put into a copying-frame, and exposed from a transparent coloured drawing. My aim is now to lessen the time of exposure as much as to enable me to work with the camera, to photograph moving objects, which I could not do till now, because for camera work I wanted 2-3 weeks.

FRANCIS DE VERESS.

Kolozsvar (Klausenburg), Hungary.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Monthly outing, June 14th. Members to meet at Wood Street Station (G.E.R.), at 2.40, and walk through Cook's Folly to Hale End. Trains from Liverpool Street 2.2 and 2.16.

ABOUT SOME DEVELOPERS.

EVERY photographer has his pet method of development, and, as a natural consequence, he is apt to decry everything but his own particular formula. This is as it should be, for a man is far more likely to do good work if he believes in his tools to such an extent that he does not care to meddle with new fangled ones. We have known certain amateur photographers who have never yet succeeded in turning out any good work, simply and solely because they have had a superabundance of time and money on their hands, which have led them into temptation. We all know that a certain large employer of labour is, according to Dr. Watts, always ready to find "some mischief still for idle hands to do," and the particular mischief that commends itself to the idle man of photographic proclivities is to mess about with all the different brands of plates and with the various developers which are placed from time to time within his reach by enterprising traders. Such a worker, at the end of a few weeks, finds his dishes, his measures, and his bottles in a state of topsy-turvydom, which is only equalled by the chaos which exists in his own brain.

A beginner is always to some extent puzzled as to the right developer to use, and if he can only get hold of something in a bottle which will coax out some kind of an image when thrown upon an exposed plate, he is satisfied. The bottle must contain a ready-mixed liquid, and so long as it will act, the aspirant to photographic fame is happy, and will ask no questions about its composition. It, of course, stands to reason that such a worker will never become an expert, although he may, by an occasioual fluke, turn out a good picture ; but still he will be better off by sticking to his bottle of unknown liquid than he will be if he is always ringing the changes upon every nostrum that is brought forward.

Within the last few years several new developers have been introduced to the notice of photographers, and each has its admirers. Some will declare that hydrokinone gives them far more certain results than anything else which they have ever tried. Others give the premier place to eikonogen, and it is certain, as one of our notes stated the other day, that several photographers are taking to it for ordinary studio work. A new developer, bi-kinol, has only just been introduced into the market by Mr. Hinton, and this, too, has already many friends. Then we have a number of old-fashioned workers who say that the pyro and ammonia "mixture as before" is as good a medicine for their complaints as they can find, and that they intend to stick to it through thick and thin.

Now it is our duty to look upon all things photographic with a strictly impartial eye, and to do our best to point out as far as we can the excellencies or shortcomings of anything in the shape of apparatus or formulæ which come under our notice. Nor are we in the habit of passing an opinion upon anything until we have submitted it to trial. With a view to ascertain

the relative merits of some of the developers now in use, we put them to a practical test in the following manner: First of all, we exposed a 10 by 8 plate in the camera, giving it sufficient time to fairly bring out —as we judged—all possible detail. We, in fact, did our best to produce a good negative by means of normal exposure, and without relying upon any kind of forcing during development. When this plate was duly exposed, it was removed to the dark room and divided with a diamond into four equal portions. We marked these on the film side with an aniline ink pencil respectively, "bi-quinol," "hydrokinone," "eikonogen," and "pyro." We then proceeded to develop each with the developing agent whose name it bore.

The first to be treated was marked "bi-kinol," a developer which is supplied in two solutions. We mixed these in the proportions recommended for a normal exposure—*i.e.*, forty minims of each to the ounce of water. Watch in hand, we looked for the first trace of the image, and noted its appearance in one minute and a-half. We judged development to be complete in four and three-quarter minutes. Result, greatly under-exposed. Next came the hydrokinone, which brought out an image in two and three-quarter minutes, but which at the end of seven minutes appeared far more under-exposed than its predecessor. Evidently, we thought, we had made a mistake, and should have kept the cap off the lens for another half second or so. But we proceeded with our work, and took up the "eikonogen" plate. In this case the sky portion appeared in one minute, and detail followed in two minutes, all action stopping at the end of six minutes. This plate had far more density than the other two, but still we should have preferred to see a far denser result. We now had only one plate left for treatment, and for its development we were to rely upon pyro and ammonia.

This old-fashioned developer we mixed in the proportions which experience has proved to be the best for bringing out the image on a plate which has received the normal exposure. Again we timed the operation, and we noted that the image made its appearance in twenty-five seconds, the action being complete in two and a-half minutes. There was every indication that the exposure had been quite sufficient, as will be seen by the time required for development to become complete. No further addition of the alkali was needed, and we may mention that the developer was restrained at the outset with bromide, and that the pyro used had been mixed for some weeks previously with a preservative in the shape of potash meta-bisulphite.

The four portions of the negative were duly placed in the fixing bath, so that they could be examined in a completed form. But the results already noted during development were in no case modified. The pyro developed portion was the only one which would be capable of yielding a satisfactory print. It was dense in the high-lights, exhibited clouds in the sky portion, and was generally crisp and brilliant. The others all suffered, more or less, as we have said, from under-exposure.

Our experiment tends to show that the old pyro and ammonia developer is not yet displaced by any newer agent. At the same time we may point out that in the latter the amateur has something to fall back upon when he finds that his negatives are over-exposed. It is a common fault into which the amateur falls, and he subsequently finds that pyro development gives nought but thin images, which are useless to him. Let him seek the new agents for a remedy, and hold fast to that one which he finds to be good. For transparency work, where exposure often extends over half a minute or more, some of these new developers are far better than pyro; and we shall take an early opportunity of detailing some experiments we have made in this direction.

REDUCING HALATION.

LAST Tuesday night Mr. Debenham read a useful paper before the Photographic Society about halation. On looking down upon a piece of plane glass at a bright spot of light reflected therefrom, the interior reflections between the two surfaces and some other conditions, render it difficult to see how much of the light comes from the back and how much from the front surface, also how much is absorbed by any particular "backing." Mr. Debenham's plan was to paint various backings for reducing halation side by side upon one surface of a prism, by which method the conditions of observation became much easier. Bitumen has long been known to form a good backing for plates, but it is troublesome to remove, and Mr. Debenham described experiments by which he had found that a solution of caramel in gum water acts even better than bitumen. The least troublesome method of backing a plate, in our experience—and the plan is but moderately efficient—is that which we devised in 1881, and published in current photographic literature; namely, rubbing glycerine over black mackintosh in a thin film, then squeegeeing the fabric upon the back of the plate. This backing can be pulled off just before developing. Perhaps the substitution of a solution of caramel in glycerine will increase the efficiency of the latter mode of working, and give little trouble to the operator.

Why does not some enterprising manufacturer introduce backed plates into the market, wrapped in pairs, so that, if opened by custom-house officers, only two plates are likely to be spoiled and fogged, instead of all in the box? Why, again, are not printed labels in four or five European languages pasted outside the boxes, stating their contents, and that they must not be opened in ordinary light? Why, again, are not the developing formulæ recommended by the particular maker not always pasted on the outside of his boxes, so that the solutions can be made up before opening a box of plates? One or two makers have already adopted the latter plan. An extra charge must, of course, be made for all these conveniences combined.

INK FOR WRITING ON PHOTOGRAPHS is made of iodide of potassium, 10 parts; water, 30 parts; iodine, 1 part; and gum arabic, 1 part. It produces white lines on the dark background.

PHOTOGRAPHIC EXHIBITIONS.

BY GEORGE DAVISON.

II.

IT is matter of common notoriety that photography in England did not long maintain the high and dignified standing which it took at the outset. No wonder, then, that photographic exhibitions should also soon lose some of the simplicity and dignity which characterised them whilst they were solely the outcome of pure, scientific enthusiasm. In the facility of producing representations of a kind, in the rapid extension of photography as a popular pastime, and the development of dependent industries, there seems to have been generated the seeds of disease or weakness, which naturally showed itself somewhat in exhibitions. Taking the state of things at the end of the first decade of such enterprises, we find medals and prizes, classification and unnecessary limitations, introduced. At the tenth exhibition of the Photographic Society of London, held in May, 1864, at the galleries of the Society of Female Artists, in Pall Mall, five medals were offered, with the impossible and odious "besting" system. One was for the "best" portrait, another for the "best" landscape, a third for what was called a "group," a fourth for architectural work, and a fifth for photo-mechanical processes. With, probably, the aim of barring some individual or individuals more mechanically skilful or painstaking than the rest, "groups" were only permitted from *single* negatives. Possibly this restriction was devised to discourage what might have been held to be the reprehensible practice of combination printing, but it hardly seems so. Amongst other conditions, there was the sweeping order that no pictures from painted or touched negatives would be permitted, a duplicate to accompany each picture. Three inches margin was allowed for large pictures, two for smaller, an unhappy recommendation to put several small photographs in one frame being appended

The character of subsequent exhibitions was not dissimilar, simplifications and improvements being introduced from time to time as far as the Photographic Society's exhibition was concerned. Coming to the present time, the leading features of the general run of exhibitions are too well known to require much description. A laudable desire to please and attract everybody, and make a financial success of the undertaking, minute classification and subclassification, piles of metal medals, consolation stakes, even handicaps, and all in such profusion that the only question with each exhibitor is, whether he will obtain a first, second, third, fourth, or extra prize—these seem to be the characteristics that circumstances have brought us to. It has been the rapid increase in such puerilities and excesses that has at last stirred up so large a section of those interested in photography to take some active steps in the matter. The special meeting of representatives at the Camera Club early in 1888 was the first sign of any combined action, and the influence of those discussions and resolutions was seen in a gradual education of the great body of exhibitors themselves, and in the increased interest shown by the press in the subject. The more definite pronouncement made at the Camera Club Conference this year may be taken as the expression of the opinions and views which, in the course of the year past, have become rife amongst photographers. The adoption of most of those conditions, and a closer following of the regulations in force at the Photographic Society's exhibition, are now fairly well ensured. The complete change will not be immediate, as is seen in the mixture of reformed rules and deference to local prejudice displayed in some of the announcements for future provincial exhibitions. However, the improvement, though gradual, is certain, and has its greatest encouragement in the proof it adduces that a higher estimation is held of the scope and value of photography.

Turning to the inception of the movement which has developed into the recent rage for reform, it is found that, as far as any individual influence can be distinctly traced, Dr. Emerson is responsible for first laying down the lines upon which the agitation has travelled, just as, guided by a severe culture, he has been the first to introduce into photography, by example and precept, much else that is valuable and likely to bear good fruit. In October, 1885, he published in the *Amateur Photographer* an article giving an outline of an "Ideal Exhibition," and it is interesting to notice how exactly the later outcry has, unknowingly, taken its watchwords from those suggestions. They are the conditions which any individual, moving under the influence of the most cultivated art of modern times, would be compelled to impose, and there is hardly more than one of the suggestions in that article which anyone could wish to alter.

The chief of these proposals were:—1. That all the judges be artists (certain names of those capable of understanding the true scope of photographic art being given). 2. One picture, one frame. 3. No retouching. 4. Uniform framing (say all gilt.) 5. That the judges be the hanging committee. 6. That there be no classes, but that the award be made for the so many best pictures. 7. Each exhibitor limited to three pictures. Such exhibitions, Dr. Emerson added, he was sure, "would do more to raise our art than the most voluminous writings." In proposal No. 7 I take it the suggestion conveyed is that nothing inferior should be received, a most important regulation for every public exhibition, and one more often adopted in earlier days than now, but chiefly then on account of limited space. One of the earliest announcements to this effect was in connection with an exhibition of the French Photographic Society in 1861, where it is stated in the *British Journal*, February 15th, 1861, a jury was appointed "to weed out" the photographs.

Now it is evident that a code of rules such as that just indicated is framed for an art exhibition purely, and it is in that connection that most of my remarks are made. A magnificent photographic exhibition, exclusively historical and scientific, might, with energetic management, be organized, but certainly any system of competition and awards would be equally out of place in such an enterprise. Even in a trade exhibition, the objectionable results of prizes and medals are now generally held to be greater than any advantages derived from such competition and lottery.

Taking photographic exhibitions as we find them, the tendency is ever towards making them art exhibitions, and, therefore, the whole question of regulations turns upon the art capabilities of photography. If there are no possibilities; if photography is to be held as a lame, limited, and mechanical means of æsthetic representation, without any power of artistic expression, as held by Mr. Stillman and one or two half-hearted supporters of his views in this country, then most of this agitation is misdirected, and it matters little whether the dignity and influence of photography be consulted in these shows, or whether they be promoted and regulated merely as a use-

ful stimulus to trade, or as a small social excitement. My remarks are entirely based upon the confident belief that photography is worthy to be wooed as a means of artistic expression, and upon a desire that its proper claims in that respect should be recognised. In this view I hold that the following conditions ought to be observed in what purport to be photographic art exhibitions.

1. That there should be no classification, and no awards whatever further than the honour implied by acceptance for exhibition.

2. That a strict and competent hanging committee should reject all inferior exhibits without fear or favour.

3. That all distinctions of amateur and professional should be entirely suppressed, all pictures exhibited being for sale unless specially exempted.

4. That the number of photographs accepted from each exhibitor be limited.

5. That each picture (save in application to decorative art) be separately framed.

In my next article I shall refer to these points, and then proceed to a brief discussion of the questions now prominent as to the constitution of boards of judges, and as to classification, opposing most strongly the hardly logical contentions against artists as judges recently published in the NEWS, and objecting to the pleas for classification put forward by some ardent photographic exhibitors.

THE EFFECT UPON TONING OF PRINTING THROUGH COLOURED GLASSES.

BY EDWARD A. GOLLEDGE.

A SHORT time ago I had occasion to interview Mr. Otto Schölzig with reference to his now well-known sensitised paper, who, after having most kindly afforded me the information required, submitted to my notice some samples of paper which had been exposed to light through some coloured celluloids; I was struck with the remarkable effect of the various tints obtained by the light acting upon the silver paper after passing through the various coloured mediums, more especially as the toned specimens produced totally different effects to that obtained when printed in the ordinary manner. I lost no time in putting the experiment to a severe test, and the result of my experiments in this direction I now desire to place before my readers.

I have tried printing through the following colours: blue, ruby, orange, yellow, and green, and it is really surprising to note the variety of tone that may be secured by the various methods. I shall mention that my aim has been to obtain as pure a black as possible, and my experiments have certainly been rewarded with success far beyond my expectations.

Of all the colours experimented with, I find green, yellow, and orange give the best results.

Blue glass seems to have very little effect unless it possesses a decided greenish tint. Ruby glass I have discarded altogether for securing a black tone in the finished print, and the very best results are obtained when employing green glass of a somewhat deep colour, and printing in direct sunlight. I have not found any marked difference in the effect produced when printing in the shade, and of course the time occupied is much prolonged.

My experiments have been conducted solely with Schölzig's matt surface and other papers of his manufacture, and although they have been carried out in a very hurried manner, I feel convinced that many advantages may be gained by adopting the method referred to.

The appearance of the print before toning is somewhat peculiar, inasmuch as it is in colour a beautiful purple brown, a colour one is so anxious to obtain, as a print of this description (which I never secured by any other means) is in excellent condition for the toning bath. My difficulties hitherto have been to get other than the brown tint, which colour will not tone to the desired black. It would appear to me—not over well acquainted with the chemistry of photography—that the action of the light upon the sensitised paper is similar to that of crystallisation. In order to obtain good crystals it is necessary to allow time for them to form, and the crystals are deposited in certain parts of the vessel only, in bold form. Quicken the process by violent evaporation, and we obtain a shapeless mass of small crystals all over the vessel. The printing process appears to be a kind of crystallization, the chlorine of the silver chloride being freed, and silver sub-oxide being deposited in a crystallised form. It is acknowledged, also, that slow printing produces better detail than quick printing, but it was not until I had experimented that I discovered that various coloured silver oxides or sub-oxides, precipitated under various coloured lights, had each an entirely different affinity for the gold in the toning bath, and that the one took the deposit of gold rapidly, whilst the other refused to take it altogether. There is no doubt that the tones obtainable by the method I describe on matt surface paper are quite equal to the best results ever obtained by any of the platinum processes. . . . Mr. Schölzig is certainly to be congratulated on having been the prime mover in this most important discovery, to improve, if not to perfect, the tones of the silver print, both matt as well as albumenised.*

In order to get the best effect, it is necessary that the paper should be printed *very deeply*—in fact, so deep that detail in the shadows is quite lost. I have found that in printing from a negative in which some parts are dense, owing to halation or some other cause, it is necessary to carry on the printing until detail in the densest part appears; this does not appear to affect the other part of the picture, which, under ordinary circumstances, would be much over-printed; also when printing from a weak negative, much finer results may be obtained by using the green glass than if printed in direct light; in fact, I am of opinion that intensification of negatives will be rendered quite unnecessary if, when printing, the precaution is taken to print through the green or yellow glass; of course, the time occupied in printing is longer, but to my mind this is no drawback to the process. For want of time my experiments have been somewhat limited, but perhaps this may come under the notice of some one who may be able to devote time in experimenting with various tinted glasses; there is certainly a wide field for research.

The after manipulations are much about the same as with ordinary printing, but when using the matt surface paper, the prints simply require a *rinse* in one water before placing in toning bath. I recommend the following bath for *pure black* tones:—

Borax	1½ drams
Uranium nitrate	4 grains
Gold	3 ,,
Water	24 ounces

Of course, if a quantity of prints is to be toned, more

* Mr. Scholzig has shown us some prints with exceedingly rich black tones produced as stated.—ED.

gold should be added, but with the bath above given I have toned from 2½ to 3 dozen whole plate prints on the matt surface paper. It is necessary to replenish the bath with gold if it becomes weak, and the same solution may be used several times, providing gold has been added.

The tungstate and phosphate bath, as recommended by Mr. Schölzig, gives fine dark tones on the matt surface paper. The time occupied in toning this paper is but a few minutes. I place the prints in salt and water, and fix in the usual manner.

The enamel and brilliantly albumenised papers take longer to tone, and it is as well to wash thoroughly before toning, and place in the last washing a dram or two of carbonate of soda. Tone until all brown has disappeared when viewed by transmitted light, and place in salt and water and fix in usual manner with a drachm or so of ammonia added to the bath. Fine black tones may be obtained by this method, although any range of tone may be had, according to fancy.

It is possible some of my readers have already tried the experiment I have endeavoured to describe, but to myself it is entirely new.

While conducting my experiments I have found that, when using deep ruby glass, the time occupied in printing is considerably less than when using yellow or orange; this fact is worth knowing, as it touches upon another branch of photography, and will encourage amateurs to use more light in their dark rooms. For my own part, I always use twelve inches of orange glass, and have developed the most rapid plates in the market without a mishap; but I feel I am encroaching upon another subject, which is not my intention. Silver printing with green glass and gold toning is my subject, and I must leave my readers to experiment and judge for themselves.

Since writing the above, it occurred to me that the prints toned in the bath with the uranium might not be permanent; I therefore placed several of them (matt and albumenized) in a strong solution of nitric acid and water for many hours without the slightest change taking place, proving beyond doubt that the tones obtained are the result of a deposit of gold, and therefore permanent

---

THE East Dulwich Society has purchased, for loan to members, a 12 by 10 camera and lens, which was on view on June 6th.

LACK OF SYMMETRY IN THE EYES.—When the average man or woman comes to be fitted with the first pair of glasses, some curious discoveries are made. Seven out of ten have stronger sight in one eye than the other. In two cases out of five, one eye is out of line. Nearly one-half the people are colour-blind to some extent, and only one pair of eyes out of every fifteen are all right in all respects.

A TONING BATH.—MM. Detaille Bros. say that when equal parts of a 15 per cent. solution of sodium hyposulphite, and of a 10 per cent. solution of alum, are mixed, a precipitate is produced, and the formation is so slow and continuous that the authors found a precipitate to be forming three months after the mixture of the solutions in the cold. A transparency placed in this solution tones slowly, the colours of the image varying from a dark brown to a reddish violet. An analysis is given of the precipitate: it contained 30 per cent. water, 28 per cent. alumina, and 38 per cent. of sulphur, consequently the authors infer that the toning is due to the action of nascent sulphur, and a plate of silver immersed in the solution for several days became quite black. The best results are obtained with gelatino-chloride plates. If the mixture be diluted with from two or three times its volume of water, it may be used to tone paper prints (fugitively?). The Mawson chloride plates are said to give very good results with this toning solution.—*Bulletin Belge.*

PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

NEW SENSITOMETER—DEVELOPMENT OF GELATINO-CHLORIDE PAPERS—BLISTERING OF ALBUMEN PRINTS—STAINED NEGATIVES—JUDICIAL PHOTOGRAPHY—HELIOCHROMY—BIBLIA PAUPERUM.

A New Sensitometer.—A clever modification of the Warnerke sensitometer has been suggested by Mr. R. E. Liesegang. In order to obtain a more even gradation of the intensities of the light on the sensitive plate to be tested than can be obtained by superimposing a number of strips of paper, he makes use of the well-known optical law according to which the intensity of the light diminishes with the distance. It will be remembered that in Mr. Warnerke's instrument the phosphorescent and the sensitive plate are placed parallel; Liesegang, on the contrary, arranges them in a certain angle—of 45 degrees, for instance. The action of the light on the gelatine plate naturally diminishes more and more with the distance. If, now, a number of threads be drawn in front of the plate, to keep off the light, it can be determined after development how far the light has acted, and a deduction can be made, as in the case of the Warnerke sensitometer, of the sensitiveness of the film. This method offers also the advantage that a narrow strip of the edge of the plate is sufficient for the trial, and that the plate tested may afterwards be safely used for making an exposure. Instead of keeping off the light by means of threads in order to produce the white lines on the plate, it will be sufficient to draw on the plate parallel lines with a concentrated solution of potassium bromide, to render the lines insensitive, so that in developing they will remain white.

The Development of Gelatino-chloride Papers.—In the newly opened flash-light studio of Professor Schirm, of Berlin, the lighting arrangements of which I have described on a former occasion, all the prints are made on development paper exclusively. For prints made by contact, Dr. Just's gelatino-chloride paper is used with the best results. About the mode of development, Mr. Wilh. Steiner, manager of this establishment, gives some practical hints in the *Mittheilungen*. It makes no difference, he says, whether the ferrous-oxalate, the hydroquinone, or the eikonogen developer be used, they all being equally suitable for the purpose; but the alkali developers are to be preferred, on account of their exceeding cleanliness, and because they may be used repeatedly. In order to obtain a pure black gelatino-chloride print, equal to a platinum print, a relatively strong developer with a large quantity of any alkali—such as potassium or sodium carbonate—should be used, to dispense with as much light during exposure as possible, for plenty of light gives brown tones, whilst they are blackened by the alkalies. As, however, bluish-black tones are obtained by too large a quantity of alkali, it is necessary to take the golden mean between light and a strong developer, and this is effected by the use of a restrainer of potassium bromide by preference, which allows an exposure giving brown tones, and at the same time a strong alkali developer giving black tones. By this means a beautiful rich mixed tone is obtained, in which the brown appears only like a warm sepia-coloured glazing upon a black image. Care should, however, be taken not to use too great a quantity of the restrainer, as in this case a loamy, greenish-brown tone is liable to appear.

Blistering of Albumen Prints and its Prevention.—At a

meeting of practical photographers which was held some days ago, an interesting discussion took place about the blistering of albumen prints. It was rightly said by a member that the disease is connected with the present mode of preparation of the albumen paper, and that the paper of the early days of photography did not blister, because then it was albumenized with fresh egg-albumen, and not mixed, as now, with blood-albumen, the properties of which are different in some degree. It absorbs, for instance, the oxygen from the air more rapidly than egg-albumen, disengaging carbonic acid. It was remarked that this interesting phenomenon of slow combustion would, perhaps, be a cause of alteration of the prints. Many a remedy for the defect was then given, most of them being probably well known to the profession, but the following one, which was said to be originally described in a German contemporary by Herr Rudolph, of Hof, seems to me especially certain in its results, and therefore to be recommended. After toning, the prints are rinsed and piled up one upon another, the larger sizes being laid separately, also the cabinets and the smaller prints. They are then, every size separately, laid between smooth oil-cloth, and the latter is placed on a smooth board and pressed with a squeegee until the prints become slightly transparent, which may be seen best by reflected light, looking at the back of the prints. They are then once more rinsed and placed in the fixing bath. Prints treated in this manner, it is said, never blister, except perhaps at the edges, if not correctly piled up; this being, however, of no consequence, as the edges are cut off. The whole manipulation, which is completed within two to five minutes, is very simple and effective, and besides, it is much cheaper than many of the other well-known remedies.

Stained Negatives.—A very effective method of restoring gelatine negatives showing the well-known yellow stain has been introduced at the Imperial Institute for Photographic Researches, of Vienna, by Mr. Robisheck. The plate is at first carefully freed from its varnish by means of alcohol, washed with water, and then placed in a dilute aqueous solution of bromine, which is obtained by adding a few drops of bromine liquid to about half a pint of ordinary water, and which is then, together with the plate, exposed to the direct sunlight. The action of the bromine very soon becomes apparent. The yellow stain disappears, and it then is well to watch the further progress by transmitted light. After the image has become clear, which requires six to eight minutes, according to the degree of concentration of the bromine solution, the plate is placed in alcohol, to remove the rest of the bromine, and then dried. In this way the restored negative can be re-used within a very short time. The results are said to be very satisfactory.

Judicial Photography.—Of the high importance of photography for judicial purposes, the following incident gives evidence. Some weeks ago, a letter which had been written twenty years ago by a convict—who is still a prisoner—was presented to Professor Max Müller, of Brunswick. On the second page of the letter there were written about five additional lines, apparently with a colourless or slightly coloured liquid; but the writing was undecipherable. Only the existence of written characters could be seen if the letter-paper was held against the light, so that the latter was reflected in the well-known manner to the eye. According to the declaration of the attorney-general, urine had probably been used by the prisoner for writing. Various chemists to whom the letter had been previously presented had not been able to develop the writing by treatment with chemicals. Prof. Müller at first himself made experiments with urine writing, and found that written characters of this kind may be easily made readable if the paper containing them is heated until it begins to turn yellowish. The written characters will then become visible in a dark brown colour. When the above-mentioned letter was treated in the same way, only a very slight yellowish tint was imparted to the writing, so that, whilst the existence of written matter could undoubtedly be stated, it was still impossible to decipher it. Now it occurred to Prof. Müller to take a photograph of this portion of the letter—on an ordinary gelatine plate, of course—and when the latter was developed, it showed the written characters very distinctly, so that they could be entirely read without any difficulty.

Heliochromy.—At the last meeting of the Berlin Society for the Advancement of Photography, which took place on Friday, the 16th of May, a letter of Herr Eugen von Gothard, of Hereny, was read, which contained interesting information about the progress made of late by Herr Fr. Veress in his experiments with photography in natural colours. According to this communication, Herr Veress has succeeded in increasing the sensitiveness of his emulsion so much, that it is now possible to produce a picture in which the colours are rendered much better than formerly within fifteen seconds, whilst in his former experiments he required two to three hours to attain a similar result. Herr v. Gothard, in his letter, promises to send shortly a number of the new pictures produced by Veress.

A Photographic Reproduction of the Biblia Pauperum.—The "Biblia Pauperum," as it will be known, is one of the most eminent productions of the art of printing, belonging to a time prior to the great invention of Gutenberg. The pictures, together with the descriptions, were cut in blocks of wood, and then inked up with the ink-ball. Upon this inked-up woodcut was placed the moistened paper, and pressed with another ball, the so-called brayer. In consequence of this imperfect mode of printing, certain inequalities with regard to the colour, and some unclear and unsharp portions were produced, and at the same time the fact revealed that the back of the paper could not be printed in consequence of the relief, resulting from printing the front side. One has repeatedly tried to reproduce these old block-printings by drawing, but all these reproductions are more or less imperfect on account of the fact that one has always anxiously avoided reproducing also the defects, *i.e.*, the uneven printing, the partial unclearness, and broken lines which form the characteristic sign of the block-printings, and an important support to the researches in the arts. By the aid of photography perfect duplicates can be produced, showing all the characteristics of the old mode of printing. Of this fact the beautiful reproduction of the "Biblia Pauperum," which has recently been issued by a Vienna publisher, gives evidence. It has been produced by means of the photo-mechanical processes, proving in this form the immense value which photography possesses in connection with the investigation of the arts.

In *Burgoyne's Monthly Circular* for this month, bichloride of platinum is quoted at twenty-eight shillings an ounce, nearly double the price it bore a few months ago.

DEVELOPERS USED BY GERMAN PROFESSIONAL PHOTOGRAPHERS.*

BY JULIUS F. SACHSE.

CATHARINA CULIE, Frankfurt, a. M.—Developer—Iron oxalate. Advantanges—For portraiture, when the artist has complete control of the lighting and exposure, I consider a developer which always works evenly as the most desirable, and that one is the iron oxalate. I have not been able to obtain equal results as to detail or lights with any other developer. It is also cleanly, and its use is not harmful to the skin. Composition—Iron, 1-3; oxal. pot., 1-4. Developer — 1-4. Accelerator — Always 30"—1-2,000.

R. Fath, Halberstadt.—Developer—Ferrous oxalate. Advantages—In comparison with all other developers, quicker action, with greater modulation. Composition—1-3. Accelerator—Negatives of children and copies, a bath of soda.

F. W. Geldmacher, Frankfurt, a. M.—Developer—Oxalate of potash and iron. Advantages—That I rarely lose a plate by over or under-exposure, a property which I cannot reach with any other developer. Composition—Potash, 1-3½; iron, 1-3; hereof 3 parts potash, 1 part iron dissolved in hot water. Accelerator—Water, 1 litre; hypo, piece as large as a pea, soak 1 min.; fix without washing.

Prof. E. Hanfstaengle, Frankfurt, a. M.—Developer—Exclusively oxalate. Advantages — Absolute freedom from fog. Composition—(A) Oxalate of potash, 1 kg.; water, 4 kg. (B) Sulphate of iron, ½ kg.; water, 1½ kg. For use, 1 part iron to 3 parts oxalate. Accelerator—Hypo for child exposure only, dissolve 1½ g. hypo in water 20 c.cm.; of this solution take 1½ c.cm. to 500 c.cm. water.

Fr. Kahlmeyer, in Osnabrück.—Developer—Ferrous oxalate. Advantages—Simplicity, cheapness, cleanliness. Composition—(A) 1,000 V; (B) 250 g. Neutral oxalate of potash crystals; 3 parts A, 1 part B. Accelerator—For short exposures add to developer 10 g. hypo solution 1 : 200.

N. Leyendecker, in Berncastel. — Developer — Iron oxalate. Accelerator—None.

Fr. E. Marr, Zweibrücken. — Developer — Ferrous oxalate. Advantages—Any desired intensity and fine gradations can be obtained. Composition—Both solutions are made 1 : 4, and for use mixed 1 : 4. (I only use extra heavy plates.) Accelerator—Plates receive ample exposure, and are developed with much bromide, also when hypo accelerator is used.

Peter Risse, in Duisburg.—Developer—Ferrous oxalate. Advantages — Surety. Composition — Both solutions saturated. Iron added according to circumstances, relative to lighting, exposure, and plate. Accelerator—Only occasionally, and then 1 part hypo, 2,000 water.

Arnold Overbeek, in Düsseldorf.—Developer—Iron and oxalate of potash. Advantages—Simplicity and great latitude. Composition—1 iron, 3 oxalate. Accelerator—With short exposures, hypo 1 : 5,000.

A. Sternitzki, Brannschweig.—Developer—In general oxalate, with short exposures (children), hydrochinon. I miss, however, here the important question, "What plates?" as in my experience, the various developers do not act the same with all makes of plates; for instance, with English and some German plates, I should decidedly prefer pyrogallol, while in the portraiture of children with the "Schleussner" plates I would use hydrochinon. Advantages—Oxalate gives with Monckhoven plates, which I mainly use, a clear picture with fine detail and clean plates; but even here it depends on the different emulsions, and often to obtain suitable negatives I resort to hydrochinon. Composition—Oxalate, both solutions saturated, and used in proportion of 1-3 to 1-4. Hydrochinon and pyrogallol according to the usual formula. Accelerator—Only unwillingly; I would much rather add a little hypo to the developer.

Carl Bellack, Leipzig.—Developer—Hydrochinon; also a mixture of hydrochinon and eikonogen. Advantages—More rapid appearance of image and completion of development with nice contrasts. Eikonogen alone works to monotone, and requires too much time for intensification. For very short exposures, eikonogen answers to start the development; hydrochinon to complete the reduction. Composition—(Hydrochinon No. 1) Water. 2,000; sulphite of soda, 180; hydrochinon, 30; carbonate of potash, 180-200; for under-exposures, warm developer to 50° R. (Hydrochinon No. 2) Water, 1,000; sulphite of soda, 90; carbonate potash, 120-150; hydrochinon, 1: for extra short exposures, children, &c. Commence development with No. 2; after detail is out finish with No. 1. (Eikonogen) Water, 1,000; sulphite of soda, 90; carbonate of potash, 40; carbonate of soda, 10; eikonogen, 20. A developer composed of hydrochinon and eikonogen as above will be found advantageous in certain cases. Accelerating bath—Never.

Theodore Klauer, in Offenbach a. M.—Developer—Hydrochinon. Advantages—Softness of shadows, with relative short exposure. Composition—(A) Water, 500; sulphite of soda, 50; hydrochinon, 10. (B) Water, 400; soda, 50. For use, 3 parts No. 1; 4 parts No. 2. Accelerating bath—Sulphite of soda, 50; water, 1,000; hypo, 2.

C. Hertel, Hofphotograph in Mainz.—Developer—Pyro-soda. Advantages—(1) Clean work; (2) great latitude of exposure; (3) black tone. Composition—(A) Solution of sulphite of soda, 1-10; pyrogallic acid, 1-5 per cent. (B) Solution of soda, 5-10 per cent. Equal parts A and B. Accelerating bath.

(To be continued.)

* Continued from page 416.

THE PHOTOGRAPHIC CLUB.—The subject for discussion on June 18th will be "Mounting and Finishing Photographs;" June 25th, "Matt Surface Printing."

AMERICAN REPRODUCTIONS.—In photogravure reproductions on Japanese paper and satin, the Lithotype Publishing Company, Gardner, Mass., make a specialty of reproducing proofs in the shortest possible time after they get to this country, and many times they have their prints ready for delivery before the proofs have been shown out of New York. The firm have added over one hundred subjects within the past year, and probably have the largest number of new subjects of any publisher in this country. In the copyrighted line, taken from American paintings, the picture, "The Mishap," a charming bit of child-life, has had a large sale.—*Picture and Art Trade.*

ETCHING METALS.—The Berlin *Papier Zeitung* describes a method of etching metals, such as zinc, from which it is desired subsequently to take prints. The image is transferred in the ordinary way to the surface of the zinc plate, which is backed with asphalt, and immersed in a bath of dilute acid. One terminal of an electric current proceeding from a dynamo is connected with the liquid, the other with the zinc plate. As soon as the current passes, the metal commences to be attacked with such rapidity, that in a few minutes the exposed portions are eaten into the depth of the thickness of a sheet of paper. In this manner the zinc may be very rapidly etched to any depth desired.

THE ROYAL CORNWALL POLYTECHNIC SOCIETY.

THE fifty-eighth annual exhibition of this Society will open at Falmouth on Tuesday, 26th August, and continue open for five days. Medals and prizes are offered in various departments, including photography.

The following are the general regulations:—

1. All exhibits must be forwarded so as to reach the Polytechnic Hall, Falmouth, not later than Tuesday, August 19th, after which no article will be eligible for competition, and no space can be guaranteed.

2. All pictures and photographs must be framed; and if left at one of the following places of the Society's authorised agents on or before Tuesday, August 12th, will be conveyed from these depôts to and from the Exhibition free of charge, namely:—Messrs. Worth and Co., Cathedral Yard, Exeter: Harris and Sons, 197, Union Street, Plymouth; J. Mitchell and Son, 15, Bedford Street, Plymouth; and Thomas Solomon and Co., King Street, Truro. The agents will not receive any article unless delivered to them free of conveyance and other charges.

3. The carriage of all other articles must be paid by the exhibitor.

4. All cases and packages sent to the Exhibition must be addressed "The Royal Cornwall Polytechnic Society, Falmouth," and must bear the name and address of the owner; the covers to be fastened with screws. The exhibitor must write on the back of each picture his name and address, its title, whether it is an original or a copy, the name of the artist, and whether he is a professional or an amateur. The works of professional artists may be sold from the gallery, through the secretary of the Society, Mr. E. Kitto, and a commission of five per cent. will be charged thereon.

5. Exhibitors must enter all articles intended for exhibition on forms provided for that purpose by the Society, which may be obtained from the secretary, or any of the above-named authorised agents.

6. This entry form must in all cases be returned to the secretary on or before August 9th.

7. The Society will not be answerable for loss of or damage to any article sent to the Exhibition, but every care will be used to prevent injury while in the Society's possession.

8. After admission no article may be removed until after the close of the Exhibition (this regulation does not apply to the photographic department for this year).

9. Discretionary power is vested in the officers of the Society as to exhibiting any article sent.

10. Board of Trade protection is granted to all new and unpatented inventions.

The judging in all departments of the Exhibition (shorthand excepted) will take place on Monday, August 25th.

The following are the regulations specially affecting photography:—

In all cases state whether the work is professional or amateur, and name process of production. All work sent for competition must have been executed within eighteen months of the date of this Exhibition. Carte-de-visite portraits are excluded from exhibition, except when illustrating some special process or novelty.

Professional Photographers.—Medals are offered by the Society for meritorious productions in the following subjects:—(1) Landscapes, (2) Portraits, (3) Composition Pictures, (4) Instantaneous Pictures, (5) Interiors, (6) Six Pictures in Platinum, (7) Transparencies for Window Decorations, (8) Pictures by Improved Processes, (9) Enlargements. All enlargements for competition must be the work of the exhibitor.

Amateur Photographers.—Medals are offered by the Society for meritorious productions by amateurs.

Photographic Appliances.—Medals are offered for improved apparatus and appliances. All exhibits in this department must be accompanied by a written explanation of their special features.

Information respecting the Photographic Department may be obtained from Mr. W. Brooks, Laurel Villa, Wray Park, Reigate (member of the general committee).

The Art Union of Cornwall (under the sanction of the Board of Trade) selects its prizes from the works exhibited by professional artists. The drawing for prizes will take place at the Polytechnic Hall during the Exhibition, viz., on Friday, August 29th, 1890. Information respecting the Art Union may be obtained from the honorary secretary, W. W. J. Sharpe, Falmouth.

All information may be obtained personally, or by letter, on application to the secretary, Edward Kitto, F.R.Met.S., the Observatory, Falmouth.

JAPANESE MULBERRY-BARK PAPER.*

BY A. LASENBY LIBERTY.

THE variety of purposes for which paper is used in Japan is not a little astonishing, including as it does such widely-differing objects as overcoats, window-panes, string, and pocket-handkerchiefs. One of the most pleasing sights I ever witnessed was at the Government paper factory at Shiebu-Ogi, where we watched hundreds of intelligent little Japanese girls and women, clad in spotless white robes, preparing the mitsumata, the bark of the paper-mulberry, or dipping and arranging the snowy layers of pulp on the rectangular straining sieves. I have here a few samples of paper given me on the occasion of this visit. It has the usual characteristics, toughness and a silk-like surface. Very little paper is exported, notwithstanding its manifest excellence, as it is costly, and the cultivation of the paper-mulberry tree (cuttings of which are forbidden to be exported) is at present confined within a somewhat limited area. The present Government are bestowing great attention to the paper industries, and experimenting with pith, old silk rags, and many kinds of vegetable products. At Shiebu-Ogi they manufacture all the chemicals used in the different processes, and the number of workers employed is quite astonishing. Paper is also made by hand labour in small quantities and varying qualities in scores of the towns and villages, and, for fibrous toughness, is far superior to European paper. The excellence of certain kinds of Japanese paper for prints and etchings need not be emphasised.

ALDEHYDES IN PHOTOGRAPHY.—The well-known property of the various aldehydes to reduce silver to the metallic state from an ammoniacal solution of silver nitrate, especially when warmed, has suggested their application to photography. But their use has hitherto been impracticable on account of their strong odour, their insolubility or difficult solubility in water, and the facility with which they are oxidised on exposure to the air. But most of these aldehydes, and especially formic aldehyde, are susceptible of combining with the acid of the bisulphites of the alkaline metals, and producing compounds which are readily soluble in water, and which appear capable of being used with advantage in many ways in the various photographic processes. Already two German chemists have patented the use of the compound produced by uniting formic aldehyde to bisulphite of soda. No experience, to speak of, has yet been gained as regards the new product, and it is not certain that it will present any practical advantage over the reduction agents already employed. It is asserted, however, that a very minute quantity of it added to the gelatine emulsion, either during its manufacture or after it is applied to the glass plate, renders the sensitive film very much more sensitive than it is without this addition, and that it may also be used in the developing bath with success. These aldehyde compounds have a marked affinity for bromine and iodine also.—*Burgoyne's Monthly Magazine.*

* A portion of a paper read before the Society of Arts.

Notes.

The French, with their love for precise nomenclature, have given to photographic science a new term—chrono-photography. Chrono-photography, expanded in our somewhat cumbrous language, means the art of taking photographs in a series of measured spaces of time, and examples may be cited in the experiments of Marey, Muybridge, Anschutz, and others. In an article on the subject which appeared recently in *La Nature*, the writer glanced at the various methods in use, the principal of which appear to be three in number:—First, that employed by M. Marey in photographing the flight of pigeons, by an arrangement which brought the bird against a perfectly black background; secondly, the plan which made the sensitive surface move in a series of equal jerks across the focus of the lens; and thirdly, the use of as many independent cameras as might be deemed necessary. These three comprise the methods which have produced results known to the public.

But, as the writer in *La Nature* remarks, "all has not yet been said on this interesting question," and inventors are still busy studying the subject. An apparatus which was highly spoken of was exhibited at the Paris International Exhibition, and, in 1888, Mr. W. G. Levison presented to the Photographic Academy of Brooklyn a new apparatus, holding the sensitive plates in a revolving drum, to bring them one after the other rapidly to the focus of the lens. Mr. Friese Greene's "mitrailleuse" camera, and the apparatus of Mr. C. V. Boys, have already been described in these pages.

Photographers who lay themselves open to be twitted for producing incongruous effects—as, for instance, when the landscape is lighted from one side of the picture, and the put-in "natural clouds" from the other—may now take refuge in the defence that painters are not at all squeamish in regard to incongruities. A case in point may be cited from the Academy. One of the artists, it seems, has introduced into a landscape the representation of a fern against which, from a picturesque point of view, there is nothing to be said, but from a botanical aspect, a good deal; for a critic who is also a naturalist declares that the fern in question is of a rare sort, and grows only in two places, neither of which is the locality indicated in the picture. The artist cannot explain satisfactorily how he came to contradict nature in this way, and the inference is that he must have borrowed the plant from a friend's conservatory.

What with photography on the one hand watching over their errors, and candid critics on the other looking out for slips, the artist now-a-days must speak by the card. Jacob dreaming of the ladder to heaven, and arrayed in the attire of a Flemish peasant of the sixteenth century, as represented by a well-known Dutch painter, would not now be tolerated. It is even possible whether doubts, in these critical days, would not be thrown upon the graceful silver birches which Turner found so effective in the composition of his pictures. They were introduced with such suspicious frequency, that the chances are that some careful inquirer might, if he had cared to take the trouble of comparing the picture with the scene depicted, have discovered that the silver birch, like the photographer's cloud, was put in. To discuss the question whether, as Lord Lytton was fond of declaring with the use of capital letters, the True and the Beautiful are one, or whether each can exist apart, would take too long just now, and we must leave the problem where it is.

The *Bulletin de la Societé Francaise* contains an interesting memoir of its late president, M. Peligot, whose death we announced recently. M. Peligot, like many other men whose researches have done so much for the progress of photography, was not a practical photographer, but his experiments in respect to the chemistry of photography resulted in much practical good. In 1855 he brought before the French Photographic Society the advantages of the double chloride of gold. He was one of the earliest to draw attention to the effect of light in colouring glass, and his repeated cautions as to the dangers of certain artificial illuminants will be well remembered. He succeeded M. Balard in the Presidency of the French Society, and was re-elected annually.

Photography is a source of income little suspected. Most people have noticed the photographs on cigarette boxes, and the attractive-looking pictures which are exhibited in tobacconists' windows, but few imagine what it costs to produce them. In the United States this method of advertisement is carried on to a much larger extent than in England. The latest business amalgamation is that of the cigarette-making firms, and one result of this will be that £17,000 a year on photographs alone will be saved on a "trust," working upon a capital of a million. The photographic adornments on cigarette boxes may appeal to American citizens, but the attraction is played out in England, and fortunately there is little chance of this "trust" being brought to the notice of English investors.

A graceful compliment has been paid to the granddaughter of Nicéphore Niepce at the last meeting of the Societé Française de la Photographie. Some time ago it was decided by the French Government, on the recommendation of the Societé, that a Jubilee medal should be struck and engraved in honour of the fiftieth anniversary of Daguerre's discovery; and it was decided by the Societé that the medal should be presented to Mdlle. Niepce on the occasion of her marriage.

The competition organised by the French Minister of Public Instruction for a prize of £80, to be competed for with the object of providing apparatus especially suitable for the requirements of tourists,

has just been decided. The decision had been postponed for some time on account of the lack of competitors; but eventually a respectable number presented themselves, and after numerous trials made by the committee appointed, a conclusion was arrived at. The conditions were that each competitor should send two lenses, one a panoramic lens of at least 100 degrees, and the other of a smaller angle, but possessing certain qualities—that is to say, rectilinearity of the lines, flatness of field, sharpness of the different planes, and equal illumination.

In the panoramic competition, M. Adolphe Martin has gained the award. In the second competition the lens shown by M. Berthiot fulfils all the conditions desired, in spite of the weight being somewhat excessive. It has therefore been decided to divide the prize offered by the Government into two equal sums of £40 each, which will be awarded to each competitor.

The photographer is a necessity at all public functions, and it may not be long before he will be considered equally necessary at private ones. We are constantly reading of the matches of the Australian cricketers being interrupted in order that the teams may be photographed. A youthful foreign prince who has achieved a little cheap notoriety arrives at Dover, and the ubiquitous photographer is seen on the bridge of the steamer struggling to take a picture of his reception. A deputation waits upon an eminent statesman in an informal way, and the photographer is on the watch to secure a memento of the visit. By and bye the services of the photographer will be as commonplace a thing as the services of the hairdresser. A photographer will follow the monthly nurse and the doctor, and newly-born babies must look forward to being photographed as well as being registered. The camera will pursue one at every stage of existence, from the first tooth upwards. Indeed, if the automatic photographic machine is going to prove the gigantic success so confidently predicted for it, it will be more convenient and more economical to have an apparatus set up in the hall, and consult it every morning as one does the barometer.

It will be a comfort to sober-minded people to know that the various idiotic competitions which have gradually been becoming a feature of modern journalism have been declared illegal, and that they will perforce be discontinued. The information which the solution of the questions proposed made known was generally of no use to anybody, except, perhaps, the winner of the prize, and it probably did him more harm than good. If any photographers should hanker after some similar vent for the display of their abilities, they can easily find plenty of problems which await solution—for there are worlds yet left unconquered for aspiring Alexanders in our art. One of them occurs to us. Why should a negative benefit by unlimited supplies of water, while it remains wet and fresh from the fixing bath, and yet be spoilt by an accidental splash which may reach it when dry?

What we mean is this. Many a good negative has been ruined by a single drop of water accidentally falling upon its film after it has been dried. The water may be *aqua pura* in the fullest sense of the words. It may be rainwater freshly distilled from cloudland, tap water, or any other water, but where the drop falls it will act as a reducer, and a spot—light by comparison with the rest of the negative—remains upon the film for ever. No one has yet, so far as we know, explained why this should be so, but there is no kind of doubt that water acts in the way described.

If the water were contaminated with hypo there would be nothing to be surprised about, for hypo has a distinct reducing action in the presence of air. This fact, we believe, is not generally known, but it can be easily put to the proof in the following manner: Take a negative fresh from the fixing bath, give it a good rinsing under the tap, and then transfer it to a pan of water deep enough to cover one-half of the film as the plate stands on edge. At the end of half an hour or so, the plate will be found, upon examination, to be much less dense on the half exposed to the air than it is on the other half which has been below water. It is unnecessary to point out that here we have a simple and easy method of reducing an over-dense negative.

We have always regarded the introducer of cheap apparatus as a benefactor to the art of photography and its votaries—provided that it is so constructed that it is capable of taking some kind of presentable picture. Many a good worker has begun with a cheap set, and has thus acquired a taste for the art, and in good time has provided himself with something better. So far, so good. But we have lately observed that certain apparatus has been introduced which can be bought for a few shillings—with chemicals and everything complete. Boys at school are commonly the purchasers of it, and when they have saved up their pocket money for the purpose, they find themselves in possession of a mere toy which is next to useless.

A plausible prospectus points out the wonders that can be achieved with the instrument, *including instantaneous pictures within doors*. We lately examined one of these contrivances, and found that its lens was shut in with a fixed diaphragm, which made it work at *f*/32. The boy who handed us the instrument for our opinion told us that no fewer than eight "other fellows" at his school had bought them. "Well," we said, "have you seen any negatives taken with it?" "No," was the reply; "but I've seen a lot of plates of clear glass taken with it." Let our readers caution their young friends not to waste their pocket money on such things, for clear glass can be obtained much more cheaply, and without the trouble of exposure and development.

ON REFLECTED IMAGES IN OPTICAL COMBINATIONS, AND THEIR EFFECT ON THE BRILLIANCY OF THE FINAL IMAGE.*

BY T. R. DALLMEYER.

THE first practical demonstration of the deleterious effects of internal reflections in lenses on the resulting image was contributed to your Society in 1867 by my late father, who, in conjunction with Sir John Herschel, gave both a practical and theoretical explanation of the "Cause of the Central Spot or Flare in Photographic Lenses," and they pointed out how, in certain optical systems, this trouble might be overcome or cured. As you are aware, the "flare-spot" is due to the formation of a real and inverted image of the diaphragm by internal reflections in the back lens upon the plate. With certain forms an alteration in the position of the diaphragm, either nearer to or further from the lens, may eliminate the effects of flare-spot should it exist. The general deductions arrived at by this investigation were: "First, the fewer the number of reflecting surfaces (other things being equal), the greater will be the brilliancy of the resulting image; second, the smaller the diameter of a lens, or combination of lenses, covering a given sized plate or area (other things being equal), the greater will be the brilliancy of the resulting image."

The final brilliancy of the image is, of course, not only dependent on reflected images in lens systems, but I propose to confine my remarks to this aspect of the subject this evening, taking it for granted that *proper* "flare-spot," as introduced by the arrangement of the systems and position of the diaphragm, does not exist.

The loss of brilliancy, due to reflection, in the resulting image is due to three main causes:—(*a*) The number of reflecting surfaces giving rise to a definite number of reflected images; (*b*) the disposition and curvatures of the lenses in the system; (*c*) their diameter as regards available aperture in the formation of the ultimate image.

So far as I know, this subject has only been approached from one point of view—viz., in general, the number of reflected images of the object due to the number of open reflected surfaces; but there is another, and, I am inclined to think, more important aspect—viz., the interference that the original light on the plate has upon the total light on the plate by reflection from the lens surfaces during exposure.

(*a*) By placing a number of lenses with different numbers of open surfaces in the separate systems side by side in a camera (all of the same focal length), and directing them simultaneously to a distant bright object, one can compare not only the number of images formed by the reflecting surfaces, but also the relative positions and brilliancy of each image.

By such a comparison you can estimate visually the more or less deleterious effect likely to be produced by the position of the images and their brilliancy on the resulting image. Elaborate drawings could certainly be made to show for any system the exact positions along the axis for each image, but the estimate of the relative brilliancy of each is better attained by the practical estimate. I have endeavoured, by placing a small camera at the back, to get photographic images with definite exposures to illustrate the comparative brilliancy in a number of instances, but the focus of the lens employed to show this requires to be so short to get sufficient depth with very small stops to bring them all out sharply that the images are so small as to be practically valueless as illustrations.

In any case, the number and brilliancy of these images alone cannot be a fair estimate of the resultant effect of the disposition of the components of the system on the detrimental effect of reflections as a whole. If the plate were absolutely black, and no reflections from it took place, this consideration alone would suffice, but the whitish surface upon which the image is received (and never uniformly lighted) receives again reflected images from the component elements of the lens system itself.

In order to exhibit these effects in a very pronounced degree, I have inserted an imitation plate *partly* (drawing) illuminated, and in the position of the lens various forms of mirrors, plane, convex, and concave.

The effect of these on the non-illuminated portions of the plate are, of course, very remarkable, the convex mirror having the least, and the concave the most detrimental and powerful effect.

The headings (*b*) and (*c*) are then here of very great importance. The greater the number of concave surfaces in the lens system towards the plate, the more will the resulting images suffer in brilliancy; and again, if the diameters of the lenses are large and concave towards the plate *after* the stop that determines the intensity, the more will the brilliancy diminish.

The diaphragm, then, you will understand, plays an important part on the brilliancy of the image by its situation. Were it not for reducing the angle included in a picture, there are many cases in which the addition of a diaphragm behind the lens might prove of advantage for brilliancy, but in any case these experiments show how detrimental the effect of a small stop in front of a combination with concavities towards the image behind it would tend as regards brilliancy in cases of powerful contrast, and might give rise to "ghosts" as distinguished from the proper "flare-spot."

The reason of this contribution arose originally from a controversy with Mr. W. K. Burton, in the PHOTOGRAPHIC NEWS, as to the claims of a new lens of my own, known as the rectilinear landscape lens, over the ordinary symmetrical combinations generally known as the rapid rectilinear. He has since agreed with me on the points at issue in a letter to the *Amateur Photographer*.

There were other considerations entered into besides that of reflected images, in number and brilliancy, that affect final brilliancy in the comparison of the two lenses named; but Mr. Burton, in any case, had entirely overlooked the aspect brought to your notice this evening, and I will certainly say that, although the rectilinear landscape has the advantage in the matter of number and brilliancy of reflected images, as regards its use in cases of powerful contrasts of light and shade, the form of rapid rectilinear is decidedly the safer as, stop for stop, the concave surface behind it (in the case of the rectilinear landscape) would have greater liability to produce ghost, although this might be overcome by reversing the lens in such cases.

The reflections of the light on the plate from the lens back on to the plate will easily explain the reversed images occasionally met with, of bright windows in interiors, on the darker portions of the picture when taken with double combination lenses in which there are concave surfaces towards the plate, even when "flare-spot" does not exist.

The slight amount of diffused light given by the num-

* Read before the Photographic Society of Great Britain.

ber of reflected images and the elements concave towards the plate, have often been preferred by artists as giving more atmosphere! I don't think "atmosphere" is quite the word, but as the eye in viewing nature is always filled with a certain amount of diffused light by the lens of the eye itself, so also a lens system that imitates this, to a certain extent, may be more applicable to artistic purposes, but is certainly detrimental for the highest scientific precision.

NEGATIVES.*

BY THOS. H. MORTON, M.D.

In all elementary books relating to photography we soon arrive at the terms "positive" and "negative," with an explanation thereof, and I do not know of a better than that given by T. F. Hardwich in his "Manual of Photographic Chemistry," 1857, who says, "A positive may be defined to be a photograph which gives a natural representation of an object as it appears to the eye. A negative photograph, on the other hand, has the light and shadows reversed, so that the appearance of the object is changed or negatived." We afterwards learn that the photographic image developed on a sensitive collodion film can be made either a positive or negative. The ordinary portraits by this collodion process taken on glass are examples of thin negatives converted into positives by backing with black varnish or other dark material which affords the necessary shadows; the white deposit of reduced silver, viewed by reflected light, being the positive image. If you made the deposit denser and used no backing, a negative would be the result, and, of course, any number of positives on sensitive chloride paper by contact and exposure to light can be printed.

With the gelatino-bromide process, which is generally in use for making negatives, the photographic image is not adapted to produce positives in the way just mentioned. The reason is that the reduction of silver takes place in the gelatine film, not on the surface, as by the collodion method, consequently the gelatine masks the image, preventing the reflection which assists to give a positive impression to the eye. We occasionally meet with a gelatine plate, when developed and wet, giving a distinct positive effect, and this does not appear to alter the printing quality.

The negative is to a photographer much the same as type and ink to a printer, or bears the same relation an etched plate has to the finished engraving; consequently it is our endeavour to produce a negative being a faithful exposition of the subject portrayed with the light and shadow reversed, and I shall confine my remarks principally to the gelatino-bromide film as usually manufactured. I presume there are few amateurs who prepare their own plates. Fortunately, that is not essential, as a good, reliable sensitive plate is easily obtained. Yet a knowledge of the various emulsion processes is highly interesting and profitable.

Negatives may be considered in reference to their defects, good qualities, and also the conditions which act favourably, or the reverse, in their production. In the first place, many defects are due to some error in the manufacture; these imperfections are less common than formerly, owing to accurate methods adopted by the makers, but we meet with troubles of this kind yet; some are not apparent until after the plate is exposed and developed. (Several examples are on the table.) Insufficient emulsion, too thin coating on the glass plate, shown by the image appearing through the back of the plate rapidly during development, and inability to get density and contrast; result in a thin, weak negative.

Impurities in the emulsion.—Some particles find their way in during preparation, or settle upon the plate when coating. Wool or cotton fibres, or hair from the head or face. I have noticed dust uncommonly like snuff, but I should think no well-regulated factory would allow an operative to indulge in this luxury. I believe special provision is made in the way of clothing and surroundings to obviate contamination by dust, &c. Finger markings, or greasiness of film, are troubles, likewise pinholes—cup-like depressions, due to bubbles in the emulsion—and scratches of film, either by careless handling or small fragments of glass in cutting. The way in which plates are taken out and re-packed after exposure is a source of anxiety, and I question which is the best plan—grooved boxes, or packing film to film, or inserting a narrow edge of paper between at the margin. The last plan appears most sensible, providing the paper is chemically pure, and only just sufficient to overlap, say, a quarter of an inch. Grooved boxes are doubtful; I have found plates impaired by long keeping in this way; the passage of air, even when light is perfectly excluded, has a detrimental action on the silver salt. Also frequent unpacking or retention in dark slides for any lengthened period, as air is not always pure, nor yet dry. As regards ordinary paper, when overlapping the film, an insensitiveness to some extent is noticed on development; quarter-plates suffer most in proportion; we lose part of the picture. Pressure on the film has been given as a cause of insensitiveness, but hyposulphite of soda is present in many papers. You can readily detect this salt by the starch and iodine test.

It is also alleged that white paper, although quite pure, will affect a bromide film, by reason of inherent luminous property; yet I have a number of plates originally packed with tissue paper many years old, which act as quickly and efficiently as a new batch

Leaving the accidental defects of plates, we may now consider the good qualities of a negative, and how obtainable. Assuming the bromide film to be perfect, and properly exposed on a well-lighted subject—either portrait or landscape—what are the conditions required to secure a first-class result? There really is not much beyond care and judgment during development; and allow me to remark, in passing, that a deep chemical knowledge is by no means absolutely essential, or how could the tyro of a few weeks produce a negative from which a print might gain him a medal at some exhibition for technical excellence?

As I before remarked, we have to make a negative which shall be a faithful copy of the subject portrayed, having the light and shadow reversed. Although the theory of the invisible or latent image caused by light, and transformed into a visible one by certain reagents, is not quite clear, we are led to believe that the action of light rays from a reflecting object through a lens affects the sensitive bromide in a variable degree according to its intensity, exerting a photo-chemical or physical change, attended with the liberation of a certain proportion of bromine. This disturbance is most in the part struck by brightest light rays—say, in a landscape, from the sky;

* Read before the Sheffield Camera Club.

and the rays from clouds and other white objects penetrate deeper into the film than those from darker bodies.

The change so far is an impression or disturbance of the molecules invisible to the eye. It is well known that the haloid salts of silver in emulsion after exposure to light are readily acted on by certain substances having great affinity for oxygen—especially when combined with an alkali—as pyrogallol, hydrokinone, &c. ; these precipitate the silver. It follows that any of these reducing agents, or so-called developers, act chemically most on the parts affected by strong light, and reduction of bromide of silver to the metallic state will be visible in the gelatine film. This semi-metallic or darkened material is virtually the photographic image and the basis of a negative. To obtain the true value of this impact of light, it is necessary to use judgment in developing. Take an ordinary pyrogallic formula :—

Pyro	...	...	...	...	...	2 grains
Am. bro.	...	...	...	...	...	½ ,,
Liquid am. (fort.)			...	...	...	1 drop
Water	...	...	...	...	to	1 ounce

I don't wish to be very elementary, but we know that pyro is the active principle, ammonia the accelerator, and the bromide of ammonia or potash acts as a retarder. When these chemicals are in contact with exposed film an action is set up, first attacking the surface particles and sinking or permeating the gelatine deeper until the limit of light-acted on material is reached, as represented in diagram fig. 2—No. 1, outline of latent image. With an

SECTION OF PLATE.

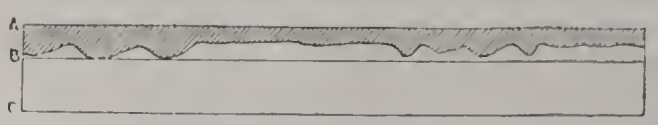
Fig. 2.



A.—Developed Image. B.—Film unaltered. C.—Glass.

accurately timed exposure and normal developer a well contrasted negative is generally produced, and after fixation in hyposulphite of soda solution there should be found a perfect image ; but a negative is not always a transcript of nature, and we ask how that is the case. Take this specimen. Thin image, no contrast, want of vigour, flat, won't make a print worth looking at. There are several reasons. First, under-development ; we remove the plate out of the dish, thinking it is sufficiently dense, and find after fixing there is scarcely any image. The developer has not penetrated to the deeper stratum of bromide affected by light. Secondly, over-exposure with the same developer will give a flat monotonous result, as the whole plate is overdone ; equally again, when under-exposed, a poor black and white hard negative, no half-tone or gradation ; a chemically fogged plate—the result sometimes of prolonged action—also staining by the yellow discolouration of pyro, which affects the film even when unexposed to light. I consider that gelatine itself, as regards hardness or impermeability, has an influence on the development. When excessively dry it obstructs the chemical action. Possibly this may account for the variable times requisite to develop some makes of plates. I have noticed old long-kept plates are more tedious. Occasionally there is a want of sharpness in detail not attributable to defective lens or error of focussing ; this may be ascribed to using a developer which is too energetic. In the collodion process, when the reducing agent was abnormally active, the particles of silver which built up the image were thrown into confusion, so to speak, and not accurately deposited on the lines laid by impact of light, hence a fuzziness. Although the wet process is not quite identical with gelatino-bromide, it suggests the desirability of gradual development.

As regards the colour of negatives, no one prefers a deep yellow stain, even if the image is well defined on account of slow printing. In using pyro or hydrochinone we generally get some yellowness ; when too pronounced it can be cleared by citric acid alum solution. If a negative is a trifle thin, a little stain helps the shadows or clear glass. It is, moreover, reasonable to look upon the colouring matter present in solution and attracted to those parts requiring density as a positive advantage. Intensification of negatives rarely gives a result equal to a properly exposed and developed plate. The reduction of thick unprintable negatives is comparatively easy, but needs care. The conversion of silver or silver oxide into a chloride or iodide, and then dissolving out with hyposulphite, will reduce the thickest negative. By experience the photographer learns by sight the appearances which indicate a good negative, and also when dealing with uncertain degrees of exposure he modifies the developer ; no one would wilfully apply a very strong developer upon a plate which might be much over-exposed, knowing that the film would be hopelessly fogged. He begins cautiously with little alkali, or less pyro or more restrainer. I cannot leave the subject of negatives without allusion to the use of isochromatic plates and yellow screen, although we are promised a paper by Professor Arnold on this topic later on. It has been recognised for some time that reflection from objects coloured red or yellow fail to impress the sensitive salts to the same extent as bodies coloured green, violet, or blue ; consequently, when developed, the true values of those colours are not brought out properly. I apprehend the rationale of erythrosin and other dyes of eosin series, as also chlorophyll and certain pigments including use of a yellow screen, subdue—or, rather, bring down—the less actinic rays to the level of those more active, and on this assumption I should imagine that a blue screen might convert the yellow to a green, and lessen the time of exposure.

The want of perfect truthfulness, as regards accurate light and shade gradations, is due, I am convinced, to the cause mentioned ; for any subject in monochrome, a neutral tint, and well-lighted, is sure to be faithful, the exposure being correct. When taking a portrait, with the countenance freckled or red patches present, a disparity of gradation is at once noticed, supposing puff, powder, or other white substance, is not used on the face before exposure ; but a negative can be made good by the retoucher's pencil ; and, speaking of retouching, which, with most amateurs is rather a weak point, how often our best negatives want just a little? All the pinhole scratches, thin shadows, and many defects, require the useful, but much abused, artist's work.

The rapidity of sensitive films, in respect to negative-making, affords a wide field for discussion. I used to take

instantaneous, medium, and slow, but find it safer to work one class, at least, in a day's excursion; and to adhere to one maker is a wise course. The very rapid are not generally adapted for landscape, unless used with drop shutter or short exposure, but for interiors I believe in them.

In concluding these fragmentary notes, in which the artistic or pictorial aspect of negatives has been purposely omitted as too extensive, I would merely say that a good negative will always produce a good print by any process. It can be reduced or enlarged without perceptible loss, and, if the negative is kept dry and properly varnished, may last for many years. Therefore the acquisition of a first-class negative as a means to an end cannot be over-rated, and the considerations involved in its production are equally interesting as any other branch of photography.

Notices of Books.

Helios, published twice a month. No. 3, June 1st, 1890. (*J. Theunis, Antwerp*).

This is a new Belgian photographic periodical. It contains photographic news of a varied description, and commits itself to no programme or leading article expressing editorial opinions. Among other things it states that the Liège Section of the Belgian Association of Photographers has fitted up an electric lantern for the projection of pictures on photographic slides, at its meetings, and illuminating a disc six metres in diameter. More than two thousand persons responded to the invitation of the Section to be present the first time it was used in public. The same journal states that M. Ch. Puttemans, Professor of Chemistry, is now giving a course of educational lectures on "Photography" at the Industrial School, Palais du Midi, Brussels. The production of ceramic photographs is one of the items on which instruction, with experimental illustrations, will be given.

Dr. Wallraff writes to *Hélios*, asking what would be the good of taking negatives in natural colours if the said colours could not be reproduced as positives upon paper. "If," he says, "I had the odd (*baroque*) idea of preserving the features of my mother-in-law, and that my lens did not refuse to yield to this extravagance, it would not be sufficient that the negative plate should be kind enough to let posterity know that she has a greenish complexion, black teeth, a red nose, and hair the colour of the coat of a she-ass; it is necessary that the positive print should be equally benevolent. We may, therefore, definitely relegate the problem of photography in colours to the same category as those of the philosopher's stone, the squaring of the circle, and perpetual motion."

It may be explained to Dr. Walraff that the photographs in natural colours on silver plates, as produced by Becquerel and others, are positives when first taken in the camera. It is to be hoped that his mother-in-law will see his letter and give him his deserts.

Agenda du Chimiste. (*Hachette and Co., Paris*, 1890).

This work, which, in the course of years, has undergone several editions, bringing all parts of it down to the latest date, is edited by M. G. Salet, of the Paris Faculty of Sciences, M. Ch. Gèrard, Director of the Municipal Laboratory at Paris, and M. A. Pabst, Principal Chemist to the Municipal Laboratory at Paris. Its value to photographers is that it is full of tables of figures and highly condensed valuable practical information—and nothing else—likely to be of use for reference to those engaged in practical and experimental work and research; there is no "padding" or wasted space in the whole book. The first edition of the little book was published in 1877, by M. Ad. Wurtz, whose dictionary of chemistry is, in France, equivalent to what that of Watts' is in England, and Gmelin's in Germany. In 1878 and 1886, subsequent editions were brought out by M. G. Salet. M. Wurtz first compiled it for the use of his students, and perhaps to save himself the trouble of continually giving them the information; they found it of such value that they had to consult it daily in their experimental work. From these facts it will be seen that it is a standard book.

The *Agenda du Chimiste* has a small portion of its space specially devoted to photography, and other portions, as in the case of tables of solubilities, and so on, are indirectly related thereto.

The following are some of the tables given in the book:—

Corresponding Quantities of Various Silver Compounds used in Photography.

Silver.	Nitrate.	Chloride.	Bromide.	Iodide.
1	1·574	1·328	1·741	2·176

0·797	0·910	1·042	0·941	1·148	1

The work gives information about the reduction of silver residues of various descriptions; also about the analysis of silver baths, and contains an exposure table by M. Derval.

FOUR FADED PHOTOGRAPHS.

"ONLY a woman's hair," once upon a time Swift wrote upon a well-known, an historic little parcel; and critics yet differ and contest in gentle periods whether the great satirist wrote it in pathos or in irony, in sorrow or in scorn. Only a woman's hair, when there is so much of that material in the world of nature! Only four faded photographs, when there are so many of them in the world of art; so many sick with that sallow complexion which indicates incurable disease and approaching dissolution. But as that hair had its value worthy of a distinctive label, so also have these photographs. In the first place, they are enclosed in what was originally such a dainty cover, a skin, as it were, of the colour and softness of cream. Then the delicacy of their make was so largely insisted on; each separate limb and member had its own peculiar praise. Next was recorded their faithfulness, which would "assist the student of art to train both eye and hand to an accurate fidelity, essential to the purity and force of the ideal creations of genius." This sentence is not that of the present writer; he is unable to weave such splendid patterns of rhetoric; he has, indeed, it may be whispered, but a poor and imperfect conception of what it means. But it has been copied literally out of the preface of the volume containing the four photographs, and surely signifies something great and splendid, for of the mountain in labour it is unnatural to expect the birth of a mouse. Then again these four photographs were to be the harbingers, the forerunners, the ancestors of others as fair, or even fairer than themselves. Suggestions were asked from the world at large to secure this end, to enable the proprietors to add to the usefulness and attractiveness of the pictures which were to follow. But no suggestions came, or if they came, they never appeared. No more photographs followed these first four. Therefore are they perhaps more distinctly precious.

Alas! Their pure creamy cover is now defiled with dirt, a laceration through the centre has been patched up with a bit of common blue paper. The four photographs, each with its allotted sheet of tissue to preserve it in its pristine beauty, are all bleached and faded; the fine detail which it is charitable to suppose once delighted the eyes of their beholders has disappeared, and on the first and last number—the Alpha and the Omega—has been written by the authorities of the British Museum Library—the sole copy, in all probability, which this heedless and careless world of ours contains—the fatal word "Discontinued," which, being translated into the language of our own mortality, is "Dead."

And now rising before us, like pale ghosts, our four photographs seem to plead for some little notice, before they disappear for ever, to plead with such mute eloquence of entreaty as a tender-hearted man may with difficulty withstand. But a little while longer and they will be gone as we shall be. Surely he who chanced upon that little packet with its sad inscription, "Only a woman's hair," and gazed upon what it contained, hesitated a little space before he gave it up to destruction. He might bury it in the earth, or, if approving of cremation, he might burn it, but in any case he would treat it reverently, and not scatter it on the floor to be swept away into the common heap by the housemaid's broom. Our four faded photographs demand a like reverence of treatment. We will touch them tenderly and with care, will give them that sort of posthumous immortality which men seek for in brass and marble, before we return them to their long sleep, not probably soon again to be disturbed, in darkness and in dust.

About two score years ago, an elegant but thin volume was published at, we will say, Little Orpington, called "Photographic Illustrations." Its contributors were members of a Photographic Society—the Little Orpington Photographic Society—and its preface stated the object with which the publication was then "brought forward." This preface is chiefly conspicuous for a dignified modesty. "It is not," says the mouthpiece of the members of the Little Orpington Society, "that we suppose ourselves to have achieved results surpassing those already attained by many artists, nor that we desire to step forward as teachers of the detail of photographic manipulation; but we wish to test the use of photography as a help to education in its highest and widest forms, and at the same time to bring forward the relation in which this nascent art stands to the work of the poetic artist." It was an idle hope, a fruitless aspiration; the result of the test was adverse. "Education in its highest and widest forms" would have none of it, and the relation between photography and "the work of the poetic artist" is in this one number by no means clearly defined.

Illustrations also were promised in the preface of "objects interesting either in themselves or in their associations," and these objects were arranged in five classes: History, Antiquities, Art, Natural Objects, Mechanics. These classes seem to rebel somewhat against the rules of logical division, inasmuch, for instance, as the illustrations under history might be placed under antiquities, and both of them again under art. The pictures, however, in this first and only number, the four faded photographs, are, or, we should rather say, were, representations of an East view of Bramhall Hall, a West view of Bramhall Hall, Dr. Arnold, of Rugby, and a Steam Hammer. The steam hammer, which is placed, not perhaps inadvertently, in close succession to Dr. Arnold of Rugby, could only come under mechanics, but the particular classes of Dr. Arnold of Rugby, and of Bramhall Hall, east and west views, are not so easily determined. The latter, we are told by some letter-press, has been held by "the family" for nearly four centuries. The picture would therefore, perhaps, be rightly classed under antiquities. Copious quotations from Ormerod's "Cheshire" give details about the arms, and rooms, and fortunes of the house which, however interesting to "the family," affect the photographer very lightly, if at all. That artist is probably altogether careless of the detailed fact that their "arms were argent, a chevron sable between three cross crosslets fitche of the second and crest on a wreath, a felon's head couped *haltered or*." More interesting than these matters, which may have contributed in some measure to the sudden and untimely decease of the Photographic Illustrations, is a subjoined so-called photographic memorandum, giving the date and the time of day on which the photographs were taken. The conditions for the taking of Bramhall Hall were not unfavourable. It was a sunny summer noon, under a blue sky flecked with floating white clouds. The lens used was a single one of $2\frac{1}{2}$ inches diameter, the focal length from the back surface was $12\frac{3}{4}$ inches, and the diaphragm $\frac{1}{2}$ an inch. The negative was taken by a modification of Le Gray's waxed paper process, and the exposure was six minutes in the camera and $1\frac{3}{4}$ hours in development.

Unless we rank the photograph of Dr. Arnold of Rugby

under the head of art, a division under which all respectable photographs might be included, we must place it under that of natural objects, fencing it off thereby—though by a somewhat strange party-wall—from Bramhall and the Steam Hammer, neither of which certainly can be regarded as an object of nature. The letter-press accompanying Dr. Arnold of Rugby's photograph gives the leading events in the life of this excellent man, as laboriously culled from the newspapers and books of reference of the time, informing the reader that he wrote at Lalcham several papers on Roman History for the Encyclopædia Metropolitana, and that he traced the eternal truths of Divine Providence in their varying application to the different states of society. His photograph was taken from a bust on a dull, frosty day in mid-autumn, by a doublet lens of 2½ inches diameter, with 9 inches focal length from the back lens, and a diaphragm of ½ an inch. The negative was a collodion one, developed slowly with pyrogallic acid—

Distilled water	...	...	1 gr. to 1 oz.
Glacial acetic acid	...	...	20 min.

Exposure two minutes.

The Steam Hammer gives occasion for a diatribe on hammers generally from the earliest periods. Its negative—collodion—was developed with protonitrate of iron, then intensified with bichloride of mercury and iodide of potassium. It is the most distinct of the four pictures; but the subject appears somewhat infelicitously selected for a "nascent" number of a photographic journal. "J. Nasmyth & Co., Engineers, Manchester," is still distinctly visible on the right of the machine, and "J. Nasmyth's Patent," is equally clear on the left. Two figures are introduced, perhaps three, but it is difficult to speak with certainty, as the third may well be intended for a wheel: and with this the photographic illustrations conclude. A similar venture, if conducted on widely different lines, might at the present day be a success.

But this venture of forty years ago was a failure. Whether it was that the "descriptive essay" which we have ventured to call letter-press, embodying, in the opinion of the writer of the preface, "the principal facts which require to be known in connection with the illustrations as briefly as possible," was a trifle too long for the public patience, or whether the "facts which require to be known" failed to impress the reader as altogether necessary, or even material, will now probably never be discovered. It may be that the reader, anxious for promised "aid in the great work of mutual education, by giving strictly faithful representations of objects which could not otherwise be laid before him," was of opinion that Dr. Arnold of Rugby was not such an object, or supposing that he was, that his portrait might have been laid before him otherwise. In any case, our four faded photographs are the only pictures to be seen in the fancy-built gallery of the members of the Photographic Society of Little Orpington, and none, it may be affirmed with certainty, will resort to any process for the purpose of reproducing them.

Photographers' Benevolent Association.—A meeting of the committee was held on June 6th at Great James Street, Bedford Road, Mr. W. Benham chairman. The grants were made, and one new member elected. Any firm desirous of assisting the Association can have copies of rules on application to the hon. sec., H. J. Beasley, 65, Chancery Lane, W.C.

Specifications Published.

10,131. *June 21st*, 1889.—"Taking Photographs in Rapid Series." William Friese Greene, Photographer, 92, Piccadilly, London, and Mortimer Evans, Civil Engineer, of Savile Club, Piccadilly.

The invention has for its object the formation of photographic pictures, and relates chiefly to the production of such pictures as are necessary to illustrate and register the movements of animals, insects, or moving objects, either taken singly or in masses, as may be desired.

For this purpose they construct an apparatus by which, with a single camera and lens, a rapid series of such pictures may be taken, and by which a series of fresh photographic sensitive films or portions of such photographic film may be substituted for those which have been exposed to the action of light with sufficient rapidity for the desired end.

This camera has already been fully described in the Photographic News. The inventors make fourteen claims.

9,869. *June 15th*, 1889.—"Instantaneous Shutters for Cameras." A communication from George Eastman, of Rochester, County Monroe, State of New York. Alfred Julius Boult, 323, High Holborn, London.

In carrying out this invention I provide a pivotted plate or shutter having a segmental slot preferably considerably longer than the lens opening. The edges of the shutter may be turned up or provided with stops, and pivotted at the same point as the shutter is a cover narrower than the shutter, having no slot, and also having one side turned up, and provided with one or more stops. This cover is so controlled by a spring or springs as to have a tendency always to lie at one side of the shutter, and when in this position is entirely clear of the slot in the shutter and the lens. The shutter is also spring controlled with a tendency in the direction opposite to that of the cover. In its normal position the shutter lies so that the slot is entirely past the lens opening, and a part of the solid portion of the shutter, as well as the cover, both lie behind the lens so that no light passes. In setting the shutter prior to making an exposure the shutter is pulled over to its furthest limit on one side by any suitable means, such as a lever or a cord provided with an external button, and secured around a pulley on the shutter spindle; this pulley being so arranged as to carry the shutter with it in one direction, but to leave it free in the other direction. The shutter is provided with two or more peripheral openings into which falls the end of a spring controlled or spring lever pivotted; the cover also is provided with one or more slots.

The action is as follows:—

When the shutter is drawn over by the cord the cover remains behind the lens, being retained in that position by the spring lever until the opening in the shutter has passed the lens, when a suitable projection upon the periphery of the shutter, or special peripheral formation, causes the spring lever to rise out of the cover which then, under the influence of its spring, passes over to the side of the shutter out of the way of the slot in the shutter. The shutter is held in its set position by the spring lever entering a slot, suitably arranged for the purpose, and to make the exposure a press button or equivalent on the outside of the case may be pushed in against the reversed end of the spring lever, with the result that the acting end of the lever is removed from the slot in the shutter, which then, under the influence of a spring, flies over, making an exposure for the length of time during which the slot passes the lens opening,

the shutter finally resting in the original position, when both shutter and cover are behind the lens.

The cover is arranged with a peripheral slot or projection which takes on to the spring lever, so as to raise it clear of the portion of the shutter necessary to allow the slot to pass, the lens opening during the setting of the shutter, after which, as already explained, the lever is raised by the shutter itself, and the cover flies clear.

By this means it will be seen that there is no occasion for capping the lens during the setting of the shutter, as the previously described cover prevents the passage of light through the lens during the setting of the shutter.

This shutter may of course be arranged in front of the lens, or behind the lens, or, in the case of double lenses, between the two, according to requirements.

By providing suitable peripheral slots, both shutter and cover may be held by a spring lever in a position to leave the uncovered slot in the shutter opposite the lens opening, so that a prolonged exposure may thus be made.

Correspondence.

PAINTERS AS JUDGES OF PHOTOGRAPHS.

SIR,—Perhaps you will allow me to make a few observations on your article of May 30th on the above subject, as I fear it will not receive the unanimous approval of those who are endeavouring to regard photography as something more than a mere imitative process. I should have asked you to grant me this favour last week, only I was in hopes that a more able pen than mine would have dealt with the matter. If photographs can possess any artistic merit—and that this is possible cannot be denied—then surely those merits can better be guaged by persons who have been trained in art. You controvert this opinion by saying that photography cannot, or should not, attempt to imitate painting, and because the qualities which make a good painting or drawing do not necessarily make a good photograph, and you quote in support of this the well-known canon of art that "a worker dealing with a particular material shall not hide its identity and attempt to make it imitate something else," and tell us with perfect accuracy that a water-colour drawing should not imitate an oil painting, or an oil painting a water-colour. But a painter in oils may legitimately endeavour to give the softness of water-colour, or a water-colourist the boldness of oils, without laying themselves open to the charge of imitation. So, too, in the case of etching: an etcher does not and cannot attempt to make his works resemble paintings in monochrome, but that is no reason why he should not strive to give painter-like qualities to his etchings. In fact, "the object of the Society—Painter Etchers—is not merely the restoration of original etching, but the re-infusion into all forms of the engraver's art of the painter-like qualities it has lost" (*Vide* Exhibition Catalogue.) These etchers do not rest satisfied with drawing their subject on the plate and then sending it away to be bitten, and the prints pulled from it in a mechanical manner. On the contrary, in order to obtain painter-like qualities, they resort to what would be called in photography dodges of manipulation, or, as you would say, "juggling" with the plate. In fact, the man who does the biting and the pulling must himself be an artist, and know how to make the best use of the materials and apparatus with which he is working. Why should not the same latitude be allowed to photography? A lens used in a particular way will give microscopic definition; if used differently it will subdue definition. Both these properties are at the service of the photographer, and it is not "juggling" with a lens to make use of them. Etching is also capable of giving the finest definition, but that is no reason why it should always be shown, whether suitable to the subject or not.

In the case you mention of a certain photograph attracting the eye of an artist, it appears to me that the award was correctly given, not because it was more like a painting than other photographs, but because it was more like a picture, and the art of photography does not lose its identity by producing pictures.

But then comes the disappointed exhibitor who complains that a medal has been awarded to a photograph which is technically bad, because it shows errors in focussing, exposure, and development. That is not so; the focussing, exposure, and development are correct *for the result aimed at;* and here comes in the art to assist the science. You seem to imply that a photograph which possesses painter-like qualities may be compared to a piece of grained wood. This is not so, for the latter is solely an imitation, and the former is not. You might fairly compare a photographic copy of an engraving with a piece of grained wood, because this is essentially an imitation, and does not pretend to be anything else. But an artistically treated photograph of a natural scene, although it may have (and must have if photography is to be carried to its highest limits) painter-like qualities, does not and cannot attempt to *imitate* a painting. To obtain the best results the science of photography must be the servant of the art. The art teaches us what we should strive for, and the science how to obtain it. Therefore, in judging a photographic exhibition, the knowledge, training, and taste of an artist should be supreme, and the scientist should not be allowed to intrude his technicalities into a realm the nature of which (*qua* scientist) he is wholly ignorant. You have written strongly against artists judging photographs, but I am glad to see that at the conclusion of your article you have written still more strongly against photographers doing so. If it should ever again be my fortune to gain a medal, I hope and pray that it may not be at the hands of a man who holds that "Turner's pictures are outrageously out of focus, and who would suggest that the artist would do well to insert in the picture the details which were lacking." WILSON NOBLE.

52, *Sloane Street, S.W., June 7th,* 1890.

P.S.—I am glad to see that Mr. George Davison has commenced a series of articles on "Photographic Exhibitions." I trust his able pen will deal with the question of artists or photographers as judges.

THE PHOTOGRAPHIC CONVENTION.

SIR,—Allow me, through your columns, to announce that the proceedings of the forthcoming meeting at Chester will be opened by the Mayor of Chester at a *conversazione* to be held at the Town Hall on the evening of the 23rd inst.

Permission has been given to photograph the following places at any time during Convention week upon the production of a membership ticket:—Conway Castle (interor and exterior), by invitation of the President and Council of the Royal Cambrian Academy of Art; Chester Cathedral and precints, by the Dean; St. John's Church and ruins, by the Rev. S. Cooper Scott; Interior and Exterior of Eaton Hall and Park, by the Duke of Westminster; Hawarden Castle and Park, by Mr. W. H. Gladstone.

Excursions have been arranged during the week to Conway Valley, Bettwsycoed, Hawarden, Eaton Hall, Vale of Llangollen, Royal Mersey Yacht Regatta, and Old Moreton Hall.

At the evening meetings papers will be read as follows:—"The Records of Photo-micrography," Mr. A. Pringle; "Imagining and Imaging," Mr. P. H. Newman; "Orthochromatic Photography with Rhodamin," Mr. C. H. Bothamley; "Photography in Norway," Mr. Paul Lange; "Astronomical Photography," Mr. A. A. Common; "A Magazine Camera and Lantern," Mr. Friese Greene. Reports also will be received from the Lens Standard Committee, and the Weights, Measures, and Formulæ Committee.

A fully detailed programme will be forwarded on application.

J. J. BRIGINSHAW, Hon. Secretary.

128, *Southwark Street, London, June 10th.*

PHOTOGRAPHS OF THE TOWER OF LONDON.

SIR,—In reference to the remarks made in your last two issues in respect to not seeing any photographs of the Tower for sale, and of the inscriptions in the Beauchamp Tower in particular, I beg to state that I have spent an immense amount of time in photographing inscriptions and other things in all

parts of the Tower, which to me and a few others are very interesting. For years past I have given up publishing photographic prints, as I have a great horror of the Bankruptcy Court. I went into publishing, to supply the middleman, who is seldom or ever satisfied at whatever price they are offered to him, and then it is mostly "sale or return" business. I need not say the return means when the prints are in such a damaged condition as to be unfit for sale, which again means ruination to the producer. I have seen 12 by 10 prints sold to the shopkeepers for a few pence each, and other sizes in proportion. I have some two hundred negatives of the Tower alone, but in the present state of the market, publication is entirely out of the question. I am still continuing my series for private circulation only, also photographs of many other buildings of historical interest. The way this state of things has been brought about is that a few capitalists have put many thousands of prints into their trade, flooding the market with trash, at about five per cent. above the cost of production, and a little man who endeavours to make an art of photography, if he attempts publication, goes to the wall. I myself have been told by the shopkeepers it is not a matter of quality so long as they are cheap, because Mr. So-and-so's pictures, which are supplied to them at half the price, sell just as well. So what inducement is there for any worker to make a venture?

Reigate, June 7th, 1890. WM. BROOKS.

Proceedings of Societies.

Photographic Society of Great Britain.

The ordinary monthly meeting of this Society took place on Tuesday evening, the 10th inst. Mr. J. Glaisher, F.R.S., president, occupied the chair.

A paper was read by Mr. W. E. Debenham on "Estimating the Efficiency of Plate Backings," illustrated by a diagram and by photographs of the reflected images from various backing agents. A series of such backings, too, was shown coated on one side of a prism, and they could thus be examined, and the light reflected from them compared by simple inspection. Such inspection would show certain substances to reflect much light, and the sesubstances could, therefore, be rejected; whilst others that promised better could be compared by photographing the images reflected from them. The first plate shown had received twelve exposures on different parts, one when using a prism unbacked, and the other eleven taken with various backings applied to the prism. In some cases no images, and in others only very faint ones, had been given in the photograph, and the substances that thus appeared to answer the best were again used on the prism with longer exposures. One substance that he found very effective was caramel or burnt sugar, used in combination with an equal weight of gelatine or gum arabic. One plate which had received three exposures—one of fifteen seconds to the uncoated prism, one of one hour to the prism coated with bitumen, and one also of one hour to a backing composed of gum caramel and China ink—showed images of the first two to be about equal; the bitumen image receiving about 240 times the exposure of the unbacked one; whilst the gum and caramel showed still less image. He was not aware that the use of caramel as a plate-backing agent had been tried before; it was certainly very effective. Another plate had received six exposures through a hole of about the $\frac{1}{40}$ of an inch diameter. These exposures had been of fifteen seconds, one minute, four minutes, and sixteen minutes on the unbacked portion, and of sixteen minutes on the backed part. The latter showed no reflections, whilst the former, even that with fifteen seconds or $\frac{1}{64}$ of the exposure, showed the ring of halation characteristic of total internal reflection.

Mr. J. Spiller said that amongst the many substances that might be thought available for plate backing, the aniline dyes could not practically be included, as they would cause stain or action upon the film if they crept on to it, as they would be sure to do. Aniline orange would dye the film, and he knew of no chemical agent capable of remaiuing the staiu. It was a troublesome job to have to remove a backing of bitumen, and he was glad to hear of a soluble substance like caramel that was so effective.

Mr. H. Chapman Jones thought the experiments shown very interesting and valuable, but that backing plates was a step that ought not to be required. They wanted to use in the film itself all the energy of the light striking upon it, not to let any be lost, then have to be absorbed by a backing. Plates were now manufactured on a commercial scale which did not require any backing. Photographs of such a scene as one containing dark trees and light clouds showed no halation with such plates. For dark interiors with bright windows backing might be required, but he would prefer to alter the conditions of the subject itself.

Mr. W. Bedford said that plates which did not show halation owing to thickness of the film owed their freedom from this defect not to the light being entirely stopped in the film, but that development did not with such thick coatings proceed quite to the back of the plate, where the light from the back surface of the glass was reflected.

Mr. T. Samuels recommended the use of collodion stained with a dye in preference to other modes of backing; but backing he considered necessary.

Mr. Debenham, in replying, said that he thought plate makers might be induced to supply backed plates. A backing might be used either of gelatine and caramel—the gelatiue of such a kind as to frill off quickly in development—or of gum and caramel, with perhaps black pigment also.

Mr. H. Chapman Jones read a paper entitled "The Staining and Clearing of Gelatine Films." He showed a great many results of experiments made upon gelatine plates; some, after the removal of the silver compound by immersion in a solution of hyposulphite of soda, but most of them upon the film coutaining gelatino-bromide of silver. The result of his experiments was to show that the substances recommended as clearing agents did not possess the action claimed for them, but that what clearing appeared to be effected was really due to the extra washing received, and that simple water would do all that any clearing would, whilst some of these agents retarded or positively prevented the clearing action which water alone would have exercised. A mixture that had been recommended of alum, citric acid, and ferrous sulphate, he had found to make a stain already existing still more pronounced. One set of experiments showed eikonogen as the only agent not producing stain, whilst with pyro there was a slight stain, and with hydrokinone a more marked discolouration, which, moreover, was not even, but accentuated at the edge at which the solution had been arrested.

Mr. T. Sebastian Davis wished to know whether Mr. Chapman Jones had made comparative experiments with distilled water as against ordinary water for the removal of stains.

Mr. Chapman Jones had not done this.

Mr. Arnold Spiller could not agree with the author of the paper. He remarked especially that he had found the mixture of ferrous sulphate alone and citric acid to be particularly useful in removing yellow discolouration. Citric acid solution, also dilute hydrochloric acid, he had used and found to be effective.

Mr. A. Mackie noted that ferrous sulphate had an intensifying effect, which subsequent applicatiou of an acid removed.

Mr. Arnold Spiller explained this intensifying action by the fact that pyro oxidised in development and combined with the gelatine. The application of ferrous sulphate then formed a compound resembling the black in writing ink.

Mr. Chapman Jones defended his conclusions by pointing to his experiments, to which he had been led by direct observation. Alum he had always found to be positively detrimental. The fixing bath that he used was hypo, to which some carbonate of soda was added, and he never used the solution twice.

A paper by Sir H. Trueman Wood on "Photographing the Induction Spark" was taken as read.

It was announced that the annual soirée iu connection with the society's exhibition would be held on September 27th, and that pictures for the exhibition must be sent in by the 15th of that month.

Mr. J. B. Stacey was elected a member of the Society.

THE LEWES PHOTOGRAPHIC SOCIETY.

MONTHLY meetiug June 6th. The prints sent iu to the quarterly competition were on view. Mr. N. S. Starnes acted as judge, and attended the uneeting specially to explain the merits and demerits of the various prints submitted to him. The certificates in classes 1 and 2 were both awarded to Mr. G. J. Wightman, who then recounted his "Twelve Months' Experience as an Amateur Photographer," in an interesting manner. In the course of his remarks he said he owed his success to the Society, and he advised all who wanted a healthy and instructive hobby to take up photography.

THE SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE monthly meetiug was held at the Masonic Hall ou Tuesday eveuing, June 3rd, Mr. B. J. TAYLOR in the chair.

The SECRETARY announced that he had an invitatiou for the Society to send a delegate to the Photographic Convention of the United Kingdom, to be held from the 23rd to 28th inst., at Chester. He then put upon the table samples of Wormald's lantern slide masks of various shapes aud tints, when several boxes were ordered, to be given to those members who had promised to present slides to the Society, so as to have them all somewhat uniform.

Mr. T. G. HIBBERT gave a practical demonstration of the Kallitype printing process. The specimeus he showed were Payne's grey in colour. The process, he said, was claimed to be permanent, and required no hot baths, calcium tubes, or rubber bands; Kallitype, he continued, being much more sensitive than ordinary silver paper, care is required in printing to fill the frames in a yellow light or weak daylight, also not to examine them out of doors, as with ordiuary sensitive paper. He found it to print in about one third the time required by silver paper. Having some printed, he then proceeded to develop the same, somewhat after the platinotype method, after which a general discussion followed, and it was agreed that as yet it was not superior, if equal, to the platinotype process, but would, no doubt, be considerably improved.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting on the 5th inst., Mr. W. COLES occupied the chair.

Mr. H. M. HASTINGS exhibited negatives taken at Uxbridge with a hand-camera.

Mr. J. B. B. WELLINGTON, who had just returned from a tour on the Continent, said that his photographic luggage had passed through eleven custom-houses, but he had experienced no difficulty whatever with the authorities.

The results of the competition Pyro *v.* Eikonogen were passed round and adjudged; Mr. H. M. Hastings being the champion of eikonogeu, Mr. C. H. Cooke usiug pyro. The conditions of the contest were, that five exposed plates should be given by Mr. A Cowan to each competitor for developmeut, the exposures being unknown. Prints from each set of finished negatives were showu, each member present marking the print he considered the best. The result showed that in the cases of over-exposed prints from negatives, those developed with pyro were considered the best, but with under-exposures eikonogen obtained the most marks.

The subject for discussion for the evening was "The Priuting Process that best Registers the Gradation of the Negative."

Mr. R. P. DRAGE opened the discussion by reading a short paper advocating the superiority of silver prints in this respect over all other kinds of printing.

Mr. W. E. DEBENHAM was of the same opiniou. For range of gradation he considered albumen and gelatine gave excelleut results: platinotype did not give the saue amount of gradation.

The CHAIRMAN said that in selecting a printing process, it was necessary to consider the subject of the picture, whether general effect or minute detail was desired.

Mr. J. J. BRIGINSHAW said that for priuting from negatives of microscopic objects, he gave preference to gelatine for the reudering of all the fine details of the negative so uecessary for this class of work.

Mr. A. COWAN said that for printing from thin negatives the best gradation was obtained with albumenised paper.

The outing on Saturday next will be at Hale End; members to meet at Wood Street Statiou at 2.30.

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

A. T.—*Donkin Relics.* A photograph of Dychtau, marked to show the spot of Messrs. Fox and Donkin's last bivouac, appeared in the *Pall Mall Budget* of 15th ult. In the ice cave on a rock ledge were found thermometers and other apparatus for determining the boiling point of water at high elevations, together with an iron stewpan, drinking eup, aud fine instruments packed in sock aud glove. There was no camera. Probably our friend had this with him strapped upon his shoulders, but the now useless revolver was found hanging on the rocks at an altitude of about 14,000 feet.

J. M. (Norwood)—*Nitrate of Soda for Wet Plate Bath.* We should not recommend you to add nitrate of soda to a collodion sensitisiug bath, because Dr. William Allen Miller proved many years ago that it diminished the sensitiveness. If you must put in something to retard the evaporation on the plate during warm weather, try the addition of a small dose of Price's purest glycerine, using as little as possible, or it may cause fog. If by chance you get in too much, sunning the bath and filtering is the best way of rectifying it.

W. V. MORRIS.—*Sizes for Stereo Camera and Plates.* Either the $7\frac{1}{2}$ by 5 camera, commonly used by amateurs with a pair of twiu lenses of about $4\frac{1}{2}$ inches focus, or one for plates $7\frac{1}{4}$ by $4\frac{1}{2}$ inches. The Holmescope is a good form of hand stereoscope, with large square lenses shaded by a hood, all other parts being left quite open.

F. R. A. S.—*Solar Eclipse of 17th instant.* We thank you for the information, and, for the benefit of our readers, make known the following particulars:—Iu the north of Africa and southern parts of Asia, the sun will present an annular eclipse, but at Greenwich it will, of course, be only partial; beginning on Tuesday next at 8.20 a.m.; maximum phase at 9.23, when about one-third or 0·37 of the sun's diameter will be obscured, and endiug at 10.30 a.m. With landscape camera and long focus lens provided with instantaneous shutter, good results, although small, ought to be obtained, these permitting of being afterwards enlarged. It would be advisable to back the plates with carbon tissue, aud possibly two or more exposures could be received upon the same plate, allowing time for the disc to travel clear. By watching the ground glass it could easily be ascertained previously what interval should be allowed to get the images well clear, and a few preliminary experiments would settle this point, and likewise the adjustment of the time shutter. Another direction of study should be the registration of the crescent-shaped spots of light under trees, always visible during the progress of an eclipse, and a further set of experiments might be made with a pinhole camera.

S. H. & Co.—*Spotted Prints.* One unmounted and five cabinets, all showing the same defects, which at first sight appear to owe their origin to bronze powder, magnesium, or other reducing particles, got iu amongst the photographs, but we are unable to discover any trace of these, even with a microscope. The fixing and washing have been very carefully performed, for there is no evidence of hypo, and your description indicates the best known method of working. Is it possible that a bad album with shaiu gold edges and margins is responsible for the mounted cabinets? Otherwise, the case remains, as you say, a "mystery."

H. F.—*The City Exhibition.* The specimens were noticed last week on page 433, and it was unnecessary to refer to them again iu this column.

J. E. D., A. W., received.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1659.—*June* 20, 1890.

CONTENTS.

THE PHOTOGRAPHIC CONVENTION AT CHESTER.

NEXT Monday the Photographic Convention will meet in the ancient city of Chester, the most old-world looking place in this country, and one which will present plenty of subjects to the photographers who attend the gathering. A disadvantageous feature is that red sandstone has been so largely used in the construction of the more interesting buildings, and that that colour is not the best for plates which have not been made red-sensitive. Time was when Chester rose boldly from the plain, and, with its ancient walls and battlements, had an exceedingly picturesque appearance, but for many years past houses have been springing up close outside its walls, and somewhat dingy suburbs cover the space once occupied by green fields. On a fine day the Welsh mountains can sometimes be seen faint and grey in the distance from the city wall. The "rows" of Chester are unique; these consist of two rows of shops—one row above the other—upon one side of the street, so that, including both sides of the street, there are four rows of shops in all. While walking in front of the upper row of shops, the pedestrian treads a pavement laid above the ceiling of the lower row of shops; the second floor of the house is above his head, so that he is in a kind of arcade, but not one of any pretensions to architectural beauty. These "rows" form a protection from the glare of the summer's sun, also from rain and snow; but altogether, arcades in street architecture are not usually found to be desirable in places north of the Alps. One or two of the streets in Berne have arcades after Italian fashion. They are liked during the few months of summer, but the tradesmen who have shops therein say that the arcades make the said shops too dark and gloomy the greater part of the year.

Photographic excursions from Chester have been planned for nearly every day during the coming week, and the most attractive are those to Conway and Bettws-y-Coed, at the former of which places the more picturesque part of North Wales begins. Great Orme's Head is within moderate distance, and from it Puffin Island and the coast of Anglesea can be seen. Once we had a day of the Robinson Crusoe kind all alone upon Puffin Island, with not even a puffin for company, because some rats were wrecked on the island several years ago, and found puffins' eggs to agree with their constitution. The tide runs with great velocity between Puffin Island and Anglesea, and any lonely sojourner on the former for a day feels grateful that the fisherman does not forget to return to the island to take him back to Beaumaris. Some exceedingly pretty photographs of the Welsh hills are obtainable from the Anglesea side of the Menai Straits, because the hills are at a suitable distance, and have a good marine foreground. Towards evening the light is best, because at mid-day the sun would be behind the hills, facing the camera. The mountain Penmaenmawr is but two or three miles from Conway, and has a railway station at its base, so is available for those who wish to do some climbing. Conway Castle will, of course, be largely photographed again next week, as it has been largely photographed before. Near the mouth of the Conway was a pearl fishery once upon a time; the pearls were found in a coarse kind of mussel. As they will be under the guidance of a scientific man, the "conventionists" are likely to make some explorations in this direction, and to return home with their pockets full of mussel-shells. There is good sea-bathing near Great Orme's Head, and a lively species of small shark, from four to six feet long, at times frequents the region between Great Orme's Head and Puffin Island.

The excursion party for Bettws-y-Coed will plunge for a few miles into the hilly part of Wales, but will see nothing of the higher mountains of the Snowdon range, unless it goes several miles farther on, along the Capel Curig road, when Snowdon itself will come into view. About the finest view of Snowdon obtainable is still farther on, near the point where the Capel Curig road meets that from Llanberis to Beddgelert; this point is high up the side of the Vale of the Waters

—Nant Gwyuant. A great lake covers the bottom of the valley, and from the other side of the lake rises the most precipitous side of Snowdon, which can here be seen from base to summit. A little inn is near the junction of the roads already mentioned, and many years ago two wayfarers were imprisoned therein by rain for two days, with but two books in the house, namely, a Welsh Bible and "Thoughts on Suicide."

The people in Wales are usually hospitable and good-natured. We know those of the south better than those of the north, and this is the kind of talk one is liable to hear from Dafydd Rees about Evan Evans, who went to have his photograph taken: "Have you heard that Evan Evans went to John Jones to have his shaps (shapes) taken, and Morgan Griffiths says it was done bad, shockin' bad, iss (yes) indeed, to goodness."

A Pembrokeshire literary man of ability and a born Welshman once compiled the following sample of Welsh-English:—

O, had I the harp of King Dafydd,
What a lively lament I'd indite,
But the verse nowadays is so rabid,
I'm almost ashamed for to write.

Doubtless the Bettws-y-Coed party will bring back with them various specimens of the Welsh-English language of North Wales as applied to photographers and photography.

NEGATIVES FOR PHOTO-MECHANICAL WORK.

OF late years the employment of photographic processes for the purpose of illustration in periodicals and books has become so general that this kind of work has not only displaced, to a great extent, the art of the wood engraver, but it has called into being a number of publications which would never have seen the light had not this quick and convenient method of producing wood blocks presented itself. Photographs in half-tone can be converted into blocks ready for the printing press without difficulty, but their want of depth makes it difficult to obtain satisfactory prints from them unless they are impressed on fine paper and with very good ink. It is different with line blocks, as they are called—that is to say, blocks which have been produced photographically from drawings in pen and ink, and which consist wholly of line work.

There is some little art required in producing a negative from such a drawing, for its chief characteristic must be that the lines upon it shall be clear as glass, and that the background upon which they are traced shall be as opaque as possible. The negative must be reversed, but in these days of films which can be printed from either side this consideration should not present any difficulty. The hardest task before the worker has hitherto been to get the strong contrast between the lines and ground, to which we have just adverted, and this was, for a long time, deemed to be impossible to attain on a gelatine plate. So the custom among those who undertake this class of work has been to reverse their negatives by use of a surface-silvered mirror placed outside the lens, and to produce those negatives by the wet process.

Many photographers might, with reason, object to take up the old process. Some because they have never made pictures on wet plates—and this is, of course, true of a number of modern workers—and others because they have not sufficient space at command to keep the old and the new methods distinctly apart. The result of this is that the special form of negative required for photo-mechanical processes is regarded as something obtside the usual range of business, and the work is left to others to do.

But such considerations need no longer stand in the way, for it is now quite possible to obtain upon a gelatine plate a negative which shall rival in its contrasts of black and white that which is produced by the aid of the silver bath. We have lately experimented in this direction with two brands of plates, and have obtained most successful results, and we are informed on good authority that there is at least one other brand in the market which will answer equally well.

The first we tried were Mawson and Swan's photo-mechanical plates, which, as their name implies, are made for the purpose. The drawings which we copied were made in black ink upon a clay surface paper, which is a recognised material for work of this character, the mineral surface giving each line made by the pen a sharp outline instead of the ragged edge which lines will often exhibit if made on card of the ordinary kind. The plates are very slow in action—much slower than those produced by the wet process—and the exposure with a small stop ran up to two minutes or more. We at first tried for development a hydroquinone formula which we found advocated in print, but it was useless in our hands. It certainly gave an image which was intensely white and black, and at first we were pleased with its promising appearance; but unfortunately we found, subsequently, that the black was by no means of a non-actinic character, and that it let the light through to such an extent that the negatives had to be rejected.

We now commenced *de novo*, but this time we took good care to depend upon pyro for development. The change in the result was most marked, and there was the further advantage of increased speed of production. Density, we found, could be obtained to any extent, and in one case where an error had been made in exposure, and the film was not quite dark enough, it was brought up to the level of the others by a short immersion in a mercurial intensifying solution. In the after operation of printing we found that the dark portions of the negatives were so opaque that no light could pass through, and they were in every other respect as good as those produced by the wet process. The advantage of being able to bring up a negative to this pitch of density without having recourse to intensification, which is apt to clog the finer lines, and often brings disaster in its train in the shape of discolouration, is obvious.

The other brand of plates which we found suitable for this work was Edwards' isochromatic. We were employing one of these plates for copying an engraving simply because it happened to be at hand, and we

were altogether unprepared to find such an intensely black and white image as it afforded. As in the former instance, the lines were absolutely clear, but on a dark brown, non-actinic ground. We need hardly say that the exposure required was much less than that necessary for the photo-mechanical plates, for, as is well-known, the isochromatic plates are well fitted for instantaneous exposures. We actually gave about one-eighteenth of the previous exposure, with the result just stated. There was here an immense saving of time, but with the disadvantage of working afterwards in the dimmest of red lights for fear of fogging the plate. Mawson and Swan's plates, on the other hand, can be worked in a yellow light without fear of disaster. The other brand of plates to which we have alluded as being suitable for this class of work is made by England, but we have not tried them.

There still remains the difficulty of reversing the negative, which is necessary for photo-mechanical work. Few photographers possess a surface-silvered mirror, and the method which some have advocated of putting the plate in the dark slide wrong side before does not work well in practice. The makers should, therefore, bring out a *film* coated with suitable emulsion for this class of work, and then the last obstacle will be removed for those who wish to add to their business by producing these negatives for process work.

THE PROGRESS OF THE PHOTO-MECHANICAL PRINTING PROCESSES.

BY HERMANN E. GUNTHER.

II.

An interesting comparision has been made of late by C. Kampmann, of Vienna, between various chromate baths for sensitising photo-lithographic transfer paper. He found that the sensitiveness yielded is greatest in the case of those baths which contain ammonium bichromate (1,000 c.c. water, 43 grammes ammonium bichromate, and neutralised with ammonia ; or, according to Professor Husnik, 1,300 c.c. of water, 70 grammes of sodium bichromate, 30 grammes of ammonium bichromate, neutralised with caustic ammonia). By using baths which contain potassium bichromate, the sensitiveness is about one-third less ; it is, however, practically increased by the addition of manganous sulphate, as recommended by W. Weissenberger. By this addition not only the time of exposure is shortened, but also the impression becomes more distinctly visible on the bichromated paper during printing, because its colour becomes then deeper brown than usually. Moreover, the addition of manganous sulphate causes the transfer-ink to adhere more firmly on the rolled-up paper during development. The bath recommended by W. Weissenberger consists of :—

Water	1000 c.c.
Potassium bichromate	40 grammes
Manganous sulphate	5 ,,

It may be applied to any of the various existing gelatinised transfer papers, and by its use the same result is obtained as with an usual potassium chromate bath of a much higher state of concentration.

So far I have spoken about the treatment of the impression transferred to the zinc or stone plate, and of the preparation of the transfer paper : I may now be allowed to add a few directions as to the best condition of the negatives destined for photo-lithographic purposes. It is generally supposed by inexperienced operators that a negative which is to be reproduced by photo-lithography should show the lines quite clear, and the rest of the film absolutely dense and opaque. The latter is, however, not only unnecessary, but even unsuitable, since, if the negative is intensified until this density is obtained, the fine lines are liable to close, or at least to lose so much of their clearness that they will print very difficultly and defectively. Provided that a well prepared transfer paper is used,* a moderately dense negative is quite sufficient. With such a negative, also, the finest lines and points are printing, whilst the so-called false tone (see page 396) which is produced on account of the whites being not absolutely opaque may be easily removed by rubbing during the development of the rolled-up copy.

In order to obtain a negative of this kind—*i.e.*, of moderate density—a "hard" working collodion should be used. I suppose that the wet collodion process is used because it gives always the best results in this special case. A very good formula, which I have tried with perfect success, is the following one, recommended by Max Jaffé, an experienced photo-lithographer :—

Alcohol	100 c.c.
Calcium chloride	1·6 gramme
Cadmium iodide	7·8 grammes
Ammonium iodide	4·7 ,,

This iodizing solution is added to 1,000 c.c. of plain collodion of two per cent.

In the case of densely drawn originals of wood-cuts—copper and steel engravings, for instance—it will generally be unnecessary to intensify the negative ; if, however, in other cases, an intensification is required, the following method may advantageously be used. The following two solutions are prepared :—

No. 1.—A cold saturated solution of chloride of mercury.
No. 2.—A cold saturated solution of potassium iodide.

To solution No. 1 so much of solution No. 2 is added that the red precipitate, which forms at first, is redissolved. The mixture must be diluted as required for use, because it would otherwise act too strongly. The plate must, of course, be thoroughly washed before and after intensification.

The darkening of the intensified negative is done with hydrosulphide of ammonia, which is diluted with about four parts of water. The negative should appear entirely darkened after this treatment ; if it is not yet sufficiently vigorous, the operation may be repeated. Care should be taken that the hydrosulphide of ammonia is not applied in the same room in which the silver baths are placed.

In the case of gelatine plates being used instead of wet collodion plates, I can recommend the following combined eikonogen and pyrogallic acid developer as thoroughly reliable, with which any desired density may be obtained. The plate is at first developed with eikonogen, until the details of the drawing are well out ; then it is rinsed with water and re-developed with the ordinary pyro developer. The negative becomes at once denser, and its density may be increased to any desired degree.

* I have noticed that repeatedly inquiries have been directed to the Editor of this journal with regard to the "New Albert Transfer Paper," which I have described in a previous number. Since, as it seems, it is not yet procurable in England, I give here the address of the manufacturers : E. Jaffé and A. Albert, Wien, Währing, Theresienga'sse 17.

Photogravure.—With regard to photogravure, in which process great improvements have been made within the last few years in Germany, two important publications of a thoroughly practical character, in which the working details of the whole process in its present form are clearly and extensively described, deserve special attention. The first one, by E. Kiewning, has been published in the *Deutsche Photographen Zeitung*; the other one, quite recently, in the *Photographische Correspondenz*, by Rudolf Maschek, of Vienna. Upon these two communications the following lines are based. The two kinds of transfer paper which are used and recommended by Maschek are the diapositive paper of Braun and Co., of Dornach, for transferring the positive image, and the papers of the Autotype Company, of London, for the production of the relief-negatives.

The correct and careful composition of the etching baths is of special importance. Maschek prepares stock solutions, which he keeps in labelled bottles. For large plates he takes 20 pounds of chloride of iron, and dissolves them completely in distilled water, until the weight amounts to 1,500 grammes per 1,000 c.c. of the liquid. Afterwards he graduates the etching liquid, adding to the single baths so much distilled water that the specific weight amounts to :—

1·420 for the first etching (41° Beaumé).
1·375 for the second etching (38° ,,).
1·330 for the third etching (35° ,,).
1·285 for the fourth etching (31° ,,).

The dusting-in of the copper-plate with very finely pulverised asphalt is one of those acts upon which depends the success of the etching process to a high degree. For this purpose the Syrian asphalt must be sifted through a number of sieves, the openings of which become finer in succession, until it passes through a sieve of fifty-four to sixty meshes to each centimetre square. To prevent the exceedingly fine powder escaping during this procedure, the sieve should be covered with a white cloth reaching down to the table, and the table covered with white paper.

A GOOD MOUNTANT.—The following mountant is strongly recommended by Mr. W. Willis for delicate prints :—Weigh out 2 ounces of the best arrowroot ; mix it into a thick paste with 2 ounces of hot water, and then add 18 ounces of boiling water, stirring briskly. Soak half-an-ounce of gelatine in water until it is thoroughly soft and swollen. Stir this swollen gelatine into the hot arrowroot, with which it will quickly incorporate itself. Add ten or twelve drops of pure carbolic acid. This forms a stiff jelly when cold, and it should be used cold, being brushed on to the back of the prints or applied to them with a sponge.

HOW FAR CAN YOU SEE?—According to an American paper, there has been a great discussion going on in Europe concerning the distance at which large objects on the earth's surface are visible. Emile Metzger mentions that he once saw Keizerspickt, in Sumatra, when separated from it by a distance of 110 English miles ; he also says that on very favourable occasions he has managed to see Guy Merapi, in Java, when 180 miles intervened. E. Hill, the civil engineer, says that he has seen Mont Blanc from Piz Muraun, near Dissentis, a distance of almost 120 miles. J. Starkie Gardner states that Mont Blanc is visible from Piz Landguard, though distant about 3 degrees. Wymper, the explorer, says that when he was in Greenland he could plainly see a mountain peak from which he was separated by 150 miles. The whole range of the Swiss Alps has been looked upon by J. Hippisly while 200 miles away ; Sir W. Jones affirms that the Himalayas have appeared to his view from the great distance of 224 miles.—*English Mechanic.*

DEPTH OF FOCUS AND DIFFUSION OF FOCUS.

BY W. K. BURTON.

THERE has been so much discussion about the two subjects with which I head this communication, that I think a few words supplementary to what I have recently written on optics in the PHOTOGRAPHIC NEWS may not be out of place.

In one of these communications I defined, or rather tried to describe, "depth of focus," and I do not consider that it is necessary to repeat the definition here.

It has already been stated that depth of focus is inversely proportional to the diameter of the aperture, and to the focal length. From these facts there may be deduced others, a knowledge of which may be of some practical use to the photographer. Thus, assuming a certain maximum amount of want of definition as permissible, or not offensive in a photograph, we can work out a very simple rule that will tell us the distance of the nearest object that will be in focus at the same time as an indefinitely distant object, with a given focal length and a given aperture. Or, on the other hand, knowing the distance of the nearest object, and the focal length of the lens, we can get the size of stop that it is necessary to use so as to have the distance in moderate focus when the nearest object is focussed for, or *vice versa*. There is always some want of precision in applying such rules, because we have to assume that a certain definite amount of want of definition is permissible, and not more, whereas it is really a matter of artistic judgment in the case of each particular subject how much the less important parts of the picture should be subordinated to the principal subject by allowing them to be out of focus. Moreover, as pointed out by Mr. W. E. Debenham, the roundness of the field of lenses prevents any rules that can be formulated from applying to objects near the side of the plate, except when a very narrow angle is included, and when, in consequence, the field is practically flat. The effect of roundness of field is, that objects near the edge of the plate, far nearer than indicated by any rule, may be in focus at the same time as the distance projected on the middle of the plate. Still, it is often useful even to know what is the nearest object not very far from the centre of the plate that will be in focus at the same time as the distance, or to know what diameter of stop is the largest that we may use with a foreground object at a certain distance focussed without getting the distance much out of focus.

In measuring lack of definition, whether due to lack of depth of focus or to spherical aberration, the term "disc of confusion" of such-and-such a diameter is used. The meaning of this is, that if a mathematical point in the image is focussed, that point will be represented in the image by a blurred spot of a certain diameter. Thus, a fixed star may be considered as practically a point. If it be said that a certain lens has so much spherical aberration as to "give a disc of confusion of $\frac{1}{100}$ of an inch in diameter," the meaning is that, however we focus our lens, the image on the ground glass will not be a point, but a spot of not less than $\frac{1}{100}$ of an inch in diameter.

It is generally assumed that it is permissible, at least in the case of "the distance" in a photograph, to allow a point to be represented by a disc of $\frac{1}{100}$ of an inch in diameter, the reason being that, when looked at from the ordinary distance that is generally unthinkingly selected by people of normal sight, such want of definition does not amount to blurring, but amounts only to a barely

appreciable amount of softness. Indeed, there are many who are not even satisfied with the amount of softness thus given in the distance even of landscapes, much less in the case of figure subjects or portraits. Mr. Debenham has farther pointed out that a rule that allows the same amount of lack of definition due to want of depth of focus for all sizes of pictures cannot be a reliable one, as we look—or ought to look—at large pictures from a greater distance than we look at smaller ones from. This is correct, no doubt, but I cannot agree that such a rule as I mention is without any use, for—always bearing certain limitations in view—I have used it in practice for years, and have found it very handy.

In the first place, as regards very small work, we ought to look at such photographs from a very near point of view in most cases, and there are differences between different people as to the nearness from which they will look at a small picture. Thus the writer—though having good sight for distant objects without artificial aid—finds that he can, without excessive strain, examine photographs at a distance of only six inches from the eye; but he believes he is right in supposing this to be uncommon, and that not many will voluntarily hold even a small photograph much nearer to the eye than twelve inches.

On the other hand, it must at once be admitted that the rule is useless for small negatives that have to be enlarged, and that it is not correctly applicable to very large work, in which considerably more softness than is represented by the $\frac{1}{100}$ of an inch disc of confusion is always permissible, or even desirable for artistic effect.

In practice, I consider that the rule that takes a disc of confusion of $\frac{1}{100}$ of an inch as a standard is fairly applicable to all work that is not to be enlarged, and that is not of a size (say) larger than 15 by 12. The rule was stated by the present writer, in the PHOTOGRAPHIC NEWS, some years ago, in a form that is not *absolutely* correct, but that is well within anything that is needed in practice, and that has the advantage of great simplicity. It was stated in words somewhat as follows:—

"To find the nearest object that may be focussed for without putting the distance more than just perceptibly out of focus with a given stop, multiply the diameter of the stop in hundredths of an inch by the focal length of the lens."

FOCUS TABLE FOR DETECTIVE CAMERAS AND OTHER SPECIAL WORK

Focus of lens in inches	Decimal Standard Stop Numbers.								Ratio Marked on Stops												Focus of lens in inches

Example:—A lens 12 inches focus is used with a stop 1½ inches in diameter (*f*/8). The diameter of the lens in hundredths of an inch is 150. 150 × 1 foot = 150 feet. What is meant, then, is that we will have the distance in very nearly sharp focus when focussing for any object at the distance of 150 feet, and not near the edge of the plate; but that if we focus for a nearer object, the distance, using a stop of 1½ inches diameter, will be very clearly out of focus—a thing that may or may not be desirable.

If we know the distance of the object that we intend to focus for, and wish to know what stop we may use so as to get the distance just nearly sharp, the rule is as follows:—Divide the distance of the object by the focus of the lens, and the result will be—in hundredths of an inch—the size of the largest stop that will not put the distance conspicuously out of focus.

Example:—A lens of 16-inch focus is being used, and the principal object is at a distance of 100 feet. It is wanted to know what is the largest stop that may be used, focussing for the principal object, without putting the distance more than a little out of focus. Divide 100 feet by 1⅓ feet (16 inches). The result is 75 and ·75 inch, or ¾-inch is the largest stop that may be used, unless it is wished to put the distance conspicuously out of focus.

These two rules may be put in the shape of formulæ, eliminating the slight error—equal to once the focal length—that there is in them both, as follows:—

$$D = (100\,d \times f) + f$$

$$d = \frac{D}{100\,f + f}$$

where—

D = Distance in feet of the nearest object that may be focussed for without putting the distance conspicuously out of focus.

d = the diameter of the stop in inches.

f = the focal length of the lens in feet (or the fraction of a foot).

This table will be readily understood from what goes before. Instead of heading the columns of figures "number of feet and inches after which all is in focus," I should prefer to head them "distance of the nearest object that may be focussed for without putting 'the distance' more than just perceptibly out of focus." In using a detective camera for the kind of work that it is generally used for, and when it is not possible to focus for each subject separately, the camera should be adjusted, before starting, by *extending* it till a distant object is just perceptibly out of focus with the stop most commonly used. If this be done, the distances in the tables will, approximately, be the distances of the objects that will be in *sharpest* focus, and all objects within half these distances of the camera will be within nearly perfect focus.

The table has been constructed on the basis of a "disc of confusion" of $\frac{1}{100}$ of an inch. If it is wished to use the table for lenses of longer focus than any given in it, still on the basis of a "disc of confusion" of $\frac{1}{100}$ of an inch, the distances must be increased in the ratio of the square of the focal lengths. Thus, for focal lengths two, three, or four times those mentioned, the distances must be multiplied four, nine, or sixteen times. If, on the other hand, in the case of long-focus lenses, the figures be increased directly as the focal lengths of the lenses—two, three, or four times for focal lengths, two, three, or four times those given—and objects at the distances thus got be focussed for, it will be found that "the distance" is, in all cases, perceptibly out of focus, but not to an extent that will generally spoil a picture.

It is true that, if such a rule be adopted, very small photographs will, when looked at from the distance that most people find it comfortable to look from, will appear "sharp all over," a thing which some photographers consider very inartistic: but then it must be borne in mind that photographs taken with lenses of shorter focal length than the shortest distance that they can be comfortably looked at from, can never give a true impression in any case, unless enlarged or looked at through a magnifier. But if enlargement be resorted to from these small photographs, the amount of lack of definition in the enlargements will be the same as if the photographs were taken direct.

(To be continued.)

PROPHETIC.—"I have a lively presentiment that the time will come when a work will be judged by its merits, and not by the method of its production; and then, with some fostering care, things can and will be done that scarcely believers, and never unbelievers, yet dream of in their philosophy."—O. G. REJLANDER.

RED GLASS.—A new red glass has been recently produced in Germany. Besides its use for the manufacture of bottles, goblets, and vases of various kinds, it will be found applicable in photography and in chemists' and opticians' laboratories. This glass is produced by melting in an open crucible the following ingredients: Fine sand, 2,000 parts; red oxide of lead (minimum), 400; carbonate of potash, 600; lime, 100; phosphate of lime, 20; cream of tartar, 20; borax, 20; red oxide of copper (protoxide), 9; and bioxide of tin, 13 parts. By a single melting a transparent red glass is said to be obtained of a very fine quality, of which various objects can be manufactured directly, without the necessity of a second heating to intensify the colour.—*Scientific American.*

PHOTOGRAPHIC EXHIBITIONS.

BY GEORGE DAVISON.

III.—THE MEDAL SYSTEM.

THERE has been such a rapid advance in general opinion regarding reformed regulations for Photographic Exhibitions that it is to be regretted that the full and essential step of sweeping away the whole prize system has not been more boldly advised and urged. Several short steps are, however, frequently safer than a rapid leap, and, no doubt, the majority will soon recognise that a system of competition is detrimental to, and should be, as far as possible, kept away from anything like a serious devotion to art. What would be thought of an argument which recommended newspaper or any other poetry competitions as a good nursing system for a poet of nature? It is the same with good art. There is certainly much that is inferior which must be, and is commonly, classed as art, and, just as these versifying competitions may develop a facility in "doggreling," so the craze for prizes may tend to multiply third-rate efficiency. But it leads to imitation and sensationalism in a matter where the best can only be hoped for from subtle insight, the result of undisturbed study and practice. These artificial classifications into good, bad, and indifferent never yet helped a man to do anything great. They may possibly have spurred on certain temperaments in an unhealthy ambition to be accounted amongst the best photographers; but the lesson is soon learnt that it is possible, by accumulated distinctions, to be accounted a "best" photographer, and yet to be absolutely innocent of originality or artistic culture. Competitions may serve the purposes of modern enterprising newspapers, anxious for an "advertiser's circulation;" but, however directed, they can never forward the highest purposes of art, whether by photography or any other technique. Perhaps the worst of all such competitions are those in which a "set subject" is given, whether poetry in couplets or stanzas to be illustrated, or abstract ideas to be schemed in concrete form and pictures of this "machinery" taken. The artist must work in a way different from this. He has to arrive at such a state of cultivation that he can understand what Nature in her varying moods says to him direct, and he may not come to her with preconceived notions of finding what some one else has first seen and expressed.

The only arguments which have been forthcoming in support of a prize system in photographic exhibitions have been based on love of excitement, on business considerations by a portion of the exhibitors, and on the anxiety of the promoters for the financial success of their enterprise. No doubt the sweeping away of awards would remove much of an inferior kind of interest which these and other lotteries excite; but this would be highly beneficial. It can hardly be believed that men will not exhibit without the inducement of these vainglorious competitions. If that be so, the probability is their exhibits are best not seen publicly at all. The whole case is fairly met by the rigid exclusion of all distinctly inferior exhibits. The adoption and efficient carrying out of this system is, I believe, the best means of improving the influence and effect of our photographic exhibitions. Such a plan has never yet been adopted in any notable open exhibition. The element of interest and competition, it may be said, will remain, inasmuch as acceptation becomes the award, and this is, to a certain

extent, true; but degree in these and in most questions is of first-rate importance. The separation is easy, and a broad classification of good and bad is a not unwholesome corrective, and is free from the evils which follow in the train of a system of "bests" and of hair-splitting and erratic judging. How easy such a wholesale weeding out would be is well-known to all who have had any experience in comparing and hanging the entries at any large exhibition. Those pictures near or upon the border-line of acceptability would at times appear to receive unequal treatment, but this is but a small objection. Generally speaking, fifty per cent. might well be spared, and no one have any fair ground for murmuring. To come to actual example, it would be possible to wax enthusiastic over what the Exhibition of the Photographic Society of Great Britain might become under such a revised and improved system. It would be a more impressive lesson to photographers, and do greater credit to photography amongst artists and the cultivated. Very little of the more harmless interest argued for the medal system would be lost. The question would be, "Are my pictures hung, and where?" I venture to think there would indeed be a wider interest roused amongst exhibitors and the public, as well as greater service done to the art. All other considerations are small compared with the improved average of the exhibition, and the higher estimation in which it would be held by those whose valuable opinion soon becomes the popular view.

It is sometimes argued that the experiment has been tried, and has proved a failure. This is not true. The experiment has *never* been made. Certainly, medals were dispensed with at the exhibition of the Photographic Society of Great Britain in 1888, but there the thing began and ended. There were too many concerned in influencing the exhibition or its management who, for some personal or business reason, took exception to any reform in this respect, and with these it has been the practice to quote the experiment as an instance in support of their view. But their contention is unjustifiable. The attempt was but a lame and disorganized one, and the intention of the change was in no way explained or understood. I lay great stress upon that point. If the aim of the reform had been fully and fairly put before exhibitors, as it ought to have been, many would have made special effort, the credit deserved would have been given, and the exhibition would have retained its supremacy. Not only was no intimation of the change given, but, if anything, less energy than usual was displayed, and the few opponents of the movement seemed to claim credit for doing their utmost to spoil the exhibition, a result that was certainly not attained. After doing their best to ensure failure, they point to the result as a triumph for their foresight; but on very insufficient grounds. The number of photographs at that exhibition was the same as usual, and there was about the same proportion of amateur and professional exhibitors; with the exception of half-a-dozen abstentions, all the customary men were represented, and the average was but slightly lower than usual. As I have said, the full reform was not effected at all. The essential portion of any such scheme—rejection of inferior exhibits—was altogether omitted. As is the rule, practically *all* the entries were accepted. And yet this is referred to as a fair test. If the members and executive of the Photographic Society of Great Britain were loyal to their organization and to photography, and applied definiteness and energy in explaining and urging forward the higher form of exhibition—a rigid weeding out, with careful and tasteful arrangement of the pictures—then the result could not fail to be superior to the ordinary annual collection. Other societies in England have already schemed out such a plan of action, and in Vienna the excellent club there established is adopting the higher form of regulations for its 1891 exhibition.

NEW PHOTOGRAPHIC OBJECTIVES.*

BY DR. ERNEST ABBE AND DR. PAUL RUDOLPH.

No. I.

Our invention relates to photographic objectives, and the improvement consists in the construction of a system of lenses in which the function of collecting the rays of light forming the image, and that of correcting the spherical and chromatic aberration, are allotted to distinct parts of the system.

In constructing photographic objective-glasses in which the advantage of an extended image-field is to be coupled with a large, effective aperture, particular difficulties are encountered in attaining the desired degree of absence of spherical aberration of the pencils of light that produce the image. In view of obtaining the extended field aimed at, objectives of the usual types require to be provided with lenses of high curvature, and these always give rise to certain residual spherical aberrations (the so-called "zones") whereby the distinctness of the image is impaired when the aperture is fully open.

For the purpose of obviating this defect, and simultaneously facilitating an improved correction of the chromatic aberration, we compose the objective of two uncorrected single collecting lenses, which, in view of the aplanation of the field, have their convex or more convex sides turned outwardly, and a correcting-system possessing an infinite, or a large positive or negative focal length, so that it does not at all, or but inconsiderably, alter the focal length of the two collecting lenses combined; the said correcting-system being constituted by two or three single lenses cemented together and arranged between, and separate from, the collecting lenses. By means of this disposition it is possible to considerably diminish the aforesaid residual spherical aberration or "zones." At the same time, it gives a wider scope in the selection of the glasses to be employed in the manufacture of the lenses composing the correcting-system. In particular, it furnishes favourable conditions for the application of those kinds of glass which have the property of almost completely uniting three colours of the spectrum, or, in other words, which neutralise the secondary spectrum, and thus produce a superior degree of chromatic correction. The construction, therefore, yields comparatively ready means for the manufacture of such highly achromatic objectives as are called "apochromatic," according to the terminology introduced by Professor Abbe.

The Death of Mr. T. B. Jordan.—The death is reported of Mr. Thomas Brown Jordan at the age of eighty-two. Mr. Jordan, who was born in Bristol in 1807, began life as an artist, and, after turning his attention to physical science, he established himself in Falmouth as a mathematical instrument maker. In 1838 Mr. Jordan devised an instrument for recording by photography the variations of the barometric column. About the same date he invented a declination magnetograph and a self-recording actinometer.

* This is a patent specification issued in England last Wednesday.

NEW PHOTOGRAPHIC LENSES.*

BY DR. PAUL RUDOLPH.

No. I.

My invention relates to photographic objectives, and the improvement consists in the construction of the objective of two separate systems of lenses, the individual members whereof have, relatively to each other, particular refractive properties.

A main difficulty to be overcome in the construction of photographic objectives, besides realising the other numerous conditions subject to the purpose which these objectives have to serve, consists in sufficiently compensating the astigmatism of the obliquely incident pencils of light, and in removing the indistinctness of the marginal portions of the field resulting from such astigmatism. And, in fact, all the photographic objectives constructed so far possess more or less this deficiency, that with an approximately plane field the focus of a group of rays within a primary (meridional) section of an oblique pencil of rays, remains at a greater distance than the focus of the group of rays within a secondary (sagittal) section of the same pencil.

After a course of investigations on the conditions whence results this anomaly, and the means of mitigating its effects, the photographic objective forming the subject of this specification was arrived at. It is mainly a dissymmetrical combination of lenses composed of two distinct systems of single lenses cemented together. This combination of lenses is characterised by the concurrence of the following two properties:—

1. That in one of the two distinct systems the positive member (collecting lenses) has a smaller, in the other system, however, a greater refractive index than the negative member (dispersing lenses) cemented thereto.

2. That each system in itself is approximately achromatised, *i.e.*, that the chromatic aberration of each of the systems, expressed by the difference of the reciprocals of its focal lengths for two different colours, is small as compared with the chromatic aberration of a single crown glass lens having the focal length of the entire objective, the latter chromatic aberration being measured after the same manner as the former.

A combination of lenses realising both these requirements simultaneously presents particular advantages. On the one hand, it admits of the astigmatic differences being removed without rendering the application of more than two distinct systems necessary, and, on the other hand, it yields favourable conditions for satisfying all the other requirements connected with the correction of photographic objectives.

The above defined contrariant combination of the two distinct systems composing the objective furnishes the simplest means for compensating the astigmatic differences of oblique pencils. This is due to the fact that a system composed of lenses cemented together, and in which the collecting lens has a greater refractive index than the dispersing lens, gives rise to astigmatic differences opposite to those caused by a system of lenses the collecting lens whereof possesses a lower refractive index than the dispersing lens.

With the mode of compounding both parts of the objective as indicated above, it is, therefore, only necessary to choose the ratios of the single lenses in both these parts in such a manner that the opposed astigmatic differences are of the same magnitude, in view of attaining compensation of this astigmatism, or an astigmatic correction of the entire objective.

But in order that the realisation of this condition does not enhance the difficulty of achromatising the whole objective, it is essential that the objective possesses also that second property as defined at the beginning of this specification, *i.e.*, it is necessary to effect the contrariant composition of the two separate systems in such a manner that at the same time each system may be in itself achromatised. It is, however, neither particularly advantageous nor in all cases practicable to perfectly achromatise the individual members of a double objective; for the mere thicknesses which must be given to the lenses may, in each member of the objective, necessitate deviations from achromatism amounting to about one-fourth of the chromatic difference of the reciprocals of the focal lengths of a single crown glass lens having the focal length of the whole objective. But it is of practical importance that the mode of composing the systems of lenses does not in itself involve any limitations even to their approximate achromatisation, and that it does not render inevitable still greater chromatic differences than are required to meet other conditions.

This last requirement may be satisfied by a suitable choice of the combinations of glass which are employed to form the two parts of the objective. The following observations may explain the principles which govern the selection of suitable glasses.

Those pairs of glasses (crown and flint) which are generally resorted to in the construction of achromatic lenses (and which a few years ago constituted the sole means of obtaining achromatism) possess this characteristic feature, that a higher refractive index invariably implies a greater relative dispersive power. (Under the term dispersive power is to be understood, as usual, the quotient $\frac{\Delta n}{n-1}$, *i.e.*, the difference between the refractive indices for two different colours divided by one of these indices, or by the mean index of refraction minus one.) A pair of glasses of this kind—which may be said to be of a normal character—admits of the application of positive (collecting) systems, if achromatism is to be attained, only under the condition that the positive element has a lower refractive index than the negative.

Recent progress in glass manufacture has, however, added to the list of optical glasses other kinds of glasses which admit of such pairs being selected, in which the relation of the refractive indices and the relative dispersive powers is just the opposite as in the other case, *i.e.*, in which the glass having the higher refractive index does not also possess the greater, but, on the contrary, the smaller relative dispersive power. Such pairs of glasses may be said to be of an abnormal character, in contradistinction to the first-named class.

The application of pairs of glasses of the last-named or abnormal character admits of the production of systems with positive focal lengths in which, without prejudice to the attainment of achromatism, the more refractory medium acts as the positive (collecting) element.

* This is a patent issued in this country last Wednesday by Dr. Paul Rudolph, mathematician, of Jena.

THERE can be little doubt, Mr. Lockyer believes, that in the Parthenon the greatest function was when the chryselephantine statue of Pallas Athené was lighted up by the rising sun. In Greece the eastern horizon was used, in Egypt both east and west.

PHOTOGRAPHY AT GREENWICH OBSERVATORY.*

BY THE ASTRONOMER ROYAL.

THE tube for the 28-inch refractor, which is of special construction, has been made by Sir H. Grubb in preparation for the object-glass which is now being figured. The experimental 4-inch object-glass referred to in the last report was mounted on the Sheepshanks' equatorial, and eighteen photographs were taken with it last summer, the lenses being separated for photographic achromatism, and the crown lens reversed to correct for the spherical aberration introduced by the separation. The best distance of separation was determined, and the photographs obtained were found to be quite satisfactory. The completion of the 28-inch object-glass has been delayed, presumably by the pressure of work on the 13-inch photographic telescopes, which have engaged so much of Sir H. Grubb's attention, but it is hoped that the new refractor will be ready for mounting very shortly.

The $12\frac{3}{4}$-inch refractor, which will be dismounted shortly, would be very useful for the observation of comets, occultations, and phenomena, for which it is well adapted. It might with advantage be mounted on the Lassell equatorial in substitution for the much heavier tube and cradle of that instrument, the provision for rotation of the mirror and tube (which necessarily adds greatly to the weight) being dispensed with. The tube of the refractor would, I believe, provide a good attachment for a large mirror, $3^m.43$ ($11^{ft}\ 3^{in}$) in focal length, which Mr. Common has generously offered to make for the Observatory. Reference has already been made to the expediency of mounting the Lassell equatorial at a greater elevation above the ground.

The 13-inch photographic refractor, with 10-inch guiding telescope by Sir H. Grubb, has been lately mounted in the new 18-foot dome over the computing rooms, and one or two trial photographs have been taken with it. The definition appears to be very good for stars near the centre of the field, but the marginal images might, perhaps, be improved by a slight readjustment of the lenses.

For determinations of motions of approach or recession of stars 457 measures have been made of the displacement of the F line in the spectra of 26 stars, and 20 of the *b* line in the spectra of 5 stars, besides comparisons with the spectra of the moon, the sun, or the sky as a check on the general accuracy of the results. Observations of Algol on seven nights confirm as far as they go the previous results indicating orbital motion. The observations of Spica made in past years are found by Professor Bakhuyzen to be tolerably well represented on the hypothesis of orbital motion with a period of $4^d\ 0^h.356$, agreeing well with that recently discovered by Dr. Vogel's photographic method. As the series of observations with the $12\frac{3}{4}$-inch refractor (extending over fifteen years), will be shortly brought to a conclusion, it is proposed to discuss them with a view to the detection of orbital motion, whether of long or short period, there being indications of this in the case of several stars.

In the year ending 1890, May 10th, photographs of the sun have been taken at Greenwich on 212 days, and of these 439 have been selected for preservation, besides thirteen photographs with double images of the sun, for determination of zero of position.

For the year 1889 Greenwich photographs have been used on 173 days, and photographs from India and Mauritius filling up the gaps in the series on 187 days, making a total of 360 out of 365 on which photographs have been measured in this year.

The sun has been free from spots on 211 days in the year 1889, the longest spotless period being October 23rd to December 11th. There were also eight other spotless periods of more than a fortnight. The mean daily spotted area in 1889 was 78, as compared with 89 for 1888; but the mean daily area for the latter half of the year was nearly twice as great as for the earlier half, being 103 as compared with 53. Again, the mean distance of spots from the equator was $5°{\cdot}46$ in the first six months, and $14°{\cdot}72$ for the last six; and both these facts thus point to the middle of the year 1889 as a well defined date for the sun-spot minimum.

The photographic reductions are complete to 1890, January 6th, and the copy for press to 1889, December 31st, is in the printer's hands.

Photographs from India and Mauritius have been received from the Solar Physics Committee, and have been measured as far as 1890, February 17th and February 14th respectively.

As regards the further discussion of the results of former years:—

Ledgers of the positions and areas of spots for the years 1882, 1883, and 1884 are being formed. Similar ledgers for the years 1878-1881 (including the results from the Indian photographs, measured under the direction of the Solar Physics Committee) have been completed, and the mean results formed.

Melbourne photographs, available for filling up gaps in the series in the years 1875 and 1876, have been measured, and the reduction attempted; but it appears, from an examination of the results, that the information received as to the orientation of the plates is incorrect, and until further particulars are obtained from Melbourne the reductions cannot be proceeded with. All the available photographs taken at Harvard College during the same years have now been measured and completely reduced, 64 having been measured in the past year.

The discussion of personality in measurements of 8-inch photographs by 9 observers, and the discussion of probable error in measurements of 4-inch photographs, have been completed and published in the Photographic Results for 1888.

* A portion of the official report of the Astronomer Royal, issued last Monday.

SOLUBLE SACCHARATE OF IRON.—Athenstaedt's process is given as follows in the *Moniteur Scientifique*: A solution of a ferric salt, 1 to 100, is precipitated by a similar solution of ammonia or fixed alkali, taking care to operate at a temperature of about 10° C., and in all cases below 15° C. The precipitate must be washed rapidly, in the dark, with distilled water having also a temperature between 10° and 15° C. The ferric hydrate thus produced is then mixed with powdered sugar in a quantity so regulated that the dry preparation will contain three parts of metallic iron to one hundred parts of sugar. The mixture of hydrated ferric oxide and sugar is maintained at the boiling point until the oxide of iron becomes dissolved in the syrup. The dry product is obtained by drying in vacuo at a low temperature. This saccharate of iron (a most improper name, as it contains no saccharic acid) may be kept in solution made by diluting the mixture when cold by pure distilled water. We are told that these solutions are clear, and that they remain so indefinitely, without any further addition or any special precautions.—*Burgoyne's Monthly Circular.*

Notes.

An interesting article in *Harper's* on modern French painters reveals the fact that there is a rival to Mr. Muybridge in the person of M. Morot, whose eye is so sensitive and so educated that he can follow the movements of a horse almost as quickly as does an instantaneous camera. This faculty has led M. Morot to be accused of painting the movements of horses as they have been ascertained by instantaneous photographs; but, in point of fact, he has never used photography at all; indeed, he had already made his observations of the movements of the horse before Muybridge gave to the world the result of his remarkable experiments. M. Morot, when a youth, spent nearly all his time in the *manège* of a friend of his family, who was a horse trainer. The result of his observations was the discovery of much error on the part of artists in drawing horses in motion. He discussed the matter with the riding-masters of Nancy, had fine sand laid down in the *manège* to catch the foot-prints, and, in order to facilitate his observations, invented a little apparatus composed of a cardboard tube, with two horizontal slits in it, one exactly opposite the other. This tube, held before his eyes, and turned sharply with the fingers, formed a shutter or "obturator," on the same principle as the shutter of a photographic camera, closing the field of vision in about the fortieth part of a second. By means of this apparatus he watched the movements of the horse and analysed them, and each element of the movement impressed itself upon his finely-cultivated retina so sharply that he was able to draw it immediately from memory.

Thus, thanks to the extraordinary sensitiveness of his eye, aided by this little cardboard tube and a patient pencil, he discovered nearly the whole theory of the horse's movements while he was still a boy; but M. Morot was not such a pedant as to adhere to the observations of what might be called abnormal vision. In painting horses in movement, some compromise has to be made between microscopic observations and ordinary eyesight. He therefore gets over the difficulty by avoiding in the principal figures all intermediary elements of movement; he selects rather the beginning or the end. In the confused mass of a cavalry charge, he will paint one horse completely, and the rest of the troop will be bits of horses, elements, and movements, all the phases which scientific analysis gives, and this agglomeration and detail create the illusion of a vision of rushing horses.

Some sharp-eyed critics have been discovering in the pictures of the Royal Academy further incongruities, one of which was alluded to in these pages a fortnight ago. The lighting of Mr. Albert Moore's picture "A Summer Night" has been called in question as not being like anything yet seen in nature. Mr. Chevallier Tayler's "The Last Blessing" is also declared to be inaccurate. The priest, in this picture, is simply holding up two fingers, whereas the whole hand should be raised, as the use of two fingers is only permitted to eminent dignitaries of the Church. Mr. Wyllie's picture of "Davy Jones's Locker" displays a slight ignorance of chemistry. The large anchor in the foreground is painted a red rusty colour, but iron under water does not take a red rust; it is only when exposed to the air that the red oxide is formed. It must be very disagreeable to artists when they find that chemistry cannot be made to correspond with art. But the anchor in question makes an effective piece of colour, and Mr. Wyllie's defiance of chemical laws is to be condoned on this score.

The death of Count Ostorog, better known as "Walery," is announced. The event came as a shock to a numerous circle of friends, as until recently he was in the prime of life and, apparently, in the best of health. Walery was a photographer and artist of no ordinary skill, and of unbounded energy. His business was recently converted into a limited liability company. It is the brother of Walery who has accompanied the expedition of the Chartered British South African Company on a special photographic mission. Some interesting pictures of Matabeleland, and probably its monarch, Lobenguela, may be expected.

Until last week, it was not certain whether the Ober-Ammergau Passion Play was a dramatic performance pure and simple, or in some fashion a religious ceremony. An incident which happened a few days ago must, however, settle the point once and for all. A prominent journalist distinguished himself by an excess of zeal, which the authorities regarded as an act of piracy. In order to provide his friends with reproductions of the scenes, he seated himself close to the stage, at one of the performances, with a photographic apparatus. He then went to work; but unfortunately, Caiaphas caught sight of him, and sent a messenger at once to stop further proceedings. Following on the heels of the first came a second messenger, demanding that the plates should be given up. The journalist refused, and was therefore taken before Caiaphas—who happened to be the Burgomaster of Ober-Ammergau—and charged with having trespassed upon the monopoly, for which certain concessionaires had paid a large sum of money. It so happened that the amateur was able to prove that he had communicated with the concessionaires, and had obtained permission. The result was a happy release, with an abundance of apologies.

Some time ago, attention was called in the NEWS to the experiments which have been made on the Continent, showing that out of a number of married couples photographed, and of an equal number of

brothers and sisters, it was found that a much larger proportion of married people resembled each other than did the brothers and sisters. The topic has emerged from the circle of photographic gossip, and has been discussed in the daily papers. A lively article appeared in the *Daily Telegraph* on Monday, in which the subject is treated in whimsical fashion. In some respects, however, the arguments of the writer are incomplete. For instance, he asks—"May a plain man catch the infection of loveliness from his pretty wife after ten years or twenty of companionship?" This theory, the writer goes on to say, gives certainly a great advantage to the owner of feminine loveliness. This is all very well; but what about the other side of the picture? May not feminine loveliness contract a few of the masculine defects? We also fail to note any moral deduced by the writer from his speculations. Obviously, if anything is to be learnt from the resemblance between married people, it is the bearing which this resemblance or want of resemblance may have upon happiness in married life. Would it not be worth while, therefore, for the legislature to insist upon the principals in divorce cases being photographed, so that some kind of data might be arrived at on this interesting point?

M. Gaston Tissandier, in an article on flash-light photography in *La Nature*, gives a hint which those who are fond of this pastime will do well to remember. He strongly urges the sitters not to place their eyes in the direction of the light, as they are almost certain to shut their eyes at the moment of exposure, and the effect in the picture will be that they are either blind or asleep. People to be photographed ought to look on one side, or better still, take an attitude of reading a book or looking at an album. The latter suggestions do not strike us as particularly novel. The piquancy of flash-light photographs lies in their unconventionality. It is quite possible, with a little ingenuity, to get pictures of domestic life where the figures shall not appear asleep, without resorting to the very much played-out book. In flash-light photography by means of magnesium powder, as in photographing by the electric light, one of the chief problems demanding attention is the suitable diffusion of the light.

The notes in reference to photography and the Tower of London have done good. They have made known the fact that the Tower has *been* photographed, although not a single copy is to be found in the place where one would naturally expect it—namely, within the Tower itself. It is to be feared there is too much truth in Mr. Brooks's complaint contained in his letter of last week, that the photographic print trade has been spoilt, so far as the producer is concerned, by excessive competition. But this competition ought not to affect the sale of photographs in the Tower.

The application of photography to household decoration is gradually making headway, and we have lately noticed, with some interest, that there are displayed in many furniture shops tasty little screens, over-mantles, &c., in which are spaces for pictures. This is a far more sensible way of utilising photographs than is the custom of putting them into albums, because visitors to one's house can look at them or not as they please. They are too often given an album of pictures to examine just as if they were children, and required something to keep them quiet. We have occasionally experienced the tortures of looking through an amateur's album, and have found it very like, but not so enjoyable, as the room of horrors at Madame Tussaud's.

Now, if photographs are used for decorative purposes, only the very best are utilised, and if one of them has a premature attack of yellow jaundice, it is instantly removed, and a fresh copy takes its place. The owner watches over them with care, and they are not suffered to run to seed. But albums get neglected, and the majority of the pictures in them are often not fit to be seen.

Another field for photographic decoration is found in fanlights over doors, lamp shades, or, indeed, in any place where coloured glass interspersed with transparencies is admissible. The glass work is not difficult to lead together, and the metal grooving can be purchased at a cheap rate at many glaziers'. An article in an American paper was lately devoted to this subject, and it professed to give full directions whereby the amateur painter and glazier could put this kind of glass work together; but, strange to say, it omitted to state the kind of flux to use for soldering the lead work. The best that we have tried is Russian tallow, although rosin will act nearly as well. The pattern to be worked out in the glass is first of all drawn full size on paper, and while this pattern lies on a table the glass is cut, piece by piece, and fitted above it into the lead work. When one side is soldered, the entire mass is turned over, and the joints on the other side are joined up with the soldering iron.

Some persons are very fond of complaining that cameras and lenses are far too expensive, and that one often pays too dearly for the privilege of having a lens bearing a well-known name. But they forget that this name is a guarantee of value, and that some time hence, when, perchance, they are anxious to sell or exchange, it will give the article a far higher selling price than would be possible without it. These grumblers would be surprised to learn the cost of some of the best material used in camera construction. One well-known maker bought the other day a log of very handsomely figured mahogany. It was as hard as iron, and a camera made with it would be calculated to stand the vagaries of climate in any part of the world. The price paid for it was at the rate of three shillings and four pence per square inch.

THE GROSVENOR GALLERY.

BY REV. F. C. LAMBERT, M.A.

THE visitor who inspects this collection of work chiefly with a view to increasing his own store of suggestions, and gatherings hints for his own work with the camera, will not find many striking pictures.

The first one will probably be No. 31 ("Youth and Age," E. E. Simmons), an old man nursing a sleeping child; the group, with its appropriate cottage surroundings, skilfully treated and truthfully rendered, with a back lighting through the cottage window. Subjects of this character are among the most suggestive to the camera man in search for suitable subjects.

No. 36 (Portrait of D. Q. Orchardson, R.A., by himself). It is most unfortunate that the nightmare-producing expression "greenery-yallery" should be so inextricably interwoven with the name of the Grosvenor Gallery, because it has a flavour on the tongue which one would gladly get rid of when there is presented to one's notice such admirable workmanship as this portrait undoubtedly contains.

No. 46 ("Goodbye," E. Harris), a clever treatment of strong outside daylight, and also cottage interior lighted by a small window. The truth of subdued, light tones is carefully worked out.

No. 72 ("Lustra," H. J. Hudson) is noteworthy for its treatment of some of the flesh parts in shade.

No. 90 ("Study of a Head," John da Costa), a small but admirable piece of careful, straightforward work. An old woman's wrinkled face under a light-tinted sun bonnet, in words does not sound anything worth painting; but it is not the subject, but the truth of the subject, that makes a picture of what might easily be a very ordinary sketch.

No. 115. Here we have another "painter painted," palette and all—viz., J. C. Noble, A.R.S.A.—by John Pettie, R.A. The portrait is not altogether restful for the eye; the strong light on the forehead, on the collar, and edge of the aforesaid palette all seem to claim attention one by one. The moral for portrait photographers, anyhow, is, do not have too many high lights struggling with each other for the observer's attention.

No. 127 ("Finished Sketch of the Traitor," by the same artist as No. 115). The title of this picture will convey a new idea to those who have followed in the ways of their forefathers in thinking that a *study* was an unfinished *whole*, while a *sketch* was a finished *part*; but with or without a title, there is much good work in the picture, even if the outlines of some of the limbs of the figures are striking.

No one will think of leaving this gallery without looking at S. P. Hall's remarkable little picture of the royal wedding party of July last (No. 141). On this party Mr. Stanley turns his back—or, rather, someone has so arranged the portrait of him (140) by Miss E. M. Merrick. On no account must be overlooked a pencil sketch of the Marquess of Salisbury, by the Marchioness of Granby. It is very seldom indeed that one sees such a clever sketch as this—a sketch truly it is, but one which drives home the lesson that a *few* lines in the *right* place are worth infinitely more than a million of them in the wrong place. (Retouchers, please note this in the largest mental capitals.)

Passing into the SECOND ROOM, 149 ("The First of September," D. Sadler) claims attention, and calls for inspection all over the canvas. It is a specimen of good workmanship, and too much of it—*i.e.*, so much detailed subject that it becomes a matter of effort to concentrate one's mind on the theme. Above this is 150 ("Court of Criminal Appeal," Sir A. Clay), portraits of some six well-known "lawyers," all very fine and large. The artist had by no means an easy task before him, and when all the circumstances of the case are grasped, it must be admitted that he has produced a creditable and memorable piece of work. Note carefully how the matter of variety, with unity of pose, has been worked out—befitting expressions as portrait studies, disposal of *twelve* hands!

No. 164 ("Washing Day," John Reid) brings up the thought, "too many figures; some are sure to move and spoil it."

No. 165 ("Miss Maude Millett," C. W. Bartlett) is an instructive study of the camera-artist. Note the effect of a side light on the flesh and white drapery; parts of the flesh seem almost too transparent for a portrait.

No. 174 ("Oporto," C. N. Hemy), a lot of good work, broadly treated in a simple scale of colour, resulting in good harmonious work, and not too much focus either.

No. 182 ("Striking a Bargain," G. King) is just the thing for camera men; many obvious hints may herefrom be gathered. Note and study this picture well. Now look at No. 155, over doorway ("Portrait"), and observe the effect of tilting the head the same way as the back of the chair tilts over: one of the arms, too, is more or less parallel. Another obvious note.

No. 205 ("A Moment's Rest," W. E. Norton). Although there is a general feeling of wishing for a bit more focus somewhere about the picture, yet, despite that unsatisfied longing, it is a painting of decided merit, and well worth the study of any artist. Of the portraits in this room, No. 203, by Hon. J. Collier, and No. 187, by F. M. Skipworth, are especially deserving of useful study.

In the THIRD ROOM, No. 239 ("A Silver Mist Melting in Softest Light," R. H. Carter), a group of fisher folk in an early morning mist, sorting and packing their catch, is a splendid picture. Here we have a reply, in part, to the advocates of the extreme fuzzy school on the one hand, and the *f*/64 school on the other, showing that it is not impossible to reproduce all the feeling of softness and distance, subdued detail, apart from fuzzy outline, and also that there may be plenty of detail, and even bright light, with a mist, without wiry crispness everywhere or anywhere. The unity of the whole picture and the melting of one plane into another, the gradual diminution of detail, are all points to be studied and remembered.

No. 248 ("Room in Brussels' Almshouse," H. Vos) is more pleasing as a collection of many studies than as a whole; the long line of figures introduces a difficulty not easy to overcome. The picture is in a low key, and broadly treated.

No. 259 ("Four Jolly Sandboys," Miss J. R. Taylor). This is the sort of subject in which a camera-man can get a long start, and it is from photographs (of the right sort) that artists might now and again take a hint in this kind of work.

Among the studies of the nude, we should select No. 288 ("A Water Baby," Hon. J. Collier), and No. 185 ("Boy and Dryad," C. N. Kennedy), as being worthy of considerable study.

No. 320 ("Portrait," L. Ward) produces a curious effect, and for the moment gives one the idea that the man is "standing on nothing" against a rather strongly tinted background.

No. 327 ("The Ramesum," J. Varley) shows admirably the effect of strong sunlight and sharp-edged shadow, without the soot and whitewash effect usually produced by the shutter maniac.

No. 341 ("Javanaise Dancers," A. Melville) gives one rather a shock. The exclamation, "What a splendid frame!" is almost irresistible.

No. 350 ("An Interior," Miss C. F. Jones), a skilful piece of work. Observe that the darker parts are not without a due share of detail. (Expose your next interior *fully.*)

Nos. 337 and 360 (Landscapes, R. B. Nisbet, R.S.W.), pictures of "almost nothing at all," and yet *pictures.* Why? Because there is truth of tone, true values, without which a painting is diagrammatic (if that), and lacking in the true essential element of every art, viz., *truth of proportion*, not only of *drawing*, but also of *detail*, of *tone* (light power), and *tint* (colour power).

One more picture, and one to linger over—viz., No. 371 ("The Missing Boat," David Green). It is not easy, nor is it pleasant, work seeking for a fault in a picture like this, which demands, and is entitled to, much in the way of praise. Some may say part of the immediate foreground is "to let"; and yet even its simplicity by no means detracts from the point of interest. Note the simple lines of the general scheme—harmony of figure-group of fisher folk, simplicity of their belongings, boat huts, and cloud drawing; the feeling of air, space, and largeness in the distance—all contribute in producing a picture of considerable power, and one which owes much to its parts being kept in true proportion throughout.

Notices of Books.

Magnesium Flash-Light Photography, by Robert Slingsby. (*London, Marion and Co.*, 1890.)

This book is written for those who intend to take up flash-light photography in a serious way, and not to take an occasional "chalky" picture by way of pastime. The pages are of large size, to accommodate specimen illustrations, and the literary contents are limited, but practical and to the point. The author tells how many more flash-lamps are necessary as the size of the apartment, hall, or theatre increases; how and where to place the lamps; how to give a large number of flashes simultaneously, and other miscellaneous information, the result of practical experience, for Mr. Slingsby has given special attention to this class of work. Much better pictorial and artistic results can be obtained by flash-light photography than occasional dabblers therein are prone to suspect. We consider Mr. Slingsby's book to be of practical value to professional and other photographers of the present time, and that it is the forerunner of a class of such works likely to appear when the system of flash-light photography is more elaborated.

On page 15, Mr. Slingsby quotes from the Photographic News of January 24th last a formula for making an explosive flash-light powder, containing perchlorate and chlorate of potash, which Professor Max Müller, of Weimar—as our German correspondent stated—"asserts" not to be so dangerous as a mixture containing no perchlorate. However this may be, we think the mixture to appear so dangerous upon theoretical grounds that, like all others containing chlorate of potash, the ingredients should be powdered separately, should not be kept mixed in bulk, but that only enough should be mixed at a time, with the feather end of a quill pen, to give the desired flash when exploded, otherwise deadly results may follow.

Photographischer Zeitvertreib. By Hermann Schnauss. (*Ed. Liesegang, Düsseldorf*, 1890.)

The matter of this work is much more interesting and instructive than its title—"Photographic Pastime"—might lead one to suppose. It is a description of such of the less practised photographic methods, including some that might be called "dodges," as are within the reach of an amateur, or of the professional photographer who likes to do something out of the regular groove of photographic business, without the necessity for any special costly apparatus—anything, in fact, that cannot be easily improvised with a little application and goodwill.

The first part of the work relates to the best means to adopt in photographing flowers, paintings, animals, snow scenes, and moving water. Then follows the photographing of electrical discharges, both natural and as produced by dynamic and other artificial sources. A very curious illustration is that of a seal photographed by its electrical condition, and not by any illumination thrown upon it.

We next come to a description of the means to be adopted for taking photographs—portraits particularly—by night. Here, in addition to a description of magnesium lamps, is a diagram showing the positions of the sitter, camera, light, and shield to protect the lens from rays proceeding directly from the flash.

In the next chapter, on photographic curiosities, we find doubles, spirit photographs, and caricatures dealt with and explained. A more serious question is then taken up, that of combined portraiture as introduced by Galton, the necessary simple appliances for which are fully illustrated. Following this chapter is one on photographing by means of what is called a pin-hole camera. Details of the method are given, but the illustration of a pin-hole photograph accompanying it has doubtless suffered in the process of conversion into a surface block necessary for use with the letter press, as it is not nearly such a perfect result as some that we have seen produced in this manner.

The tables given of time of exposure for different sizes of pinhole, and what stands for length of focus, should be found useful to any who may think of trying this method of producing photographs. Photographing by the aid of a telescope is a chapter which may be turned to practical account. Without going into astronomical photography, it not unfrequently happens that it is desired to obtain a larger image of some distant object than can be got with the lenses at hand.

The stroboscope, which is next described, requires more elaborate apparatus for the production of the necessary photographic negatives, but the same cannot be said of the photo-kaleidoscope pictures that follow in the work.

We have not exhausted the contents of the book, which includes printing with floral borders, printing direct from natural objects without the intervention of the camera, and other matters calculated to interest those readers who are not satisfied with merely treading the most beaten roads, but find pleasure in exploring the bye-paths which lead to results of a more unaccustomed character. The work is plentifully illustrated, and in such a way as to materially facilitate a ready grasping of the methods described.

CONVERSAZIONE OF THE ROYAL SOCIETY.

Breath Figures, and their Relation to Photography—Reversal of the Image in Breath Figures—The Rising Sun and Egyptian Temples—Sun Gods—Photographs of Wild Beasts—Photography and Forestry—Astronomical Photography—More Photographs of the Eggs of the Great Auk—Platinotype Portraits—Tornado Photographs.

Last Wednesday night the annual ladies' *conversazione* of the Royal Society was held at Burlington House. The president, Sir George Stokes, and his daughter, Mrs. Humphrey, received the guests. Among those present were :—

Dr. John Evans (treasurer), Professor Michael Foster and Lord Rayleigh (secretaries), Dr. Archibald Geikie (foreign secretary), the Lord Chancellor, Duke and Duchess of Sutherland, Earl and Countess of Rosse, Earl Compton, Lord Bramwell, Lord Thurlow, Lord Sackville Cecil, Lord Arthur Russell, Lord Basing, Lord Coleridge, Mr. A. J. Balfour, Lord Justice Fry, Bishop of Limerick, Admiral Sir John Hay, Admiral Sir George Richards, General Sir Peter Lumsden, General Sir Lewis Pelly, Sir James Caird, Sir Lyon Playfair, Mr. Justice Stirling, Sir William Thomson, Sir Henry Barkly, Sir James Paget, Sir George Paget, Sir Henry Roscoe, Sir James Douglass, General Sir Beauchamp Walker, Sir John Lubbock, Sir Henry Rawlinson, Sir William Bowman, Sir F. Burton, Sir Frederick Abel, Archdeacon Farrar, Mr. Calderon, R.A., Professor Storey-Maskelyne, M.P., Professor Norman Lockyer, Sir George Baden-Powell, Mr. W. H. Preece, Sir R. E. Welby, Sir Benjamin Baker, Mr. G. A. Spottiswoode, Sir William Savory, Sir Frederick Bramwell, Mr. Moulton, Q.C., Dr. J. H. Gladstone, Sir Charles Wilson, Mr. H. H. Johnston, Sir Frederick Pollock, Professor and Mrs. Sidgwick, Dr. Quain, Rev. J. R. Diggle, Dr. Ogle, Mrs. W. K. Clifford, Miss M. Shaw-Lefevre, Miss Kensington, Miss Clough, Miss Sellars, and Lady Ashburton.

Mr. W. B. Croft, M.A., exhibited some breath figures, showing that polished surfaces placed near to bodies in low relief often take an impression of the detail, which is made visible by breathing upon the surface. The period of exposure varies in different circumstances.

Mr. Croft says :—"1. A coin is lightly pressed on a freshly split surface of mica for thirty seconds ; the mica takes a breath figure of the detail of the coin. 2. Paper printed upon one side has lain for ten hours between two plates of glass ; the print appears in white letters on both. Part of this phenomenon, although not with print, was noticed by Möser in 1840. 3. Sometimes the print appears in black letters ; the same impression may change from white to black. 4. Coins are put on the two sides of a piece of glass and electrified for two minutes ; each side has a perfect impression of that side of the coin which faced it. An electrotype plate may be reproduced in a similar way. These effects were partly indicated by Karsten in 1840. 5. An electric spark is sent across glass. Five superposed bands appear, black and white, of decreasing breadths, as well as three permanent scars. Riess, 1840. 6. The mieroseope shows water particles over the whole surface, larger or smaller as the effect is black or white."

A strong point of interest in these breath figures, from a photographic point of view, is that they are liable to something resembling "over-exposure" when the electrical action is continued too long, for then the image is entirely or nearly obliterated. Upon suitably rubbing the plates, however, the image comes out, as if the rubbing had removed some film ; in this latter respect there is as yet no parallel in photography, so far as we know, although, when church windows are "overdone" and rich in fog and halation, rubbing down the surface of the negative with turpentine will usually bring pictorial details into view. A still stronger point of interest about the breath figures is, that sometimes reversed images are obtained ; sometimes the image will come out as a positive, sometimes as a negative, and Mr. Croft tells us that he does not know the conditions governing the reversal. These phenomena too much resemble some of those familiar in photography not to make it reasonable to suppose that they bear some relation to each other. From a theoretical point of view, they are of interest ; in the case of breath figures, at all events, the image is not reversed by liberated bromine.

The breath images are sometimes full of exquisitely sharp detail, and they are somewhat stable, for Mr. Croft keeps them stored in plate boxes, like those for negatives, and they do not seem to fade. Dipping the plates in water and wiping them with a cloth smudges the images, but does not remove them. They can, however, be removed by rubbing the plate hard with damp leather.

To get a breath image of a coin, the following method is adopted :—A piece of patent plate glass is taken and washed, and wiped clean ; such perfect cleaning as usual in photography is not necessary. Another sheet of glass is taken and laid upon the table ; a slip of tinfoil is then laid on the sheet, then comes the piece of clean glass, and the coin on the top of all. One conductor of a Wimshurst electrical machine is connected with the coin, and the other conductor with the strip of tinfoil between the glasses ; the machine is then turned for two minutes. The glass discs of the machine are fifteen inches in diameter, and are turned at the rate of about one revolution per second. The poles of the machine are arranged at the sparking-distance of about half an inch, as a safe-guard against the electrification of the coin being overdone.

Breath images are sometimes obtained simply by taking a piece of paper printed on one side, and leaving it for some hours between two sheets of patent plate glass.

Möser, Hunt, and others made many experiments on this subject in the days of old, and Karsten found that, on suitably electrifying a coin on the top of a pile of plates of glass, he could get an image of the coin on every plate, and always on its upper surface.

Professor J. Norman Lockyer, F.R.S., exhibited, by means of the lantern, photographs of a number of Grecian, Egyptian, and other temples, including some of those of Thebes, taken by Captain Abney. Mr. Lockyer pointed out to the assembled company that many of these temples pointed east and west, and were open at the ends, so that the rising or the setting sun could stream through each temple, and illuminate the *sanctum sanctorum* at the other end ; the temples, therefore, are like horizontal telescopic tubes, with a collimating axis. To show that this idea is worth considering, he pointed out how a king's palace and a second structure near a temple both had openings which would permit the passage of the rays of the sun through the two buildings, and then through the great temple of the sun god, Ra, "The Lord of the Two Horizons," a title which has more meaning to the astronomer than to the archæologist. This idea of Mr. Lockyer's we therefore think to have more to support it than some of the numerous speculations about sun gods. A pamphlet has been issued, purporting to be written a thousand years hence, satisfactorily proving to our descendants that the present Professor Max Muller of Oxford has no existence, but is a sun god, a solar myth. Professor Lockyer is a

kind of sun god in his way, for has not a celebrated ballad described him as the "owner of all the corona?"

Dr. H. P. Bowditch exhibited some specimens of American composite photography.

Mr. Gambier Bolton exhibited some lantern pictures of animal and bird studies photographed from life. These studies were the result of eighteen years' photography at home and abroad, and they include slides of the newly discovered zebra (*equus greevi*, stuffed), and Mr. Yorke's photograph of the quagga, from life. Mr. Bolton told the assembled listeners that he believed the latter to be the only photograph of the quagga in existence; it was taken but a few months before the death of the animal. The peculiarity of Mr. Bolton's photographs was that they were taken by long exposures—that is to say, exposures of one or two seconds' duration—in order to avoid the harsh shadows incidental to instantaneous photographs taken in direct sunlight. Among the photographs was one of the green monkey, as well as of several other rare beasts. From its restlessness, he found the leopard the most troublesome animal to photograph, and nervous dogs with long, flapping ears caused difficulty.

Some admirable platinotype photographs by Mrs. F. W. H. Myers were on view; they displayed refined artistic taste, and good technical skill. Several of them were portraits of public celebrities, including Bret Harte; the others were chiefly character portraits. One of the best of them represented two cherubs.

The Royal Meteorological Society exhibited some tornado photographs. Among others, there were fourteen photographs showing the devastation caused by the tornado at Rochester, Minnesota, U.S., on August 21st, 1883. The great force of the wind in the tornado was illustrated in a very striking manner by two of the photographs, as one shows a horse impaled by a large branch of a tree, and another shows pieces of straw driven end-on into the bark of trees. There were two photographs of a tornado cloud taken at Jamestown, Dakota, U.S., June 6th, 1887. The cloud funnel was twelve miles to the north. The Society also exhibited a photograph of a tornado cloud taken in the storm on June 22nd, 1888, showing the spiral-shaped funnel trailing at a considerable altitude in the air at the other side of a lake, New Hampshire, U.S.

Professor H. Marshall Ward, M.A., F.R.S., exhibited a selection of transparent photographs, showing (1) various trees and plants from different parts of the world, including European oak, beech, spruce, the Indian banyan, palm and bamboos from Ceylon, and Californian pine; (2) illustrating the microscopic characters of some important timbers, such as are employed for determining their nature; also various details in the anatomy of healthy wood generally; (3) a selection of photographs of diseased oak and spruce, showing how different are the symptoms exhibited by the same timber when attacked by different fungi. Illustrations of several destructive fungi were on view, and some details of their action given. As an example of the uses to which photography may be utilised in forestry, we append a list of those transparencies exhibited by Mr. Ward which relate to the diseases of timber and plants caused by fungi:—

A block of the wood of oak destroyed by *Thelephora Perdix*. A similar block of oak destroyed in a very different way by *Polyporus dryadeus*. A similar block, also oak, showing the again different mode of destruction due to *Polyporus sulphureus*. Transverse section of a branch of oak destroyed by *Polyporus sulphureus*; the light parts are filled with mycelium. Longitudinal section of wood of oak destroyed by *Telephora Perdix*. The cavities of vessels, &c., are filled with fungus hyphæ, which pierce the walls and dissolve them by means of soluble ferments (*enzymes*), reducing the structure to a friable or rotting mass. Very highly magnified. A block of spruce destroyed by *Polyporus mollis*. A similar block, also spruce, showing the very characteristic and different mode of destruction due to *Trametes radiciperda*. Stump of a young tree attacked by *Agaricus melleus*, a destructive parasite. Portion of bark of a tree bearing fructifications of *Polyporus sulphureus*, a destructive parasite. Portion of branch of beech attacked by *Nectria ditissima*, one of the fungi which causes "canker." Specimens of wood suffering from "dry-rot," due to the ravages of *Merulius lacrymans*. A withered leaf covered with "mould," one of which (*Botrytis*) is capable of parasitic existence on living plants of various kinds.

Mr. Isaac Roberts, F.R.S., exhibited sixteen original photographs of stars, nebulæ, and clusters, including five photographs of the Great Nebula in Orion, namely:—1. A negative with five consecutive exposures, each of 5 seconds, 30 seconds, 1 minute, 3 minutes, and 6 minutes respectively, showing the stars in the trapezium, and the progressive photographic development of the nebulosity around them. 2. A negative showing the appearance of the nebula, with an exposure of 15 minutes. 3. A negative showing the nebula, with an exposure of 81 minutes. The third nebula (H 1,180) is also shown on this plate. 4. A negative with an exposure of 205 minutes, showing great extensions of the nebulosity, and that the nebula (H 1,180) is connected with the Great Nebula. 5. A negative with dual exposures, and an interval of five days between them, illustrating a method for detecting variable stars of short period. The suspected variables were indicated by circles drawn around them. He also exhibited:—6. A negative of stars in the constellation Cygnus, showing more than 16,000 stars on four square degrees of the sky, with an exposure of 1 hour. 7. A negative of the nebulæ (81 and 82 Messier), and a nebulous star in Ursa Major. 8. The Spiral Nebula (51 Messier) in Canes Venatici. 9. The Dumb-bell Nebula (27 Messier) in Vulpecula. 10. The Ring Nebula (57 Messier) in Lyra. 11. The Globular cluster (13 Messier) in Hercules. 12. The Great Nebula in Andromeder. 13. Nebulæ in the Pleiades. 14. The double cluster in the sword handle of Perseus. Remarkable groupings amongst the stars are also shown. 15. The minor planet Sappho on the 30th December, 1886. The trail of the planet during 60 minutes was shown within the circle drawn around it. 16. The minor planet Sappho on the 7th January, 1887. The trail is within the circle, and, by comparing its positions on the two photographs, the distance it has moved during seven days can be measured.

Mr. Edward Bidwell again exhibited some photographs and models of the eggs of the great auk, but in somewhat larger number than at the last *conversazione* of the Royal Society, as published in these pages at the time. The prints measured 6 by 4 inches, and were upon bromide paper; they were executed by Mr. Kidd, who had been engaged to travel with Mr. Bidwell over a large part of Europe for the purpose.

The great auk, or garefowl, formerly existed in large numbers on the coast of Newfoundland, from which country, and from the rocky islets off Iceland, most of the birds and eggs now in collections were obtained. In consequence of the quantities killed for food by the English and French fishermen, the bird was exterminated in its American home early in this century, but it survived in

Europe until 1844. There are 77 recorded specimens of the great auk, 14 skeletons (fairly perfect), and 67 eggs. The collection of photographs exhibited consisted of two views each of 55 of the eggs, photographed to scale. The models were cast in moulds taken direct from the eggs.

THE COSTUME ALBUM.

THAT the ablest and best of human endeavours are too often misunderstood and maligned is a truth so trite and obvious as to require little illustration. Whether it be from envy, which, like a shadow, pursues merit and proves it substantial; or from ignorance, which is unable to comprehend desert; or from indifference or laziness, which is too idle to look for it, some of the greatest benefactors of humanity have been suffered to languish in obscurity, or have met that which is worse, the exasperating destiny of ridicule and reproach.

These reflections are likely to be aroused in the deliberative mind by the Costume Album, which has been laughed at by the superficial as the "latest of American notions," and nothing more. It has been regarded simply as a pretty picture book, instead of a collection of moral memoranda, as it really is, and its author, no doubt, intended it to be, and its untoward fate in this respect recalls in a remarkable manner that of a great work with a somewhat similar ethical purpose, an abortive birth of some fifty years ago.

That "virtue should supersede crime and establish peace and harmony on earth" is, it will be generally allowed, something devoutly to be wished. How this desire may be accomplished was discovered by an author of the name of Thomas Wirgman, who published in 1837 a book entitled "The Grammar of the Five Senses," which he regarded as a first step in infant education. This infant education was also to be an universal education, and "established," in the author's words, "for ever." It was presented by him to the Bishop of London in the hope that the Bishop might cordially enter into its ideas, and suggest it as a text-book throughout the whole world. Moreover, severe scrutiny was invited for the detection of *one* single untenable proposition, for which a reward of ten pounds—who was to be the judge in the matter is not stated—was offered by the author.

This book, beginning with the five senses, illustrated by the simple notions of an umbrella, a tree, a drum, an apple, and a rose, proceeded incontinently in its second chapter to the metaphysical considerations of space and time. The volume was adapted to the childish intelligence by the aid of colours, in small parallelograms of about 1½ by ½ inch. Eternity appeared a pale arrangement in orange; Time was distinguished by a heavenly blue; pink dignified Conception and Understanding. The error of the great Aristotle was thus demonstrated to the infant, "for in his catalogue of ten notions he has introduced *quando* and *ubi*, thus converting the only two mental recipients into mental activities, viciating *(sic)* the whole science at its commencement, and frustrating his own laudable design." But, notwithstanding its condemnation of the Stagyrite, its attractive colours, and its author's estimate of its correctness, the Bishop of London seems to have treated it with disregard, and the Queen—to whom a special presentation copy was submitted—acquainted Mr. Thomas Wirgman that she could not entertain applications for its use to "really improve the state of education for the infant population," and coldly referred him to her confidential advisers for the future.

The American mind which conceived and brought forth the pregnant idea of a Costume Album has been as much misunderstood as the unlucky author of the "Grammar of the Five Senses." Already, indeed, has the shaft of ridicule been aimed at this elegant conception, and many imperfectly acquainted with its object have spoken of it with disparagement or vilification. It has been supposed to be merely a *Magasin de Modes*, a common fashion book, with this sole difference, that the person draped exists not in imagination but in reality. Were it nothing but this, it might, perhaps, deserve the obloquy with which it has been assailed, but its inventor beyond doubt aimed at something higher, intended some noble moral end far other than a mere idle gratification of the eye. We may conceive him to be a second Adam Smith, dealing with the influence of custom, and fashion, and association upon the moral sentiments.

In this way of thought a Costume Album may be regarded as a continual monitor, or a *vade mecum* of good advice. As, when a new fashion of dress comes in, the folly of the outgoing fashion is commonly perceived and insisted on, so many actions which the principle of association has connected with that dress are afterwards seen face to face in their naked deformity. The sentiments of conduct are, perhaps, as much influenced by fashion as the sentiments of beauty. As the dress of one time seems at another absurd, so also does the behaviour. What is to-day supposed to be elegant is pronounced hideous to-morrow; what is to-day regarded as good and worthy of approbation is denounced to-morrow as bad and morally indecent. Suppose, if an illustration be required, that a lady possesses in her Costume Album a photograph of an apparel which she had made or "confectioned" for the express purpose of beholding a bull fight at Seville, or of assisting at a pigeon shooting match at Hurlingham. The very next photograph in her collection represents her in the modest attire suitable for attendance at her own parish church, in which attire she prays devoutly to be delivered from the pomp and vanity of this wicked world. Surely a moral lesson will be conveyed to the most heedless and inattentive mind by such a pictorial juxtaposition. Surely the most bird-witted—without any reference to the pigeons at Hurlingham—woman will be thereby mentally benefitted.

Thus, the Costume Album will become a valuable diary of life's experiences, teaching her what to seek after and what to avoid. If we suppose the prices of her varied raiments to be added to them, after the fashion of a linen-draper's ticket, though the appearance of the photograph will be in no way bettered, yet what a valuable lesson in economy will hereby be gained!

The pigeon shooting attire, besides presenting a record of time used, to say the least of it, for no profitable or praiseworthy purpose, will, with its adventitious ornaments and wholly unnecessary elaboration, remind her who once wore it how great an expense was then thereby incurred; the parish church apparel, showing no immoderate outlay, and "quoted," to borrow a mercantile flower of expression, "at a modest figure," while it affects her with no pang of bygone extravagance, will, at the same time, cheer her heart and strengthen her future endeavour with a sense of an accomplished duty likely to bring about a temporal and eternal advantage. Again, the many changes of her

costume in a short season will remind her of the mutability of life, of the uncertainty of happiness, and of the nature of the only true good, unchanging, and eternal.

Here is a dress which she wore at that dinner party of A's, where a hired man, an alien to the profession of a footman, spilt a plate full of soup down her back. Then she thought she should have died with vexation and chagrin; now she wonders how such an accident could have affected her equanimity. Here is a ball dress with an infinitesimal irregularity of fit; she remembers what words she used to her dressmaker in regard to it with remorse and shame. Here, again, is the dress in which she showed that mean jealousy of her husband at that picnic at X's. How often has she since confessed to herself, while looking upon its representation in her Costume Album, that her anger was wholly idle, and misplaced, and foolish, inasmuch as it was within an ace of wrecking all her happiness in the future. And so against all the other evil passions of the mind—those harpies which prey upon the human heart—the Costume Album may act as a memorial and as a warning.

Not a dress in that book is without its own little history of good or evil, known probably to herself alone. So she may repair to this excellent volume, as to another "Pilgrim's Progress," in any spare moment of serious meditation, and see herself, as it were, in a looking-glass. Nor is the advantage to her alone. Finding the folly of envy, malice, hatred, and all uncharitableness so clearly recalled to her by her Costume Album, she will have the chance—and probably use it—of improving her own character, and thereby adding to the happiness of those around her. Nor is this even all. After she herself has passed away, her children may in their turn learn a lesson from her old Costume Album. Turning over its pages, from the gay sprightliness and vivacity of the dress of their mother's youth, to the grave and sedate sobriety of her apparel in old age, they will receive such moral instruction and benefit as could hardly be produced in them by any alien record, and their earliest thoughts of the vanity of the world, their first earnest conviction of the frail estate of human things, may be born in them by the inspection of this "latest of American photographic notions."

May the book long flourish which is fraught with such wholesome counsel, and meet not the unhappy fate of the book of Thomas Wirgman. It is truly sad to read the concluding words of his preface. "Should the reverse of this pleasing dream take place," says the author of the "Grammar of the Five Senses"—anticipating the possibility of its ill success—"should its writer still meet with the same apathy and indifference which have signalized the last forty years of his existence, his theory, together with his dialogues, must for ever die; unless, indeed, like the Pythagorean theory of the celestial bodies, after a lapse of many thousand years it should find another Copernicus to bring it into play." *Absit omen!*

The Photographic Convention.—Since our last issue, and up to the time of going to press, we have not received from the Photographic Convention a copy of the official programme, or any additional details as to the Chester meeting. From another source information comes that Mr. Friese Greene will exhibit one or more of the new cameras for taking a considerable number of photographs of moving objects per second, as well as one or two other interesting pieces of mechanism. The lantern machines for projecting the said photographs on a screen are at present defective, but are likely to be all right in a few weeks' time.

MR. TOOLE AMONG PHOTOGRAPHERS.

A subscriber has sent us a copy of the *Melbourne Argus* containing the following narrative. Says Mr. Toole:—

"I have to sit again for my photograph, and you may as well come along with me. Having my photograph taken always reminds me of one occasion when I was taking a stroll on Hampstead Heath with Beerbohm Tree. We met a little travelling photographer, who wanted us to have our pictures taken for sixpence each, frame included.

"'But I've never had my picture taken before,' I said, 'Does it hurt much?' 'Why, Lor' bless you! no,' he says, 'it's as easy as anythink. Just you stand steady, and I'll take yer in two minits.'

"'But I'm so nervous—you must let me hold my friend's hand, and you must take us together. What do you put that black cloth over your head for? Have you hurt yourself?'

"This necessitated his leaving off to explain to us the use of the black cloth, and by that time we told him we had become so nervous that he must promise not to look at us while we were being taken. The moment he turned his face and began counting, Tree and I made the most frightful grimaces imaginable at the camera. The man took out the negative, scrutinised it with a puzzled expression, and said, 'I can't make it out. Somethin's gone wrong—yer faces have come out like puddens, they're all over the shop. 'Ave another try, gents.' We had another 'try,' repeating our protests of nervousness, and inducing him to turn his head away. We contorted our faces worse than before, and you never saw such extraordinary productions in your life as those photographs. The man was very crestfallen, and we told him we did not think much of his machine, paid our money, and strolled on. Presently we were accosted by another photographer, who invited us to have our portraits taken.

"'How much?' we asked him, and when he quoted the same price as the first man, we said, 'Why, we have just had them taken by a fellow over there, and he only charged us twopence each, but we were not very well pleased with them, and have a mind to try you.'

"He looked furiously in the direction of the other man, and his temper did not improve when he came to examine the negative, because we went through exactly the same fooling as before. We paid, and left him with the very evident intention stamped on his countenance of going over to 'have it out' with his rival for underselling him, and thus ruining trade.

"Of course, we subsequently bestowed life annuities on both of these men.

We had now arrived at the photographer's, and followed Toole into the little office, the walls of which, as is usual with such places, were hung with every imaginable specimen of work done on the premises. Consequently, we were not prepared to see Toole lean over the counter and ask the young woman attendant if she could recommend him to any place in Melbourne where he could have his photograph taken. The girl stared at him, but there was such a look of humble and inquiring gravity in his face that she only smiled, and said he could have his likeness taken there.

"Yes," said Toole, in a deprecatingly considerate tone of voice, "but I shouldn't like to put you out, you know. Now, if you could tell me of some place where they make a business of it, I should be so much obliged."

The girl, repressing a tendency to laugh, for his manner was full of a pleading earnestness, assured him that they made a business of nothing else, and asked what style he would like to be taken in.

"Well," he answered thoughtfully, "I don't quite know, for I was never taken before, and I don't know which style hurts the most. I believe a group is the least painful form, so I think the three of us would like to be taken in a group."

"Well, now, here is a group. Would you like to be taken in this style?" and she handed him one of those remarkable pictures in which two young men stood bolt upright in the background, while three others were disposed at their feet in what are called picturesque attitudes, the whole five looking as

stiff and uncomfortable as disconcerted pickpockets. Toole gazed at this sadly for a few minutes, and plaintively remarked, "Oh, I see, it takes five to make a group; just you wait here a moment while I run down stairs and get a couple of men out of the street to make up the number, so we can be taken in a group," and he turned to go.

"No, no," said the girl, "there are five here; I havn't a group of three to show you, but three can be taken just as well as five."

"But wouldn't it be more painful with only three?" Toole asked innocently, but got no answer, for the girl dived behind a little screen, from which she presently emerged with a heightened colour, and said if we would please to step upstairs to the next floor but one, she would arrange everything through the speaking tube. Now, it is a bad thing to commence laughing when you are not quite certain of your power to stop, and I am sorry to say one of Mr. Toole's companions was in this case by the time we reached the first landing. This was occupied by a merchant's office, full of packing cases and samples, in which two or three clerks were working, while the man of business was seated at a little desk all by himself. With a hurried injunction of "Don't laugh," Toole preceded us straight into the room, and, addressing the man at the desk with a smile of cheerful serenity, said, "We have spoken to the young lady downstairs, and she arranged us through the speakiug tube. We want a group of three, please, as I understand it doesn't hurt more than five, and I hope you wont't keep us long, as I have an appointment."

I thought the man of busiuess would have fallen backwards out of his chair, but he recovered himself, and said, with a smile, "I think, sir, you are mistaken."

"Yes, we want to be taken," said Toole, pretending to be deaf. "Any style you think best, you know. I should like to arrange my hair first."

"I said, sir, I think you have made a mistake. If you want the photographer he is on the next flat."

"As flat as you like," Toole answered. "I've seen some of 'em raised, but I don't think it any improvement. You won't keep us more than ten minutes, will you?"

"You have come to the wrong office, sir," said the merchant, raising his voice. "What name did you want?"

"Oh, yes, we'll have a frame, if it's all the same price—not that I am particular to a shilling or two. Perhaps you can show us some specimens?" Toole's countenance was smiling amiability itself.

I felt my lips beginning to quiver when the merchant rose solemnly from his chair, leant on his knuckles across the desk, and proceeded to bawl directions how to find the studio upstairs to Toole, who listened intently with his glass in his eye and his hand to his ear. But I missed the termination of the scene, for our other friend was suddenly seized with a violet fit of something between a cough and a sneeze, which sounded so suspiciously like an uncontrollable outburst of laughter smothered in a handkerchief, that I was obliged to lead him out and thump him on the back. We heard the directions being shouted out—half the city might have heard them for that matter—and presently Toole joined us not a bit flustered, and quietly remarking that it appeared we had made a mistake, for the studio was on the floor above. As Mr. Toole's man had actually been there in the morning, and made an appointment for him with the photographer, no further pranks could be played there, and the sitting only occupying a few minutes, we again descended to the street.

The Photographic Club.—The subject for discussion on Wednesday, July 2nd, will be "Matt Surface Printing." July 9th, Report of Delegates to the Photographic Convention. Saturday, June 28th, outing at Pinner; tea at Queen's Head at 6.30.

The British Association.—This year the British Association meeting will be held at Leeds, and will begin on Wednesday, September 3rd, under the presidency of Sir Frederick Abel, C.B. The president of section A (Mathematical and Physical Science) will be Mr. J. W. L. Glaisher, F.R.S., who long since has achieved eminence as a mathematician, and is the son of Mr. James Glaisher, the president of the Photographic Society.

NEW SALTS EXHIBITING OPTICAL PHENOMENA.

Among the most extraordinary and beautiful optical phenomena presented by organic compounds, it would be difficult, or perhaps impossible, to find any rival in this respect to two new products lately obtained in the laboratory of a Viennese chemist, Dr. Edmund Morvan. Nothing similar has been seen hitherto, and it is expected that the careful study of the physical properties presented by these compounds may ultimately bring out new ideas with respect to our theories of light and colour.

The first of these is an organic compound of oxide of zirconium, and is named by its discoverer zircon-ethyl-methyl-phthalein. The other belongs also to the aromatic series, and is called monococyl-metadihydroxyl-benzol.

These compounds exhibit hitherto unknown properties of refraction and fluorescence. The former appears yellow by transmitted light, and green by reflected light—that is, it looks like a brilliant yellow liquid with a bright green fluorescence.* The latter appears violet and green under the same conditions.

The first-named compound shows a remote resemblance to the substance known for some time past as fluorescin, but is distinguished from it by its ready solubility in water, and also by the fact that when treated with nitrate of silver it yields a bright red precipitate of nitrate of zirconethyl. Under the influence of the electric current it presents most interesting features. In a very weak solution, in a small glass tube hermetically sealed and submitted to an electric current, it changes its colour to blood-red, and shows a light blue fluorescence; the latter, says Dr. Morvan, is due to zirconium. On afterwards breakiug the tube and neutralising with a minute quantity of ammonia, the substance resumes its original aspect and fluorescence.

A weak solution of the monococyl-metadihydroxy-benzol, placed in a hollow prism, refracts light strongly; on its spectrum beiug thrown upon a screen, both colours of the fluorescence disappear. The zircon compound behaves in a similar manner. Removing the white screen and collecting the coloured rays by means of a lens—the rays thus collected now forming a simple ray—the latter, on being conveyed through a common prism, is spread out again into a spectrum, in which not only the fluorescent colours are wanting, but also their complementary tints. These are certainly most interesting properties, such as have never before been noted in any substance. But there are many other wonderful properties to which we have no space to allude here.—*Burgoyne's Monthly Magazine.*

Correspondence.

FLANGE SCREWS OF PHOTOGRAPHIC LENSES.

Sir,—At some meetings of a sub-committee of the Photographic Convention, certain sizes were suggested as standards for the flange screws of photographic lenses.

We, the undersigned, who were present at the meeting, with every desire to assist in the settlement of this important question, were convinced that the sizes arranged would not be universally adopted by the leading manufacturers. We felt, however, quite confident that it would be possible to arrange a series of flanges which could be adopted by ourselves, to which we could arrange to make all our lenses in the future, and which should also be of such a character that the majority of lenses now in the market should screw into them.

We are making careful investigation into the matter, and we have gone quite far enough to see that we shall be able to adopt such a series of sizes. Several important considerations are being carefully considered, amongst which may be mentioned the absolute necessity of arranging a series of diameters which are in suitable ratio to the dimensions to which the lenses themselves must be made. In order, therefore, to obtain standards that will be in future adopted by the leading makers, we are carefully arranging a series of sizes to which we shall work in future, and which we shall submit for the careful consideration of the Photographic Society of Great Britain, and the Photographic Convention.

THE CONVENTION VISIT TO OLD MORETON HALL.

Sir,—Many of your readers who propose visiting Old Moreton Hall during the Convention week will be greatly disappointed to find it undergoing a course of whitewash and tar. The creamy old plaster and woodwork are being daubed all over with glaring whitewash, and where the timbers and carvings come it is receiving a coat of tar on the top of that. I don't know if this piece of vandalism will be finished, and the scaffolding removed, in time for the Convention visits, but I thought it best to make known what is being done and what to expect. If the council can suggest some other of the fine old mansions with which the country abouuds as an alternative, it would be well. Richard Keene,

Dalby Cottage, Western Bank, Derby, June 14.

PASSING PHOTOGRAPHIC PLATES THROUGH FOREIGN CUSTOM HOUSES.

Sir,—About passing plates safely through foreign custom houses as well as our own. I have soaked off some safeguards from an old box. The plates should be in grooved wood boxes, with small squares of orange or ruby glass in the cover and bottom through which the officers can see that the boxes cannot contain cigars. I never had one opened.

Plaques photographiques. Si la boite est ouverte les plaques seront complètement perdues. Messieurs les officiers de la Douane sont priés d'avoir la bonté de regarder dans l'intérieur au travers des verres de couleur.

Vetri preparati per la fotografia. Se la casetta viene aperta i vetri sono intieramente rovinati. Si prega l'officiate della Dogana ad avere la bonta di osservare a traverso dei vetri colorati.

Photographic plates. If the box be opened the plates will be utterly ruined. The officers of the Custom House are begged to examine the inside through the coloured glass.

Those who take glass or films in ordinary card boxes must take also the consequences.

When will the dealers have the good sense to supply orange or red paper made adhesive for the repair of damage to boxes, camera-bellows, or tents, or for making a temporary changing place behind a farm window?

When will they have the sense to make grooving fit for modern sheet glass, with thin partitions, instead of going on for generations making grooves to take wet plates and plate glass?

For use abroad the boxes might be made much less in thickness to take each dozen. Now, four grooves go to an inch and an eighth. There ought to be six in that spacing. Compactness is tried for by grooves for ten plates each, back to back, a woeful business.

I have beautiful boxes made by Mr. Meagher for me to take abroad, with the partitions of vulcanite, I believe. But finer grooving might and ought to be made than the dealers give us still, and we put up with. J. J. Cole.

Mayland, Sutton, June 19th, 1890.

A PHOTOGRAPHIC SOCIETY IN CAMBERWELL.

Sir,—It has been suggested that a Photographic Society should be formed in Camberwell, and in furtherance of this a few amateurs residing in the neighbourhood have arranged to meet at the Stirling Castle Hotel, Church Street, on Wednesday, the 25th inst., to consider the matter.

With your usual courtesy, perhaps you will be able to find room in your valuable journal for the insertion of this letter, as no doubt some of your readers, amateur or professional, interested in the subject may be glad to know of the formation of such a society, and willing to promote it by attending the meeting. George C. Pike.

South Road, Camberwell, June 17th, 1890.

Proceedings of Societies.

London and Provincial Photographic Association.

At the meeting on the 12th inst, Mr. H. M. Hastings occupied the chair.

Mr. S. G. B. Wollaston spoke about a method of development, using first eikonogen to get detail, and then following it with hydrokinone to obtain great density.

The Chairman exhibited some platinotype prints, and also some prints on Pizzighelli paper; the latter he considered to be better prints than he usually was able to get on this paper.

Mr. J. S. Teape showed prints from the same negative by four processes. Aristotype, cold bath platinotype, Pizzighelli, and albumenised papers were used. Aristotype was slow in printing, but for detail and gradation of tone he preferred it to either of the other processes he had used.

Mr. W. E. Debenham said that, having regard to the question under discussiou—the printing process that best registered the gradation of a negative—he was in favour of a glazed surface paper, such as albumenised or aristotype paper. The majority of the members present were of the same opinion.

A point was raised whether the printing process that best rendered the gradation of a negative gave the most artistic effect. This led to some discussion, in the course of which various views were expressed on the subject, but no definite decision resulted.

Hackney Photographic Society.

Mr. A. R. Dresser read a paper on "Hand-Cameras" on Thursday last, the President in the chair. There was a good show of hand-cameras.

Mr. Dresser, who has taken over fifty prizes, brought a number of enlargements, and considerable time was spent in examining them. In addition to the cameras, the lecturer showed one of his own construction fitted with a Voigtlander wide-angle lens, which he preferred almost to any other; it gave sharp pictures. He used a shutter with which he could get auy exposure up to $\frac{1}{300}$ of a secoud, and could, moreover, use either roll-holder or plates at will without any extra trouble. He had taken a jumping dog with it, and other things equally fast, without the least sign of motion on the part of the subject. For plates he had used Paget's and Fry's, but preferred the new films of Eastman's, which he found faster than any other for negatives.

Dr. GERARD SMITH, the president, spoke of lightning marks in the latter, but was assured by the representative present that this had now been overcome, and was a thing of the past.

A number of lantern slides was put through the lantern, illustrative of Mr. Dresser's work.

Mr. ABRAHAM showed his newly perfected hand-camera, fitted with a Taylor lens and focussing arrangement.

THE SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE annual excursion took place on the 11th inst. to Bolton Abbey and Woods. By invitation a goodly number of members of the Rotherham Photographic Society joined the train at Masbro', leaving Sheffield Midland Station in suitable weather for the taking of pictures. On comparing notes, it was found there were altogether fifteen cameras which had been used, and about one hundred and forty-five plates exposed, and ten Eastman's films. After tea, several plates were exposed on the members and friends.

THE NORTH MIDDLESEX PHOTOGRAPHIC CLUB.

June 9th.—Mr. WALKER in the chair.

Mr. G. J. CLARKE delivered a lecture on "Photographic Optics," first speaking of the action of light when entering or leaving one medium of different density to the other, so as to make quite plain the reason of the action of lenses, and afterwards speaking of the defect incidental to different lenses, and the means by which they were overcome; he illustrated his remarks by means of well-drawn diagrams.

Mr. MCINTOSH wished to know if a stop placed behind as well as before a single combination lens would prevent distortion of marginal lines, and whether it would introduce other and more objectionable disadvantages.

The SECRETARY: Such an arrangement would prevent such distortion, but would cut off more than half the light, even with the largest stop, and with smaller ones the proportion would be much greater, besides which it would practically form a tube of the diameter of such stops, and of the length which separated them, thus allowing only a very small portion of the plate to be illuminated. As this would reduce the angle to a very small one, any picture taken with an ordinary landscape lens of the same angle would not show any distortion, and be free from the inconvenience.

Mr. GOODHEW: Would not sandwiching the new Jena glass, which is affected by the atmosphere, between two plates of other glass affect the optical properties?

Mr. CLARKE explained that allowances were made for such alteration.

On Monday, June 23rd, Mr. W. T. Goodhew will open a discussion on "Development."

LENSES.—A Correspondent of *The Beacon* (Chicago) says:—"My first portraits, and fairly good ones, too—I myself being the judge—were made with a lens ground from the bottom of a tumbler, and I have had landscapes in at least one exhibition taken with a 10-inch focus spectacle 'eye,' but, for all that, I generally carry a Gundlach and a Ross whenever I go out, and mean to add a Bausch and Lomb-Clark as soon as I can afford it."

BROTHERLY LOVE.—The Newcastle (England) Photographic Association sets a good example to societies generally in realising the beauty of the lines:

"Behold how good a thing it is,
And how becoming well,
Together such as brethren are
In unity to dwell."

Instead of the silly jealousy that too often obtains between the professional and the amateur, the members, mostly professionals, under the impression that the amateur was less able to pay his dues, resolved to reduce them by one-half for the purpose of bringing amateurs in in larger numbers. Is it any wonder, after this, that the Newcastle men are at the very top of the tree?—*The Beacon.*

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

J. E. D. (Huddersfield).—*Mode of Publication.* You might send prints to Messrs. Marion and Co., Messrs. W. and D. Downey, or to Messrs. Waterlow and Sons, asking their terms for publication. If neither of these firms will undertake it, you could get them reproduced in collotype or Woodburytype, and make your own arrangements for sale. Prompt action is desirable.

A. W.—*Maignen's Softening Water Process.* We find two patents credited to P. A. Maignen, of London; the first is for "Improvements in Filters," dated December 14th, 1887, No. 17,220; the second is for "An Improved Automatic Separator," dated March 28th, 1888, No. 4,760. Neither of these makes reference to a process of *softening*, but solely to methods of filtration through asbestos cloth and a series of conical perforated vessels. It is, however, likely that the employment of lime could be conjoined with the filtration system, and so a general purification result.

C. E. E.—*Ferro-Prussiate Paper.* The address of a maker has been sent to you by post.

SENSITISED PAPER.—Since writing to you last week all the rest of the paper has been printed, toned, and fixed without any other result than that already reported. Three more prints received.

H. S. (Antwerp).—*Pinhole Photography.* The most recent formula is that of Lord Rayleigh, who read a paper on the subject at the Newcastle meeting of the British Association. (See report in the NEWS of September 20th last, page 611.) The apertures worked were one-sixteenth of an inch for 9-feet focus, and it was stated that with a focal length of 66 feet the hole might be as large as the pupil of the eye. You might also refer to "La Photographie sans Objectif," by Captain R. Colson (Paris: Gauthier-Villars, 1887), which has for a frontispiece a view of the Dome des Invalides, taken at a distance of 100 metres on a gelatino-bromide plate in twenty seconds, with an aperture of 0·3 millimetre, and focal length of camera 0·13 metre. Mr. George Davison's pinhole photographs, shown at the last year's Photographic Exhibition in Pall Mall, were eminently satisfactory.

S. W.—*Tower of London Inscriptions.* Mr. Wm. Brooks has himself answered your point in his letter to the NEWS, page 466. At the Crystal Palace Exhibition last year a very complete series of the Tower of London, including many of the wall inscriptions, was shown upon the screen during several evenings, and excited a good deal of interest. Although Mr. Brooks tells us that his pictures are not yet published, it is well to know where they could be procured in the event of a demand arising.

P. M.—*Photography in Colours.* This question has been pretty well threshed out of late, and the conclusion seems to be that a very protracted exposure is required, without the possibility as yet of transferring the results to paper. Nor have we conclusive evidence that the coloured impressions are permanent, or bear free exposure to light.

EDGBASTON.—*Acid Toning and Fixing Bath.* When alum and hypo are mixed together in solution there is a slow decomposition, resulting in the separation of free sulphur, to which the toning is chiefly due.

H. H. B.—*Aristotype Paper.* It is advisable to separate the toning and fixing processes. For toning, use the chloride of gold with excess of chloride of potassium and neutralised with chalk. Fix afterwards with hypo or sulphocyanide. See pages 196, 288, and 368 of present volume.

A. M. M.—Your letter received. It requires consideration, and we will write to you in the course of a few days.

J. G. M. and others received.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1660.—*June* 27, 1890.

CONTENTS.

THE PHOTOGRAPHIC CONVENTION AT CHESTER.

LAST Monday evening the Photographic Convention began its 1890 meeting in the ancient city of Chester, and was warmly welcomed there by the Mayor, Mr. J. Salmon, and the Mayoress, who gave the visitors a reception in the Town Hall, and at the same time invited three or four hundred private guests to meet them. Floral decorations were profuse; the hospitality was upon no limited scale, and an official welcome was given by the Mayor in the assembly room in the building. Symptoms of pomp and state were visible, in the form of two doorkeepers, one bearing a sword given to the Corporation of Chester by Henry VII., and the other supporting a mace, or the mace supporting him. At the official welcome the Mayor said that it was his wish and intention to make an impression upon his Conventionalist visitors at that, their first visit to Chester, in order that they might have an opportunity of receiving them again. Mr. Andrew Pringle, the late President of the Convention, then resigned his office to Mr. C. H. Bothamley, and at the same time stated to the listeners that from his acquaintance, short as it had been, with the Mayor, and from what he had seen of his ability, business capacity, and hospitality, he was convinced that the inhabitants of Chester had acted most wisely in the election of the present chief magistrate of their city. The new President of the Convention then delivered his opening address, after which came a musical entertainment, in which Miss Annie Griffith, Miss Macdonald, Mr. Webster Williams, Mr. T. Muir, and others took part.

A display of photographs and photographic instruments was laid out in the Council Chamber, in which the chief feature of novelty was a costly and elaborate piece of photo-micrographic apparatus made by Mr. Swift by order of the Privy Council, and designed by Mr. Andrew Pringle; it was specially planned to secure freedom from vibration, and to give abundant means for adjustment. Of this instrument and some of the other apparatus we shall have more to say hereafter.

The visitors were highly pleased with their reception, and with the numerous photographic attractions of Chester. We asked the city surveyor how he managed to keep the mouldy old buildings from falling on the dwellers therein, and burying the latter in the ruins. He replied that he often had to condemn new houses, but not old ones, for jerry builders were unknown in early times; thus was this apparent marvel explained. He also informed us that some people in Chester had long had the idea which we mooted last week, that it would be well if there were a wide, clear space all round outside the old city walls, and that the houses of the new suburbs should not be built close up thereto; he added that one citizen was doing what he could, at his own expense, to improve the present state of things in the respect stated.

Last Tuesday morning there were excursions to Llangollen and to Moreton Old Hall; the latter was found to be under repair, and somewhat in the state described in a letter last week in these columns. The weather was fine, and the Llangollen party enjoyed their excursion over the hills exceedingly. In the evening the report of the Lens Standard Committee was read. Messrs. Dallmeyer and Beck gave data suggestive of an alternative or modified scheme, and the whole matter was referred back to the committee. There is a hope, and a somewhat prevalent opinion, that the opticians may come to some amicable and unanimous conclusion as the result of coming conferences.

On Tuesday evening, also, Mr. A. Haddon read a paper on "Lens Standards," and Mr. Gambier Bolton one upon "Animal Photography," in the course of which he projected upon the screen those pictures of wild beasts of which mention was made in these pages last week, in our description of the *conversazione* of the Royal Society. Among the photographs was one of the quagga, an animal now supposed to be extinct. Mr. Yorke took the negative long ago, and now will not part with it for love or money. Additional particulars will be found in the paper of Mr. Gambier Bolton, who is the delegate of the Camera Club to the Con

vention. Steps ought be taken to obtain a few of the the most indestructible and permanent positives possible from Mr. Yorke's negative. The quagga is an animal somewhat of the zebra type, but being heavier than the zebra, has been killed off first, as the area in which it lived with the lion and other carnivorous beasts became more limited by the extension of the bonndaries of civilisation. The unfortunate zebra will follow the quagga.

On Wednesday afternoon there was an excursion by steamboat up the river Dee to Eaton Hall, the seat of the Duke of Westminster, at which place some group photographs were taken. It rained throughout the whole trip; some of the excursionists were out in the rain in the stem of the little boat during the whole excursion, there and back; others were packed like sardines in the little cabin, in which also from fifteen to seventeen excursionists were obliged to stand up the whole time. A few tarpaulins, so disposed as to protect parts of the boat from rain, would have been a thoughtful precaution, if no better means were available.

On Wednesday morning the annual meeting of the Convention was held in the City Hall, and a regulation was made to increase the number of provincial members on the council. It was also settled that the next meeting of the Convention should be held in Bath, that is to say, the 1891 meeting. On Wednesday evening Mr. Andrew Pringle read a paper by Mr. P. H. Newman on "Imagining and Imaging;" this was followed by one by Mr. C. H. Bothamley on "Orthochromatic Photography with Rhodamine," and with another by Mr. Paul Lange on "Photography in Norway."

Yesterday, Thursday, the chief excursion was to Conway, under the guidance of the President of the Convention. Views of the exterior of Conway Castle were taken, and then of the inside, after which the whole party, including Mr. Pringle, the ex-president, and Mr. Ting Fan Chang, secretary to the Chinese Embassy, lunched at the Castle Hotel, a well-known home of art, belongiug to Miss Dutton, and containing antique furniture which once belonged to Louis Phillippe; also paintiugs by some of the best artists of modern times, and some rare specimens of Venetian glass. Mr. Briginshaw photographed the whole party at the luncheon table. Plas Mawr, an old mansion in Conway, built in the days of Edward I., was next visited, and photographs taken therein of Queen Elizabeth's room by Mr. Briginshaw and Mr. Watkins; the latter made use of his new exposure meter for the purpose. The annual exhibition of the Royal Cambrian Academy of Arts was going on in the building, and included paintings by Sir Frederick Leighton and others. Some of the grand old chimney pieces of Plas Mawr were draped for the purposes of the exhibition, so could not be photographed. The members of this excursion party returned by separate trains, as some would not leave at the appointed time to listen to the reading of papers at Chester in the evening.

PERCENTAGE OF FAILURES.

If all photographers were as careful to call attention to their spoilt plates as they are to their successes, we should be better able to appraise their capabilities than we are at present. We speak more particularly of outdoor work—for in a properly conducted studio, where the operator is able to guage his exposures to a nicety, and where a developer of definite and unvarying composition may be reasonably expected to bring about a certain result, spoilt plates are few and far between, although there must always be a percentage of failures—to please patrons and from other causes which are not altogether under the control of the worker.

With out-door work it is different. In one respect the worker of bygone days, with his cumbrous impedimenta and his wet plates, was better off than his successor of to-day. It was incumbent upon him to develop his plate immediately after exposure, and although this entailed the use of a dark-room or tent, and a druggist's shop full of chemicals, yet the trouble involved had the compensating advantage of informing him at once of his success or failure. If the former, he departed on his way rejoicing, and if the latter, another plate was collodionised there and then, and the exposure was repeated. There was also some satisfaction in the thought that he knew the history of his plate, for he had cleaned the glass, had possibly prepared his own collodion, and knew that the bath which he had so carefully compounded would not play him false. He knew, too, that a trifling error of exposure one way or the other could be readily corrected during development and intensification.

The modern dry-plate worker, on the other hand, has many pitfalls into which he is apt to fall unless he is constantly on the alert. He does not make his own plates—except in rare instances—but he knows that he can rely upon well-known brands for uniform excellence. In the early days of the gelatine process complaints of plates which frilled and displayed other disagreeable defects were rife, but these faults have almost entirely disappeared, and it is quite an exceptional thing to meet with a plate which does not give fair results. The only danger to which the purchaser is liable is that of meeting with a box of stale plates. This has once or twice occurred to us when we have purchased in country districts, where there is not as yet a large demand for such goods, but never when we have been able to obtain the plates direct from a London warehouse. Such plates tell their own tale by general insensitiveness, by mottling, and still more conclusively by the metallic stain which forms a border round their edges, and which is plainly seen after development by reflected light. It is true that the stain will give way to alcoholic treatment, or to a weak solution of the ferrideyanide reducer, but its presence is as the wrinkle of old age, which brings other troubles in its wake.

The pitfalls to which we have referred have not, however, to do with faulty plates, but are brought about generally by the carelessness or ignorance of the worker himself, and it is according to his success in

steering clear of them that his capacity may be gnaged. If it ever fell to our lot to choose a good worker from a number of applicants, we should not dream of submitting them to the ordinary ordeal of a competitive examination by means of written questions and answers. In spite of the universality of this custom, we are certain that it does not bring the best men to the front. Those with the best capacity for cramming, and who have the most retentive memories, are those who win, while the man with the creative brain, and who has power at his finger ends instead of book knowledge, is left far behind. Our plan would be to give each man a packet of, say, four dozen plates of a recognised brand, and to turn him loose with his camera in a certain district or county. He who produced from those plates the largest percentage of good negatives would be the man for us, supposing that in other respects he was not objectionable.

But what percentage of failures by the ordinary worker may be considered allowable, and to what causes are those failures mainly attributable? Most of our readers know by experience what it is to start on a photographic trip with several dozens of dry plates, with anticipations respecting those articles which are seldom realised. We pass by the common losses caused by injudicious exposure, for these faults are generally attributable to want of experience, and the remedy is obvious. Now and then an old hand is caught napping, and over-exposes a plate, not by error of judgment, but because he forgets to insert in the lens the particular diaphragm which he had intended to use. He will not fall into this error if he is careful to let the various operations of focussing, exposing, &c., follow in regular order, and more especially if he makes it a rule to examine the picture on the ground glass while the lens is provided with the same stop that is to be used for exposure. The experienced man will always do this, for he knows that he can judge of the exposure necessary far more accurately by examining the picture in this way, and noting the amount of illumination which it has, than he can by the best tables which were ever conceived or constructed.

Another accident by which a negative is often rendered useless occurs when it is necessary, in consequence of the position of the sun, to shade the lens. We are in favour of using a properly constructed shade for the lens under all circumstances, but usually the hat does duty for want of something better; and too often its rim will cause an unlooked-for eclipse of the upper part of the picture. The negative from which the greatest results were anticipated is generally the one which exhibits some vexatious freak of this kind, and the uninteresting one, which might be spared, remains perfect in every respect. Other accidents are in many cases due to the over-elaboration of construction which distinguishes modern cameras. Working with one of these instruments lately which was provided with every conceivable movement, we noticed that one or two of our pictures were quite out of focus, although we had taken every precaution to see that the image was sharply defined on the ground-glass previous to exposure. We traced the fault to the loosening of certain screws which control the to-and-fro movement of the back of the camera—a movement, by the way, which is never required except in the case of a lens of abnormally short focus. The mere act of drawing the shutter of the dark slide was sufficient to disturb the position of the camera-back, with the result described. A certain proportion of negatives are commonly lost by the superposition of one image on the top of another, by access of light during changing, and by entry of light through faulty cameras and dark slides. A small number are also lost by beginners who often forget to draw their shutters, and the plate remains unexposed. All these pitfalls assail the photographic worker, and he must be looked upon as uncommonly successful if his failures amount to as little as ten per cent. We know that there are numbers who will tell us that they never go wrong, and that if they take out with them fifty plates, they will bring back fifty faultless negatives. We have found that such boastful beings produce negatives which are faultless only in the eyes of their parent.

PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.*

PRESIDENTIAL ADDRESS BY C. H. BOTHAMLEY, F.I.C., F.C.S.

At our meeting last year we were celebrating the jubilee of the photographic negative, and my predecessor in this chair very fitly devoted the greater part of his address to a summary of the history of photography during the past fifty years. Although, as you will remember, that address had a somniferous effect on the delegate from the Leather Bellows Club, the rest of us listened with much interest to the admirable account of the rise and development of photography which was laid before us. The events of a year usually require much briefer treatment than the events of half a century, and a review of the progress of the past twelve months is unfortunately made easier by the fact that little, if anything, of first-rate importance has been done. No discoveries or inventions of far-reaching influence have startled the photographic world.

Much interest has been excited by the announcement that an Austrian, Herr Veresez, had made a decided step towards the solution of the problem of producing photographs in natural colours. It is understood that the method is based on Carey Lea's researches on the photo-compounds of silver, and that it differs from earlier methods in that the sensitive material is used in the form of an emulsion. How far the results are in advance of those obtained by previous experimenters is a point on which there are differences of opinion. It seems practically certain that, at any rate, some improvement has been made in the permanence of the images, and we shall look forward with much interest to the results of further experiments by the same worker.

This problem of photographing objects in their natural colours is of very great interest. It seems to be the one thing on which the non-photographic public has set its heart; nor are photographers lacking in enthusiasm. How far these desires are likely to be realised we cannot tell. More or less imperfect photographs in colours have often been obtained, but they are not capable of multiplication in the way in which we make hundreds of prints from one and the same negative. Whether we shall ever obtain a chromatic negative process is at present merely a matter of conjecture; we can only say that the direction in which the solution of the problem is to be looked for is not yet apparent.

In dealing with another difficulty—the proper monochro-

* Read at the Photographic Convention at Chester.

matic rendering of coloured objects—we have made much greater progress. No marked advance, however, has been made since last year, and the general adoption of orthochromatic methods is impeded by the facts that their successful employment, especially for outdoor work, necessitates certain modifications in well-established methods of working ; that the preparation of the plates involves some manipulative skill and acquaintance with the selective sensitisers to be used ; that it is not at all improbable that a sensitiser with a similar name, but of greatly inferior power, will be used unless great care is taken in purchasing the materials ; that the commercial products upon which many have to depend do not at present represent the maximum possibilities of the methods. Nor is this true only of this country. Examination of many reproductions of pictures shows that some Continental workers have not obtained complete mastery over the capabilities of the processes, even for the particular class of work in which their advantages were most quickly recognised. The whole question of colour, physical and physiological, scientific and artistic, is very complex and difficult. Accurate knowledge and conceptions are comparatively recent acquisitions, and it is therefore not surprising that in the practical treatment of its various problems progress is somewhat slow.

Development and developers have, as usual, attracted much attention. Eikonogen has gradually obtained a firm hold as a useful addition to our developing reagents, its special value lying in the fact that it enables us to obtain well-gradated negatives where other developers would be very liable to give excessively strong contrasts. It follows that in dealing with very short exposures eikonogen is of the greatest service. In portraiture also it gives very fine results.

Catechol or pyrocatechin has not been fully investigated, partly on account of its high price. Quite recently, however, Dr. W. H. Perkin, jun., has described a ready method of preparing it from guaiacol, an allied substance much lower in price. In this connection it is interesting to note that Colonel Waterhouse has recently shown that guaiacol itself is a developer, though it does not possess any exceptional powers.

One very important fact in connection with the principles of development has been established by Mr. Lyonel Clarke in the course of his elaborate experiments on different developers, and has been confirmed by later experiments of my own made for quite another purpose. It is, that the maximum sensitiveness that a plate will show—in other words, the maximum detail obtainable for a given exposure—is the same for all developers, and for all variations in the composition of one and the same developer. Different developers differ, however, very considerably in the time required to make the maximum detail visible, and it follows, of course, that the gradations of the resulting negatives are very different. That, in a word, is the nature of the difference between developers—a difference in gradation, and not in the maximum detail obtainable, provided that the action of the developer is continued for a sufficient length of time. Recent papers contributed to the Photographic Society by Abney, and to the Society of Chemical Industry by Hurter and Driffield, are worthy of careful study in connection with the question of development.

Photo-mechanical printing processes have made no remarkably new departure, but their applications continue to increase. Cheap illustrated papers, and a great increase in the number of the illustrations in magazines of all kinds, constitute unmistakeable evidence of the usefulness of these processes. Without photo-mechanical printing, a paper like the *Daily Graphic* would be impracticable.

Chromo-typogravure, which produces the fine results seen in *Figaro Illustré*, and chromo-collotype, which as yet is not often seen in this country, produce results in many respects superior to those of ordinary chromo-lithography. They are at present our furthest advance in the photographic production of coloured pictures. Colour printing with photogravure, I may perhaps remind you, will reproduce water-colour drawings with a fidelity so great that it may deceive even the artist of the original drawing.

The applications of photography to scientific purposes become every day more numerous and varied, and I do not hesitate to say that it is in this direction that photography has won, and probably will win, its greatest triumphs. Here it is without a rival or competitor, and does services which nothing else is capable of doing. As a method of fine art it occupies, and probably will always occupy, a subordinate position.

In no branch of science have the photographic results been of greater importance than in astronomy. Mr. Ainslie Common, encouraged by his great successes with his big three-foot reflector, has constructed and set up in his observatory at Ealing a magnificent five-foot reflector, in almost every respect the most powerful and most perfect telescope that has ever been made. It was designed and erected especially for photographic work, and its performances will be watched with great interest. You will, I am sure, share my pleasure in knowing that Mr. Common has very kindly promised to give us, at our meeting next year, an account of the later developments and results of astronomical photography. Mr. Isaac Roberts, with a much smaller reflector (twenty inches) at his private observatory at Maghull, near Liverpool, has produced some of the most remarkable photographs that have yet been done. Some of these I am fortunate enough to be able to show you, and I would especially call your attention to the wonderful photograph of the great nebula in the constellation Andromeda, which shows that in this nebula we have a new Saturn in the actual process of formation. The condensed central mass, and the system of long oval rings surrounding it, can be very clearly seen. Of the important bearing of this result on the nebular hypothesis I cannot here speak. It must be a source of great satisfaction to all photographers to know that Mr. Roberts's splendid work, like that of Mr. Common before him, has this month been awarded the blue ribbon of science—the Fellowship of the Royal Society.

A very remarkable recent result is Professor Pickering's discovery that a certain star is really a double star with its components too close together to be resolved by telescopes. The discovery was the result of observations on the variation in the definition of photographs of the spectrum of the star.

Mr. Andrew Pringle will tell us that photography has its triumphs in dealing with the minute as well as with the immense, and some of those triumphs he will bring before us during this meeting.

Amongst other things, photography has been largely and systematically applied to the study of lightning, and by Lieutenant R. Abercromby to the study of clouds and meteorology ; by Lord Rayleigh to the study of the effects of electrification on jets of liquid ; and by Mr. C. V. Boys to the investigation of falling drops of water. Mr. Friese Greene will describe to us a new form of magazine camera which he has invented, and which is especially suitable for investigations of the kind to which I have just referred. An account of Mr. Muybridge's work we heard from his own lips last year, and this year Mr. Gambier Bolton is to tell us of the results which he has obtained in applying photography to the study of animals from a different point of view. There is, in fact, no branch of natural science in which photography is not rapidly becoming indispensable.

If the applications of photography to science have been numerous and successful, the same cannot be said of the applications of science to photography. Most of the problems awaiting solution at our last meeting still remain unsolved. The careful experiments of Mr. Chapman Jones have given us accurate knowledge of some aspects of mercurial intensification, but of the real nature of the latent photographic image, of the change which silver compounds undergo when exposed to light, and of many other reactions which underlie some of our most important processes, we are still almost entirely ignorant. The reasons are not very far to seek. The investigators in these subjects throughout the whole world at the present time may almost be counted on the fingers. I say *investigators* designedly ; of experimenters of a certain kind we have enough and to spare, but of competent investigators there are very few indeed. The fundamental problems to which I have referred are very complex and difficult, and their investigation requires a knowledge of chemistry and physics much greater than is usually possessed by photographers, and, on the other hand, a

better practical acquaintance with photography than competent chemists and physicists usually have. Further, they involve many micro-chemical and electro-chemical changes with which we are at present imperfectly acquainted. In the less difficult questions of *technique* and processes, the relative merits of different modes of treatment and the like, we might have expected to find more satisfactory progress; but here also we have made no great advances. From time to time, it is true, papers appear in the journals recording so-called experimental investigations of the action of various developers, relative sensitiveness of different plates, and similar matters. In not a few instances they leave us just where we were. So far as the advancement of photography is concerned, they represent merely so much wasted time and wasted material—wasted because, for want of attention to some indispensable conditions, neglect to eliminate important sources of error, want of distinction between several possible causes, and the like, no definite conclusions can be drawn from the evidence offered. The enthusiasm of the experimenters is undoubted, and if a thirst for notoriety is not always invisible, we may take it that a desire to advance photography is their chief incentive. Why, then, do their efforts so often lead to nothing? Chiefly from a want of training in the art of experiment; from want of acquaintance with the scientific method. A really good experimenter is a rarity; an accurate observer must be both born and made, and is a still less common species. With very rare exceptions indeed, the scientific method, which includes not only the arts of experiment and observation, but also the power of properly co ordinating the facts, and of making accurate deductions from them, is only to be acquired by careful and long training. Such training, it is a mere truism to say, very few photographers have had, but to it we must undoubtedly look for our future progress.

I do not, of course, mean that good work cannot be done in photography unless a man has a profound acquaintance with chemistry and physics. I see before me a sufficient number of living examples to at once disprove any such assertion. The scientific method lies not in the matter, but in the manner. It would be out of place here to attempt any definitions or illustrations of what the scientific method really is. We might define it negatively as that which is usually absent in photographic experiments, but that would not take us much further. One of the most important characteristics of the scientific method is great reserve and caution in making deductions; one of the chief characteristics of not a few so-called photographic experimenters is a fatal facility for making hasty and incorrect deductions from imperfect data. No stronger proof can be found of the fact that photography is comparatively in its infancy, that its fundamental principles are not generally understood, than the rubbish which is sometimes brought before photographic societies in the form of papers—papers which even now and again escape the waste-paper baskets of the photographic journals. This latter catastrophe, of course, only happens when the editor is away on a holiday. Similar productions are characteristic of all crafts or arts which are still carried on largely by rule-of-thumb; they would not be tolerated in societies of a truly scientific character, or in an art which was really carried out on scientific principles.

Photography has an artistic as well as a scientific and technical side, and if I have not unnaturally dealt with the scientific questions first, I do not forget that the majority of photographers regard the artistic aspects as the more important. In the artistic development we may, I venture to think, congratulate ourselves upon steady and well-founded progress. Argument as to whether photography is or is not a method of fine art is no longer necessary. Its place has been taken by discussions, often of an animated kind, between the different schools of photographic artists—naturalisties, naturalists, realists, and the like. Very few who are competent to deal with the matter now refuse to admit that, in the hands of a man of artistic temperament and training, photography may be a method of pictorial fine art just as much as mezzotint or sepia. We shall all admit that the possession of a camera and lens will not make a man an artist; neither will the possession of a palette and a box of paints. It is also true that a very large majority of the photographs which we see are far from having any claim to be regarded as works of art, but is that not also true of the bulk of the paintings which are produced? Fine art, I take it, lies not in the method, but in the use of it; in all cases it is the man, not his medium of expression, that determines the result.

In 1873 Mr. P. G. Hammerton, the well-known art critic and editor of the *Portfolio*, very clearly and tersely summed up the case against the claims of photography to rank as a method of fine art. "(1) It is false in local colour, putting all the lights and darks of natural colouring out of tune. (2) It is false in light, not being able to make those subdivisions in the scale which are necessary to attain relative truth. (3) It is false in perspective, and consequently in proportions and forms. (4) Its literalness and incapacity for selection and emphasis are antagonistic to the artistic spirit."

Most of this was true enough seventeen years ago, but we have advanced a little in our knowledge of science and art since then. Falsity in local colour has almost disappeared before the development of orthochromatic methods, the principle of which was discovered in the very year in which Mr. Hammerton wrote. Falsity of light arises mainly from the use of plates of unsuitable quality, and from imperfect knowledge of exposure and development on the part of the operator. Falsity in perspective and the proportion of forms is entirely a question of the proper or improper use of lenses, and need not exist at all. Literalness and incapacity for selection and emphasis are defects in the photographer more than in photography. How far we have advanced in this direction I will bring to witness, if not Mr. Hammerton himself, at any rate Mr. Hammerton's paper. In the January number of this year, speaking of the photographs which illustrate Miss Agnes Giberne's book, "The Ocean of Air," the *Portfolio* says, "But what it concerns us to observe is, that though they are merely literal transcripts from nature, and no other artistic faculty than that of selection has been exercised in their production, this faculty alone has sufficed in several instances to produce genuine works of art. If an artist were to take, for instance, the "Trees in a Mist," photographed by Mr. Sutcliffe, of Whitby, it is not too much to say that he would find it difficult to improve the composition, or to alter a single line for the better."

In their assault on the fortress of art, photographers have already carried the barbican, and many may be found in the outer ward. A few have even forced their way into the inner court, but the keep remains in the hands of the painters and sculptors, and in their hands, I doubt not, it always will remain. Every method of fine art has its limitations, and in the case of photography these limitations are, in many respects, more severe than in any other method. I, for one, accept Mr. Ruskin's *dictum* that every true work of art shows distinctly the method by which it has been produced, and that its character and possibilities are largely determined by the method. I have little sympathy with those whose chief anxiety seems to be to make their photographs look like something else. I believe that if photography is to maintain the position it has already won, and is to make further advances as a method of fine art, we must not only be fully acquainted with and make the most of its capabilities, but we must also quite clearly recognize its limitations. We must be content to admit that there are certain classes of subjects which come rightly within the scope of the painter, but are unfit for treatment by photography. In our appreciation of a picture we cannot forget the method by which it has been produced; and when, for example, you see a photograph professedly of an incident which took place before photography was invented, the unreality and want of truth is too prominent. You are unable to rid your mind of the idea that, after all, it is only a literal representation of a group of models. When, too, we see photographs which profess to represent those human emotions which we commonly hold sacred from intrusion, a sense of unfitness more than counterbalances any pleasure arising out of mere technical artistic skill. All this has been pointed out before, more appropriately and with much greater force, by the *doyen* of photographic artists, Mr. H. P. Robinson. Latterly in America they have very largely

developed the practice of photographic competitions, prizes being given for the best set of photographs illustrating some poem or part of a poem or story; and to some extent the practice has, unfortunately, like the potato beetle, spread to this country. If the subjects are properly chosen, with due regard to time and place, such competitions may not do any harm, though it is contrary to experience to expect that any real fine art will be developed in such a manner; but when the outcome is photographs of such scenes as a girl in agony by the deathbed of her father, done, of course, with the help of models—to take only one example out of those which you may see in the American magazines—it is an outrage upon one's sense of the artistic fitness of things.

Even where groups of figure studies of the class to which I am referring are successful, the result is often due to the models quite as much as to the photographer. He has to be content with the best he can make of them; he cannot with his camera alter lines and expressions as a painter can with his brush. In the hands of a few masters, pictures of this kind are undoubtedly often successful; but in the greater number of instances they are not at all pleasing to anyone but the photographer and the models, and sometimes not even to the models. I hold that in the interests of photography as a method of fine art, it is to be regretted that photographers do not chiefly confine themselves to the classes and subjects that photography can deal with excellently, instead of striving after effects and results which, from the essential limitations of the method, are a severe strain on its capabilities. What class of subjects, you may ask, do I regard as proper to photography from the artistic point of view? I would reply, portraiture pure and simple, with studies of figures in costume, and groups, if you like, provided that they are put forward as such; landscape and seascape, in which figures are either subordinate or absent altogether. At the risk of making invidious distinctions, I would cite Wellington's "Eventide," Mayland's "There is Sorrow on the Sea," Gale's "Sleepy Hollow," many of the studies of Sutcliffe, and many of the landscapes of Green, as examples of the class of work which seem to me to show photography at its best. Someone may raise the old objection that in dealing with pure landscape and seascape you have not sufficient human interest; you can only represent the literal beauty of your subject, and have no opportunity for the idealisation which some hold, though others do not, to be essential to all fine art. I decline to accept the dogma; but, even if it were true, I would reply in the words of Fra Filippo Lippi:—

> "If you get simple beauty, and nought else,
> You get about the best thing God invents:
> That's somewhat; and you'll find the soul you have missed
> Within yourself when you return him thanks."

What can be done to promote the advance of photography, scientific and artistic? The development of a desire for better training, and the provision of means to satisfy the desire. Here, as in many educational matters, we are behind our Continental competitors. Germany has long had an efficient school at Berlin, under Professor H. W. Vogel, and there is a well-known school of a more technical character at Schloss Grönenbach, under the direction of Herr W. Crönenberg. Zurich has a new photographic laboratory full to overflowing. Austria has its new and splendid Photographic Institute, with abundant accommodation, and a large staff of teachers under the direction of Professor Eder, and they attract students not only from all parts of the Continent, but also from England and America. Here in this country we have the schools at the Polytechnic and the Birkbeck Institute, and in various science and University Colleges up and down the country instruction is given in the principles and practice of photography, but all of them together are scarcely equal to the Institute at Vienna, and they confine their attention almost exclusively to teaching, doing but little in the way of research. In America they are not even so well off as we are. So far as I can learn, there is only one school of any importance, that at Chatauqua, and I am informed on very good authority, that very little desire is shown to take advantage of the instruction offered, and that the school is only kept alive by the energy and self-denial of its teachers.

It has been proposed to found a Photographic Institute in this country, and we shall all be agreed that, founded on a right basis and conducted on right lines, it might be of incalculable benefit to photography. Founded on a right basis and conducted on right lines—that is the essence of the whole matter, so far as possible success is concerned. An Institute of Photography, I take it, should teach, and examine, and conduct original research. It might possibly also act as a court of arbitration in disputes involving technical matters, but the advancement of photography in all its branches and aspects, by teaching and research, should be its chief business. It should be thoroughly, though not ambitiously, equipped; it must be free from connection with commercial interests of any kind; above all, it must be free from the immaturism which so often clings round present-day amateurism.

Whether, when all these conditions were fulfilled, it would attract a satisfactory number of students, is a matter of conjecture. We English are slow to avail ourselves of our advantages in matters educational, even where the knowledge to be acquired has a direct monetary value. The experience of existing schools is not altogether encouraging, but the prestige which would attach from the beginning to a properly equipped institution especially devoted to photography would probably do much. The standard of every-day requirements in photography is gradually being raised, and there is little doubt that better instruction will be necessary to produce and maintain the higher degree of skill demanded. One thing is certain, that when the establishment of such an institution comes within the sphere of practical politics, the members of the Photographic Convention will not be backward in their support of it.

After all, the real progress of photography depends no more on institutes than the progress of civilisation and human knowledge depends on Acts of Parliament. The welfare of a community depends on the conduct and character of the individuals composing it; and the progress of an art or craft depends on the skill, the thoroughness, the enthusiasm of the individuals who practise it. We, as a Convention, are banded together to advance the interests of photography, and all that appertains thereto. As a Convention, we are endeavouring to justify our existence, and in some measure, at least, we are succeeding; but whatever we may do as a body, we have each an individual responsibility, an individual duty, towards the art which we practise—to see to it that our own work, be it much or be it little, is honest and thorough, the best that it is in us to do. Am I not right in holding that the spirit which should animate every follower of the photographic art is the spirit which inspired the poet when he wrote—

> "In after days, when grasses high
> O'er-top the stone where I shall lie,
> Though ill or well the world adjust
> My slender claim to honoured dust,
> I shall not question or reply.
>
> "I shall not see the morning sky;
> I shall not hear the night wind sigh;
> I shall be mute, as all men must,
> In after days!
>
> "But yet, now living, fain were I
> That some one then should testify,
> Saying—'He held his pen in trust
> To Art, not serving shame or lust'
> Will none?—Then let my memory die
> In after days!"

MESSRS. KEGAN PAUL, TRENCH, TRÜBNER, & Co., have published "Practical Notes on the Preparation of Drawings for Photographic Reproduction, with a Sketch of the Principal Photo-Mechanical Printing Processes," by Colonel J. Waterhouse, B.S.C., Assistant Surveyor-General, India. This work was originally published, it is said, in 1887 as a series of papers in the *Indian Engineer*, with the object of bringing together the results of long experience in preparing maps and plans for reproduction by photo-zincography; but the scope of the volume, which is divided into eight chapters, with an addendum, has been extended to include drawings of all kinds, supplemented by information gleaned from the few authors who have written on the subject.

PAINTINGS AT THE GOUPIL GALLERY, NEW BOND STREET.

BY REV F. C. LAMBERT, M.A.

Messrs. Bousson, Valadon, and Co. have now on view two series of paintings, both of which are of some peculiar interest to those concerning themselves with current art. The first is a set of water-colour drawings by Madeleine Lemaire, illustrating "Flirt," the latest novel by Paul Hervieu. The series comprises some thirty-six small pictures, separately framed, the chief feature being the semi-decorative floral border, which strongly reminds one of a certain style of photo-album. While admitting that the artist has executed these floral edgings in many cases with conspicuous skill, yet it is a question of some importance for artists of all sorts—including photographers—as to whether any such decorative work is, or is not, out of place around figure studies. Three larger pictures are free from this question. One of these three (No. 39, "Melancolie") and one of the smaller ones (No. 11, "Poste Restante") show how the artist can manage the play of light in and out the folds of crimson plush. As this is a material which presents some difficulties to the ordinary photographer, he would do well to study these two, and also look at many of the others, as they contain for him numerous hints as to the arrangement and pose of people in modern costume.*

The second series comprises thirty-one "oils by the veteran Russian artist, Ivan Aïvasovsky. It is interesting to know at the outset that all this series have been painted after the fifty-second anniversary of the artistic career of this artist celebrated at St. Petersburgh in 1887. Space does not permit much detailed criticism of the various paintings. The general impression conveyed by them is that they most probably represent climatic conditions which are exceptional, and outside the usual experience of English eyes. In several instances they remind one very strongly of some of the Norwegian and Swedish painters. Every one visiting this room will be struck with the large size of No. 10 ("The Supreme Moment"), a shipwreck scene in mid-ocean, with waves rolling mountains high," depicted on a canvas of Dorè-esque proportions. It has some fine colour passages; some of the water looks *very* wet, cold, and transparent, but without saying such mountain billows do not exist in extreme cases, it may be questioned whether those who ever have been in such peril as herein shown, would be sufficiently reliable evidence for the construction of such proportions as are admittedly of extremely rare occurrence.

In Nos. 11 ("Bather") and 17 ("Dead Calm") clouds are shown which, in this country, do not usually take that shape so near the horizon.

Nos. 19 ("Sea-Piece") and 21 ("Night Effect") gave an impression of a want of some stronger skylight with such vivid reflections.

The two skylights in No. 18 are rather puzzling.

Nos. 14 ("Argonauts") and 16 carry us into the region of speculation. In No. 14 the chief feature of interest is cut into by the frame. In No. 16 ("Destruction of Pompeii") the spotty lights in foreground and streaks in sky are painful reminders of defective emulsion. In No. 26 the sun, or full moon, whichever it may be, seems of an unusual shape.

One may often see the sun's disc when low down and near the horizon, apparently compressed vertically into a shape somewhat elliptical, but the sun in No. 26 does not seem to have been affected quite in this way.

All the pictures are, undoubtedly, well worth careful inspection, even if only to teach us English folk that our way of seeing and doing is not the only way—not even necessarily the best way.

* For an article on this artist, consult *Art and Letters*, December, 1888.

IMAGINING AND IMAGING.*

BY PHILIP H. NEWMAN.

I suppose it is pretty generally admitted now that photography, within certain well-defined limits, is a legitimate means of artistic expression, and in spite of mutterings and echoes heard from time to time to the contrary, statements that the various scientific processes by which light becomes an image maker, "only serve to degrade nature," are not seriously maintained in the face of demonstrations that such results, when they occur, are due to the want of ability on the part of the photographer, shown in the selection of his subject or the choice of his implements. A further proof of the alliance between fine art and photography is the increasing desire of photographic societies and conventions to leaven the purely scientific with the purely artistic, the materialism of lenses and chemicals with the emotional and the æsthetic. And here I may be permitted, perhaps, to acknowledge the great compliment that has been paid me in being asked to address you on these latter subjects. I am the more stimulated to do so, however, from feelings of gratitude as an artist for the benefits and assistance photography has conferred upon me. It has been argued that scientific studies and the exercise of optical and mechanical processes are not expected to be found side by side with that divine afflatus which should pervade the artistic nature—in a word, that photographers have no imagination. I can only conceive of this as a jest, and must treat it as such.

It is true, personally, I can only allude to my photographic capacity as of the humblest, although I have succeeded in imaging now and then all I have focussed, yet I am entitled to bear witness to a phenomenon of the dark room, which makes it at once a great school of imagination. I know of no exercise of imagination my mind has undergone equal to that experienced when developing a plate, as to how the latent image would turn out; and I will even confess, although I never thought to do so even to my bosom friend, in the dark room, that my imagination has begun to develop the image when no chemical formula would do it. I need not tell you, who have doubtless in your time undergone this hallucination, that no hypo would ever fix the picture. But to be serious, we have all of us imagination, and it will grow and bear good fruit if we will allow it, enriching the gardens of our minds, and making pleasant avenues for art to linger in. Our great danger is, undoubtedly, that science and dry fact will tend to dwarf and kill our imagination, especially if, moreover, we encourage that pernicious vice of looking at everything *only* through the camera.

Photography has been working amongst us, as Mr. P. H. Emerson says, "for fifty years for better or for worse," and I am afraid, if I believed in everything or much which he has written, I should have to admit "for worse." I should have to say to you to-day, gentlemen, when Daguerre addressed that meeting of the French Academy on the 19th of August, 1839, and showed it the hitherto fugitive image fixed in a picture of silver, he sounded the death knell of fine art; but I do not believe in all Mr. Emerson has written, and fine art is reprieved.

It is not my intention to drag you page by page in a review of the book I allude to—"Naturalistic Photography"—or that portion of it which relates directly to fine art, most of which you have, doubtless, read; I shall only have occasion to touch upon it here and there. My only reason for mentioning it at all is, that enthusiasm for one branch should be without prejudice to the whole tree. One aspect of fine art does not necessarily cover the entire field, though the solemn and authoritative *dicta* of this book would imply that it did. No-

* Read at the Photographic Convention at Chester.

thing that comes within Mr. Emerson's purview that is not naturalistic in art is to be tolerated, and unless you focus the subject, so to speak, with his lens you must be wrong. As tastes for ever vary without being necessarily bad, this contention is surely inartistic and illiberal.

In a chapter devoted to "Naturalism in Pictorial and Glyptic Art," Mr. Emerson careers through the schools, from Pharaoh in Egypt to Reynolds in Leicester Square, from China to Bouverie Street, from Japan to the Royal Academy; with the touch of a magician's wand, with the stroke of a pen, with a few dozen pages acutely sensitised to the true impressions of art at all periods, this book disposes of the whole question. The *cognoscenti* and the *savants*, the art critics of ancient and modern times, have indeed lived in vain; their writings, with little exception, can be shown by the fierce light of naturalism to be so much waste paper, that ought, of course, at the earliest opportunity, and in the eternal fitness of things, to crumble into dust—that dust which has been cast into the eyes of an hitherto misguided world. Mr. Emerson falls into ecstacies, however, over Egyptian lions, and discriminately tolerates some Assyrian ditto. Touching Greek art with a light hand, he points out with satisfaction that Appelles' greatness was due to his imitation of nature, and that previously Apollodorus was the first true painter, but "that the innovations made by him in the relation of foreground and background cannot be compared to the improvements effected by the Brothers Van Eyck in modern times." This is a far cry, and I dare say the Brothers Van Eyck and Appollodorus would be as astonished as we are at the comparison. Mr. Emerson recommends the frieze of the Parthenon to our notice, and lingers awhile among the Romans, admiring particularly the heads of Nero of Commodus in the British Museum. Riding his hobby of naturalism at a canter through Pagan times, he pulls up with the horse of Seleue, bowing his compliments to the Greeks for the height of their horizon, and whom, it is refreshing to find, he considers "very advanced."

We then find ourselves with Mr. Emerson loftily surveying early Christian art in a tolerant spirit; but he is very intolerant when art was tied and fettered by priestly domination in mediæval times, and he shall not be blamed, excepting that he does not dwell sufficiently on the protection the Church afforded art, and the loving naivty with which it was inspired. We will not follow him across China and the East, but watch him running *amok* against everything and everybody in the Renaissance who does not fulfil his standard of naturalism. Such men as Dürer get off by the skin of their teeth, and the only artists standing out as worthy of the greatest commendation are the Van Eycks and Holbein. Something, however, has to be said for Andrea del Sarto, but Michael Angelo, Raphael, and Corregio are swept away like chaff before the wind. Benvenuto Cellini, the author of the *Perseus*, is not recognised as a sculptor, but as a goldsmith, and as to Rubens and Vandyck, &c., the less said the better. Hogarth stands out among the English school of painters with Crome and Gainsborough, and perhaps Constable as an associate; but Reynolds, Turner, Nasmyth, Stanfield, Linnell, and Maclise go by the board. I will not weary you further, or twice kill the killed; it has been reserved for Mr. Emerson to convert the Temple of Fame into a slaughter-house, and I would rather he held the entire monopoly; but, as his book speaks so authoritatively on a subject with which you desire I shall have something to say, it is necessary for me to do something towards clearing the ground, and it shall be my task to show you where I consider are obvious mistakes.

Mr. Emerson's battle cry, or rather, his killing cry, is Nature! nature! nature! go to nature! Well, I am with him: we are all with him, being sane men; but *what* nature? He says the Greeks went to nature; many sculptors have told him so. Truly it needed not that; he might have evolved that from his inner consciousness, if he could not see it. How, then, *what* nature did they go to? Was it the nature of a labour-stunted physique, a brain-killed body, a factory-degenerated virility? Did they study arms from a sewing-machine girl, legs from a ballet dancer or a cyclist? Where would Mr. Emerson image his legs from to-day, even with the help of all the rectilinear lenses he possesses? Of course, I mean that the legs should be artistic legs, such as a Greek would have modelled. I think we should find Mr. Emerson rather at his wits' end if he had to draw such legs, unless he is well grounded in anatomy, or happened, by a fluke, to be visited by an exceptional model whom he could photograph. The general type of images of legs he could get would not come up to the standard of what Mr. Emerson's imagination would dictate, and I should not be surprised if, after all, we did not find him, having put the camera on one side, assisting his imagination by taking a look at that Elgin frieze we all so much admire; not to copy, oh, no! but just to see how the old fellows did it. Then, if he had to get a whole body, say a *Venus de Milo*, without a trace of stays, how then?

But I forgot Mr. Emerson cares for none of these things, but would rather have a peasant woman from nature than a Venus, Virgin, or Saint from imagination and cultured ideal. Well, there is no accounting for taste; but it is hard he will not permit the freedom in others he takes himself. There are still those equally earnest men in art who prefer the Saint, the Virgin, the Venus of ideal and refined culture to the peasant woman. By the way, I should like to know how Mr. Emerson is affected in relation to this subject by that exquisite remark of Balzac's.—"*L'une des gloires de la société c'est d'avoir crée la femme, là où la nature à fait une femelle.*" Freely translated: "One of the glories of society is, that it has created woman, where nature has only made a female." Surely, Mr. Emerson, the ideal is not so hopeless after all, and it is just possible that a great intellectual effort to attain an ideal on a reasonable substratum of nature might be partially successful, and not altogether Utopian; at least, even if for argument's sake we demolished the old masters to a man. Mr. Emerson should surely know it is no reproach to photography that though the camera can do much, it cannot do impossibilities; the intellectual effort in its use must, to a great extent, be subject to the model it focusses. You cannot make a silk purse out of a sow's ear in photography, much as you may do in that way in painting; but, on the other hand, are you always sure of making the best of the sow's ear as such? Not at all, unless you bring considerable artistic ability to bear upon the treatment of your subject; and when, instead of the sow's ear, you have, say, a very beautiful woman to photograph, the difficulty and the intellectual effort becomes infinitely greater, and you will be glad of some hints from Sir Joshua, to say nothing of Raphael and Rubens, besides Holbein, Titian, Gainsborough, and the favoured few Mr. Emerson tolerates.

(To be continued.)

Correspondence.

CENSURES ON PHOTOGRAPHIC DEALERS.

SIR,—Noticing several letters which have appeared in the pages of some of your contemporaries, conveying sweeping censures on photographic dealers, I deem it only just to state that, during a professional experience extending over thirty-seven years, save in one instance I have never met aught but the fairest treatment; and in this solitary exception the offender could scarcely be regarded as a dealer.

Mr. Otto Scholzig, whom I particularise, because he has been so distinctly mentioned, has satisfactorily supplied me with paper for several years, during which period I have but once had occasion to call attention to a faulty parcel, damaged perhaps through some lack of care in packing; it was at once replaced without a question—a practice I have invariably found to hold good with *all* other houses with whom I have had business transactions.

It affords me much pleasure to offer this unsolicited testimony to the fair and straightforward dealing of this large section of the photographic community, who are, in too many instances, blamed on very inadequate grounds.

Winwood, Tunbridge Wells, June 20th. WM. MAYLAND.

PHOTOGRAPHY IN GERMANY.

BY HERMANN E. GUNTHER.

Stripping the Film of the Gelatine Negative—Unfavourable Opinions of the Aristo Paper—Toning Silver Bromide Transparencies on Opal Glass.

Stripping the Film of Gelatine Negatives.—There are several good methods of stripping the film of gelatine negatives, which may be used to produce reversed negatives for photo mechanical purposes, though I have always found that the process is of absolute certainty only in the case of the specially prepared gelatine plates of the trade. A method, however, with which I have repeatedly succeeded is the following, worked out by M. Charles Petit, professor of the renowned photographic reproduction establishment of Paris, and recommended of late by a well-known French amateur photographer, in the *Archiv*. The finished negative, after thorough washing and drying, is placed for ten minutes in a bath of 100 c.c. of water, 5 grammes of potassium or ammonium bichromate, and a few cubic centimetres of alcohol, allowed to drain, and dried in the dark. It is then exposed, at first from the glass side, for ten minutes in the sun, or forty-five minutes in diffused light, the gelatine film being covered during this operation by a black paper. Then the film side is exposed for a little shorter time. The plate is then washed in several changes of water until the latter remains clear, and dried. It is, however, necessary, in order to ensure success, that the gelatine film retain a certain degree of moisture, such as it would have acquired if it had been dried for twenty-four hours in a cellar. In order to strip the film, an incision is made in it by means of a sharp pen-knife about one-eighth of an inch distant all around the edges of the plate, then one corner is lifted, and the film carefully stripped. After stripping, the film is placed reversedly upon another glass plate of a little larger size than the film, in order to facilitate the operation; an expansion of the exposed bichromated gelatine film does not occur. This transferring process is done best by placing the glass plate on the bottom of a dish filled with clean water, and the reversed film upon the plate. The whole is then lifted and allowed to drain for a moment; to obtain perfect contact between film and glass, a piece of letter paper is placed on the glass, and the excessive water pressed out by means of the ball of the hand or of a squeegee. It is then put away for drying. The stripped film can, of course, also be used as negative film, and in this case, after the drying which follows the washing out the bichromate, a coating of plain collodion can be imparted to the gelatine surface, then a five per cent. gelatine solution to which some glycerine has been added. By this coating the bichromated gelatine film below, which is very fragile, is made more resistant. The stripping of the film is then done in the same way as described above.

Unfavourable Opinions of the Aristotype Paper.—It is a fact very often to be met with in daily life that the better a thing and the more successful it is, the greater is the number of the envions, who try to oppose it by all means. This is the case now with the aristotype paper, which, by all who have printed with it and judge it disinterestedly, is designed unanimously as the paper *par excellence* for amateurs. On the many advantages and merits of this paper has been written so much, that it would be needless to repeat it; be it sufficient to state that the number of its admirers and adherents grows from day to day. This, however, is by no means to the liking of some persons, who disregard all that they have not invented themselves, and who therefore search for defects and disadvantages of the material—in most cases, however, vainly. So to the aristotype paper the objection was made from the very beginning of its existence that the high gloss of the surface of the finished prints was inartistic and even offensive, and a German contemporary quite recently contained the following criticism: "The aristotype paper, with its uncertain tones, with its vulgar high gloss, and the faded details, is very seldom suited for artistic effects." If the writer of this judgment had ever seen the splendid and most artistic views of mountains printed on aristo paper by M. Vittorio Sella, of Biella, or the beautiful landscapes of Mr. Cronenberg, he would, perhaps, have altered his opinion. With regard to the glossy surface of the aristo prints, it is only necessary to remember that they can be produced as easily with a matt surface, by squeezing them on a ground glass plate instead of a plate glass or ferrotype plate. They are then very much like platinotype prints as regards the tone and the surface, with the difference, however, that their sharpness is much greater than that of platinotypes. Genre pictures and portraits are specially suitable for this treatment. Mr. Alfred Stieglitz, one of our most eminent amateurs, who had sent to the last Jubilee Exhibition at Berlin a large number of genre pictures printed on aristo paper and toned with the platinum toning bath, writes in Professor Eder's "Year-Book:" "A celebrated professor, one of the most bitter enemies of the aristo paper, asked me whether my pictures were printed on platinotype paper? And he was highly surprised when I answered, 'They are *aristo* prints, toned with platinum.' This example shows the small importance of such judgments, and for what reason they are published.

Toning Silver Bromide Transparencies on Opal Glass.—This process is, in general, not quite simple, because a sensitive silver bromide emulsion, after the reduction, *cannot* be toned directly. The ordinary gold baths are useless, since the reduced silver is too coarsely grained. It is, therefore, necessary to transform the picture at first into a silver chloride print. Dr. Miethe recommends for this purpose the following solution:—

Water...	1000 c.c.
Alum	20 grammes
Potassium bichromate	10 ,,
Hydrochloric acid	20 ,,

After a few minutes the print is well washed, exposed for about two minutes, and developed with the citrate developer. According to the time of exposure, the tone varies from red, through brown, to black.

A Fine Arts Exhibition is to be held at Poona in September next, when a money prize and two silver medals are to be offered for photography. Two out of the three judges for this section of the exhibition will be photographers.

The Bureau Scandinave, Brussels, has organised a photographic excursion to the west of Norway, to leave Rotterdam on Thursday, the 14th August. Arrangements have been made for the use of a dark room in each hotel at which the excursionists may stay.

Birmingham Photographic Society.—The first half-day excursion of the season to Coventry took place on Saturday last. Mr. F. W. Hardy, of the Coventry Society, accompanied the members to the principal architectural buildings of the city. The next excursion is fixed for July 12th.

Notes.

Usually the judging of competing photographs and the awarding of prizes in connection with an exhibition are looked upon as thankless and almost disagreeable operations. Where the task is performed by ladies the reverse seems to be the case; at least, so we learn from our lively contemporary, *Woman*, which states that "Mrs. Eveleen Myers (sister of Miss Dorothy Tennant), Miss Edith Scannell, and Miss Ida Vernon have just concluded the pleasant task of adjudicating on some 300 photographs by 'ladies only.'" If these ladies found their duty a "pleasant" one, and if the lady competitors are also satisfied with their verdict, we would suggest that Mrs. Myers, Miss Scanuell, and Miss Vernon be invited to assist the judges of the next exhibition in Pall Mall. Up to the present no exhibition year has passed over without some little heartburning on the part of someone. Perhaps the introduction of ladies might do away with all asperity. We ought not to forget, in connection with this subject, to mention that the 300 photographs alluded to formed the first Amateur Ladies' Photographic Competition, and that the first prize of a gold medal was awarded to Miss E. Dora Anderson.

One of the periodicals of the "Bit" class offers a prize for the best answer to the following question: "What are the best uses to which photography can be put?" There cannot be the slightest objection to the discussion of such an interesting question, but it must be confessed that the reason given for the wording of the question is puzzling. It is, so we read, put in the above form so that those who know nothing of photography may have an equal chance with those who are familiar with the art. One would have thought that in such a competition the latter would be first and the former nowhere; but perhaps the editor of the paper in question has some convincing proof of the contrary up his sleeve. If so, every photographer would much like to hear what it is.

Mr. P. O'Brien, M.P., is apparently quite convinced of the value of photography as a political argument. First, he secures with his own hand some photographs of the peculiar process known as "shadowing." Next he has copies of the pictures handed about in the House of Commons. Lastly, he has an optical lantern apparatus placed on a barge, which is anchored off the Houses of Parliament, and throws images of the said photographs on a screen for the delectation or otherwise of the members. The question is, what will be the next stage? Hitherto, the most singular discrepancies have been evident between the accounts given by Irish members who have been eye-witnesses of certain scenes, and the official versions furnished by the police. Will it come about in future, when Mr. Balfour traverses a statement, that he will be silenced by the triumphant production of a photograph of the scene in question? If so, and if the evidence of photography is valuable, then the Irish police will have to be furnished with instantaneous cameras, so that Mr. Balfour may be able to give an adequate rejoinder to the photographs of his opponents by producing the police picture. This kind of thing would, at all events, open up very interesting discussions, and give an opportunity for speaking to the photographic members of the House. Indeed, the freemasonry of photography, and the friendly feeling it fosters, might positively be beneficial, and considerably soften the acrimony of the debates on Irish questions.

Photography and the photographer have always been an irresistible source of fun to Mr. Toole. His interview with the Australian photographer, related last week in these pages, shows that he has not yet exhausted his joking propensities in this direction. Mr. Toole's recently published "Reminiscences" abound in allusions to his photographic experiences. Some of his pranks in the studio must have been extremely funny. He tells how, when he, Phelps, and Charles Mathews were playing "John Bull" at the Gaiety, they were photographed together for the *Illustrated London News*. The photographer was very much impressed with his work, and very anxious; and just as he had posed the group to his entire satisfaction, Phelps gave one of his little nervous coughs. Mathews remarked, "It's no good trying to get your tragedy cough into the picture, Phelps; it can't be done." They were photographed in character; Phelps had on one of his heavy tragic wigs, and Mathews one of his tall comedy hats. Just before the last pose the photographer suggested that Mr. Mathews should take off his hat. "It will make your face lighter," said he. Mathews, in his quick, merry way, taking off his hat, said, "Don't you think if Mr. Phelps took off his tragedy wig it would make *his* face lighter?"

At the last meeting of the Royal Astronomical Society Mr. Knobel gave an interesting account of a visit he had paid to Dr. Vogel's observatory at Potsdam. Referring to Dr. Vogel's new photographic telescope, just finished, Mr. Knobel said that, with the exception of the French telescope, this was, he believed, the first introduced for the photographic survey of the heavens which had been entirely completed. Mr. Knobel was also privileged to examine some photographs taken with this telescope, with one hour's exposure, of the Nebula of Orion. Incidentally, Mr. Knobel said that Dr. Schriener, who has been devoting much attention to the photographic magnitudes of stars, informed him of the conclusion at which he has arrived, that white stars require only one-tenth of the exposure of red stars to give the same photographic magnitude; it is, therefore, difficult to determine the magnitude of stars when they differ materially in colour.

The experiment tried by the *Pall Mall Gazette* of asking the frank opinion of the various artists whose pictures are reproduced in its publication, "Pictures of

1890" was a hazardous one, but on the whole it has come out of it fairly well. At the same time, it must be confessed that the remarks which find fault are more interesting to read than those which express satisfaction. We gather, for instance, that Mr. John Brett, A.R.A., knows something of photography, for he writes: "If you turn to page 37 I feel sure you will agree with me that the print is extremely weak. Not having seen the negative, I cannot with certainty indicate where the fault lies, but my opinion is that the negative was thin. . . . The printer has printed it with the utmost care, but a thin negative is past praying for." Mr. Colin Hunter is also dissatisfied. He is "sorry to say that my picture seems to have suffered more than usual in transferring it into black and white." Mr. C. N. Kennedy thinks his pictures are good "considering the badness of the photograph," but Mr. Yeend King, who sent a "particularly good" photograph, finds that his work has suffered through being over-reduced. Sir J. E. Millais misses his moon, which "up" in the painting has "gone behind a cloud" in the reproduction. Mr. W. B. Richmond is exceedingly candid when he says, "I should not be just to myself nor to you if I expressed a favourable opinion—I think they are very bad indeed." Mr. G. A. Storey observes that, "Considering that I sent you a very brown photo, I think my picture comes out very well," which is consolatory, though we should like to know what Mr. Storey means by a "brown photo." Mr. Walter Winch also lays blame on the unfortunate photographer, as "the reproduction is as good as it could be, considering the quality of the photograph."

Mr. E. J. Poynter unconsciously points out the cause, probably, of most of the dissatisfaction when he says, "I consider that the reproduction of the water-colour of the 'Queen of Sheba' is good, considering the difficulty which the colouring of the work presents to the photographer." Exactly! The colouring of many artists' work, notably that of Mr. John Brett, whose pictures have in them all the colours of the rainbow illuminated by the limelight, *does* present difficulties. To make a good copy of a painting requires special knowledge and special skill. Artists possibly do not recognise this, but think that anybody who has a camera can photograph a painting. If they want good printing reproductions, let them get the best photographs obtainable.

Manufacturers in all trades know that to be successful in business they must see that economy is practised in all departments, and many men owe their financial success to their care that nothing shall be used wastefully. But there is a limit to economy, as in all things, and it is sometimes difficult to avoid the temptation of overstepping the line. In the manufacture of dry plates this temptation takes the form of making a given quantity of gelatine emulsion spread itself over a larger surface of glass than is desirable, or of reducing the proportion of silver in the emulsion to the smallest possible quantity. The practice of this kind of economy is a suicidal policy, for although a certain number of amateur workers may be attracted at first by cheapness of production, they will soon learn that it is better to pay more for a better article. The difference of the results obtainable with a plate which is liberally coated, and that which is poor in emulsion, is enormous, and careful workers are not slow to find it out.

It is said that a Paris photographer claims that celluloid as applied to photographic films is a French invention, on the ground that in the spring of 1882 he showed some of these pellicles at a meeting of the Photographic Society of France. We have often heard that Frenchmen have claimed Waterloo as one of their victories, and their claim to celluloid is about as well founded. Celluloid was discovered by Parkes in this country more than forty years ago, and it was at once proposed to use it as a support for the photographic negative image; and it would have been so used had it not been for the circumstance that the solvents used in collodion acted upon it. An aqueous solution of gelatine has no such effect upon it, and, therefore, the idea has again been revived, and has at last taken practical shape.

Photography is very often allied with other occupations, and does good service in adding to the income of a man whose ordinary work is of a far different kind. This is commonly to be observed in out-of-the-way country towns where the population is not sufficient to support a photographer who depends entirely upon picture making for his living. An instance of this mixture of occupations we lighted upon the other day in an old-fashioned town in the heart of Sussex, where the only photographer in the place seemed to be a kind of Jack of all trades. First, he was a disciple of St. Crispin, and his work-bench was covered with old boots and shoes in various stages of completion. Next he was a taxidermist—and he told us that amateur naturalists for miles round sent him birds and beasts to be stuffed. Specimens of his skill in this way were hung upon all the walls of his shop. Then he was a beemaster, and he showed us two hives with their glass superstructures crammed with honey-comb. He also dealt in rabbits and other wild beasts, but his heart was evidently in his photography.

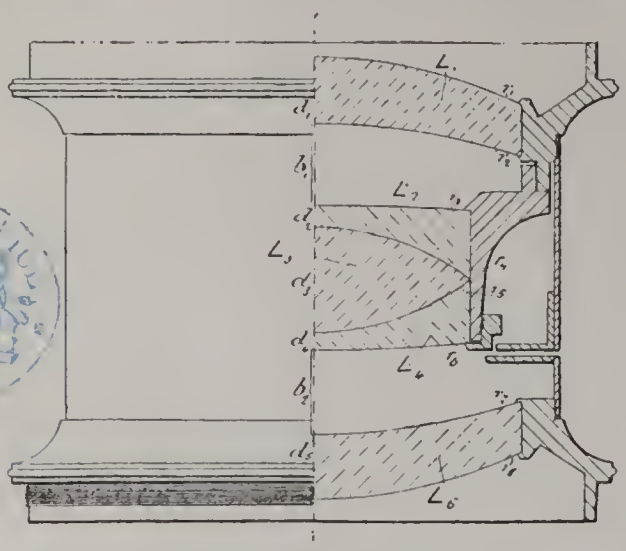
This humble worker had constructed his own studio, and all his own apparatus except his French half-plate portrait lens. One of the glasses of this lens he used for landscape purposes, and very good pictures he turned out with it of noted places in the neighbourhood. For these he found a ready sale, and the printing and toning of them give him continual occupation in the summer months. As we parted with him, we could not help thinking of the number of workers we have known who, possessing a battery of lenses and expensive apparatus of every kind, cannot produce pictures of equal merit to those which were lying amid the chips of leather and the stuffed birds in this worthy man's shop.

NEW PHOTOGRAPHIC OBJECTIVES.*

BY DR. ERNEST ABBE AND DR. PAUL RUDOLPH.

No. II.

In the annexed drawing, an objective carried out according to our invention is shown partly in outside view and partly in section. L_1 and L_5 are the two collecting-lenses, made in this case of concavo-convex form. The correcting-



system consists in the biconvex lens L_3, and the concavo-convex dispersing-lenses L_2 L_4, the two latter being composed of glass having such power of chromatic dispersion as is necessary to compensate the chromatic aberration of the lenses L_1, L_3, and L_5.

According to the kinds of glass used in the construction of the described objectives, and according to the special conditions to be realized by the total result obtainable from the system, a perfectly symmetrical arrangement of the lenses, such as is shown by the figure, may, in certain cases, suffice; in others, where a wider range of means for corrections or for removing objectionable reflections is desired, a dissymmetrical arrangement may be preferable.

In the following tables we append three numerical exemplifications of the manner in which lenses of given kinds of glass have to be ground for carrying our invention into operation. In these tables the letters r_1 r_2 r_3 r_4 r_5 r_6 r_7 r_8 denote the radii of curvature of the lens-surfaces marked by the said letters in the figure. d_1 d_2 d_3 d_4 d_5 are the central thicknesses of the lenses, and b_1 b_2 the respective air-distances between the lenses L_1 L_2, and L_4 L_5. All dimensions are expressed as fractions or multiples of the focal length of the entire system taken as unity. To obtain the dimensions of any particular objective, all that is necessary is to multiply the numerals given in the tables by the focal length required. The kinds of glass to which the tables refer are determined in the first example by the refractive indices n_D, n_F, and n_{G1}, corresponding to Fraunhofer's spectral lines D and F, and the line H_γ of the spectrum of hydrogen respectively, whereas in the second and third examples the indices n_D and n_F only are employed.

I.

Symmetrical arrangement. Apochromatic correction (the secondary spectrum removed).

Radii:	Thicknesses of glass and air-distances:
$r_1 = -r_8 = +0{\cdot}2574$	$d_1 = d_5 = 0{\cdot}034$
$r_2 = -r_7 = +0{\cdot}3847$	$d_2 = d_4 = 0{\cdot}011$
$r_3 = -r_6 = +2{\cdot}3040$	$d_3 = 0{\cdot}056$
$r_4 = -r_5 = +0{\cdot}1374$	$b_1 = b_2 = 0{\cdot}042$

Glasses employed:

	n_D	n_F	n_{G_1}
L_1 L_3 L_5:	1·51840	1·52457	1·52956
L_2 and L_4:	1·57950	1·58745	1·59388

Position of diaphragm close behind lens L_4.
Largest effective aperture: 0·16.
Angle of field: about 90°.

II.

Unsymmetrical arrangement. Achromatic correction.

Radii:	Thicknesses of glass and air-distances:
$r_1 = +0{\cdot}2473$	$d_1 = 0{\cdot}033$
$r_2 = +0{\cdot}3767$	$d_2 = 0{\cdot}010$
$r_3 = +2{\cdot}2000$	$d_3 = 0{\cdot}062$
$r_4 = +0{\cdot}1324$	$d_4 = 0\,011$
$r_5 = -0{\cdot}1452$	$d_5 = 0{\cdot}036$
$r_6 = -2{\cdot}4350$	$b_1 = 0{\cdot}041$
$r_7 = -0{\cdot}4272$	$b_2 = 0{\cdot}044$
$r_8 = -0{\cdot}2798$	

Glasses employed:

	n_D	n_{G_1}
L_1 L_3 L_5:	1·50932	1·52037
L_2 and L_4:	1·56808	1·58231

Position of diaphragm close behind lens L_4.
Largest effective aperture: 0·16.
Angle of field: about 90°.

III.

Symmetrical arrangement. Achromatic correction.

Radii:	Thicknesses of glass and air-distances:
$r_1 = -r_8 = 0{\cdot}4401$	$d_1 = d_5 = 0{\cdot}050$
$r_2 = -r_7 = 1{\cdot}3503$	$d_2 = d_4 = 0{\cdot}020$
$r_3 = -r_6 = \infty$	$d_3 = 0{\cdot}130$
$r_4 = -r_5 = 0{\cdot}2001$	$b_1 = b_2 = 0{\cdot}100$

Glasses employed:

	n_D	n_{G_1}
L_1 L_3 L_5:	1·51780	1·52901
L_2 and L_4:	1·56745	1·58233

Position of diaphragm close behind lens L_4.
Largest effective aperture: 0·30.
Angle of field: about 50.°*

PHOTOGRAVING ON SENSITIVE PAPER.—Mons. D. Stravos Zellis, of Alexandria, indicates a process which he has always found to succeed perfectly. Taking a sheet of thin white paper, he traces on it the title he wishes to photograve at the bottom of his negative, and oils it on both sides; having taken away the excess of oil by pressing it between two sheets of blotting-paper, he varnishes it again on both sides and leaves it to dry. He then cuts away at the foot of his negative a piece of gelatine equal in size to the prepared paper, and replaces it with this, sticking it on by means of a solution of gum-arabic and water. He then presses away the little bubbles of air which prevent its perfect adherence, and, this done, waits until his work dries. If, when taking a proof, it is seen that the written letters do not give a very white impression on the sensitive paper, it will be necessary to retouch the characters which come out badly on the reverse of the oiled paper. To write the titles, Mons. D. Stravos Zellis uses a mixture of gum-arabic, lamp black, and water. The process is simple, costs little, and gives excellent results.—*Annales Photographiques.*

* Continued from page 475.

* In the patent the inventors claim—"In a photographic objective, the combination of two single collecting-lenses, and a compound correcting-system composed of single lenses cemented together, the said correcting-system having a large focal length, and being placed between the collecting-lenses, substantially as described."—ED.

NOTES ON THE REPORT OF THE LENS STANDARD COMMITTEE.*

BY A. HADDON.

Before submitting the report drawn up by the Lens Standard Committee, I propose to state the history of this Committee, and the reasons for the recommendations at which it has arrived.

At the meeting of the Convention held in Birmingham, 1888, a committee of five members was appointed, at the suggestion of Mr. W. Taylor (Leicester), "to consider the adoption of the standard lens fittings recommended by the Photographic Society of Great Britain, or to suggest alterations of that system, and to take or indicate such steps as may be considered necessary for its effective establishment." The Committee thus appointed consisted of Messrs. A. Cowan, A. Gifford, A. Haddon, J. H. Pickard, and S. G. B. Wollaston.

That Committee met twice during the time which elapsed between the Birmingham and London meetings, and the Chairman (Mr. Wollaston) drew up a report, which was submitted to the Council, and it was decided that the same should be read at one of the evening meetings. After the reading of the report, Mr. W. Taylor proposed that the report be not adopted, but be referred back to the Committee for further consideration. Mr. Conrad Beck seconded the motion, which was carried.

At a meeting of the Council held in London on February 21st, 1890, the Committee was reappointed, consisting of Messrs. A. Cowan and A. Haddon (Mr. Wollaston having previously tendered his resignation as Chairman of the Committee), with power to add to their number. It was thought advisable to increase the number by adding to the list the names of three gentlemen well known to you—viz., Mr. W. Bedford, Dr. J. Edmunds, and Mr. H. M. Hastings, F.C.S.

We discussed the *pros* and *cons* of different methods, so as to formulate a system of standards which should be practical and popular, and as we had only the report of the Photographic Society of Great Britain to guide us, we thought it best to consult those gentlemen who are daily engaged in the superintendence of this kind of work. In addition to this, so as to ensure a meeting, a few of the leading opticians were called on personally, and their promise to attend obtained.

The Secretary of the Committee made a few remarks on the subject in hand, and then called for any suggestions that anyone present might wish to make.

Mr. W. Taylor (Leicester) opened the discussion, and, among other things, referred at some length to standard gauges to be used in connection with the screwing of lens mounts, and pointed out that, whatever system was finally adopted, it was necessary to seriously consider gauges, as, unless these were absolutely true and of the same size, to the ten-thousandth part of an inch, or even less, the resulting work could not be interchangeable. Mr. Taylor did not mean, as some seemed to have inferred, that the lens mounts themselves should all gauge to anything like the one ten-thousandth of an inch. It would be impracticable as a manufacturing operation to screw thousands of lens mounts to this degree of accuracy. Mr. Taylor than showed two sets of steel gauges, such as he had devised for his own factory, in order to ensure as near constancy as possible in the diameter of the screwed portions of mounts and flanges. He also mentioned that steel gauges for the smaller sizes of lenses did not last more than one year, in consequence of the slow but constant wear they underwent during their use. It was impossible to harden them, as during this operation they generally warped to such an extent as to become valueless. He had, however, partly overcome this difficulty by hardening certain removable pieces which could, after the operation, be replaced in exactly the same positions.

In connection with the standard unit for diaphragms, Mr. Dallmeyer suggested $f\text{-}\sqrt{10}$, and mentioned that at the recent Photographic Conference held in Paris $f/10$ had been adopted, so as to introduce the decimal system in connection with diaphragms. He considered his own suggestion better, as in order to obtain the intensity value of the stops it is necessary to square the denominator, and in his case it would only be necessary to strike off one nought, whilst if the French system were adopted two noughts would have to be struck off in order to obtain the unit area. Your Committee agree with Mr. Dallmeyer that the method he has suggested is extremely clear and thoroughly scientific, although there is much to be said for the powers of 2. If they were starting a system anew, they might well recommend Mr. Dallmeyer's suggestion for general adoption. But, as against this, they have to take into account the number of diaphragms that have been marked on the f-4 system, as recommended by the Photographic Society of Great Britain, and, therefore, think that it would be unwise to make an alteration now, more especially as the $f/4$ system is at present getting to be well understood and widely used.

Messrs. Debenham and Beck also spoke on this subject, and finally, when the question was put to the vote as to which of the three systems should be recommended for adoption, $f/4$ as the standard unit was carried by a large majority.

The next point for discussion which was raised resulted in a proposition from Mr. Dallmeyer, seconded by Mr. Beck, that a special meeting of opticians be called in order to settle the sizes of the screwed portions of lens-mounts and flanges.

The last subject that was brought before the meeting and voted upon on this occasion was screws for attaching cameras to tripods and for fixing rising fronts, &c. As nothing better was suggested than appears in the report of the Photographic Society of Great Britain, this was put to the vote and carried unanimously.

The meeting was then adjourned till the 9th of May.

Prior to the meeting of May the 9th, a circular was drawn up, and about two hundred copies posted to the different opticians whose names appear in the London Postal Directory. This circular embodied the different suggestions that had been made, and contained a copy of the resolution proposed by Mr. Dallmeyer and seconded by Mr. Beck. The response to this appeal for data was very meagre.

As the meeting of the 9th of May consisted almost exclusively of opticians, and was more or less of a private nature, we need not enter into details, but will only give the results arrived at.

On this occasion between ten and twelve opticians were present. Some data as regards diameters of the screwed portions of the mounts of lenses and numbers of threads to the inch were handed in for tabulation; but these data proved to be only approximate, no attempt having been made in any case to measure accurately the diameters, and the necessity for accurate guaging having been apparently not realised.

On discussing these results, it was found that the diameter of the smallest lens mount, where screwed to receive the flange, had been derived from an old guage prepared by Andrew Ross. This thread has been copied by several younger makers, and it is believed that some 100 to 120,000 lenses of this particular size have been manufactured and are now in use. Upon considering this state of things it was proposed that this size should be adopted in the future. This was carried unanimously. Mr. Dallmeyer thereupon very kindly offered to supply specifications as regards exact diameter, thread form, and thread rate for this screw, which was understood to be 1·5 inch in diameter.

The next larger size, 2 inches about, was then discussed, and for the same reasons as given above with regard to size No. 1, this was put to the vote, and carried by a majority (6 for, 2 against). Thereupon Mr. Dallmeyer promised to supply data for this screw also.

It was then proposed that the standards of the Photographic Society of Great Britain, with the above modifications, be accepted; this was lost by 3 voting for, 5 against the proposition.

The Photographic Society of Great Britain had kindly lent their standard gauges to one of the gentlemen present, and the gauges were upon the table for examination.

With regard to the form of screw to be adopted in connection with lens-mounts, it was proposed and carried that the thread form known as Whitworth should be adopted.

It was then proposed, seconded, and carried, that as the present was not a sufficiently large representative meeting, another meeting be called, and that all opticians be invited to

* Read at the Photographic Convention at Chester.

send in to the Secretary of the Committee exact measurements of lens mounts and flanges, with their thread rates for all the classes of lenses which they manufacture.

The meeting was then adjourned till the 21st of May.

As soon as possible a second circular was sent out to all opticians, as on the previous occasion, and as a result eight statements were received, and these were tabulated.

From the data thus tabulated, it appears that Messrs. Newton and Co., Reynolds and Co., Suter, Taylor, Taylor and Hobson, and the Stereoscopic Company, have been for some time past manufacturing lenses in accordance with the specifications of the Photographic Society of Great Britain.

The tabulated results also showed that what had been supposed by Mr. Dallmeyer to be 1·5-inch guage, and which had been adopted as one of the standards by the previous meeting, was in reality 1·513-inch. The screw which had been supposed to be a 2-inch also turned out to be 1·98-inch. It also appeared that there was some considerable divergence between these mounts and those issued by the younger houses, who had copied the Andrew Ross mount without access to the Andrew Ross gauge, and now manufactured these screws of such various dimensions that there was no certainty of interchangeability of these so-called 1·5 and 2-inch mounts, among some half dozen makers, who all considered they were making the same screws. Upon these facts becoming clear, the whole subject of the resolution which had been adopted at the last meeting had to be reopened.

In the discussion which followed, Dr. Edmunds was the first to speak—this being the third meeting—and he told those present that in considering standard screws they had three things to bear in mind: 1st, the diameter of the screw, and that in all cases this should be measured on the outside of the male screw, full diameter; 2nd, the form of the thread; and 3rd, the screw rate or pitch—*i.e.*, the number of threads to the inch; and that it was absolutely necessary to keep each one of these points separate and distinct. As regards the diameters of the screws, he would advise the English inch as the standard, as anyone who wishes to make standard gauges can easily turn up a ring or plug gauge, and then compare it with the standards kept by the Board of Trade for this purpose, and in that way ensure uniformity of manufacture and complete interchangeability. He would therefore most strongly advise any odd fractions of an inch that might occur in any of the sizes as at present manufactured to be abandoned, and the inch and simple submultiples, as $1\frac{1}{4}$, $1\frac{1}{2}$, $1\frac{3}{4}$, 2, &c., to be taken in their stead. In olden times, before the screw-cutting lathe was invented, Mr. Holtzapffel originated certain forms of threads, and, though these at the time were as perfect as could be expected under the circumstances, yet now that we have a more scientific method for originating screws, we should use it and put aside these old forms. For brass work, where the maximum of strength is required, he had no hesitation in saying that an angle of 60° was preferable to any other, and that the top of the thread should be flat. The work could be turned down to the exact diameter, and then screwed up; if the original surface between the threads was left so as to form the flat when finished, the screw would be of the required diameter. The form of thread recommended by the late Sir Joseph Whitworth was an angle of 55°, rounded at the top and bottom. This form of thread could not be surpassed for cast iron, but was not the best for other metals where the greatest strength was required. The number of threads was not so important so that it was uniform.

In answer to these remarks of Dr. Edmunds, it was pointed out that a flat top thread, in the case of photographic lenses, would be more likely to bind if it were bruised, and therefore the rounded Whitworth angular form of thread would be preferable on this account. Shot chasers of the Whitworth form can be obtained all over the world from any respectable tool maker, whilst if an angle of 60° were adopted the chasers would have to be specially made, which would considerably increase the cost. Dr. Edmunds agreed that these were very good reasons why the Whitworth thread form should be adopted, especially as the maximum strength in the case of photographic lens mounts was not required.

It was then proposed and seconded that since, from the statements supplied, the diameters of the lens adopted at the last meeting were not exactly 1·5 and 2 inches respectively, but a small fraction larger in the one case and smaller in the other, those resolutions be rescinded in order to clear the way for further discussion and suggestions. This was put to the vote and carried.

It was then proposed that in all cases the English inch be taken as the unit of measurement. Carried unanimously.

It was then agreed that, in consequence of the difficulty of measuring internal diameters of flanges, &c., all terms of measurement be regarded as made upon the outside diameter of the male screw thread.

The next point discussed was whether the present smallest size of the Photographic Society of Great Britain standards, viz., 1·5 inch, was not too large for the mounting of lenses for hand-cameras. The majority were of opinion that it was, and that a smaller size was necessary, and finally it was agreed to start with the smallest diameter 1-inch, and the next 1·25 inch.

It was next proposed, seconded, and carried (by nine for, and five against) that 1·5, 1·75, and two inches be the next sizes, and that the others rise by half an inch up to four inches, and then by one inch, as prescribed by the Photographic Society of Great Britain.

It was then stated by some that certain lenses look overmounted with a mount of two inches in diameter, and, in addition, it would enable those opticians who have up to the present issued lenses a little over 1·5-inch to make adapters which could fit 1·75 inch without increasing to any serious extent the weight or bulk of the lens mount, and this new intermediate size would be very useful for the double purpose.

It was then unanimously agreed that the form of thread should be that known as the Whitworth angular thread.

The last matter to be settled was the rate or pitch, and it was agreed that for the smallest sizes up to 3 inches inclusive, the number of threads to the inch should be 24, and for the $3\frac{1}{2}$ and upwards, 12 to the inch, these being the two thread rates recommended by the Photographic Society of Great Britain.

Mr. W. Taylor (Leicester) then proposed a series of standard adapters to carry any lens one size larger, and that these should be numbered; also that lenses, adapters, and flanges should be so adjusted that when the mount is screwed home in its flange, with or without adapter, the diaphragm, index, or other fitting shall always stand in the same convenient position.

Report of the Committee, consisting of Messrs. W. BEDFORD, A. COWAN, Dr. JAMES EDMUNDS, Mr. H. M. HASTINGS, and Mr. A. HADDON (Secretary), *appointed to consider Lens Standards.*

The committee appointed "To consider the adoption of the standard lens fittings recommended by the Photographic Society of Great Britain, or to suggest alterations of that system, and to take or indicate such steps as may be considered necessary for its effective establishment," now submit their report as follows:—

We have carefully, with the aid of the leading opticians, considered the subject remitted to us, and we hope that our recommendations will not only receive the sanction and support of this meeting, but be universally adopted by all who desire the improvement and fuller utilisation of photographic apparatus.

1. We have not seen any reason to depart from the existing "Photographic Society Standards," which, as far as they go, we adopt. The modifications hereinafter suggested are either in the nature of explanation or amplification of those standards.

2. We recommend that the English inch be taken as the standard unit of length with regard to all measurements in connection with lenses, flanges, adapters, and camera screws.

3. That the form of thread for lens-mounts, flanges, adapters, and screws, be that known as the Whitworth angular thread, and in order that there may be no unisunder-

standing with regard to this, we append the specifications, so that any one, wherever situated, can originate this thread-form for himself.

4. That all measurements where screws are concerned be made on the outside of the thread of the male or plug screw when finished.

As to Lens Diaphragms.

We recommend :—

5. That the aperture of the standard unit diaphragm have a diameter equal to one-fourth the equivalent focus of the lens, and be marked "1," the approximate focal length of the lens or combination being engraved on the mount.

6. That diaphragms with smaller openings should have apertures diminishing in area to the extent of one-half the preceding one, so that the second diaphragm should be marked "2," indicating that twice the exposure is required when this stop is used compared with what would have been necessary had diaphragm "1" been used under exactly similar circumstances. The diaphragms should therefore be marked :—

f 4	f 5·6	f 8	f 11·3	f 16	f 22·6	f 32	f 45·2	f 64	&c.
1	2	4	8	16	32	64	128	256	&c.

7. Should a lens not admit of a diaphragm with an aperture as large in diameter as f 4, nor exactly any one of the above-mentioned sizes, we still recommend that the largest diaphragm should be marked with a number in accordance with its area with reference to this unit, and that all diaphragms of smaller area be marked in conformity with the above series.

8. In the case of lenses having working apertures larger in diameter than f 4, the diaphragm with largest aperture should be marked in accordance with its value, and the next ·25 or ·5, if either of these be admissible, and then according to the series given above.

As to Screws for Attaching Lenses to Flanges and Adapters.

9. We recommend the following to be the external diameters of the screwed portions of the lens-mounts for the attachment of the same to the flanges :—

Diameter of Screw in Inches.	No. of Threads per Inch.	Diameter of Screw in Inches.	No. of Threads per Inch.
1	24	*3·5	12
1·25	24	*4	12
*1·5	24	*5	12
1·75	24	And upwards,	
*2	24	advancing by	
*2·5	24	inches.	12
*3	24		

* Screws thus marked are already the established standards of the Photographic Society of Great Britain.

As to Flanges and Adapters.

10. We recommend, in order to provide that all lenses fitting the same flange shall stand with their diaphragm, indices, or other fittings in the same convenient working position, that every ring or muff screw gauge shall bear a zero mark upon its face, and that such part of the lens-mount as is desired uppermost be set to coincide with the zero when the lens is screwed home in the gauge.

11. For convenience and uniformity the zero should be placed where the thread becomes complete, *i.e.*, where the point of a tool cutting such screw-gauge would lie in the plane of the ring face.

12. We recommend that standard adapters to carry any lens in a flange one size larger than its own be numbered as follows :—

Number	1	2	3	4	5	6	7	8	9	10	&c.
Inside Screw ...	1	1.25	1·5	1·75	2	2·5	3	3·5	4	5	&c.
Outside Screw...	1·25	1·5	1·75	2	2·5	3	3·5	4	5	6	&c.

13. The standard adapters to be adjusted in the same manner as the flanges with regard to same convenient working position of diaphragm indices or other fittings of lens mount.

As to Camera Screws.

14. In the case of metal screws used for attachment of camera to tripod, fixing rising front, or any other movable parts of the camera, we recommend that these should be of the form known as the Whitworth angular thread, and of the following diameters and pitch :—

Diameter	$\frac{3}{16}$-inch	$\frac{1}{4}$-inch	$\frac{5}{16}$-inch	$\frac{3}{8}$-inch
No. of threads per inch	24	20	18	16

As to Lens-Hoods.

15. With a view to convenience and to the interchangeability of lens-caps, time-shutters, &c., we recommend that the outside measurements of lens-hoods be finished off to one or other of the sizes given in paragraph 9, and that for each sized camera all the lens-hoods be, as far as practicable, finished off to the same external dimentions.

Appendix.

The Whitworth thread is constructed as follows :—Two parallel lines are drawn, separated by a distance equal to 0·96 of the pitch (distance between two threads) ; these are intersected by two sets of parallel lines inclined to each other at an angle of 55°, and meeting top and bottom, one-sixth of the total depth of the angular thread thus formed being cut off at top and bottom and rounded down.

The altitude of the resulting thread is 0·64 of the pitch.

PHOTOGRAPHIC EXHIBITIONS.

BY GEORGE DAVISON.

IV.—Classification.

In the last article of this series it was argued that competition is incompatible with the best interests of photographic art, and that, instead of awards, a system of rigid rejection of inferior exhibits would not only ensure keen interest in exhibitions, but would also make for the higher credit of photography. It may also be remarked that, with the sweeping away of awards, there go by the board most of the difficulties and evils which follow in the train of the competitive system. Amongst the worst of these are those which are introduced by the practice of classifying photographs which purport to be artistic productions. Even under a prize system the balance of reasonableness is strongly in favour of doing away with classification in the art section of an exhibition. Classification leads inevitably to difficulties, whether with competent or incompetent judges. The absence of classification, if the jury be qualified, can be met with no such objections. The case is somewhat different with scientific exhibits, where the divisions are sharp, and special experts are required.

It is argued that a certain amount of classification is essential to make judging possible or easy, that it encourages the prosecution of special branches of work, and finally, that the very general adoption of classification proves a need in that direction. Only the second of these contentions has any force, and in that experience has taught that classification does not stimulate special applications.

To begin with, how much classification is to be observed? Where shall the line be drawn? If, on the ground of fairness to exhibitors, and to make the work easy for the jury, divisions are commenced, there is no rational limit to the process. The principle being allowed, every one has a right to be classed separately for some difference in his subject or process, and the same argument which is

advanced in favour of separation would require separate judges practised in the respective branches or divisions. This is an absurdity at the outset. If music be taken for analogy, it must be remembered that the abstract beauty of the music is independent of the instrument by which it happens to be produced. There is nothing analogous in saying that it is easier to judge musicians classified into trombonists, pianists, and the like, than if taken together in competition. This idea carried out in photographic competitions would require subdivisions into wet-collodion work, photographs taken with doublets, photographs taken with triplets, hand-camera prints, and so on, distinctions which have nothing to do with the artistic merit of the work. It may possibly stimulate the trade of making bassoons, and the practice of playing that instrument, if it be known that large prizes are specially offered for proficiency in performing thereon, but I am of opinion that such artificial stimulus has generally proved a failure. The rather general adoption of classification in no way proves its advisability, but merely shows that the attention of photographers is too exclusively turned to the mere practical and mechanical means employed, and that those responsible for exhibitions have acquired the idea that manifold subdivisions conduce to attract a large body of exhibitors.

The whole of the arguments that I have objected to are based upon a misapprehension. The question as to whether a certain landscape is better than a certain portrait never arises, nor should it be the function of the judges to arrive at a conclusion which is to be placed first, which second, third, fourth, and so on. No one is qualified to make such distinctions. Each judge would, if working independently, have a different view of the order to be observed. The proper object of the judges is to place the stamp of their approval upon those photographs in which artistic merit is found, and in this a fair general agreement ought not to be a difficulty. There is no limit placed upon the awards. They may be few or many. The awards are equal. One would imagine, from the cry for all this classification for purposes of comparison, that pictures great enough to be worthy of distinction by artists were freely scattered about in photographic exhibitions, whereas the fact stands that in the best of our exhibitions there are never more than six or eight pictures of any completeness. The method of "no classification" works admirably at the Exhibition of the Photographic Society of Great Britain. The difficulty in that, the best of all our exhibitions, is to find eight or ten pictures really worthy as works of art. Generally speaking, only three or four awards seem to be given on these grounds—an equal number, perhaps, being overlooked—whilst the remainder go for some excellence or interest as novelties or eccentricities.

The invariable effect of classification, both with qualified and with incompetent judges, is to multiply prizes. Rigid classification in some degree coerces a judge into yielding here and there in deference to what appears to be the wish of the promoters. A great point is justly made of leaving everything to a good jury, and, in this view, classification is but a farce, and a device for inveigling photographers to send exhibits.

For those who must have classes, there are one or two suggestions worthy of consideration. There should be no divisions according to size; it is a slur upon the judges, and is only part of an ignorant and catch-penny system. There should be no distinction of amateur and professional; it is either a pandering to bad performers, or an excuse for multiplying awards. There should be no hand-camera class or enlargement class in the art section. Instantaneity and amplification find a place in the scientific section, but as pictures, all these should rely simply on their artistic qualities. There are endless anomalies and absurdities introduced by classifications to which it is needless to refer. My experience would lead me to condemn the whole system. If it is best that awards shall be freely bestowed upon every decent workman, those who clamour for classification are right. If it is desired to establish higher claims for photography than are generally admitted, then let the same tests be applied as are brought to bear in painting and in sculpture.

DEPTH OF FOCUS AND DIFFUSION OF FOCUS.*

BY W. K. BURTON.

THE principle from which we may deduce rules that will tell us what diameter of stop to use to get lack of definition proportionate to the focal length of the lens used, is as follows:—

With a comparatively near object focussed for, the disc of confusion, representing a point of a distant object, will be proportionate to the focal lengths of different lenses, when the actual diameter of the stops is the same for all the lenses. In other words, to get a falling off of definition in the distance, proportionate to the focal lengths of the lenses (and therefore approximately proportionate to the size of the picture, if wide-angle lenses be avoided), the stop must be of the same diameter, whatever the focal length of the lens.

From this principle the following simple rules may be deduced:—

If it be wished that "the distance" appear quite sharp when the picture is viewed from a distance equal to the focal length of the lens—that is to say, from the distance, about, that any intelligent person would select for looking at it from—the diameter of the stop must not be larger than $\frac{1}{200}$ of the distance of the object focussed for.

If the stop be as large as $\frac{1}{100}$ the distance of the object photographed for, "the distance" will be perceptibly out of focus.

If the stop be as large as $\frac{1}{50}$ the distance of the object focussed for, "the distance" will be markedly out of focus.

It will be understood that, when "the distance" is mentioned above, what is meant is any object at such a distance that it sends practically parallel rays of light from a point to the whole of the aperture area of the lens. This, for all ordinary photographic lenses, is a few hundred times the focal length of the lens, or anything more.

From the above rules adopted in practice, I have deduced one or two rough approximations as to the maximum diameters of aperture that are admissible in practice. Thus, I find that, no matter how long or how short the focal length of a lens used for landscape work, it is seldom that an aperture of more than about two inches is permissible, on account of the falling off due to lack of depth of focus, whilst in the majority of cases it is not easy to use an aperture of over 1½ inches. Again, in portraiture I find that, whatever the focal length of the lens, or the size of the picture, it is difficult to use an aperture much over 3 inches in diameter, and this on account of the want of depth due to size of aperture only.

* Continued from page 474.

One small point in connection with depth of focus is worth mentioning before I go on to another subject. If we focus for a comparatively near object, and use such a stop as to bring about a certain approach to sharpness in "the distance," we will have the same amount of sharpness (or of want of sharpness) at a distance from the camera of just about one half the distance of the object focussed for. If, for example, we focus for an object at the distance of 200 feet from the camera, whatever stop is used, there will be the same amount of sharpness in "the distance" and in an object at 100 feet from the camera. If, therefore, we wish to divide the focus, or, rather, the lack of focus, equally between the foreground and the distance, we should focus for some point twice as far from the camera as the nearest bit of foreground.

These latter statements hold true only when leaving out of consideration roundness of field and the use of the swing back.

Diffusion of Focus.—This is a subject that has always been of much interest to photographers, but that has had its interest revived lately on account of the views put forward by a set of photographers who call themselves "Naturalists." These photographers—amongst whom are numbered several of those who undoubtedly excel in the production of photographs that are really pictures, and who must, therefore, if possible, be listened to with respect—contend that it is not advisable to have any part of a photograph as sharp as a good photographic lens will make it. It has been contended that the sharpness given by a photographic lens of good quality is greater than ought to be permitted in a photograph, simply considering the matter from an optical point of view. This is a thing that I cannot admit at all, and I think I have satisfactorily proved, in a paper read before the Camera Club, that the contention will not stand the test of a thorough examination. On the other hand, as a mere matter of artistic taste, of "feeling," or of whatever we may be pleased to call it, it has been stated by several of the most artistic workers of the present time in photography that no part of a photograph should be as sharp as it could be made by the use of modern photographic lenses. Coming in this form, the opinion is one that should demand respect, even from those who do not agree with it.

But besides this there is another reason why, in certain cases at least, it seems advisable to sacrifice the keenest definition that it is possible to get. I refer now to those cases in which, on account of the comparatively large apertures that must be used to bring the exposures within reasonable limits, a part of the subject must be markedly out of focus. We have such cases in portraiture, especially in the case of large sizes, and when we have such cases, the fact that one part of the subject is in "wirey" definition, makes the parts that are out of focus only to a moderate extent appear offensively "fuzzy" *by contrast*. To prevent this contrast, the extreme definition is sacrificed by introducing what is generally called a "diffusion of focus" arrangement. Such an arrangement prevents extremely sharp definition, even in the part of the image that is actually focussed for, whilst it does not at all, or does only slightly, increase the lack of definition in other parts of the subject, and, in any case, reduces greatly the *contrast* of parts in the sharpest focus and in less sharp focus.

(To be continued.)

MR. THOMAS BROWN JORDAN, whose death is announced, was the inventor, in 1838, of an instrument for photographically recording the variations of the barometric column.

ANIMAL PHOTOGRAPHY: ITS DIFFICULTIES, USES, AND ABUSES.*

BY GAMBIER BOLTON, F.Z.S.

THE animal and bird studies from life which I shall show you to-night are generally admitted to be the results of one of the first serious attempts yet made to combine, in however small a degree, scientific and artistic qualities in animal photography.

Commencing in 1872 with a three-guinea set from our old friend Fallowfield, of Lambeth, in the days of wet collodion plates and cumbersome apparatus, I have, off and on, both at home and abroad, continued my work amongst birds and animals ever since, labouring under many difficulties of which the portrait, landscape, and hand-camera photographer knows nothing—a puff of wind moving the mane, tail, or feathers: the slight sound causing the twitching of an ear, the quick action of the eye and nostrils, or even the movement necessary in breathing, spoiling hundreds of otherwise perfect plates, many of them only taken after hours, and, in some cases, even days of watching; and, as I shall presently show you, it is quite a common occurrence to use thirty to fifty plates on a single animal or bird, and in some instances nearly one hundred half-plates have been exposed and developed before the one *perfect* negative has been obtained.

From this you will see that a good deal of patience is required—some would call it obstinacy; anyhow, a determination not to be beaten, but to return to the task day after day until the result satisfies you; a natural taste for, and some idea of, zoology, and a certain amount of artistic training is also necessary before the proper positions for the various subjects can be selected—positions that will please and satisfy naturalists, artists, and the general public (three rather hard task-masters); whilst to take up this work with the idea of producing only *the best possible results*, throwing aside all others, must mean such a heavy outlay and expense as to prevent it from ever being made to answer from a financial point of view, at least in our day.

With so many public and private zoological collections around us, there is little or no demand at present for animal photographs, except amongst the learned societies and artists; but we must remember that animals and birds that are useless to man have had their day, have already reached and passed their zenith, and the time is not far distant when photographs of many of these will be sought after, and, like a really good large photograph of the quagga or dodo to-day, would be almost priceless. For following these we have many, such as the bison, aurochs, zebra, giraffe, and hippopotamus fast disappearing before the march of civilisation, and it can only now be a question of a comparatively few years before they, too, become extinct, and we shall be compelled to turn to paintings and, above all, photographs to show our descendants what they were like.

This, then, I consider the first and greatest use of animal photography, and I am glad to say that it is being recognised as such at last; for, as some of you know, the British Museum authorities have lately ordered a set of these studies to be framed and hung in the Geological Section at South Kensington; and if, as I feel sure there are many here who, naturally fond of zoology, have taken up photography as an amusement, I would urge them, especially if they travel, to lose no opportunity of getting good negatives of the more scarce variety of animals and birds, as they will be invaluable for future reference. Do not waste your plates on such childish, easy subjects as swans, deer, cattle, and sheep; our exhibitions have swarmed with them from time immemorial. They have been taken in every conceivable position years ago in the old days of wet collodion and long exposures, when there *was* some difficulty attached to the work. But I urge you to aim somewhat higher. Read up the habits and peculiarities of the animal or bird you propose taking, and endeavour to show them plainly in your finished print, and you will not only be giving yourself real pleasure, but also benefiting the generations to come.

* Read at the Photographic Convention at Chester.

Let me here pause for a moment to answer a question that I am continually being asked, "What is a *perfect* animal photograph?" First and foremost, it should have had sufficient exposure to bring out all possible detail in the hair or feathers and in the shadows, detail being necessary in this branch of photography almost more than in any other. It follows from this that the perfect photograph, though taken in sunlight (which should be avoided if possible), should not be an instantaneous one, but should have had a fair exposure. I know that this means hours of watching and waiting, when a snap-shot might be obtained in a few moments, but the resulting negative is very different; one is of little or no use to anybody, the other may be of use to naturalists and artists for all time. The perfect animal photograph, then, should be free from heavy shadows, full of life, yet unrestrained and natural in position and expression; *all four legs and the tail* should show distinctly, and the mane (if any), nostrils, ears, and eyes, and *hairs round them*, should be microscopically sharp.

I would urge these things particularly upon those who are called upon to judge animal studies, as this is the real test of the perfect one; and may I also add a word of warning? Take care that the photograph was not from a *stuffed* subject, as taxidermy has been brought to such a pitch of perfection (especially abroad) that unless a very careful examination is made, in many cases one may be taken in.

Animal photography is not only useful to the scientist, as I have endeavoured to show, but also to the artist. There are still some, I am sorry to say, who deny that they ever use them, and, as the dealers tell me, slip in and out of their shops looking as though they had committed an unpardonable sin; but, from what I have seen and heard, I am convinced that all use them, and many openly admit their indebtedness to photography, whilst not a few possess cameras of their own, and may be seen using them constantly. It was the need of an artist in the country requiring a special position of a tiger to sketch from that first induced me to publish my series; as going the round of the London dealers, I found that, though one or two had made an attempt to bring out some large-sized photographs of animals, they were taken so small originally as to be woolly and flat, and of no use whatever to the artist; and I was convinced then, as I am now, that no one can hope to succeed in this by occasionally working with a hand-camera, but he must use a large camera, and devote his whole time—in fact, his life—to the work.

I have touched on some of the difficulties and uses of animal photography; let me now speak briefly of its abuses.

I am sorry to say that the professional photographer has a good deal of blame to bear, for he is, I fear, hopeless in this respect. Take a walk round any city and look in at their windows, and you see rows of dogs' *heads*, lacking expression as much as they do bodies, dogs, and cats lying down in sleepy positions, or sitting up looking like wooden dummies, horses and cows with three legs and a smudge representing the tail or ears, all with the scared look that tells of the assistant not far off waving a handerchief or clapping his hands, or taken at such an angle that the heads are large enough for elephants, whilst the bodies fade away into the distance, "fine by degrees, and beautifully less." It is amusing to enter with a dog and say in a quiet way that you wish him taken *standing*, and above all, with his tail *up*. The innumerable excuses that will be invented, the old, old story that heads are so much more fashionable and artistic, that they look so natural when lying down or sitting up, anything but standing, and above all, without that exasperating caudal appendage *raised*.

I have heard photographers lament the waste of time and plates used over a child's portrait, but when they have heard of the hours of watching and hundreds of plates thrown into the waste box before good negatives of the dogs standing and with their tails up can be obtained, they have thanked their stars that *their* lines have fallen in more pleasant places.

Of course there are very rare instances where it is right to take only a head; for instance, when the body is badly shaped, deformed, or injured; but these are very exceptional circumstances, and I would, therefore, urge the professional photographer the wide world over to look to this matter at once, and try to introduce a little more life and expression into his animal photographs, particularly into those of the horse and dog.

But professional photographers are not the only ones to abuse this branch of our art-science. There are amateurs, I regret to say, men high up, in fact, at the very top of the tree, whose pictures (for they are nothing else when the animal portion is left out) have won and are still winning medals at every exhibition, and whose work is pointed out to the rising generation as a model for them to aim up to. They rightly introduce animals into their work, but, using a wide-angle lens, get such hideous distortion as to become perfectly painful to those who have to sit and gaze upon these "nightmares" day after day, as many of us are often compelled to do during a club or "one man" exhibition.

Others, too (and here many of our very oldest workers are the chief offenders), rather than lose some picturesque group, will take a negative with a horse, cow, or donkey's tail or ears blurred from movement, thinking, probably, that the charm and beauty of the whole composition will draw off the attention from such a trivial fault. But surely even our friends the (photographic) naturalists would not strain their theory so far as this, and endeavour to make the blurred ear or tail the starting point for the out-of-focus portion of their picture.

But there are, I regret to say, far worse offenders than either of these. Amongst the changes which I have seen during my photographic life is that of a school of men which has sprung up during the last three or four seasons, calling themselves detective-camera animal photographers. Now there is no harm in using a hand-camera occasionally for animal photography especially if it is made to focus and show exactly what is being taken at the moment of exposure, on the twin-lens principle, for by this means many very valuable negatives can be obtained with a slowed-down shutter, and by working on cloudy days; but the school of which I am now speaking will have none of this. With box cameras and a rough scale for focussing by, they rush about in blazing sunlight taking snap-shots at every conceivable living thing that comes within their reach, and in every possible position; in fact, as we have seen with regret at several exhibitions lately, they simply prostitute this branch of scientific photography by showing us hideous caricatures of some of God's noblest works—animals taken at such an angle as to be all head or hind-quarters, minus one or two legs, an ear, or a tail; lions yawning and scratching themselves, dogs climbing up trees, giraffes all body and no head—things done for the sole purpose, as they often admit, of raising a laugh at the unhappy animal's expense. How, I venture to ask, would one of these so-called artists of the funny school like to see themselves, on show in a shop window, taken when suffering from influenza, a bad toothache, or when they have just trod or sat down upon the business end of a tin tack? Surely our aim should be a higher one than this, and if we are going to devote our time to zoological photography, let us at least try to show our subjects in the most artistic and natural positions.

Forgive me if I have spoken too strongly on this subject, but when we see signs all around us of animals fast dying out, and being rapidly exterminated as civilisation advances, it is surely time for someone to make a stand, and, in endeavouring to point out the uses of animal photography, not to pass by in silence its glaring and manifold abuses, which not only scientists and artists have condemned, but which the good taste and better education of the rising generation has taught them *are* abuses; and I trust sincerely that those who have perpetrated them will leave this branch of photography alone for the future, and turn their attention and *talents* to something a little less ambitious than the endeavour to win for themselves the proud title of *the Landseers of photography*; for this cannot be laid claim to by any precocious aspirant after a few months of practice at animal photography, but can only be hoped for after years of hard work of head and hand; and besides such a title as this, all those vapoury names of kings and princes of hand-camera work which they

have arrogated to themselves must fade into insignificance, for there may be many kings and princes, but we have at present no Landseer.

I propose showing you, first, two slides as an instance of *how not to do it*. The first is that of a lion (?) standing behind the bars of his cage. This slide, I am told by the maker, has been sold by thousands, and is used all over the civilised world with lectures as an example of what the king of beasts looks like. Beyond a nose and a few hairs there is absolutely nothing but a very fine study of iron bars. The hand-camera school are particularly fond of these negatives, one of them observing last year that he thought the bars gave a greater idea of the animal's ferocity and strength ; he forgot to add that he could not possibly photograph them *without* the bars, as he was not permitted to get inside the outer enclosures at the Zoological Gardens.

The second slide that I propose showing you is that of a bull-dog, bought from a shop window in London last week. This is rather a good specimen of its kind, but he is strapped down in the long grass apparently to a rock, and, as a study of a collar, strap, grass, and stone, is good, but there is very little bull-dog ; and how anyone could ever be tempted to waste a plate on such a really good subject in such a hideous position as this is one of those things that will probably never be revealed till later on.

I shall next try to show you what I hope you will agree in saying is *the way to do it*. Commencing with the *Carnivora* (taken standing, in dull light, and without the bars), we will pass on through the *Ungulata*, leaving the birds and dogs till the end.

I would mention that all these studies were taken with an ordinary whole-plate camera and Ross lens, rarely instantaneous, but most on dull days, the majority having had exposures of from one to two seconds.

Mr. Gambier Bolton then exhibited about fifty slides, which, he mentioned, had this season been exhibited at the Royal Society, Burlington House; Royal Institution (twice), and before the Zoological Society, London; and had been awarded medals at the Crystal Palace two consecutive years.

Proceedings of Societies.

Photographic Society of Great Britain.

The technical meeting of this Society was held on the 24th inst., Mr. Leon Warnerke in the chair.

Mr. H. Chapman Jones brought forward a double dark slide that he had produced at the meeting held in January last. He had then also exhibited two plates that had been kept in this slide, and that showed with under-exposure patches of increased development opposite to where the hinges had been. These hinges had originally been of leather, but this material had been removed, as it had been found to cause fogging at the part of the plate opposite to it, and a woven material had been substituted for the leather. On the plates shown in January, which had been placed in the slide immediately after the new material had replaced the leather, he had attributed the markings to increase of sensitiveness, which, he thought, was caused by the same substance in the leather which had at first caused fogging, having penetrated the woodwork and being given off afterwards in such small quantity as to be insufficient to fog, but enough to exalt the sensitiveness. Some members had then suggested that there was not an increase of sensitiveness in that part of the plate opposite to the hinges, but a decrease in the rest of the plate, due to the wood or varnish used. He thought that he could now show that this theory was not the correct one, as he had since kept plates in the slide for some months, plates cut out of larger ones of which he had kept the remaining pieces, and on developing he could not find the slightest difference in sensitiveness, or any mark opposite the hinge. The absence of the marking now he considered to be due to the emanation originally belonging to the leather and left in the wood having exhausted itself in the first week or two.

The Chairman mentioned that he had had a slide which caused fogging, not due to leather, for there was no hinge to it, as it was one of those where the shutter was made to draw out entirely. The inside of this shutter was varnished, and there was a projection in the cut-off which scraped away the varnish in two lines. Plates placed in this slide showed clear spaces opposite to these lines, whilst the rest was fogged. Further to test it, he had scraped an image on the shutter, and found that a plate, after keeping in the slide for some time, reproduced the image in the same way that the lines had been reproduced. He could not say what was the composition of the varnish that gave off such a deleterious action.

Mr. Atkinson remarked that he had found great difficulty in keeping flexible celluloid films flat in the press whilst printing. He also noticed that they were not flat in the camera when there was any tension on the rollers of the dark slide.

The Chairman said that to get the celluloid to lie flat whilst printing, a press must be used with many screws at the back. He had one of twelve by ten size, the back of which had been sawn nearly through in lines making twelve squares, on each of which a screw was brought down. He thus secured good contact.

Mr. Atkinson remarked that it was a complaint that there was no good way of varnishing celluloid. He had found Mawson's varnish, supplied expressly for celluloid, to answer exceedingly well.

A Member referred to the use of gold size thinned with benzole or turpentine ; but

The Chairman stated that gold size darkened so much in time that its use was a serious disadvantage. A solution of amber in chloroform made a varnish that answered very well. Some linseed oil darkened very much, whilst other samples did not do so. Linseed oil was boiled sometimes with lead, and sometimes with manganese. In the former case darkening must be expected. There was a work of Spon's giving several details on the subject.

Mr. Scamell said that there was also one of Weale's series, by Field, in which various formulæ would be found relating to varnishes and drying oils.

Mr. Atkinson asked whether celluloid films were liable to decay.

The Chairman had some now that he had had for fifteen years, and could find no change in them.

Mr. W. England considered that they were as durable as glass.

The Liverpool Amateur Photographic Association.

At the meeting in the Club Rooms, 3, Lord Street, on June 19th, Mr. Paul Lange presided, and the following were elected members of the Association : Messrs. Albert Proctor, Alexander Cannon, Wm. T. Philip, J. N. Stolterfoht, and James D. Paterson.

The President reported on the excursion to Rossett and Gresford on the 7th inst., when about thirty members and six ladies were present, and 200 pictures were secured. He mentioned that the next excursion would take place on July 19th (whole day), to Bolton Abbey. He also entered into a detailed explanation of the Chester Convention, and recommended the use of Mawson's backed plates for taking the interior of Eaton Hall.

On the 31st July Mr. J. W. Wade, vice-president of the Manchester Amateur Photographic Society, will give a paper on "Landscape Photography," with illustrations in charcoal, and he will also introduce a chapter on architectural photography. Later on, in August or September, the Britannia Company is to give a demonstration with their alpha paper.

A fine mounted print was presented to the Society by Mr. Friese Greene of the Convention members group of 1889, taken on 24 by 20 glass plate slightly cut down.

The late Mr. J. W. Robinson, junr., a young member of the Society who died last month, has bequeathed his camera and outfit to the Association for the use of the members of the Society.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

AT the meeting on the 19th inst. Mr. J. J. BRIGINSHAW occupied the chair.

The next meeting being the annual meeting, officers for the ensuing year were nominated in accordance with the rules.

Mr. J. P. EVERITT showed prints in platinotype of negatives taken at the outing at Hale End the previous Saturday. He also passed round silver prints from the same negatives for comparison, arising out of the discussion of the previous week.

Mr. W. E. DEBENHAM was in favour of the albumenised prints as showing more ærial perspective and gradation, an opinion that was shared by many other members present.

Mr. T. E. FRESHWATER also showed some prints taken at the same outing; these were on Pizzighelli paper. Replying to a question, Mr. Freshwater said these had taken two and a half hours to print.

A question from the box was read: "Is there any advantage in printing through green glass on to silver paper?"

Mr. PASK said at the Photographic Exhibition recently held in the City, some silver prints were exhibited which were stated to have been printed under green glass.

The HON. SEC. said that he had used with advantage a sheet of green gelatine in printing from collodion negatives when they were of a slatey tint.

Mr. T. E. FRESHWATER exhibited some prints from negatives taken during his holidays last summer; these, in several cases, showed a dark broad band down the centre, which he attributed to unequal coating of the plates.

Mr. W. E. DEBENHAM said a piece of loose string hanging down behind the lens would produce a similar effect. Various theories were put forward to account for the markings; it was, however, generally agreed that they were caused by some defect of the camera.

Mr. FRESHWATER said he would bring his camera down to the next meeting; he believed it to be quite perfect.

A question from the box was read: "Can anyone tell what is 'bone dryness?'"

Mr. W. E. DEBENHAM said he should consider an article to be in this condition when no moisture was perceptible to the senses.

PHOTOGRAPHIC CLUB.—The subject for discussion on July 2nd will be the "Report of the Convention Delegates"; July 9th, "Photographing Theatrical Scenery."

RECEIVED.—From Messrs. Piper and Carter, "A Casket of Photographic Gems": A Collection of 500 Dodges, Receipts, Entertaining Experiments, &c., in connection with the Art of Photography and its Branches, collected, classified, and arranged for ready reference, by Ingles Rogers." The compiler explains that the favourable reception of the pamphlet entitled "One Hundred Photographic Dodges" induced him to produce a work of a similar nature on a larger scale, culled from the photographic literature of the past half-dozen years. Like the former work, the present one is intended "as a ready reference book for the 'old hand,' as well as a means of instruction for the beginner, and to form a handy pocket companion for both." The book consists of 142 pages, and contains as frontispiece a specimen of Messrs. Waterlow and Son's collotype work, representing Cookham Lock, with a party of pleasure seekers returning from Henley Regatta.——The same publishers submit a copy of the "Evolution of Photography," by John Werge. It comprises a chronological record of discoveries and inventions, contributions to photographic literature, and personal reminiscences extending over forty years, and is illustrated by plates giving portraits of those whose names are identified as leaders in the advancement of the photographic art. We will say no more of this book at present than that it is divided into four periods: the first deals with such facts as bear on the discoveries, early researches, and ultimate success of the pioneers of photography; the second embraces a fuller description of their successes and results; the third is devoted to a consideration of patents and impediments; and the fourth to the rise and development of photographic literature and art.

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

TEIGNBRIDGE.—Our Holmescope came from Messrs. H. T. Anthony and Co., of New York, but we believe they are procurable from the Eastman Photographic Company, 115, Oxford Street, W.

L. E. M.—*Printing Hard Negatives.* Improved results can sometimes be obtained by sunning the paper prints from the back. Another method is to screen off the under-exposed masses of shadow by one or two folds of tissue paper, or use a thin transparency as a mask to be superposed whilst printing. Perhaps the best method is to coat the finished hard negative with collodion emulsion, give a brief exposure to light through the back, develop, and work with this compound negative. Or, lastly, reproduce the negative with full exposures at both stages of this operation.

F. M. S.—*The Solar Eclipse.* You seem to have been more fortunate than observers in London or the metropolitan district, where, owing to the clouds and rain, the eclipse was scarcely visible.

J. S. R. (Brighton).—*Yellow Stains on Albumenised Prints.* Failing to discover the cause of the yellowish colouration, unless it be hypo, it is at least satisfactory to find that the prints may be so easily cleared by immersion in dilute hydrochloric acid; but you must remember that if working with rose-tinted paper the acid will dissolve out the whole of the rosaniline, and necessarily alter the tone of the print.

VIATOR.—*Smokeless Powder.* We have seen the photographs to which you refer, but the military considerations involved scarcely come within the province of discussion in these columns.

A. W.—*Maignen's Softening Process.* Further enquiry has elicited the fact that the inventor proposes to boil powdered charcoal with lime water, and then use this preparation for softening water by stirring in a small quantity, and afterwards filtering through his asbestos cloth.

L. P. (Norwich).—*Aluminium Lens Mountings.* Not an alloy of aluminium, but the pure metal itself is now employed by several leading opticians in the mounting of their lenses, for the sake of diminishing their weight. With care they ought to prove incorrodible, but we cannot answer for sea-spray not affecting the metal.

M. T.—*Hypo Eliminator.* Hydrogen peroxide has already been proposed, but is not easy to procure, and it may possibly act upon the albumen coating, if not upon the finely reduced metal constituting the image. It is far preferable to depend upon a thorough washing, or even upon treatment with a weak acid, to destroy any remaining trace of hypo.

J. G. M. (Scarboro')—*Printing out Emulsion.* This may be the ordinary collodio-chloride, such as described at page 203 of the YEAR-BOOK, or Captain Abney's gelatino-citro-chloride; see his "Instructions in Photography," pages 288 and 289. If neither of these will answer your purpose, apply to Mr. Friese Greene for a suitable preparation, or to Messrs. George Houghton and Sons, High Holborn, W.C.

INTAGLIO.—*Electro Carbon Reliefs.* These were executed as far back as 1860 by Mr. J. W. Swan, specimens being shown in the historical collection at the International Inventions Exhibition. Seven years later, Mr. Woodbury produced some plaster casts from his gelatine reliefs, and showed them at the Dundee meeting of the British Association, stating that these could be copied by the electrotype process if desired. Many later experimentalists have worked at the same subject, some of them taking casts in Spence's metal.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1661.—*July* 4, 1890.

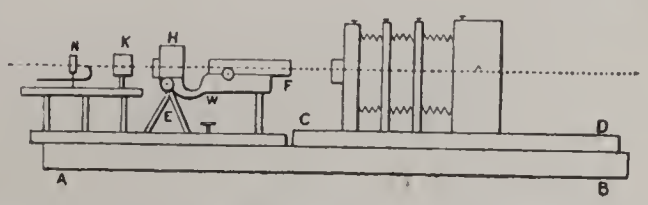
CONTENTS.

NOVELTIES AT THE PHOTOGRAPHIC CONVENTION.

THREE instruments of special novelty were exhibited at the Photographic Convention at Chester; one of them was a new photometer, another a photo-micrographic camera of new design, and the third a new magazine camera.

The photometer was the invention of Mr. Frederick H. Varley, and his article describing it will be found in another column. Mr. Friese Greene exhibited the instrument to the Convention. It consists of a rotating disc with two variable apertures, which can be opened or closed during rotation by the ingenious mechanical contrivance known as the Furgusson paradox. The light from the one source passses through one of the apertures, and the light from the other source through the second aperture. A comparison is made by means of two shadows, the relative depth of which is regulated by the size of the apertures. When the shadows are balanced, the angular aperture of the two orifices is read off. The advantage of this instrument is, that both the electric light and the standard flame are measured when they are at the same distance from the screen; consequently the two shadows are of equal size, so the density of the shadows for equal areas is the same when balanced. This feat, we believe, has not previously been achieved in photometry, except in the wedge photometer of Dr. Wollaston, which, however, is of too limited a range to be suitable for most practical purposes. Mr. Varley and Mr. Friese Greene are arranging some experiments for determining by means of this photometer the value of direct sunlight in candle power; also the value of reflected light from the clouds, blue sky, foliage, and other objects. Scientific data of this kind will be of interest to photographers.

Another remarkable piece of apparatus exhibited at the Convention was a photo-micrographic instrument designed by Mr. Andrew Pringle, and constructed by order of the Privy Council by Messrs. James Swift and Son. In high photo-micrography absolute steadiness of the apparatus is as necessary as it is in large astronomical telescopes, or in the galvanometers used in working the Atlantic cables; therefore the chief feature of Mr. Pringle's instrument is its great steadiness and solidity. Its principle may be explained by the aid of the accompanying diagram, in which A B is the base-



board of mahogany, measuring 6 feet 8 inches by 20 inches, and C D is one of two pieces of heavy solid mahogany forming a tramway on which the camera slides in brass guides, and to which it can be firmly clamped by screws. The camera takes half-plates, and has an extension of from eleven inches to four and a-half feet. A special feature of this invention is the brass cradle, W F, which is so formed as to hold both ends of the microscope tube when high powers are used; thus all vibration of the tube at the eye-piece end is prevented. H is an adjustable stage, with a sub-stage condenser; K is an achromatic condensing lens, and N the lime cylinder for the oxyhydrogen light. The cradle is steadily mounted at one end upon a brass trestle, two legs of which are shown at E; at the other end it is supported below F. The lime light part of the apparatus is mounted upon a platform, so that it can be made to approach to or recede from the microscope, and to give a divergent or parallel beam of light at the will of the operator. The whole of this end of the instrument turns round upon a base-board to permit the adjustment of the object. The ultimate destination of this apparatus is the Royal Veterinary College, Camden Town, London, where a room in the basement has been specially arranged for its reception, and where it will be fixed on a support of heavy masonry, resting upon a foundation of solid concrete.

The third novelty of mark exhibited at the Conven-

tion was a new camera, a great improvement upon the one described a few months ago in these pages, for taking negatives upon an endless film at the rate of from five to ten or more per second. The original camera, invented by Mr. Friese Greene and Mr. Mortimer Evans, paid out a certain length of film for each picture, and this slack length was suddenly drawn into position for the exposure. The later camera, first publicly exhibited at the Chester Convention by Mr. Friese Greene, was the invention of Mr. Frederick Varley, and in it the film is never allowed to slacken, but is kept taut by means of springs acting differentially inside the paying-out roller and the receiving-roller, so that the two rollers have always a balanced spring-pull in opposite directions. When a length of film is required for exposure a disturbing element comes into play in the shape of a horizontal roller, which rises and draws off exactly the length of film required for the next picture. By this instrument the film is paid out with great steadiness and regularity, and none of the film is wasted, for each negative is separated by but a narrow line from its successor. Application has been made for a patent for this camera, which is likely to be useful for military and other purposes, in addition to those purposes which Mr. Friese Greene had in view when he started the idea of cameras of this class. With the optical means at present in use in such of these cameras as have been constructed, he says that he finds exposures at the rate of about five per second to be the best speed for obtaining good negatives sufficiently near each other in time to convey the idea of life and motion when successive positives from them are projected at the same speed upon a screen by means of a suitable lantern.

As to this matter of speed, Mr. Greene said to the Convention: "The familiar experiment of the complete ring of light seen upon whirling a burning stick in a dark room, shows that the sensation of sight lasts for a short period after the mechanical action which produced it has ceased. This period is probably different for different eyes, and for different amounts of excitation even in the same eyes; I hope to prove, at some future date, by the pictures taken with the machine camera, that some people see them perfectly on the screen when they are produced at the rate of three a second, that others see them perfectly at four, five, and six a second. Of course, the size of the picture upon the screen, and the amount of light which the lantern can give, have something to do with it too. If the light be very intense the effects last much longer, so that you can run them through slowly. For the present purpose it may be assumed that a speed of from three to seven per second will be enough to show life-like effects to any audience, or to represent nature in motion as we see it. The duration of visionary impression varies with the powers or structure of the eye in different individuals, just as the time necessary for the recovery of the tone of the retina varies in passing from brightness to darkness."

THE PHOTOGRAPHIC CONVENTION AT CHESTER.

LAST week we published particulars about the Photographic Convention at Chester, until the time of going to press, when the members of the Convention were leaving Conway. The Castle Hotel, at Conway, where lunch was taken by the excursionists, and at which Mr. Bothamley, the President of the Convention, is well-known, is a centre for artists, and much visited by Americans in the summer months when *en route* from Holyhead to London, because Miss Dutton, its proprietor, has a large collection of works of art of various kinds.

Here we found original works by Cipriani (the founder, with Sir Joshua Reynolds, of our Royal Academy), Romney, Sir Thomas Lawrence, David Cox, Frederick Tayler (the late President of the Royal Water Colour Society), J. W. Whittaker and J. D. Watson, both distinguished members of the same Society, Joseph Knight, who is one of our best English etchers, Dawson Watson, Buckley Ousey, Edwin Ellis, R. Somerset, Dan. Fisher, R. Gallon (the President of the Crichton Art Club), Peter Ghent, W. L. Banks, W. B. Turner, J. C. Salomon, Charles Potter, and others. There is also a handsome specimen of the Old English Water Colour School of the middle of last century, by Smith of Chichester. Its purity of colour is in marked contrast with the water colours of modern days, in which body colour is so freely used. There is a half-length life-sized original portrait of Dame Penderil, of Boscobel, notorious for her loyalty and fidelity to the gay and popular though ungrateful monarch, Charles II.

The Conway and Bettws-y-Coed parties returned by various trains to Chester in the evening. The majority returned by the earliest train to be present at the reading of papers, and in this train was Mr. Ephraim Wood, the chief superintendent of the Chester and Holyhead line, who was fully alive to the business advantages of a number of professional and other photographers being at work in his district, and afterwards scattering pictures thereof broadcast all over the country. He personally superintended the excursion arrangements.

On Thursday evening, Mr. Andrew Pringle read a paper entitled "The Record of Photo-Micrography," and the report of the committee on "Weights and Measures" was read. Mr. Friese Greene also read a paper, entitled "Suggestions," from which we give to-day a quotation in our leading article, and more extended descriptions of the instruments he described than he had time to put before the meeting.

On Friday last views were taken by the excursionists at Hawarden Castle, and in the evening there was a dinner of the Convention at the Grosvenor Hotel, Chester, which great hotel is under the genial management of the experienced Mr. Foster. Mr. Bothamley presided, various after-dinner speeches were made, and a number of recitations and songs contributed by the members. The hard-working honorary secretary, Mr. Briginshaw, was "toasted," and was styled "The Father of the Convention."

On Saturday morning last there was a meeting of the General Committee, at which Mr. William Bedford was appointed President of the Convention for the Bath meeting next year. In the middle of the day most of the members left Chester.

PHOTOGRAPHING FLOWERS.

It is a remarkable circumstance in these days of universal photography, and when some kind of photographic apparatus can be found in more than one house in every street, that flowers, the most beautiful gifts of inanimate nature, should be almost entirely neglected by the camera bearer. They are within the reach of nearly all, for although some of us are destined to spend the best part of our lives amid bricks and mortar, and in houses whose back gardens take the form of "leads," still we have friends who, better off than ourselves, are provided with greenhouses; or, by the expenditure of a very modest sum at the nearest florist's, we can provide ourselves with a bouquet of beauty. Artists who devote their first attempts to still life eagerly take up flower and fruit painting, attracted, of course, by the wonderful and unending contrasts of form and colour which these models afford. Perhaps it is mainly because photographers are excluded from the chromatic world that they have not paid more attention to this branch of work. Whatever be the reason, flowers are neglected by photographers. In our photographic exhibitions we seldom see pictures of flowers, and, as far as we can remember, only one worker, whose beautiful orchids won prizes at all the exhibitions half-a-dozen years back, has seriously devoted his energies to portraying Flora.

There are certainly difficulties to be met with in photographing flowers which do not often assail those who are engaged in the more ordinary paths of work. One of the chief of these is the necessary nearness of the objects to the camera—a difficulty which will be at once appreciated by anyone who endeavours to focus upon his ground-glass screen the image of a flower-spangled hedgerow. It is at once seen that, owing to the various planes of the different petals, only a few can be brought to a sharp focus at one time. It is of course the same if we attempt to photograph a single flower or a mass of flowers in a greenhouse, but here we are relieved of one great difficulty in having a perfectly still atmosphere to work in. But, whereas in the open air it is next to impossible to reduce the growth to one plane, unless, indeed, we clip away half its beauty with a pair of shears, in the greenhouse we are able to mitigate the evils to a very great extent by adopting certain precautions. The flowers, being in pots, can be moved about and grouped as we may think best, and any petal bearing stems which are obtrusively prominent—and therefore out of focus—can be held back by the temporary expedient of attaching to them grey lines of the thinnest binding wire. We have tried this plan many times with great success, but care must be taken in adopting this method of pulling the stems out of their natural position that they are not so awkwardly placed that the dodge is likely to be detected. Care must also be taken that the wires used are properly concealed.

In photographing flowers in a greenhouse it will generally be necessary to provide some kind of background. The entire beauty of the picture will be sacrificed if the straight lines of the beading between the glass panes come into view, and more especially if the bright sky is seen through them. A square yard of some good tinted material—such as is used for ordinary studio backgrounds—will answer the purpose better than anything else, but it should, if possible, be stretched on a frame, so as to present one even, unwrinkled surface. In the absence of a greenhouse, and when we wish to photograph flowers in the form of a bouquet, we shall do well to conduct operations in the studio or in an ordinary room. In the first case no difficulty should present itself with regard to lighting, for curtains, screens, and blinds are under ready control, but in an ordinary room, as in the case of portraiture, special arrangements have to be made.

The flowers must first of all be grouped as artistically as possible, and may by preference be held in some kind of ornamental vase. This should be of glass or of some light coloured material—such as alabaster—in order that there may be contrast between it and the flowers which it holds. This vase should be placed near a window where there is a good diffused light—not actual sunlight—with a looking glass or white screen at the other side, so as to reflect light on its shady parts. The background should not be too dark, nor should it be of a pronounced pattern of any kind. All must be as light and airy in design as possible. The flowers themselves must not be matted together, and it will be found that a few—say some choice roses or lilies relieved by sprigs of maidenhair or feathery grasses—will be far more effective than a great number.

We have occasionally seen flower photographs—generally roughly coloured—exposed for sale in some of the shops, and they are useful as a guide to show what to avoid. These flowers appear to have been grouped and supported on a sheet of white cardboard, with the result that a heavy black shadow—a kind of mourning band—borders them on all sides, for the light in which they have been photographed appears to have come from the front, that is, behind the camera. Strong contrasts are most easy to obtain in photographing flowers, and they should be carefully avoided, firstly, by suitably lighting the object and providing a proper background, and secondly, by giving a prolonged exposure with a small stop, so that development may proceed without the least forcing and blocking up of the high lights.

The lens which is kept to use for flower work is one of the rectilinear type. Almost any lens except a portrait lens will do for photographing flowers, provided it can be well stopped down. To get the best results it is as well to use isochromatic plates, and many published pictures have shown us all what good service such colour sensitive plates will do in this particular field of work. But ordinary plates, if used with a yellow screen behind the lens, and with the protracted exposure which that course entails, will give results which are difficult if not impossible to distinguish from those obtained by the use of isochromatic plates.

A short time ago we selected a number of yellow, red, and blue flowers, and photographed them with ordinary plates under the conditions just described, and also with colour sensitive plates, and we could hardly distinguish any differences between the two sets of negatives when afterwards compared.

Now that spring has "unlocked the flowers to paint the laughing soil," photographers have an opportunity of taking their portraits, which should not be missed. If the pictures appear to have no particular value, the operation of taking them will at least bring a return to the worker to showing him the effects of various colours on the sensitive surface of his plates, and teaching him how those effects can be modified by means at his disposal.

A NEW PHOTOMETER.

BY F. H. VARLEY, M.I.E.E., F.R.A.S.

IN writing upon photometry, it is as well to pass in review the various appliances that have been devised for obtaining a measurement of the comparative intensities of different sources of light. This at once brings us to an adopted standard of light, unfortunately as purely arbitrary as the foot rule is for a standard of length. This standard is termed the candle power, and is the amount of light produced from a sperm candle burning 132 grains (or 8·553 grammes) of spermaceti per hour, the pressure of the barometer being 760 millimetres, and this standard is the adopted one employed by all the gas companies for measuring the c.p. (candle power) of their gas.

The celebrated Dr. Wollaston, the discoverer of palladium and inventor of the goniometer, employed for his researches a wedge-shaped trough, with glass sides, filled with an inky fluid. Both the standard light and the one to be compared had to pass through this intercepting medium; thus, the gas-flame passed through the thicker end of the wedge, and the standard through the thinner, and the lights were moved nearer or farther apart until the shadows cast by both were equal; the intensity of the light being determined by the mean section of each portion of the wedge through which the respective lights passed. In his astronomical researches he used wedges made of neutral tint glasses, and with these he determined the value of light coming to us from the stars. The value of Sirius he gives as being that of $\frac{1}{20000}$ millionth part of that produced from the sun; the sun, according to the same authority, being equal to the light produced by 5,563 wax candles burning at one foot distance from the screen.

Professor Wheatstone employed a vibrating bead of silvered glass, and the two lights to be compared appear, by reflection, as two parallel luminous lines. By employing the law that "the intensity of the illumination of any body in the presence of a source of light will depend upon its distance from that source;" and secondly, that light decreases as the square of the distance of the luminous body; a distance is found when the luminous parallel lines are equally bright—that is to say, that by altering the relative distances of the two lights until the luminous lines appear to be of equal intensity, and squaring these distances from the vibrating bead, the different illuminating power of the two sources of light is readily measured.

In place of the vibrating bead of Wheatstone's, the Bunsen screen is generally adopted, a long scale having at one end a standard candle, and the light to be measured at the other, is provided with a tram line, upon which runs a carriage carrying the Bunsen screen. By moving this screen between the two lights until a position is found where both surfaces are equally illuminated, and measuring its relative distance from the two lights, and squaring their distances as before mentioned, their measurement is obtained. These photometers are fitted up in a room painted a dead black in every part, so that no false light by reflection shall interfere with the correctness of the readings. With such an apparatus a light up to 400 candle power can be measured; but when an electric arc light has to be determined, the photometer room would have to be from 50 feet to 100 feet in length to obtain the balanced illumination of the Bunsen screen. If we are measuring a 10,000 candle-power arc light, the distance would be as follows:—Standard candle from screen one foot, electric light from screen 100 feet, that taken as the value of the square of the distance—namely, 100 by 100 = 10,000 candle power at one foot.

Professors Ayrton and Perry have devised a photometer by which the distance of the electric light from the screen may be very considerably reduced. The light falls upon a given area—say a circular inch—and passes through a concave lens which diffuses the light, and causes it to spread out, the area of the diffused circle depending upon the distance of the screen from the concave lens. Assuming that it be made to cover a plane exactly ten inches in diameter, the decrease of illumination will be proportional to the square of the diameter, or a one-hundredth part as bright. By this device the distance of the electric light from the concave lens can be reduced to ten feet, when it would balance the standard light at one foot from the screen, or, in other words, $10^2 \times 10^2 = 10{,}000$, the amount of light produced from the electric arc.

Captain W. de W. Abney has obtained the reduction of the brighter light by employing rotating sectors which allow only a given quantity of light to pass, which he can vary at will by opening and closing the sectors whilst they are being rotated, and he determines the value of the light by calculating the areas of the wedge-shape openings. Figs. 1, 2, and 3 illustrate this.

Fig. 1. *Fig.* 2. *Fig.* 3.

Fig. 1 shows the sectors open to full extent, viz., 90°, when 50 per cent. of the light will be intercepted, and 50 per cent. pass through.

Fig. 2 shows the sectors open 45°, when 75 per cent. of the light is stopped, and 25 per cent. passes through.

Fig. 3 shows the sectors open 18°, when 90 per cent. of the light is stopped, and 10 per cent. only passes.

The photometer I am now about to describe differs from all these in being a direct reading instrument, in which the standard and the light required to be determined are both placed at the same distance from the screen shown by fig. 8.

Two discs, perforated by semi-ring-shaped openings, the breadth of which are equal, as shown in fig. 5, are

mounted on an axis with their openings reversed, so that when the outer half-ring is fully open (extending to 180°) the inner ring is entirely closed; or if the outer half-ring is open to 90°, then the inner ring will be opened to

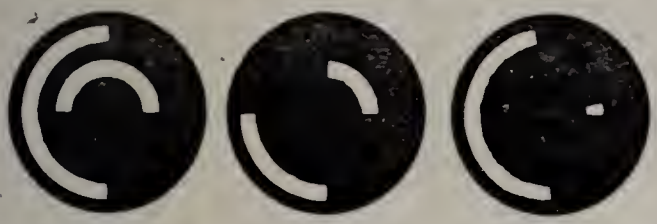


Fig. 5. *Fig. 6.* *Fig. 7.*

the same extent, as shown in fig. 6. In that case, when the discs are rotated, two complete circles are formed, through which an equal amount of light will pass. Again, as in fig. 7, the outer ring is nearly open, and the inner

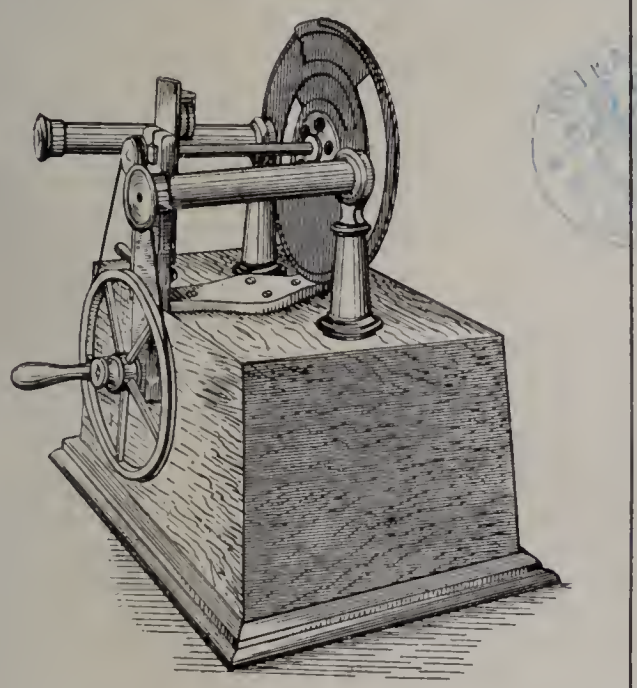

Fig. 4.

one only partially so. As before, two rings are formed upon rotation, but the amount of light which passes through will be unequal, being, in fact, directly proportionate as the extent of the degrees of arc of the openings are to one another. If, say, the outer ring is opened 160°, and the inner 20°, in order that the more intense light passing through the inner circle shall balance the standard light passing through the outer, all that has to be done is to read off the respective degrees and write them down in the form of fractions—that is, $\frac{20}{160} = \frac{1}{8}$; from this we ascertain that the light is eight times more intense than the standard. Instead of the conventional division of the circle, we divide the half-circle into 2,000 parts, for the purpose of obtaining a finer or more extended range of reading up to 1,999 times.; these divisions, by means of a vernier, can be further subdivided ten times, and read up to 20,000 candles in round numbers.

The breadth of the semi-ring-shaped windows in this instrument is one inch, and in front of the discs are two equal collimators, one of which projects a disc with a black centre, and the other a corresponding luminous spot. They are regulated so that when the light falling upon the screen from both sources is equal, a uniform disc is obtained; but if one or the other preponderates, a disc with a grey spot, or a grey marginal ring with a bright spot, indicates which of the two sources of light reaching the screen predominates.

In order to regulate this, it is necessary to open one of the windows and close the other until a balance is obtained. This is effected by bringing into play a modification of the well-known Furgusson paradox: the rear disc is carried by the central axis, and the front disc by a long sleeve fitting over it; both the central axis and the sleeve are provided with tooth wheels. Above these is an axis which carries two wheels, one with a hundred teeth, and the other with ninety-nine teeth, which are readily placed in or out of gear by a jointed lever; when in gear they cause the two discs to shift or turn upon each other, and so open or close the windows. It is convenient in some cases to dispense with the collimators, and determine the values of the light by comparison shadows, in which case a T-shaped screen is employed pierced with

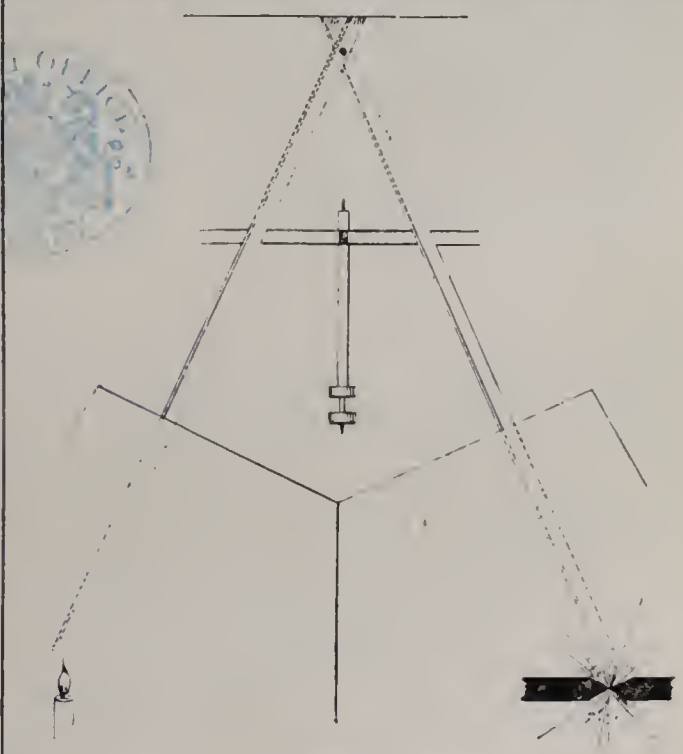

Fig. 8.

two holes each a circular inch in diameter, the centres of which are of a distance apart which corresponds with the mean diameter of the circular windows through which the light passes on to the screen. The middle partition forming the T prevents one light from interfering with the other. The apparatus is set in rotation by turning a band wheel, and the windows adjusted until the two shadows balance. The values are read off from the divided scale of 2,000 parts, which is numbered from left to right, and right to left, giving at once the fraction values of the ratios of one aperture to the other.

Photographic Society of Upsala. — Mr. N. C. Duner writes that the number of the members of this society now reaches fifty, and that it has been resolved to hold an exhibition of members' work in the autumn.

Photo-Micrographs of Diatoms.—MM. A. Traun and Witt, in their work on the fossil diatoms of Hayti, describe their peculiar method of photographing these objects. They first photograph the diatoms with a magnification of not more than 100 diameters, and afterwards enlarge the negatives, so as to obtain a photograph magnified 500 diameters, proper for photo-printing. Fine details are said to be brought out, which are invisible to the naked eye in the smaller photograph.—*The Microscope.*

DEPTH OF FOCUS AND DIFFUSION OF FOCUS.*

BY PROFESSOR W. K. BURTON, C.E.

THE introduction of "diffusion of focus" was first suggested by Mr. J. Traill Taylor, and first put into practical shape by the elder Dallmeyer. Practically, "diffusion of focus" is brought about by allowing a certain amount of positive spherical aberration to go uncorrected, and, in the case of the "diffusion of focus" lenses introduced by Dallmeyer, the spherical aberration is introducible at will by the unscrewing of the back lens of the posterior element of a lens that has already been illustrated in the course of these communications.

There has been a great deal of discussion as to whether the introduction of spherical aberration can actually *improve* the definition in any planes or not, and I do not propose to enter into this much-vexed question here. It does certainly, I am convinced, in many cases result in a practically more harmonious picture than results from a perfectly corrected lens, and all that I propose to do here is to try to explain the result of working with a lens not completely corrected for spherical aberration, and to touch on one point in connection with this that has, I think, so far been overlooked.

I use for the illustration of this matter a couple of cuts taken from the PHOTOGRAPHIC NEWS of April 6th, 1888, in illustration of a paper that was read by Mr. T. R. Dallmeyer before the Photographic Society of Great Britain, on "So-called Depth of Focus and Diffusion of Focus."

Figure 1 is intended to represent the rays of light passing from a point O through a lens that is without any spherical aberration, and that come to a focus at I. A point at O is thus represented by a point at I. Points at o_1 and o_2 will, on the other hand, be represented by spots of light of the diameter of the cones of light at i_2 and i_1. Now, as the diameter of a point is zero, the spots of light representing points nearer to and farther from the plane focussed for are, in this case, indefinitely larger than the point representing a point in the plane focussed for, and the contrast is, therefore, indefinitely great.

Figure 2 represents the same state of affairs as figure 1, but that there is, in the latter case, a certain amount of spherical aberration introduced. It will be seen that, in this case, a point at O is not represented by a point at I, but by a spot of a quite appreciable diameter; whilst, on the other hand, the spot shown at i_2 is no larger than where there is no spherical aberration; that at i_1 is not much larger. The *contrast* is thus very much less.

A point that may not be of much practical importance, but that has, I think, been overlooked in all the discussion

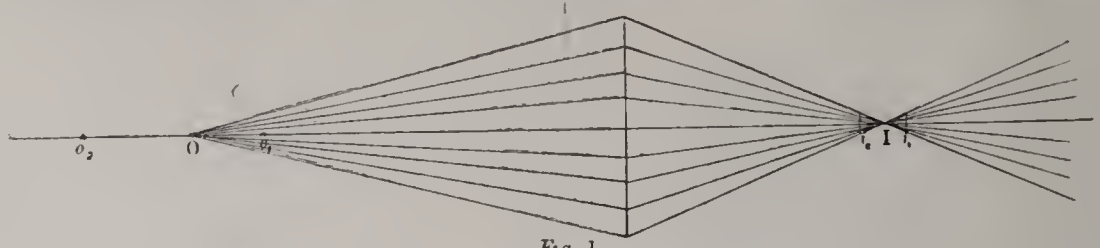

Fig. 1.

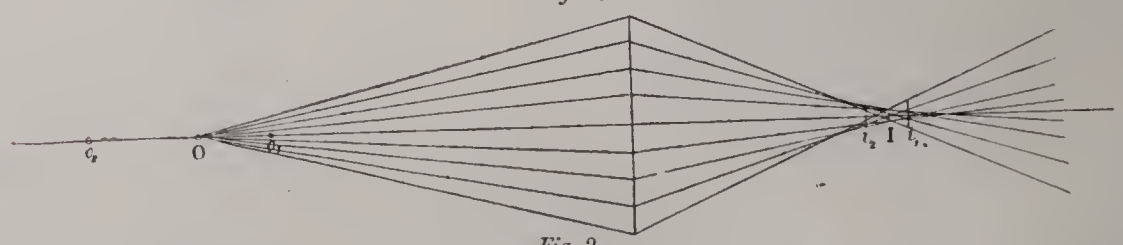

Fig. 2.

that there has been on this question of "diffusion of focus," is this. It has, so far as I know, always been assumed that, in using a diffusion of focus lens, supposing a point to be focussed, the ground-glass will be so adjusted as that it will cut the cone of light where the diameter is the smallest—that is, at I on the cuts that are given above. I believe, however, that in practice this is not so, but that focussing is done more nearly for that part of the cone where the light from the edges of the lens comes to a focus, and that for the reason that a certain increase of diameter means a much greater increase of area towards the edge of the lens than near the middle, so that the *brightness* of the cone at that part where the rays from the edge of the lens meet will be far greater than at any other part, and focussing will be done for that part; where a point in the image will be represented by a very small bright spot with a halo round it, points both nearer and farther off being represented by bright rings filled with a dimmer light. Focussing will, I consider, be done not for the plane I, but somewhat more nearly for that of i_2. I have tried—not very successfully, I fear—to show what I mean in figure 3. I have re-drawn the last figure, but showing the lines that are supposed to represent light, thick in proportion to the amount of light that passes through

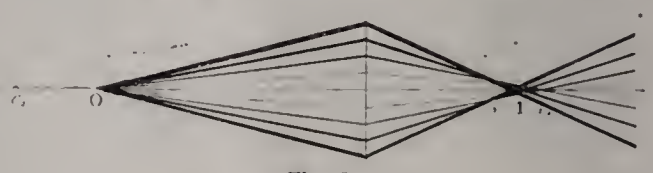

Fig. 3.

the ring that is immediately enclosed by each pair of lines. This light, beginning from the centre, varies with equal increments of diameter, in the ratio of the numbers 1, 3, 5, 7, &c. It will be seen that the greatest concentration of light is between I and i_2. It is already recognised as advisable that, in the case of a lens with adjustable diffusion of focus, the focussing should be done after the adjustment is made. I think what I have just explained is in great part the reason of the advisability.

Diffusion of Focus in Landscape Lenses.—The lens above mentioned as the invention of Dallmeyer, which allows of introducing diffusion of focus at will, is an expensive form

* Continued from page 475.

of portrait lens. It is quite possible, however, with the cheapest form of lens—namely, the single landscape lens—to produce all the effects of diffusion of focus simply by increasing the opening to a certain extent. Thus, a single lens with the opening increased to anything between about *f*/16 and *f*/8, according to the form and the kind of glass used, will give a very soft image, and the apertures mentioned are such as are quite sufficient for portraiture with modern dry plates. In fact, for very large work, there are reasons for preferring the single lens, with aperture opened as described, to any other form of lens.

The only objection to the single lens used as described is that, if we wish diffusion, we are practically confined to the use of a fixed aperture, for an aperture only a little greater than that which will give a pleasantly soft image will give one that is intolerably fuzzy, whilst one only a very little less will give an image quite sharp in one plane. Another objection is that in many cases, especially if the lenses be of second-rate quality, the opening of the aperture gives rise, not only to a certain amount of spherical aberration—which is wanted—but to chromatic aberration also, which is very troublesome.

All this refers to the use of landscape lenses, but for portraiture only. Until lately it was considered that diffusion of focus was of use only in the case of portrait work. I have, however, stated that recently some photographers, whose opinion must be respected on account of the work that they have done, have stated that they think that no part even of a landscape should be quite sharp. Far the best way in which to avoid this sharpness, if it is to be avoided, would be to use a suitable diffusion of focus lens. Unfortunately, no lens with diffusion of focus arrangement suitable to landscape work has, at the time of writing, been specially designed. The "portrait" or "portrait and group" lens of Dallmeyer is not suitable except for small sizes, because, if used nearly full aperture, some parts of a landscape are liable to be put *wildly* out of focus; if even a moderately small stop is used the spherical aberration intentionally introduced by the diffusion of focus arrangement is corrected, and some plane of the subject is represented quite sharply. Even the single lens, if the aperture be opened till there is perceptible diffusion, will, in most subjects, except in the case of small sizes, give some parts of the image far too much out of focus. There is, at the present time, some demand for a landscape lens that will allow of the introduction of quite perceptible diffusion at will, with apertures at least down to about *f*/20. It should not be a difficult problem for opticians to design such a lens, and doubtless we shall have one before very long.

[The table of figures in Professor W. K. Burton's article on the diffusion of focus, published in these pages on June 20th last, was calculated and compiled by Sir David Salomons—a circumstance omitted to be stated at the time because of a printer's error.]

Royal Institution.—The general monthly meeting will be held on Monday, July 7th, at 5 p.m.

Obituary.—The Rev. F. W. Hardwich died a few days ago, and his departure is a great loss to photography. For a long course of years his "Text-Book on Photographic Chemistry" was the chief one connected with the subject, and to this day it holds that position in relation to the collodion process. We also regret to have to announce the death, last Sunday, of Mr. C. G. Collins, the camera maker, who was well-known and respected by the older photographers as well as by those of the dry-plate period.

IMAGINING AND IMAGING.*

BY PHILIP H. NEWMAN.

That is an ingenious idea of Mr. Emerson's where he compares art with the barometer, rising towards naturalism and falling to the abyss of conventionality; and he tells us that if we map it out we shall find on the apices of the ascending curves the masters of sculpture of the Egyptian and Assyrian Lions, Phidias, Van Eyck (a long jump that) Dürer, Holbein, Da Vinci, Titian, Velasquez, Donatello, Rembrandt, De Hooghe, Corot, Millet, Gainsborough. Now I don't suppose he will in the least mind which of these we examine, so let us take Van Eyck, and see what the celebrated "Arnolfini and his Wife" (Mr. Emerson's favourite picture) will prove for him. Now, please believe me, I should be unworthy the title of an artist if I did not admire this painting intensely, and it may be granted at once that you need not be an artist at all to admire it, or to realise its extraordinary merits; they are patent at a cursory inspection; also that it was unquestionably painted from nature, but with Mr. Emerson we will look deeper. I had a tolerable recollection of the picture—as who has not—but I have been to the National Gallery on purpose to study it since reading Mr. Emerson's book, and what did I find? As he says, "It is wonderful in technical perfection, in sentiment, in truthfulness of impression. Note the reflection of the orange in the mirror, with what skill it is painted; it fact, the whole is full of life and beauty, the beauty of naturalism. It is a masterpiece good for all time, and yet it is but the portraits of a merchant and his wife. No religious subject here inspired John Van Eyck, but a merchant family, yet in many ways the picture remains and will remain unsurpassed." Quite so. But there is something more, something that is as apparent to the student as its naturalism, or any of the qualities we have enumerated, something that needs no searching analysis, something anyone may see, something John Van Eyck would have been the first to admit, but which Mr. Emerson has not referred to.

This something, what is it? It is conventionality, style, and without which this picture would not, in an artist's opinion, be the magnificent work of art it is. The folds of the drapery in the wife's robes denote careful arrangement and conventional treatment and drawing, indicative of the style of the period; that due ordination and sub-ordination of parts of magisterial line and breadth of effect discoverable in this school, and manifest in this and other important works of the accomplished master. Undoubtedly this, as in many works of the period in the Low Countries, is wonderful to have been done without the aid of photography, and it would well serve Mr. Emerson, or anyone else, as a text to enlarge upon, as to how photography can be made useful to painters; but he has only chosen to use this illustration to show how Van Eyck went direct to nature for his models; but this needs no insistance. Raphael, and many other painters whom Mr. Emerson abuses, did precisely the same thing, and conventionalised no more than Van Eyck has done (for *pace* Mr. Emerson) I must maintain the picture is brimming with conventionality and style, a style that was carried on among the Flemings to Holbein's time, and is conspicuous happily in his best work. But why does this painting at the end of the middle age period attract our author's notice so much? Is it because he thinks that it at all shows what might be obtained if photography could ever be done in colours? If such is his idea, let me tell him at once that he would be dreadfully disappointed, for he would miss that added charm of individuality, without which no work, pictorial or glyptic, appeals to us or retains our sympathy; that charm that comes of art which is based on a study of nature, but which is a totally different charm to that of *nature*, excepting now and again in her rarest moods, or where man has meddled with but not marred her.

But if a man photographs a field or sea, and paints up to his transferred outline from colour memoranda, and many studies, and never so well, Mr. Emerson is horrified at what he calls a counterfeit, howbeit landscape and sea painting based upon such counterfeiting has reached a higher standard of

* Continued from page 496.

excellence—as mere painting—than at any time in the world's history.

Then what about imagining and imagiug? Where may the two combine, and where, from the camera point of view, must they be friends apart? Mr. Emerson has cut the Gordian knot, but he has not solved the difficulty; he ridicules an ideal, excepting what may come of itself out of nature, so the art of difficulty, as far as he is concerned, remains precisely where it was. The faet is, each of us must solve the difficulty for himself, and in his own way. If he be a genius he will have little trouble; if he is not, he will save himself many plates, much chemicals, and more disappointment if he looks up some of the authorities our author affects to despise; and whether the photographer be a genius or not, it will be just as well for him to see where others have succeeded and where failed. Amongst these he will, of eourse, come across Rejlander, and will see that he kept imaging and iuagining together to a very wonderful extent indeed, and he only failed because of his models. If he could have obtained some of the models Phidias and Apelles could get, the history of photography would have been as great in æsthetics as it is in science. Photography is not to blame for this; she must be content with the models she can get, and do the best she can with them; and very much she cau do, if the artistic faculty is cultivated (if not native) by a searching study of the old masters of form, sentiment, and composition, and especially if the photographers will abstain from short-focus lenses, and can be persuaded to burn all their small stops. Bad photography has a great deal to answer for in the multiplication of copies of iuferior work, leading our attention to detail rather than to breadth and simplicity, which should be the characteristic of all art, pictorial or glyptic. False notions of taste must, of necessity, be encouraged by such multiplication, especially in those less cultivated minds which look upon every photograph as a picture. This alone should stimulate every photographer to strive for the best from an art poiut of view.

The matter of detail has affected the arts of design and picture painting alike, and very importantly; its influence is discernible in every exhibition, and is distiuctly a bad one in the true interests of art. I am glad to think that my views coincide with Mr. Emerson's on detail in art work, and agree with him as to its limitations to that which is fundamentally necessary. I have alluded to this question of detail in auother lecture,* but I feel its import so greatly as to dwell upon it with renewed emphasis here.

The tendency of artists to paint bits, and amateurs to purchase them, was never so great as in the present day. Nothing could be said against it were these bits looked upon —as they should be—as merely a means to some great and legitimate artistic end; but when one is deafened by the parrot cry of "Nature, nature, nature!" one is apt to lose patience and ask, Why is this aimless sort of thing going on—this painting of elaborate passages in nature, with subtle reflections and interminable detail that tell us nothing but that in competition with the camera mau's eye aud brain are inferior instruments, if the product is to be looked at as the true end of fine art? Well, I do not believe it is, or ever will be. We are passing through phases of change; if the camera has stimulated some of our younger painters to study nature lovingly and searchingly, they must look upon it as a means to an end; and while they may be congratulated on escaping the far more dangerous Charybdis of a tricky impressionism—as demoralising as it is false—they must avoid the Scylla of sacrificing breadth to detail. The image should on no account content them unless it bodies forth their highest thoughts and aspirations and most poetical ideas.

People talk of realism and idealisu, impressionism and naturalism, fashionable verbiage that only conjures up the ghosts of thiugs in art; they seem quite to forget, or to ignore, that these *isms* are but the robes of art, the fanciful draperies with which the goddess coquettes with all but her true votaries, or illusory fires with which, like a will-o'-the-wisp, she leads a purblind and bungliug *dilettanteism* into the bogland of cant and empty phrases. No! art is uot got on easy terms; she is ever a coy goddess; but when you can unveil her of these *isms*, and you are really face to face, you will find her the same to-day as she was far back across the dim centuries to your predecessors—fair, modest, truthful, with wide, honest eyes, searching the hearts of man, sounding the intellectual depths of struggling human nature, telling truths calmly, piously, earnestly, affording her true worshippers most gracious and pleasant consolation, and ennobling them for ever. I warn you that art that does not do all this is not true art, but one of those weird lights that will drown your soul in a quagmire.

Mr. Emerson is exceedingly bitter on the religious side of art. We, of course, must all regret as much as he that priest-eraft at many periods did put it in fetters, but, without being fanatical, it is possible and just to be grateful to the religions of the world—heatheu or Christian—for creating and preserving to us the monuments that exist. It may be weakness, but I am none the less proud of it, that when I stand before the cathedrals of this country, or northern France, I am thankful to be alive to see them, and to know that the bishop builders have formulated for me a prayer in stone. Am I, are you, to put these thiugs by as toys of a puerile age, and say, "All sentiment, my dear sir? Art teaches us better now; the bishop builders were all very well in their way, but the French Revolution, plus the Zolaciples, gives us a truer gospel, don't cher know; you'll see it through the camera if you'll only stick to nature." I often wonder if men who practically say or think this sort of thiug know anything about art at all; they certainly don't expect art to say anything to them or teach them anything. One says to you, "I don't want the story at second-hand; I know the page of Lempriére the artist got it from;" and so, forsooth, because he has not inveuted a legend he is not to paint it. Because he has never seen a hero he is not to imagine one, and give pleasure and instruction to a less imagiuative brother by a picture for fear the brother should ask, "Are you sure it all happened just so?" or say, "Of course you photographed the hero, dear boy."

Fancy a painter being commissioned for a picture or fresco of *Prudence* for the adornment of a town hall or law courts, and being prohibited froin using the admirable and instructive subject of *Ulysses and the Syrens* because the painter—let him be able to paint ever so poetically—did not invent the story, and could not get a photograph of the syrens. Again, and for similar reasons, I am not to buy a *Perseus and Andromeda* to hang upon my walls, do I want a lessou in chivalry never so much. Some of the rising painters have laid these teachings somewhat to heart, and to their cost, for, instead of boldly taxing their imagination, they have tried to make a compromise between nature and art. A most ludicrous instance of this is present to my mind, where the subject painted was this very *Perseus and Andromeda* naturalistically treated; the figures were fairly painted, as paintings, and undoubtedly extremely like the models, but these, of course, were of such a poor and uuheroic type as to suggest that they had by some means been deserted by their bathing machines. The monster was too flabby to describe. Another *Andromeda* occurs to me; here the painter had exercised all the imagination he was capable of, and had used his model so judiciously as to obtain a fine figure; yet his mistake was as grave as in the former case. This *Andromeda* seemed, excepting for her silver handcuffs and chain, to be sunning herself after the bath, while the emerald waves and purple islets suggested a strand where monsters never came and chivalry was scarcely needed. The poetical insight wanting in these instances might serve to support Mr. Emerson's argument against painting such subjects, did we not know that it has been painted worthily more than once in our own time; and, above all, remember that while painters are many, artists are, and ever will be, few.

(To be continued.)

THE PHOTOGRAPHIC CLUB.—The subject for discussion on July 9th will be "Photographing Theatrical Scenes;" Report of the Convention Delegates. July 16th—"Iron Printing Processes." Saturday, July 12th—Outing at Rickmansworth; train from Baker Street at 2.16.

NOTES.*

BY COLONEL J. WATERHOUSE, R.S.C., ASSISTANT SURVEYOR-GENERAL OF INDIA.

Eikonogen Developer.—Some eikonogen, lately received from Europe, was on arrival in crystals of a pale yellow colour, quite free from brownness; but, in the course of a few days, it gradually turned of a deep brown purple colour, though kept unopened. This coloured coating dissolves easily, forming a solution of a strong brown-madder colour, leaving the clear crystals, which are not so soluble.

For developing, the solution recommended by the maker in the printed instructions given with the eikonogen was not found to answer. A better developer is that given by Dr. J. Nicol in the *American Annual and Photographic Times Almanac* as below. It works well with Wratten's plates and with Eastman and other films. The formula is—

A.—Eikonogen	... ...	5 grammes or ounces
Sodium sulphite	...	10 ,, ,,
Water	... ...	100 cub. cents, or fl. oz.
B.—Sodium corbonate	...	7·5 grammes or ounces
Water	... ...	100 cub. cents. or fl oz.

For ordinary use, to one part of *A* and one part of *B* add two parts of water; but the proportions may be varied, density and contrast being increased by adding more of *A* or less of *B*, or *vice versâ*. Bromide is not necessary, but in hot weather a little would probably be an improvement.

When solution *A* is made with the fresh yellow crystals, it has only a pale yellow or greenish colour; but if the crystals have become brown, the solution is a dark green, becoming gradually darker by keeping, especially by access of air. It should, therefore, be kept in well closed bottles filled up. The mixed developer has a yellowish colour, and does not become very dark by use. Several plates can be developed in the same solution, a little fresh being added if necessary, or the plate may be transferred to a fresh bath to bring out detail in deep shadows. In some cases a better method will be that described by Mr. B. J. Edwards in this year's Year-Book of Photography, of first developing with a normal developer to bring out detail, and then finishing off and gaining intensity by a similar developer with a full dose of the developing agent restrained by bromide, because the eikonogen seems to have a tendency to give a thin image full of detail, and special treatment may be required to give force and brilliancy.

The above developer works very cleanly, and is quite free from any tendency to stain either plates or fingers. With it, as with other developers, the character of the result seems to depend on the idiosyncrasy of the particular make of plate used, though this does not appear to be so much the case as with hydroquinone. On the whole, eikonogen seems likely to be a valuable addition to our resources, especially for instantaneous work, and probably for developing paper prints.

Eastman's New Films.—The new transparent film for use in roller slides, brought out by Messrs. Eastman and Co., has many good qualities, but several improvements must be made in its manufacture before it can be considered perfect.

It appears to be made from a solution of pyroxyline in acetate of amyl, with the addition of a large proportion of camphor. As was pointed out by the writer in the Photographic News in March last year, collodion prepared with acetate of amyl gives a very structureless, tough film, and it was suggested that such a film would be very suitable as a support for gelatine emulsion, as the new Eastman films show it to be. These films are beautifully clear and colourless, showing only a very slight colour on white paper, but unfortunately they are full of small specks of dust or undissolved material, which cause lumps on one side of the film and corresponding hollows on the other. The slight want of contact may not be of much consequence in printing, but for all enlarging purposes these spots greatly diminish the value of the films, and would ruin the appearance of the prints from them. At present the writer has only used the films in the ordinary Eastman carriers, cutting off pieces of film from the roll as required; but it is difficult to get them to lie flat in the carrier frames, and the thicker celluloid films are much better in this respect. The films are very sensitive, and work clearly and well with the eikonogen developer; they stand a high temperature fairly well without ice or the alum bath, and give very perfect sharpness of detail, more so than the matt-surfaced celluloid films. Some of the writer's negatives show another very peculiar defect, a kind of branch-like markings all over the image, but specially noticeable in parts of an even medium density, such as sheets of water, and they may most easily be seen crossing the blank margins, where the film has been protected from the light by the carrier frames. This defect has, the writer believes, been noticed in some of the journals, and attributed to electrical action, an assumption which is well warranted by their appearance; but how the markings are produced, whether by tension or strains caused in rolling the films on the spools, or in stripping them from their original supports in a very dry atmosphere, there is nothing to show. If a piece of film be cut off the roll and developed without being exposed to light, the marks may be seen very clearly in branched and single lines running in the direction of the length of the films. They have the appearance of being produced by faint sparks. A piece of the film crumpled up strongly in the hand, then opened out and developed, showed no such marks due to the crumpling, nor did pulling out the film strongly in jerks show any; though in the present very damp state of the air here it would be difficult to excite electrical action. The marks seem to occur only in patches on the films. It is to be hoped that their cause will be discovered and removed.

Notwithstanding these defects, which seem likely to be easily remediable, the new films promise to be an enormous improvement over paper films in the roller slide, for which they are specially adapted. The writer has found that paper films fail entirely in cases when they have to be kept a long time between exposure and development, and are practically useless for travellers and explorers unless they are developed immediately or within a month or two of exposure. The writer has not had a good opportunity of testing the keeping qualities of exposed celluloid films; but he has found that the films themselves lose much of their original sensitiveness by keeping even a few months. Some very sensitive American films which were received here in August last are now only of an ordinary sensitiveness, but otherwise good. No particular precautions have, however, been taken in keeping them, and they have been taken to Europe and back in the time.

* From the *Journal of the Photographic Society of India.*

Notes.

Advertising detective agencies move with the times. One advertises in this fashion: "Instantaneous photography for secretly securing photographs of persons when together or separately, for identification and corroboration." We are rather inclined to think the advertiser, like the lady in the play, protests too much. "Instantaneous photography for secretly securing photographs of persons when together or separately," is all very well in theory, but difficult to reduce to practice. Still, we do not doubt the possibility in a good light. It would be instructive to have the experiences of the operators in the employ of the detective agency; at the same time, it is quite possible (if a story coming from Paris be true) to turn photography in such cases as are hinted at in the advertisement to a questionable use. The Parisian story is, that an Austrian gentleman, after dining at his hotel, went out to enjoy a walk in the *Bois*, and, suddenly remembering an appointment he had made, summoned a cab to take him in the direction he had to go. He had not been in the cab many minutes before it stopped, and a man entered it quickly, and closed the door behind him. Before the Austrian had time to cry out, a handkerchief saturated with chloroform was held to his face, and he became partially unconscious; the next thing he knew was that he was in a room, and was being photographed by the electric light. The explanation of this mysterious business is that the gentleman's wife was anxious to obtain a divorce from him, and to bring about the object she took steps to obtain a photograph of her husband. All, then, that was necessary for the fabrication of an accusing picture was to procure a photograph of a notorious lady, and to combine the two pictures, "which," says the paper relating this veracious story, "could be easily done by an ordinary photographer." We should say that there was about as much truth in this story as there is in the efficacy of the photographic appliance advertised by the detective agency.

It is impossible to commend the use to which an American firm of publishers has applied the art of photography. They photographed the pages of the "Encyclopædia Britannica," and from the photographic plates printed and sold a spurious edition. Fortunately, some of the articles were written by Americans and copyrighted in America, and thus Messrs. A. and C. Black, the owners, were able to proceed against the infringers of their rights. It is curious to note that the point upon which the English firm was able to obtain judgment was also made use of as a defence, the defendants contending that these articles by American writers were nothing less than a trap laid for the American public and American publishers. If this be so, all that an impartial person can say is, so much the better.

Lenses whose behaviour is eccentric are not unfamiliar to photographers. A lens which has hitherto borne an irreproachable character has been known to refuse to come to a sharp focus, and to otherwise annoy its owner. Indeed, one well-known photographer in such a case has been heard to express an opinion gravely that the lens was drunk. However this may be, a microscopical objective seems recently to have behaved in a most extraordinary manner, as the proceedings at the last meeting of the Royal Microscopical Society will show. It appears that a committee, consisting of Mr. Mayall, Dr. Dallinger, and Mr. E. M. Nelson, had been appointed to examine a new objective in which great interest was manifested, and a report was to have been submitted to the members at the last meeting. The committee, however, failed to bring up the report, and for a full and sufficient reason.

Mr. Mayall explained that when the committee proceeded to test the objective by photographing an object, they found, to their disappointment, that the visual and actinic foci were not coincident. However, by guessing what focal allowance to make, they succeeded in obtaining out of the out-of-visual-focus a very nearly sharp photograph. But as this want of coincidence would have made the lens very inconvenient to use, they returned it to Jena for alteration. After a lapse of several weeks Dr. Czapski, of Jena, replied that he had not found any trace of a "chemical" focus non-coincident with the visual focus, and the objective was again forwarded to London. Again the committee went to work, and this time the visual focus agreed with the focus in the photograph. In fact, as Mr. Mayall remarked, the transit of the objective from London to Jena had somehow got rid of the "chemical" focus. This, to say the least, is unsatisfactory, and we would have wished that some other explanation had been given. The Microscopical Society evidently were not equal to the task of solving the mystery, and unless the theory of the photographer mentioned above be accepted, it is difficult to account for the abnormal condition of the lens in question.

A curious experiment in what may be called stereoscopic science has been made by Dr. Schobben, a member of the Antwerp section of the Belgian Photographic Association. Recently he exhibited before the section a series of stereoscopic views shown by two lanterns placed side by side. Each lantern contained half a stereoscopic view, and a coloured glass was placed in front of the lens, red for the view on the right-hand side, and green for that on the left. The views were then thrown on the screen, and the spectator looked at them through a pair of spectacles with red and green glasses (red for the right eye, and green for the left). The result was, it is alleged, that the spectator saw a *non-coloured* image with as much relief as in the stereoscope.

Here are a few foreign items which may not be without interest. A new photographic society has been started in Amsterdam. Photographs are admissible at the forthcoming exhibition of architecture in Italy.

This, by the way, is the first of the kind ever held in that country. The photographic exhibition which has been in course of organization at Grenoble was opened on Tuesday, and will close on the 30th of August. A very admirable specimen of photo-collography by M. Balagny is presented with the June number of the *Bulletin de la Société Francaise de Photographie*. The subject is a view of the interior of the Paris Exhibition.

A smart piece of work was done by a newspaper agency over the appointment of Sir Edward Bradford, the new Commissioner of Police. The secret as to the successor of Mr. Monro had been well kept, and until the announcement was actually made in the House of Commons on Friday night no one knew anything of the matter. Yet the early editions of the evening papers of the next day contained a very fairly-executed portrait from a photograph. Possibly Sir Edward knew what was in store for him when the appointment was made known, and had his photograph in readiness for the journalistic artist.

A Boston blacksmith has made a discovery that may revolutionise the arts of photo-engraving, electrotyping, and even type-setting. He has found that pen-and-ink sketches on common writing paper can be transferred to iron as distinctly as if the mould was of greater size. Two plates, one 3½ by 5 inches, and the other 5 by 6 inches, are shown by him as a proof of his ingenuity. Upon the smallest one is written the Lord's Prayer, the letters being quite distinct. The others contain outline drawings. He explains his work in this way: "What you see on them is done with a common steel pen on a piece of thin paper. The paper, when prepared, is pinned into a sand mould, iron is poured into the mould, and the writing is transferred to the casting." The explanation is not quite so satisfactory as one could wish. As the white rabbit said in "Alice in Wonderland," "there is a good deal to be done first." What does the inventor mean when he says, "the paper, when prepared?" How prepared? He seems to have missed what, probably, is the most important part of the process.

We were told lately by a well-known manufacturer of photographic apparatus that there is an extraordinary demand for detective cameras this season, and that although he had a large staff of men at work on these articles alone, he could not keep pace with the demand. It seems incredible to those who are not experts that this instrument should have become so popular, and yet that it should not fulfil its destiny and justify its name by being used by our police force for the detection of wrong-doers. At one time there were hopes raised that by its deterrent aid crime would become almost extinct. But all good photographers know well that this blissful state of things will never come to pass through the aid of secret camera work, unless, indeed, the criminal classes will consent to pose themselves on sunny days in front of the instrument. Our weather is too precarious, our streets are too dark, and our quarry is too sharp to enable us to execute any such work in a haphazard kind of way.

Gelatine plates are usually of such excellent quality that few failures can reasonably be ascribed to them. A case was, however, brought before our notice the other day where a raw amateur had complained to the maker of one of the best brands of plates in his market, that several of his pictures had been spoilt by pinholes in the film, and he sent one of his negatives, with his letter of complaint, as a guarantee of good faith. The maker was able to prove, by raising a portion of the film from the glass, that it contained no holes, and that the clear spots on the surface were due to careless development. Many workers are apt to forget that certain samples of gelatine are at first most repellent of water, and that it is a wise precaution with all plates to use a soft camel-hair brush, in order to establish contact between film and liquid.

The "Obernetter" adds yet another film to the many which are now on the market, and it appears to be a preparation of gelatine rendered insoluble, and to resemble celluloid in all its good qualities. We trust that it will be found possible to sell it at a price which will approximate to the price of ordinary dry plates, for the great difference in cost between celluloid and the plates which it aims at superseding is the chief stumbling block to its use. Another consideration which at present bars these films is the difficulty of adapting them to apparatus which has been made to accommodate glass plates without a considerable amount of trouble and inconvenience. Modern workers lack the patience of their forefathers, and will not be troubled with difficulties if they can possibly help it, but still the £ s. d. matter is the one which they consider most.

Photographers who have had leisure on their hands, and who have not been obliged to consider too much the bread and butter side of their work, have often produced amusing puzzle photographs. These have generally consisted of such subjects as a man playing chess with himself, or a person holding his own head in a dish, and so on. Most photographers know how such things can be done, but few would imagine that the pictures were possessed of any marketable value. A certain transatlantic worker thinks differently, and he advertises that he will show all his hanky-panky tricks—which he calls "freak photography"—for a compensatory number of dollars. This is quite excusable in an American, for it is well known that he can see money in a thing where a Britisher would discern no glitter of hope. It was only the other day that a report reached America that Sarah Bernhardt might possibly have to lose a leg by amputation. An American speculator immediately wired that he would—if the event came off—give a long price for the limb and the sole right to exhibit it. We slow Britishers would never have thought of such a thing.

PHOTOGRAPHIC EXHIBITIONS.

BY GEORGE DAVISON.

No. V.—Hanging Committees and "Amateur and Professional."

It is a necessary consequence of any system from which picture classification and prizes are banished that there should be a strict and competent hanging committee, which should reject all inferior exhibits without fear or favour. The best committee would consist of those held to be qualified judges, provided that some or all of them possessed practical experience in arranging and hanging pictures. As compared with the task of selecting those pictures which possess artistic qualities, it may seem comparatively easy to weed out what is distinctly inferior, and a board consisting of ordinary practical photographers might, perhaps, do this with fair accuracy. At the same time, it must be remembered that the functions of a hanging committee are by no means limited to rejection of the worst entries. They also include distinguishing in a broad way the degrees of merit, to ensure that a picture of the highest quality shall not be placed in an inferior position. The best exhibition would undoubtedly be one in which only such work is accepted as would be worthy of a place on or next the line. Pictures which are held to be fairly treated by "skying" or "flooring" ought not to be accepted at all. It is a common thing to hear even the exhibitors themselves say that they would rather not have their pictures hung at all than have them put out of reach of inspection.

It is essential, then, that there should be amongst the members of a hanging committee those who are free from what may be called photographic prejudices; that is, those who, with or without a knowledge of photography, would judge of the entries purely as pictures (as a poet might judge of poems) without consideration of the mechanism employed, and exactly as they would judge of a series of exhibits in any other black and white process better recognized in art. A photographer is by no means unlikely to pass by a work with the highest artistic qualities as even unworthy of a place in the exhibition, if it happen not to be marked by any sensational effect, or by what is peculiarly known amongst us as "technical qualities." There will, no doubt, be very few pictures having the highest qualities for the hanging committee to be troubled about, but they ought to be competent to deal with those that do appear, and it is in the hope and expectation of seeing more such perfect pictures by photography in the future that such lines as these are penned.

Where space in an exhibition is practically unlimited there is much scope for pleasing arrangement. One thing, however, must be kept prominently in mind, that it is the pictures that have to be seen, and not the accessories or the scheme for displaying the exhibits. Art in displaying exhibits must be concealed.

Where the frames abut one upon another throughout an exhibition an unobtrusive arrangement may be made which approximately gives the effect of panels. To hang such an exhibition sucessfully means that the director should first of all know well, and partly divide out, *all* the pictures he has to deal with. The work is best done where the whole of the exhibits in a section are arranged by one individual, and not piecemeal by several. The after labour and difficulties are reduced two-thirds if *the whole* of the pictures can be mapped out upon the floor before any one portion is actually fixed up. The prior selection of those which are to occupy the principal central positions, and along the best line of sight, is at least essential. A large treatment is called for, and, at the same time, throughout the operations close consideration has to be given to points of detail in regard to harmony and symmetry and quality of work. Hanging committee duties are probably sometimes taken up lightly without any conception of the responsibilies or of the powers called for in such a function. There are very few men who are absolutely deficient in taste, but in some cases pictures have gained attention and superiority of position from such "hangmen" purely from their size and wealth of gilt moulding, or from good selling characteristics, and this without any consciousness of error.

In the work of placing pictures, constant vigilance and energy are needed, and, for the effective and satisfactory hanging of a large room or gallery, the "artist-hanger" must have all the exhibits in his mind's eye, and must not object to physical effort and frequent experiment. In regard to some few details it may be observed that the general practice affects large pictures in two ways. If they are held to be good, they are selected as centres; if bad, they are skied. On either hand of the centres some approximation to symmetry by arranging pairs, or similar blocks of frames, is arrived at. It has become the custom for exhibitors to desire to have their pictures, particularly if small, hung together; but it cannot be of any importance to a collection of *pictures* that they should be all together, although it is advisable for a technical series. A *picture* should be in a frame by itself. In the scientific section, which a hanging committee does well to keep entirely distinct, or in a portion of the gallery by itself, the difficulties are not, perhaps, so great. The exhibitor decides by his entry form whether he wishes to enter his exhibit as of scientific interest or as a picture, or if he does not do so the committee can easily do it for him. When exhibition authorities are alive to the proper method of working a high-class scientific exhibition, specialists might have to be called in, but at present the purely scientific applications of photography are very little illustrated in our exhibitions.

Another regulation which, at the outset, I proposed as a plank in a good programme for an exhibition of art photography was in regard to the peculiar division sought to be set up between amateur and professional. My proposal was, "That all distinction of amateur and professional be entirely suppressed in such an exhibition, all pictures being for sale unless specially exempted."

If it were possible that there could be a class of wealthy workers fully devoted to photography and to developing its highest possibilities other than as an avowed profession, nothing could be better; but this, as in other arts, we know to be an impossibility. A class to do the highest good must be professional. Dilettantism never yet helped on any cause very far. Busy men who take up photography merely as a pastime cannot pretend to show what can be done by its means. Neither, of course, can those who work at photography in the ordinary studio and topographical grooves. Art knows no "amateur and professional," save to express by it badness and goodness. The absurd restriction involved in the distinction between amateur and professional prevents photographs being sold at exhibitions. If the photographs were good pictures, they would be demanded and sold.

Those of us who pride ourselves on being amateurs seem to be claiming credit for the hopeless mediocrity and the worthlessness of our photographs. This system tends

to keep photography low in general estimation. People ask with unblushing readiness for the gift of a photograph. Like most things cheap, they are also considered nasty. Much of the value of a work is given by that which the producer puts upon it himself. Everyone interested in photography must hope to see more and more photographers whose work is worthy of it publish their pictures in some form creditable to the art. Only let them take competent opinion before doing so. The rubbish that is sometimes sold in exhibitions and published in our journals —particularly, I fear I must say, in those of our American friends—cannot fail to do great harm by exciting ridicule at the expense of photography.

In regard to regulations for photographic exhibitions, the removal of classification would, of course, sweep away the absurd division of amateurs and professionals. If competition is unfair (which it is *not*) between those with studios and those without, so much the worse for competition. Let it be done away with. The artist wishes to see the best; the interests of photography call for the best. There can be no defence for giving awards to a class because the work of those composing it is *not so good* as that of another class.

THE RECORD OF PHOTO-MICROGRAPHY.*

BY ANDREW PRINGLE.

It may, perchance, be matter of wonder as well as of interest to some of you that the history of general photography has been, to a great extent, bound up with the history and record of photo-micrography; not that the special application of photography to microscopy has in any direct way influenced general photography, but rather because the men trained by education, and perhaps fitted by nature, for microscopic study, which is equivalent to saying minute and accurate observation have found photographic *technique* useful, and have turned their observant minds to photographic wants.

And, moreover, images projected by a microscope are so evidently convenient for the study of any method of graphic representation—the enlarged image can so readily be kept steadily fixed on one plane, the optical qualities of the projected image can be so readily examined, the worker is so wholly independent of weather—that there is not much cause for wonder in our finding some of the earliest experimentalists in photography using the projected microscopic image as the subject for their photographic researches. Last year I had the honour to review before you the progress of photography during fifty years, but this year I take you back, if you will be pleased to accompany me, to a period more remote than fifty years ago. Let us turn to the year 1802, and we shall find—probably in the journal of the Royal Institution—records of the experiments of Wedgwood and the observations of Humphry Davy on "Leaves and Wings of Insects taken by Solar Light on Prepared Leather." This surely is early enough in the history of photography. It is well known that both Fox Talbot and the Rev. J. B. Reade used the solar microscope, and many other names famous in the records of photography are also found in the early annals of photo-micrography. Mr. Reade is known to have produced photo-micrographs in 1837, insects being his chief subjects, but in 1839 he produced results greatly superior to his efforts of 1837. About 1838 the prototype of our triple achromatic condenser was brought forward by Dujardin, and in '39 or '40 Dancer used the gas microscope and photographed therewith on silvered plates. Donné and Foucault, in Paris, presented engravings from photo-micrographic Daguerreotype plates in what Moitessier called a "magnificent atlas." The first instance known to me of the use of polarised light for photography was in 1857, when M. Bertsch exhibited in Paris crystals of salicine photographed by polarised light. About the "fifties" a great many names are found, many of them well known to us, as Shadbolt, Diamond, Maddox, Wenham, Viles, besides many *savants* of other countries. Dr. Maddox showed at the Royal Society, in 1867, photo-micrographs illustrating a paper he then read.

Enormous strides were made in our science by Dr. Woodward, an army surgeon of the United States; in fact, his work may be said not only to mark, but to constitute, an era in photo-micrography. His work first claimed notice about 1864, and consisted not only of medical subjects, but of diatoms taken at very high magnifications.

I am not aware of the exact date when Dr. R. L. Maddox first produced a photo-micrograph, nor can he fix the date himself, but I have here a photograph of P. Angulatum × 3,000 diameters of superlative excellence produced by my friend in 1838 or 1839. This was by no means his first attempt, as is easily seen from the high quality of the negative now in my possession. It is not within my subject to describe even briefly the apparatus used by these early workers, but I may say that the illumination used by them was either the gas microscope or sunlight, and many ingenious forms of heliostat were used. Dr. Woodward's heliostat was specially admirable, and Dr. Maddox designed one of high quality and moderate price. Still, in this country at least, direct sunlight can never be depended upon, and in the days of wet collodion the photo-micrographer must have had frequently to lie idle. In the present day, with the much more sensitive plates at our command, we can utilise as radiants not only the electric arc, but electric incandescent lamps, such, for example, as Dr. Van Heurck uses with such success; limelight, such as I use myself; and even the light of ordinary paraffin lamps.

Perhaps I may be excused if I dwell with a certain fondness on the photography of bacteria. I believe that Dr. Robert Koch, the eminent bacteriologist of Berlin, was the first to publish photographs of bacteria; this was in 1877. In his paper "On the Investigation of Pathogenic Organisms," translated by Mr. Victor Horsley for the New Sydenham Society, Koch speaks very strongly in favour of photo-micrography, and even says he would prefer a bad photograph to a drawing, however good; but it seems that at a later period he found certain difficulties of colour to be almost or quite insuperable, and he was then inclined to make less of photo-micrography than he had previously done. Dr. E. Klein, F.R.S., was also inclined to condemn our science for his purpose, for in "Micro-Organisms and Disease," third edition, 1886, I find these words:—"Micro-photography, by which microscopic specimens of bacteria are photographed, has hitherto yielded results so unsatisfactory that even Koch, who first introduced it, has abandoned it in lieu of accurate drawings made in the usual manner." Possibly, when Dr. Klein wrote this his words were true, but certainly he has changed his opinion now, as I have very good reason to know.

I could name a considerable number of books and a very great number of papers which are illustrated by photography. George M. Sternberg not only illustrated a book of his own on bacteria by photo-micrographic prints, (second edition, 1883), but has written a book of careful and detailed instructions for the practice of the science. Dr. E. M. Crookshank is in the same position; he has published a book largely illustrated by photographs of bacteria, and he is also the author of "Photography of Bacteria." A paper read by Dr. Crookshank to the Photographic Society of Great Britain, and illustrated by his negatives, first directed my attention to bacteriological photography. In 1885 both Hauser and Van Ermengen published photographs of bacteria, and after the works of these men the science may be said to have gained a sure footing; the chief obstacle to success, the stumbling block of all these earlier workers, was the difficulty of *colour* rendering, unless the preparations were suitably or deliberately stained for photography. Colour-correct photography, then, forms one of the foundation stones of the edifice of photo-micrography so rapidly rising among us.

My remarks up to this point have been purposely made to lead up to certain stages in the records of photo-micrography, and we have reached the stage of colour-correct rendering of stained objects. There is another photographic

* Read at the Photographic Convention at Chester.

matter which has been alluded to in passing, but must now be more particularly treated. I have referred to increased sensitiveness of our plates. Just as Wedgwood, Davy, Reade, and Talbot used photography for microscopic work, and in practising the one elaborated the other, so Dr. Maddox, in the search after certain photo-micrographic effects, fell upon gelatine emulsion photography. I need not tell you how Bennett revolutionised photography, but I must point out the effect his discovery had on photo-micrography. We are no longer dependent on sunlight; we can work with the very highest powers without undue length of exposure; the developed image is quite fine enough for any purpose; and nearly all the difficulties and inconveuiences of wet collodion and silver bath are removed from our path. The advantage in reduced exposure is not by any means a matter of time only, for, during prolonged exposure, there is imminent danger of movement either from tremor or from alterations of temperature, both of which are fatal to success, but most difficult to avoid. We have, then, at the present day, advantages purely photographic which were not within reach of the masters of photo-micrography of past years; we have plates much more sensitive, aud so we get results much more rapidly, much more certainly, and with much less expense; but in a large class of cases we get results much better—sometimes, in fact, we get results which, without orthochromatic photography, we could not obtain at all. The indefatigable Koch was stopped by colour difficulties, as already stated; but it is interesting to know that, so far as I have seen, the very best photographs of bacteria published up to the present time are by Drs. Fraenckel and Pfeiffer, colleagues or assistants of Koch. These bacteriological photographs are so fine that I have brought a few of them for your inspection. They are all, or nearly all, produced by orthochromatic methods, and while I cannot quite agree with all the directions given in the text of No. 1, still, there can be but one opinion as to the results these gentlemen have achieved.

I would point out that some of the methods of staiuing most followed by bacteriologists and microscopic technologists in general would afford excellent examples of subjects difficult to photograph on ordiuary plates. *Tubercle bacilli* are usually stained either red on a blue ground, or blue on a yellow-brown ground. Violet coloured *bacilli anthracis* are very frequently found in preparations counter-stained with Bismarck brown or vesuvin. The fungus of *actinomycosis* shows best stained blue, red, and yellow, and I shall presently show you the orthochromatic results from such a staining. A much valued multiple stain—my own favourite stain for ordinary pathological aud physiological tissues—consists of bright blue for nuclear, bright red for connective, and orange more or less bright for proto plasmic tissues. I venture to assert that no ordiuary plate will properly render a section well staiued by this method, yet with yellow-sensitive plates, and the use of screens chosen for each occasion, I am in the frequent habit of photographiug such subjects, and I generally end by getting good results. I could show you bacteria sections photographed repeatedly on ordinary plates, and with the greatest skill and care I could bring to bear, where there is not a trace of a microbe; whereas with a colour-corrected plate the organisms stand out clear and unmistakeable. My paper is not intended to be a course of instruction in photo-micrography, but is rather an attempt to point out by how much and by what means our science has advanced, is advancing, and will doubtless continue to advance.

The advances made since the infancy of our science have been simply astounding. Conceive the time and conceive the labour when the principle of "correcting lenses for photography" was undiscovered. Petzval, about fifty years ago, showed the way to this correction in photographic lenses, but not till long after that did photo-micrography become so important in public estimation that opticians were forced to consider the correction for microscopic objectives. Some opticians do not seem to have grasped the subject even yet, but there are others who have done so most successfully.

And again, resolution aud definition, which, though perhaps technically distiuct, are nevertheless bound together, depend on angular, or rather, numerical aperture. The earlier opticians might get their objectives with visual and chemical foci coincident, they certainly did attain to very flat field images; but they were incompetent, and, indeed, do not seem to have been desirous to get large aperture with other qualities good. Resolution, or separation of line from line, depends on fixed laws relating to numerical aperture. A lens having a numerical aperture of 0·30 will, in the most actinic part of the spectrum, resolve 38,000 lines to an inch; N.A. 1·00 (the highest air angle) gives the power of resolving 127,000 to the inch, while N.A. 1·4 is capable of resolving nearly 180,000 per inch, Now many of us possess objectives having apertures nearly approaching to N.A. 1·4, while lately Zeiss produced a glass having a numerical aperture of 1·63. I shall show you some work done with this glass by Dr. Van Heurck, of Antwerp.

When the system of immersion was introduced an enormous stride was made, and an enormous additional power gaiued. If we have a dry lens our numerical aperture is evidently limited to the extent of the air angle—180°, or n.a. 1; but when water immersion was introduced, and still more when homogeneous immersion, the numerical aperture was at once increased to a very large extent. It may seem a paradox that we can get a glass to embrace a larger angle than 180°; at first glance this seems to bespeak looking round a corner, but the explanation is simple enough. We do not look round a corner, but in our angular aperture of 180° we include more pencils of light. If, for example, with a dry lens we can include 1,000 pencils, we can with water immersion (by virtue of the higher refraction index of that liquid) include 1,300 pencils, and with suitable oils 1,500; while, if we use not only suitable oil, but suitable glass for our condeusing arrangements, we can, as already stated, reach to 1,600. But, beyond this gain, immersion greatly improves the qualities of our objectives; it increases working distance, improves illumiuation, and mitigates the tendency to diffraction images.

Herein, theu, lies one of the great advances made in our optical appliances. We vastly improved the performance and increased the range of our objectives by the immersion system. Amici seems first to have noted the beneficial effect of water immersion, but the system, I believe, was first carried into practical effect by Nachet or Hartuack. Mr. Wenham seems to have suggested, but not used the homogeneous immersion system, and the great optician Abbe, of Jena, worked out the matter, and brought Wenham's idea to full fruition. Oil of cedar, in virture of its refractive index and its dispersion coinciding nearly with those of crown glass, is the oil generally used for homogeneous immersion. But it must be borne in mind that, in order to get the full effect of this system, the objects themselves must be mounted in a medium of high refraction index, and this process is very apt to lead to error in observation. Mr. Nelson rarely photographs diatoms at any angle beyond the air angle, in order, as I undertand, to avoid these errors of interpretation due to mounting objects in these media of high refraction indices. Unstained physiological tissues are often destroyed for observation by being placed in glycerine, and a piece of glass placed in a bottle of water is not in advautageous circumstances for examination.

I have now to touch on the latest, and one of the great advances made, and this one affects in a very special manner our science of photo-micrography. On account of the nature of the glass used previously to but a few years ago, opticians found it impossible to correct objectives for more than two regions of the spectruu; lenses were corrected for the blue and yellow regions, or perhaps more commonly for the green and red, and when using such lenses under conditions at all trying we find fringes of colouring bordering our objects; in other words, we have a marked uncorrected residual spectrum. But Abbe and the firm of Schott, working together, at last succeeded in making glass with different refracting and different dispersing powers from the powers of glass previously made, and as a result Abbe has formulated and Zeiss has made objectives far superior in correction to any we have ever had before. The photographic results are distinctly superior to those obtainable by use of more ancient objectives, and there is, moreover, a marked improvement in the images even for visual observation. Three spectrum regions at least are made practically coincident

in foci, and the colour fringes are, if not wholly eliminated, at least greatly reduced. Some English opticians have produced with the new glass—which, as has lately transpired, contains fluor spar—very good "apochromatic" glasses, apochromatic being the term used to describe this new phase of optical achievement. It is claimed that by use of this new glass greater numerical aperture can be obtained in conjunction with equally good or better general qualities, such as flatness of field, illumination, &c.

So far, I have mentioned *special* advances that have been made; I may now say *broadly* that the optical improvements consist of the attainment of larger angle without loss of general quality. I think I may say that the history of microscopic optics has been the history of numerical aperture. There always was, and there ever will be, a limit to the aperture possible with a given focal length, but now more than ever we are getting long focal length and large aperture conjointly. In microscopic optics the word penetration must creep in sooner or later. Penetration or "depth of focus" is the suppositious power of focussing on two planes at right angles to the optic axis simultaneously, sufficiently accurately to prevent visible blur. It is manifestly impossible to focus on two such planes equally sharply, and the question is simply, "How much blur is permissible?" In artistic photographs it is a matter of taste; in scientific micrography it is a matter of mathematics. Penetration decreases directly as aperture increases, but decreases as the *square* of magnification. It is, therefore, beyond argument that the more the aperture—and, consequently, the more the resolution—we can get with the least magnification, the greater will be the penetration we shall obtain; and, therefore, what we have to search for is an objective of low power, with as wide a working aperture as can be achieved without damage to the corrections and general qualities of the objective. With a given focal length opticians reach a point of aperture beyond which they cannot go without injury to the quality of the objective. That is where we shall always stand; but our standpoint will from year to year be pushed onward, and our optical appliances will from year to year improve.

Speaking for myself, I am well satisfied with the optical contrivances we have to-day, but I look with eagerness for some advance in photographic power; particularly I long for greater power to cope with certain colour effects and colour combinations frequently met in my experience. I have no spark of doubt that in the process of time every candid investigator of microscopic objects who wishes a graphic representation of his objects of study will employ photography as his delineator; and I maintain that the scientific investigator of scientific facts is bound to use for delineation the only scientific method of delineation—photographic.

Appendix *(Objects shown in Illustration).*

(1.) Books.—"Bacteria," by G. M. Sternberg, second edition, 1885; "Photography of Bacteria," by E. M. Crookshank, 1887; "Mikro-photographischer Atlas der Bacterien Kunde," by Fraenckel and Pfeiffer, Nos. 1 and 2, 1889; "La Chambre Noire et Le Microscope," by Jules Girard, 1869.

Prints, &c.—Collection by Dr. R. L. Maddox from 1868 and onward—diatoms, insects, silica films, &c.; Diatoms by Thomas Comber; Diatoms, &c., by Dr. Clifford Mercer, Syracuse, U.S.A.; various objects by Mr. Rafter, U.S.A.; Scrapbook of Bacteria, by A. Pringle, 1878 and onward.

WEIGHTS, MEASURES, AND FORMULÆ USED IN PHOTOGRAPHY.*

Report of a Committee consisting of W. Bedford, C. H. Bothamley (Secretary), A. Cowan, A. Haddon, A. Levy, A. Pringle, and G. Watmough Webster, *appointed to consider the Weights, Measures, and Formulæ used in Photography. Drawn up by* C. H. Bothamley.

General Considerations.

The question of Weights, Measures, and Formulæ divides itself into two parts—the system of weights and measures to be used, and the method of using them.

A. *Weights and Measures.*—Choice lies between the English system, or a modification thereof, and the metric or French system.

The metric system is now almost exclusively used for scientific purposes. Its advantages lie not so much in the magnitudes of the units, but in the facts that there is a simple definite relation between the measures of weight and the measures of capacity, and that it is a decimal system, the multiples and submultiples being powers of ten.

It is necessary to point out, however, that the relation between measure and weight is only theoretically exact at 4° C. (39·2° Fahr.), at which point the unit of weight, *the gramme*, is the weight of *one cubic centimetre* of pure water weighed in the latitude of Paris. At the ordinary temperature of 15° C., however, the deviation resulting from the expansion of the water amounts to only 8 in 10,000, and is negligable for all practical purposes. Only in investigations of a very refined character need the divergence be taken into consideration.

With respect to the English system it is necessary, in the first place, to point out that the old "Apothecaries' Weight," with its ounce of 480 grains, and its submultiples, the drachm and the scruple, is no longer legal in the buying and selling of chemicals, and it has not been included in the "British Pharmacopœia" since 1864.

The legal units of weight in which dealings in chemicals, and all materials except gems and precious metals, are transacted, are the *pound avoirdupois*, the *ounce avoirdupois*, and the *grain*. The pound contains 16 ounces, or 7,000 grains, and the ounce contains 437·5 grains. The relation between the grain and the ounce is inconvenient.

The English units can be used, and are frequently used decimally. Quantities are expressed in grains and decimal parts of a grain, and there is no greater difficulty in writing 205·0 grains than in writing 12·96 grammes. Grain weights from 10,000 grains to 0·01 grain can easily be purchased.

* Read at the Photographic Convention at Chester.

The relation between weight and fluid measure is of precisely the same kind as in the metric system. The gallon is the bulk of ten pounds of water at 62° Fahr. ; a fluid ounce is the bulk of an ounce of water at 62° Fahr. ; 16 fluid ounces, or 7,000 fluid grains, is the bulk of 16 ounces, or 7,000 fluid grains, or one pound of water at 62° Fahr. Since the relation is quite exact at 62° Fahr., it is more exact at the ordinary temperature than in the case of the metric system.

Below the ounce, however, such a relation does not exist. The submultiple, the *minim*, has no simple relation to the grain, and this arises from the fact that when the fluid ounce was changed from the bulk of the troy ounce, or 480 grains, to the bulk of the avoirdupoise ounce, or 437·5 grains, the old mode of subdivision was retained, and we now have the fluid ounce of 437·5 grains divided into 480 equal parts or minims. A minim is therefore the bulk of only 0·911 grain of water, and to take the minim and the grain as equivalent introduces an error of about 10 per cent.

Fluid grains are, however, in use for chemical purposes, and the relation between the grain and the fluid grain at 62° Fahr. is precisely the same as that between the gramme and the cubic centimetre at 4° C. Measures graduated in fluid grains can be obtained without difficulty, and have been used by many photographers for a considerable time.

Whilst fully recognising the advantages of the metric system, we are also bound to recognise the facts that the English system is much more familiar, that the weights and measures of this system are possessed and used by almost all photographers, and that a knowledge of decimals sufficient to enable a decimal system to be used easily and accurately is by no means so widely diffused as is desirable. It follows that the general adoption of the metric system will at any rate require a considerable time, and in dealing with formulæ we recommend a method which is independent of the system of weights and measures used, provided always that the relation of the unit of weight to the unit of measure is the same as that existing between the gramme and the cubic centimetre, or the ounce and the fluid ounce.

RECOMMENDATIONS.

A. *Weights and Measures.*—1. If the metric system be used, weights will naturally be expressed in grammes and measures in cubic centimetres.

2. If the English units be used, the minim and the drachm should not be employed at all. All weights should be expressed either in grains or decimal parts of a grain, or in ounces and fractions of an ounce ; all measures in fluid grains, or in fluid ounces and fractions of a fluid ounce.

B. *Formulæ.*—3. Formulæ should give the number of *parts* of the constituents, by weight or measure, to be contained in some definite number of *parts, by measure*, of the solution. The mixture can then be made up with (*a*) grammes and cubic centimetres, or (*b*) grains and fluid grains, or (*c*) ounces and fluid ounces, according to the unit selected.

4. The standard temperature for making up solutions should be 15° C. or 62° Fahr. No appreciable error will be introduced by the fact that these two temperatures are not quite identical.

5. Formulæ should give the quantities of the constituents to be contained in x parts of the finished solution, and not the quantities to be dissolved in x parts of the solvents. When a solid dissolves in a liquid, or when two liquids are mixed, the volume of the solution or mixture is, as a rule, not equal to the sum of the volumes of its constituents. The expansion or contraction varies with the nature of the solids and liquids, and the proportions in which they are brought together. In making up a solution, therefore, the constituents should first be dissolved in a quantity of the solvent smaller than the required volume of the finished mixture, and after solution is complete, the liquid, cooled if necessary to the ordinary temperature, is made up to the specified volume by addition of a further quantity of the solvent.

6. It is very important to specify in the case of liquids whether parts by weight or parts by measure are intended. The equivalence between weight and measure only holds good in the case of water and liquids of the same specific gravity—a fluid ounce of ammonia solution or of ether weighs less than an ounce ; a fluid ounce of strong sulphuric acid weighs nearly two ounces.

7. Whenever possible, formulæ should give the quantities of the constituents required to make up 10, 100, or 1,000 parts of the solution.

8. When a mixture (*e.g.*, a developer) is to be prepared just before use from two or more separate solutions, it is desirable that the proportions in which the separate solutions have to be mixed should be as simple as possible, *e.g.*, 1 to 1, 1 to 2, 1 to 3, 1 to 10.

9. When metric units are employed the original French spelling, "gramme," should be used in preference to the contracted spelling, "gram," in order to avoid misreading and misprinting as "grain."

APPENDIX.

Weighing and Measuring.

A brief description of the correct methods of weighing and measuring may be of service to photographers who have had no laboratory training.

Measuring.—The correct reading is the horizontal tangent to the meniscus ; that is, the horizontal line which touches the lowest point of the curved surface of the liquid in the case of water and all liquids which wet glass, or the highest point of the curved surface in the case of mercury and similar liquids. When the liquid is so opaque that the meniscus cannot be seen, the reading must be taken at the apparent horizontal surface of the liquid. The measuring vessel should be exactly vertical, and the eye of the observer should be exactly on a level with the surface of the liquid.

Weighing.—To assume that the weights in the two pans are equal when there is a distinct deflection of the index of the balance towards one side is obviously incorrect. To take the weights as equal when the beam is at rest, and there is no deflection at all, also gives untrustworthy results. The balance should be made to vibrate, and the weights in the two pans are equal when the index makes *equal excursions on either side of the position of rest*, which is usually the centre.

NEW PHOTOGRAPHIC LENSES.*

BY DR. PAUL RUDOLPH.

No. II.

IN an objective consisting of two distinct systems, the contrarious elements required for compensation of astigmatic deviations are obtained without prejudice to full liberty as regards achromatisation of each single system, by compounding one of the systems—presuming both to be positive systems—of a normal, the other of an abnormal pair of glasses (the terms "normal" and "abnormal" being taken in the sense of the definition as given above).

The elements of actual construction of objectives, as specified in Tables I, II, and III, furnish examples for the practical application of this invention under varying conditions.

The opposite character of the pairs of glasses in the two separate members of a doublet are, however, conditional to the desired effect only in case both these members are required to be positive (collecting) systems, and if both are also required to assist in a notable degree in the concentration of the rays of light, or, in other words, in the diminution of the focal length of the objective. For many purposes it may, however, be sufficient or even advantageous to assign the function of the concentration of the rays of light wholly or principally to one system (principal system), viz., in such a manner that the other need not produce any notable refractory effects in the sense of a diminution of the focal distance, it having simply

* Continued from page 476.

and essentially to act as a correcting system, which admits of a relatively large positive or even negative focal length. According, as in this particular case, the principal system consists of a normal or of an abnormal pair of glasses, the positive or the negative element of the correcting system must be made to have the higher refractive index; the nature of the pair of glasses of which the correcting system is composed—*i.e.*, whether it is of a normal or of an abnormal character—is, however, non-essential, provided its focal lengths be taken very great. If, however, a negative focal length which is not very great as compared with the focal length of the principal system be given to the correction system, the latter, in order to insure the conditions of achromatisation, must be composed of a pair of glasses of the same character as the principal system; *i.e.*, either both of pairs of glasses of the normal, or both of pairs of glasses of the abnormal character.

The elements of construction, as specified under IV, serve to illustrate an anastigmatic combination of lenses of this last kind, in which one of its members constitutes such a correcting system of a negative focal length, both members consisting of normal pairs of glasses.

The new type of photographic doubtlets thus set forth admits, as is shown by the preceding explanations and the examples appended to this specification, of many modifications of detail, which modifications do not, however, introduce any novel features. The focal lengths of both parts of the double objective may have any ratio whatever; the system consisting of an abnormal pair of glasses and likewise the correcting system—assuming this latter case to enter into consideration—may constitute either the anterior or posterior member of the combination; finally, a great variety of glasses may be employed for carrying out the constructive principles as stated above, provided they leave sufficient scope for the selection of such pairs as are prescribed in each particular case by the foregoing directions.

All these special alternatives of practical construction are intrinsically dependent upon the particular purpose which such an objective has to serve, and the corresponding conditions regarding the aperture, the size of the field, and the degree of perfection required with respect to correction. Whenever these particular conditions on the one hand, and the optical constants (refractive index and dispersive power) of the available kinds of glasses, on the other hand, are given numerically, any optician versed in the treatment of problems of this kind is enabled, guided by the preceding remarks and the examples appended at the end of this specification, to numerically determine, according to known methods, those elements of construction (radii, thicknesses of lenses, air distances) which will sufficiently compensate astigmatic deviation, beside furnishing all the other usual corrections. In particular, no novel constructive feature is introduced by making one (*vide* Table III) or both of the cemented systems of the doublet to consist of three instead of two lenses, which may be particularly advantageous in such cases where the objective is to have a large aperture. For inasmuch as the use of three single lenses has no other aim in view but to distribute the effect otherwise attained by a single lens, over two, made of the same or similar kinds of glass, the substitution of a triple for a double lens belongs to those expedients which are ordinarily made use of by practical and theoretical opticians in order to attain an increased number of elements affording means for optical correction.

In the annexed drawings, three different arrangements of objectives, carried out according to my invention, are shown in full size, partly in elevation and partly in section. According to fig. 1 the anterior system of lenses is com-

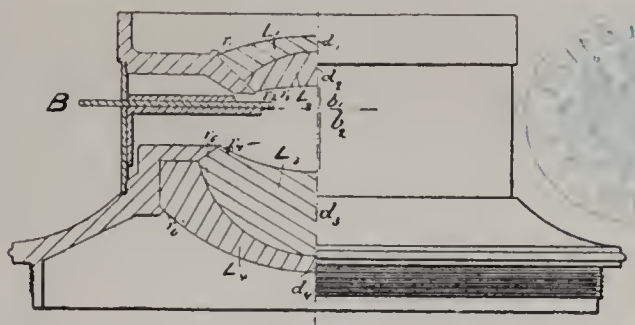

Fig. 1.

posed of the dispersing lens L_1 and the collecting lens L_2, while the posterior system consists in the collecting lens L_3 and the dispersing lens L_4, all these lenses being concavo-convex. B is the diaphragm. In the objective represented by fig. 2, the anterior system L_1 L_2 is com-

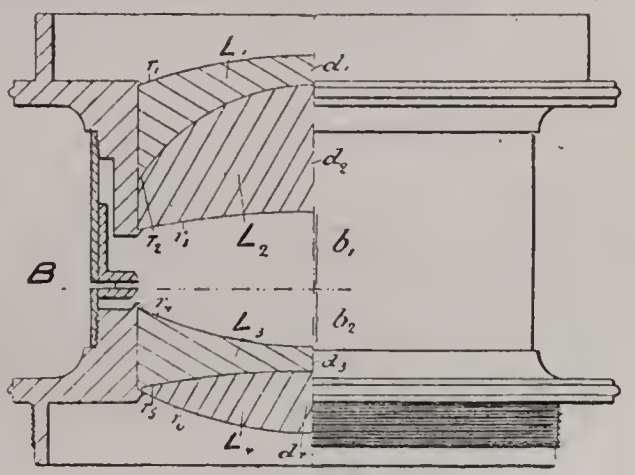

Fig. 2.

posed alike to the preceding one, whereas the posterior system consists in the biconcave dispersing lens L_3 and the biconvex collecting lens L_4. Fig. 3 again shows a

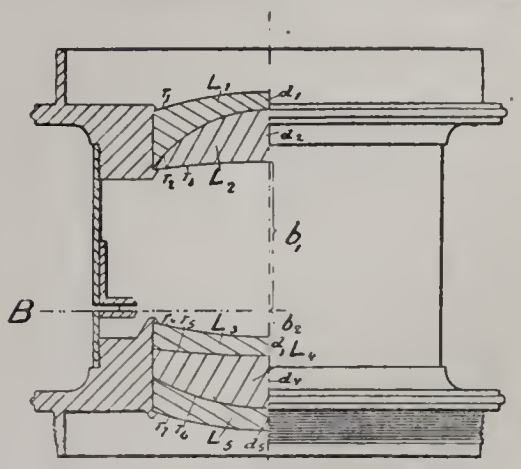

Fig. 3.

like system L_1 L_2, while the posterior system comprises two concavo-convex dispersing lenses, L_3 and L_5, and the concavo-convex collecting lens L_4. The letters r_1 r_2 r_3 r_4 r_5 r_6 r_7, to be referred to hereafter, denote the radii of curvature of the lens surfaces to which they are applied, d_1 d_2 d_3 d_4 d_5 the central thicknesses of the lenses, and b_1 b_2 the distances between the diaphragm B and the lenses.

Patent Intelligence.

Specifications Published.

11,994. *July 29th*, 1889.—"Polishing Engraved Glass or Plate or Sheet Glass." JABEZ FACER, Glass Etcher, Collis Street, Dennis Park, Stourbridge.

The invention relates to cut and engraved flint and coloured glass or sheet or plate glass, and has for its chief object the polishing of glass without the use of pumice or rotten stone and putty powder. For this purpose I provide a bath composed of hydrofluoric acid and sulphuric acid in equal proportions, with a sufficient quantity of water added to reduce it to a convenient strength for working purposes. In cases where metallic or other ingredients are introduced into the glass for colouring purposes, the addition of a small quantity of nitric acid or muriatic acid is beneficial.

The mode of operation is, then, to wash the glass with the acid until the desired brilliancy is attained.

I make no claim to the ordinary use of hydrofluoric or other acids for any of the branches of decorative etching as at present practised.

What I claim is:—

The use of the above-mentioned acid bath for the purpose of polishing cut and engraved flint and coloured glass or plate or sheet glass, and thus accomplishing by a chemical process what has been hitherto performed by mechanical appliances combined with the use of most injurious powders and manual labour.

12,648. *August 10th*, 1889. "Obtaining Alloys of Aluminium." JOHN CLARK, 80, Great Brook Street, Birmingham, Metallurgist.

The object of the invention is to operate upon any silicate of alumina with certain reagents in such a manner that when the said prepared silicate of alumina is mixed with the metal or metals intended to be alloyed with aluminium, and is melted therewith, the intended alloy of aluminium with such metal or metals is produced; or, if the prepared silicate of alumina is brought into contact in any convenient manner with such metal or metals while in a melted or plastic condition, the intended alloy with aluminium is thereby produced in a similar manner.

Correspondence.

PERSPECTIVE IN PHOTOGRAPHY.

SIR,—May I take the liberty of expressing a fear lest a passage in the presidential address, which we have all heard or read with such interest, may be so misunderstood as to discourage a study of much importance, namely, that of the relations between visual and photographic perspective. Commenting on Mr. Hamerton's case against photography in his well-known essay, that "It is false in perspective, and consequently in proportions and forms," the President said that "falsity of perspective and the proportion of forms is entirely a question of the proper or improper use of lenses, and need not exist at all."

I venture to submit that though this reply appears practically complete as regards the apparent distortion of portraits taken too close to the sitter—which Mr Hammerton had instanced as a special fault inherent to photography—yet, as a general statement, it is incorrect, and, I fear, misleading. For the real difficulty of the question, "how it is we can look on a friend's face or figure without feeling the distortion which would be unpleasantly obvious in a photograph taken from a position equally close," is not touched at all, but remains a problem which should be solved with scientific completeness, and not merely salved with a remedy, practically efficient, perhaps, in many cases, but yet applied empirically, and not indeed always applicable.

We cannot help recognising that some differences must really exist; for our graphic delineation is on a plane surface, corresponding neither to nature itself, nor to our vision of it. But still more important is it to recognise that such a sense of perspective as belongs to even the most cultivated visual perception—or, to the painting which may embody that perception—will never exactly correspond to the strict geometrical perspective of a good lens, however well selected and placed. For what we see in nature is affected to us by subjective modifications not similarly present when we look on its pictorial representation — photographed or painted—and photography cannot depict what is only subjectively present. In viewing natural scenes, we naturally apprehend actual rather than apparent magnitudes and forms; our perceptions being dominated by past experience and acquired knowledge. For as these strictly apparent proportions and forms change from moment to moment as we move, they are gone before we have fairly laid hold of them. And in the mass of such changing and varying perceptions, which we suppose to constitute the image of nature as we survey it, the constancy of our memory or conception of *actual* forms and magnitudes, which are always the same, preponderate to a greater or less extent, according to our cultivation, and according to the familiarity or strangeness of our surroundings. It is thus that a just sense of perspective is a comparatively late product of observation and mental development, and that different parts are apprehended in differing proportions — often contrasting strongly with the utter rigidity and geometric accuracy of the apparent image formed by a lens. It is thus, too, that "falsity of perspective" means one thing to artistic feeling, and another to geometrical accuracy. We cannot have a real science of photographic perspective unless we fully recognise all the facts—psychical as well as physical—and such a science is greatly needed, rightly to direct our efforts.

I am persuaded, from other passages in the presidential address, and from what Mr. Hamerton has written in other essays, that these remarks are not really discordant with the views of either authority; and with such a feeling I have ventured to write this letter. W. H. WHEELER.

HACKNEY PHOTOGRAPHIC SOCIETY.

SIR,—Below is our programme for July and August, 1890:—

July 10th—Demonstration, "Exposure and Development," Mr. Birt Acres; July 19th—Excurson to St. Albans (trains leave King's Cross, G.N.R., 2.40; July 24th—Discussion on excursion work; August 14th—Demonstration, "Intensifying, Reduction, and Varnishing." Mr. R. Beckett; August 16th—Excursion to Carshalton (train from London Bridge at 2.18); August 28th—"Portraiture and Retouching," Mr. J. Hubert.

Prizes will be given for the two best photographs taken on Society excursions. Other prizes for work done during the present year will be given, of which due notice will be sent to each member. In each case an entrance fee of 1s. will be charged. Members not having paid their subscription for present year are requested to send on at once to the treasurer.

W. FENTON JONES, *Hon. Sec.*

12, *King Edward Road, Hackney, N.E.*

THE LATE MR. BAYNHAM JONES.

SIR,—I regret to say that the oldest photographer in this country died on the 19th ult. at Cheltenham.

The late Mr. Baynham Jones was known to me for many years, and the last time I saw him was in London last year at the Jubilee Convention. A lawyer by profession, he was from first to last a most enthusiastic amateur photographer; but to convey to the minds of yourself and readers what kind of man the late Mr. B. Jones was, I think I cannot do better than make an extract from the "Evolution of Photography":—

"Looking round the hall on the opening night, and scanning the features of those present, I was coming to the conclusion that I was the oldest photographer there, when I espied Mr. Baynham Jones, a man of eighty-three winters, and certainly the oldest amateur photographer living; so I willingly ceded the honour of seniority to him, and, as soon as he espied me, he clambered over the rails to come and sit at my side and talk over the past—and quite unknown to many present—aspects and difficulties of photography. Mr. Baynham Jones was an enthusiastic photographer from the first, for in 1839, as soon as Daguerre's process was published,

he made himself a camera out of a cigar box and the lens of his opera glass, and being unable to obtain a Daguerreotype plate in the country, he cut up a silver salver, and worked away on a solid silver plate until he succeeded in making a Daguerreotype picture. Mr. Baynham Jones was not the first photographer in this country, for the Rev. J. B. Reade preceded him by about two years; but I have not the slightest doubt of his being the first Daguerreotypist in England, and in that jubilee year of 1889 he was working with gelatine plates and films, and enthusiastic enough to come all the way from Cheltenham to Loudon to attend the meetings of the Jubilee Convention of photography."

He was a genial and kindly old man, and one of the old school which is rapidly becoming extinct.

11A, *Berners Street, July 1st*, 1890. JOHN WERGE.

Proceedings of Societies.

London and Provincial Photographic Association.

At the meeting on the 26th inst. Mr. J. T. Atkins occupied the chair.

The Chairman drew attention to a new French developer, "La Daguerrienne." Several plates could be developed in the same solution, and the results were stated to be very good.

Mr. J. S. Teape had recently experienced cases of frilling when plates were put in the alum bath, which, however, disappeared when the plates were fixed.

Mr. Pask asked whether perchloric acid, added to the silver solution, 10 drops to the ounce, would preserve sensitised albumenised paper.

Mr. W. E. Debenham said perchloric acid was a preservative in itself, but it would not protect the paper from the effects of a bad atmosphere.

Mr. Teape asked if any members had seen phosphorescence in the dark room on a plate insufficiently washed when placed in the alum bath.

Several members had noticed this, but no one could give any explanation as to the cause.

Hackney Photographic Society.

At the meeting held on Thursday last, Mr. W. L. Barker presided.

Mr. Dean showed a negative having traces of fog very apparent, but explained that he poured a solution of caustic over it in developer.

The Secretary said that that would explain the fogginess.

Mr. Grant showed some prints taken from negatives by a guinea hand-camera of Griffith's, but had found the dark slides, in two cases out of three, had let in the light.

A fine platinotype print by Mr. Wesson was shown.

The Secretary handed round some Wormald's masks.

From the question-box: "How can staining by hydroquinone developer on bromide paper be avoided?" Several members had complained of this.

The Secretary said that he had found by using a few drops of ten per cent. solution of brom. potassium he overcame it.

Mr. A. Barker had seen cyanide of potassium recommended.

Mr. Crouch then gave his paper on "Lenses." He described the various forms now in use, and spoke very favourably of single lenses, which many people objected to on account of distortion. He, however, had not found so much lately as used to be the case. The lecturer said lenses were made too rapid, and that *f*/11 was rapid enough for anything. He advocated use of lenses as follows:—For quarter-plate, 3, 6, or 8, and a 9-inch focus; half-plate, 4, 8, and 12; 7½ by 5 and whole-plate, 5 or 6, 12 and a 15, or 18 inch. He objected to portrait lenses.

Mr. W. L. Barker wanted to know why the lens tube of a wide angle was so narrow.

Mr. Crouch said that it made it more portable.

In answer to the Secretary, Mr. Crouch said that the iris diaphragm gave no extra protection from flare spot. He liked diaphragms in this form, as there was no danger of losing them, and you could the more easily use them. Rust on glass was caused by an oxide formed on the surface, and was due to the presence of lead. It should be polished out.

The Chairman then called on Mr. J. O. Grant for his paper on "Selection of Apparatus."

Mr. Grant advised the beginner to get a half-plate camera to start with, as amateurs always got dissatisfied with a quarter-plate, on account of its being too small. He, however, recommended a cyclist to get a hand-camera such as Shew's. He disliked the idea of rushing off and buying a second-hand camera, as many were not quite safe to use, not being light-tight. He preferred the back to rack out instead of the front, as there was no danger then of cutting off.

In answer to various questions, Mr. Grant said that with Kinnear bellows the folds must sometimes be gathered up so as not to cut off the view. He thought that between the lenses was the best place for the shutter.

The Secretary asked what was the advantage of having both a swing front as well as swing back?

Mr. Crouch pointed out that in using wide angle lenses it was often really necessary, through there not being room to use the back alone.

Mr. Capell was troubled with jarring with his Newman shutter.

Mr. Crouch said that Dr. Roland Smith avoided this by leaving his band of shutter loose.

The Bath Photographic Society.

On Saturday, June 28th, the members visited Lacock Abbey. The party, numbering seventeen, was conveyed by brake *vid* Box and Corsham. The drive of thirteen miles is very picturesque, but the incessant fall of rain prevented work *en route*. Upon arrival at the Abbey, Mr. C. H. Talbot conducted the party over his premises, describing minutely the structural changes effected by himself and ancestors, as well as pointing out that which through many generations had remained intact. The Abbey, we gleaned, was purchased from Henry VIII. by Sir William Sherrington, who converted it into a Manor House. The work of change was further carried out by Mr. Jno. Ivory Talbot and Mr. Wm. Henry Fox Talbot. Although Mr. Talbot says the style of architecture has not been so well preserved as it might have been, the place abounds in treasures in art, science, and literature. Excellent paintings by known artists, many of remote date, remarkable specimens of antique, and numberless objects of scientific interest are there; but what was of especial interest to photographers are those unique and early specimens of the photographic art which made the name of Fox Talbot so famous. These date from 1834 onwards. Fox Talbot was known to his friends as a very rapid experimenter, able to follow an idea and results in quick succession over a wide field of research; hence so much ground covered. Mr. Talbot showed the company several albums of photographs produced by his father by means which he discovered anterior to his publication of the Photogenic and Calotype processes in 1839 and 1841 respectively. The etched copper plates prepared for Fox Talbot's photoglyptics and a number of specimens of the process were shown. Notwithstanding the incessant rain, cameras were fixed and several views of the buildings taken. Upon leaving, the members were cordially invited by Mr. Talbot to return on a more photographically favourable day next season, which they promised to do. Tea was served at the Red Lion, at which votes of thanks were passed to Mr. Talbot, and to Mr. Austin J. King for his generous present to the Society, namely, provisioning the brake *en route*. An invitation to visit Prior Park from Canon Williams was read by the secretary, and unanimously accepted for July 26th. Swift's new hand-camera, "The Memorandum," Powell's developoids, and other novelties were drawn attention to on the road. It was also decided to discontinue the indoor meetings at the Institution until next September, but regular outings will be supplemented.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

June 17th.—Mr. H. G. RIDGWAY in the chair.

The HON. SECRETARIES reported upon the recent exhibition, which has resulted in a small balance on the right side of the ledger.

New members, to the number of twenty-two, were then elected, and arrangements as to outdoor meetings concluded.

The subject for the evening was an exhibition of and discussion upon "Hand-Cameras," examples of which were submitted by the local dealers and by various members.

Mr. J. HEDLEY ROBINSON, in opening the discussion, exhibited an ingeniously simple and compact instrument, constructed by himself, which was small enough to be carried in the pocket, but at the same time a business-like little affair, taking lantern-size plates. Slides were exhibited by Mr. Robinson, which amply showed its capacity in his hands. Commenting upon the cameras on view, he was inclined to fear that, unless very carefully manipulated, there was danger of shaking the camera when releasing the shutter; and he advocated the principle of holding the camera firmly in both hands, taking a sight along the top at the subject, and firing the shutter off by squeezing the bulb in the mouth, which, if not elegant, is at least practical. The subject of lenses next came under consideration, and he spoke highly of the single form, concluding with a sensible piece of advice—not to use stale plates for work of this kind.

Other members then commented upon the cameras of their choice, and the meeting broke up.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

A MEETING was held at St. Edmund's College, June 16th, Mr. B. KARLEESE in the chair.

Mr. G. A. THOMASON gave an epitome of the excursion to Coventry, and gave notice of the whole day's excursion to Wilmcote and Stretford on July 19th.

Seven new members were elected.

Mr. W. J. HARRISON, F.G.S., then gave his paper on "Orthochromatic Photography," which was illustrated with a large number of negatives and prints and lantern slides taken by the lecturer, showing the advantages of orthochromatic plates over the ordinary; also prints of negatives taken from oil paintings with screens of different intensity. He said that ordinary plates could be made to give the proper gradation of shade by soaking them for two minutes in

Erythrosine	1 part
Water	7,000 parts

and then drying in dark room, and that although great strides had lately been made in orthochromatic photography, yet no satisfactory way had been found for photographing reds. In the developing room it is as well to cover the red glass with brown tissue paper.

The CHAIRMAN said that he found exquisite detail in the shadows of negatives taken on orthochromatic plates.

Mr. MIDDLETON said that Dr. E. Albert develops in a *blue* light; but his process of preparing the plates is a secret, and he uses no screen. Father Perry used the same in his astronomical studies.

Mr. TUCKER had photographed the spectrum of steel at a white heat, by placing it between two carbons connected with the dynamo, with great success. The plates were first soaked in eosine.

Mr. HARRISON exhibited a number of prints and negatives, showing good work, on the Vogel-Obernetter orthochromatic plates; these were the work of Mr. Gotz, the English agent for these plates. Also some capital landscapes and flower subjects, lent by Mr. B. J. Edwards, and taken on his isochromatic plates.

RECEIVED.—From Messrs Iliffe and Son, "The International Annual of Anthony's Photographic Bulletin," 1890-91. It is full of information, contributed by authors of acknowledged ability, and the illustrations, which are examples of the application of photography to illustrative purposes, are numerous. The price of this midsummer annual is two shillings.

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

S. B. (Aldershot).—*Finely Ground Glass.* For the final grinding of glass intended for focussing screens, use the quality known as flour emery, moistened with water, and rubbed between two glass surfaces with slight circular motion. This will furnish two screens at one operation. Another plan is to grind the glasses singly upon a zinc plate with flour emery and water. Mr. F. H. Varley's instructive chapters were those of recent date, to which you doubtless refer.

P. L.—*Changing Plates.* By consulting their convenience as to time, many local photographers will give you facilities by loan of dark room for a few minutes; and a list of hotels providing this accommodation is given in the "Cyclists' Manual and Road Book." Several amateurs manage to do it in absolute darkness by the touch, but this requires some practice and forethought. The simplest lamp is a three-fold framework of stiff cardboard filled in with cherry or ruby fabric, with a triangular flanged plate of iron to drop over the top, and a night light, or cup of hard paraffin with a wick, placed within.

J. B. (Maldon).—*Liesegang's New Fixing Agent.* We have not yet tried it, but chloride of magnesium solution is stated to have great power of dissolving the haloid salts of silver, so much so that with two baths applied successively the whole of the unaltered silver may be removed. We know that Fox Talbot originally employed a strong brine of common salt for this purpose. An experiment well worth trial might be the attempt to use a concentrated sea-water for fixing, which would contain both these salts in solution. Be sure and use enough liquor to accomplish the desired end.

M. E. T.—*Cleaning the Margins of Mounted Photographs.* Whether framed or kept in portfolios, the broad mounts are sure to become dingy in course of time; the best mode of cleaning the card is to rub it with bread-crumb, and not india-rubber. Especially avoid the use of the white vulcanised rubber, now commonly employed as a pencil eraser, for the fine particles contain so much sulphur, and are certain to cause fading of the photograph.

A MEMBER.—*The Parent Society's Exhibition* will be held once more in Pall Mall. Three months' notice is surely time enough to get ready, and your works will be judged by a high-art jury of pre-eminent qualification.

L. A. D.—*Friese Greene's Opal Cards.* The specification has been published; No. 7,747, dated May 9th, 1889. The cards are coated with a mixture of zinc white, turpentine, and pale gold size, either with or without a preliminary treatment with sulphuric acid of specified strength to parchmentise the paper.

S. N.—*Old Earthenware Dishes.* Those which have been used long enough to develop cracks extending only through the glaze may be cured by warming cautiously in a slightly heated oven, and rubbing in melted paraffin. Actual fractures are more difficult of treatment, shellac cement or marine glue being the best ingredients for trial.

TYRO.—*Col. Waterhouse's New Developer.* It is scarcely correct to describe it as a preparation of gum guaiacum, although derived from it by destructive distillation. Guaiacol is an oily body of strongly aromatic odour, soluble in alcohol and alkalies. Being liquid the required dose is measured off, shaken up with the prescribed quantity of alkaline carbonate, and used immediately as a developer.

R. M.—*Photographers' Benevolent Association.* Subscriptions for the current year are now overdue, and should be paid to Mr. H. J. Beasley, 66, Chancery Lane, W.C.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1662.—*July* 11, 1890.

CONTENTS.

CHROMO-COLLOGRAPHIC PRINTING.

ILLUSTRATED BY A PICTORIAL SUPPLEMENT.

TO-DAY we present our readers with a supplement in colours, executed entirely by photographic means by Messrs. Waterlow and Sons, who have furnished the following information as to its method of production. It is one of a series of coloured photographs of remarkable bindings of old books among those in the British Museum.

The process is simplicity itself, and being so simple and effective, it is somewhat surprising that it has not been generally introduced before. Similar results have been published before, but we believe only by means of chromo-lithography in combination with collotype printing; the present supplement has been produced by improvements upon that method devised by Mr. J. D. Geddes.

Perhaps the process may be most easily explained by beginning with the production of the red portion of the print. The book is laid horizontally on a table, and illuminated by diffused light. A reversing mirror is employed, and a very long exposure given with an orthochromatic plate, because, the reds not being pure, but containing a proportion of yellow, it is usually found that more detail is obtained than by the use of ordinary plates. With the long exposure, the other more actinic parts of the design are to a great extent obliterated, so that the plate requires little or no blocking out to make it ready for printing.

Upon another negative plate the blue portion of the design is obtained by an exceptionally short exposure and normal development. All the rest of this plate but that representing the blue image is then quickly blocked out, because skilled work is not necessary; it can be done in ten minutes by an inexperienced person of average intelligence.

The two extremes, red and blue, having been obtained in this way, representations of portions of the design in other colours are obtained on the same principle by modifying the exposures and the development and blocking out the parts of the negative not required. Four colours, of course, require four plates.

When a portion of the cover of the book is gilt, that part of the design is printed from the collotype plate upon paper in gold-size varnish, which is afterwards gilt in the usual way.

In the supplement are four printings, three in colours and one in gold. In the matter of gradations of tone, the results are as good as with many more printings in chromo-lithography, and more true to the original. To get the exact colours an artist had to be sent to the British Museum with a palette, where he matched on paper the tones presented by the cover of the book. This process represents, in a remarkable way, worn or torn portions of the cover; the collotype plate seems to lend itself to the pictorial reproduction of such details. The possible applications of the process to colour illustration are barely indicated by the supplement, and experimental research is now being made in the endeavour to apply the method to a variety of subjects, including negatives from nature and the reproduction of paintings.

The printings from the collotype plates are performed in the ordinary way, only special care is taken in the selection of the pigments which, in combination, will match exactly the colours of the original. Messrs. Waterlow & Sons have now no less than eight German and French steam collotype machines at work, and as they occasionally get orders from the Continent, it is interesting to know that at last a stand is being made against foreign competition, which has so long held sway in this particular branch of industry. We have inspected several well-known collotype printing establishments on the Continent not nearly so well equipped as the works in Finsbury, in which the present supplement was produced. The fact is, that the prices for ordinary collotype printing are so low that without a good supply of steam machinery, adequate division of labour, careful attention to details, and skilled workmen at every point, it is a class of work likely to bring in little remuneration.

PHOTOGRAPHY BY TELEGRAPH.

In this age of hurry every man of business is enabled, by modern appliances, to do in a few hours the work which our forefathers would have considered more than sufficient to occupy them for a week. The introduction of railways would seem to have inculcated the notion that everything must move at railroad speed, and it is impossible to foresee where this desire for rapid movement will stop. The first step towards quick communication was the semaphore system. This was replaced by the telegraph, and the telegraph in its turn has been largely supplanted by the telephone. Every city and town in the world is now covered by a complicated cobweb of wires, all converging to one central point, where the exchange is situated, an arrangement which permits anyone to communicate with any other member of the association. Within a short time, we are promised that the phonograph will be so perfected that it will record any sounds submitted to it, and, like an obedient clerk with a memory that never forgets, will at any time repeat the matter that has been consigned to its keeping.

Our telegraphic system has always been pointed to as one of the most remarkable triumphs of science, and one which has proved how reality will occasionally outstrip romance, and the improvements in telegraphic instruments which have been introduced within the past few years would have surprised even those who prophesied so much with regard to what developments might be brought about. News from every part of the habitable globe is constantly pouring in upon us, and by means of a wonderfully perfect organisation, and by the help of the press, we receive this news almost as soon as the events which it deals with have taken place.

A vague notion of how this is all brought about is all of which the general public can boast. They know that the payment of sixpence will entitle them to hold telegraphic converse of a limited nature with anybody in Great Britain who is within touch of a post-office, and this knowledge leads them to believe readily in any report which tells of coming and greater wonders.

A report of this kind has been raised from time to time by means of those paragraphs which occasionally appear in our newspapers, the origin of which it is difficult to discover. It has been the fashion for some time to link Mr. Edison's name with anything startling of an electrical nature. This is not surprising, for Mr. Edison has already accomplished such wonderful things that there is some excuse for regarding him as a magician. It does not, therefore, excite any great feeling of surprise when it is stated that he is engaged upon a scheme for telegraphing a picture of an event taking place at a distant point. The report is probably false, but it may be true, and so it is as well that we should consider how far such a rumour may be within the bounds of possibility.

There is more than one contrivance by which the actual handwriting of a person may be conveyed from one place to another by means of the electric current. The most noteworthy, perhaps, of these is Cowper's writing telegraph, which a few years ago was at work for some time experimentally between Woking and Waterloo Stations on the South Western Railway. In this system the pen at the transmitting station was in contact with certain apparatus which varied the resistance of the current as the pen was moved over a slip of paper which travelled by clockwork. These variations affected a similar pen charged with ink at the receiving station, and the handwriting—somewhat cramped, it is true, by the necessities of the case—was reproduced. Now it is obvious that if handwriting can be transmitted in this way, the transmission of a drawing executed in simple lines—that is to say, what is popularly known as a pen and ink sketch—cannot be impossible. And as a matter of fact drawings, of a kind, executed at a distant point were reproduced by telegraph many years before Mr. Cowper's writing telegraph was ever conceived.

In the year 1850 Bakewell, taking advantage of the observation made long before his time that the electric current would decompose certain salts, and so produce a coloured stain upon paper impregnated with those salts, perfected his telegraphic system. It was cumbrous in design and somewhat slow in action, but it was capable of reproducing a picture under certain conditions, the chief among them being that the design must be executed in resinous ink on tinfoil. It will be seen at once that such a necessity at once relegated the instrument, ingenious as it was, to the domain of experimental things, and the contrivance is now forgotten except by those who take an interest in looking up old text-books of electricity. Not many years ago the idea was revived and very much improved upon by M. d'Arlincourt in his autographic telegraph. Some results achieved by this instrument we saw at the time of its invention, and we may broadly say that the reproduction had the same relation to the original that a Meisenbach block has to the photograph to which it owes its origin—in that it was expressed in lines. This line reproduction was, indeed, a necessary outcome of following out Bakewell's method, which may be briefly described as follows. The drawing in resinous ink on tinfoil was placed on a revolving cylinder. A metallic point was caused to touch this cylinder, and to traverse every part of it as it revolved, so that if this point had been a cutting tool it would have cut a screw thread from end to end of the cylinder; but its object was merely to bring about electrical contact, and so complete a battery circuit. But whenever the point went over a resinous line the current was for a moment interrupted, to be reinstated once more when the tinfoil was touched.

These interruptions were recorded at the receiving end of the wire, where another cylinder revolved covered by chemically prepared paper, and traversed by a similar pointer. So long as pointer No. 1 touched the tinfoil, pointer No. 2 decomposed the salts in the prepared paper, and left a coloured line; but directly pointer No. 1 went over the non-conducting resinous

line, the electricity was cut off, and pointer No. 2 left no trace. The result was what we should call a negative—a picture composed of white lines on a dark background. It is possible that by some means photography could be made to simplify the arrangement, and it would certainly not be difficult to obtain a picture on tin-foil by its aid; but the game would be hardly worth the candle.

If it be true that Mr. Edison is experimenting in this direction, and has any dream of causing photographic action to take place through the medium of an electric current, he would probably turn his attention to selenium as the most promising agent for his purpose, for we know that this curious substance possesses the remarkable property of varying its resistance with the amount of light which is shed upon it. Professor Graham Bell has obtained some startling results from it in his photophone experiments, and it may possibly lead the way to the reproduction of a picture at a point distant from its place of origin. A dream of such possibilities has occurred to many, but that dream has not yet taken substantial shape.

THE PHOTOGRAPHIC CONVENTION AT CHESTER.

At the Photographic Convention at Chester the following officers and members of Council were appointed for the coming year, and for the management of the Bath meeting in 1891 :—

President—William Bedford. *Hon. Secretary and Treasurer*—J. J. Briginshaw, 128, Southwark Street, London. *Auditors*—E. Clifton and T. Charteris White. *Council*—London members: A. Cowan, H. M. Hastings, A. Haddon, A. Pringle, Friese Greene, J. Traill Taylor, F. P. Cembrano, F. A. Bridge, G. Davison, C. Phipps Lucas, C. H. Benham, W. H. Walker, A. Levy, A. Mackie, J. B. B. Wellington, R. P. Drage. Provincial members: O. Berry, Wrexham; A. A. Carnell, Plymouth; J. Martin Harding, Shrewsbury; W. J. Harrison, Birmingham; R. Keene, Derby; W. Lang, jun., Glasgow; Paul Lange, Liverpool; Major J. Lysaght, Cork; E. Marlow, Birmingham; George Mason, Glasgow; T. S. Mayne, Liverpool; W. W. Naunton, Shrewsbury; J. B. Payne, Newcastle-on-Tyne; J. Porritt, Leicester; B. J. Sayce, Liverpool; A. Seaman, Chesterfield; J. M. B. Smith, York; John Stuart, Glasgow; H. Sturmey, Coventry.; A. Tate, Belfast; W. Taylor, Leicester; J. M. Turnbull, Edinburgh; G. Watmough Webster, Chester; and A. Werner, Dublin.

During the excursion to Hawarden Castle, on the day before the Convention left Chester, the weather was splendid for photography; massive cumulus clouds were floating about, and every now and then bursts of sunshine came down between the clouds. Mr. Gladstone was fortunately absent during the Convention visit; we say "fortunately," because a statesman has as much right to a term of private life as anyone else, and the Photographic Convention cannot be numbered among those bad-mannered intruders who almost force themselves upon his privacy.

During the Convention visit, a terrible tragedy took plac in frout of the City Hall at Chester. A father murdered his only son with a bludgeon, then raised the body on the end of the weapon, aud tossed it high in the air. The childless mother next appeared upon the scene, and he gave her a blow behind the head, the sound of which could be heard all over the square; she likewise sank at his feet a corpse. Officials of the Eastman Company, as well as some other photographers, were looking on, but, from excitement or other cause, forgot to use their kodaks. The murderer's countenance betrayed no symptoms of regret; on the contrary, he smiled unceasingly, and rubbed his back up and down against a post, uttering unhallowed squeaks of trinmph. For a moment only did he show signs of contrition, by bending over his wife's body, and squealing, "O Judy, dear Judy!" The sympathies of the observers were evidently on the side of the culprit. How is it that Punch always has as much mob sympathy on his side as does the villainous old wife-murderer, Henry VIII.? Punch and Judy shows are but survivals of Italian puppet miracle plays, and, in his native clime, Punch originally was Pontius Pilate.

THE PHOTOGRAPHIC CONVENTION AT BATH.

About midsummer next year the Photographic Convention will meet in Bath, and with the experience of the past the managers will be better able to deal with the difficulties of the future. Unless the excursion for any particular day is but to a moderate distance, or to a place of bnt average attractiveness, it is evidently a mistake to draw the members back while several hours of daylight remain, in order that they may be present at the reading of papers in the evening. Presumably the chief excursion from Bath will be to Chepstow Castle and the banks of the Wye as far as Tintern Abbey, which includes, perhaps, more beautiful scenery than is to be found anywhere else within similarly easy distance of London. Unfortunately, between Chepstow Castle and the Wyndcliff a private park includes the western bank of the Wye, and those who go to Tintern by road have to pass over two or three miles of ground away from the river, and totally destitute of pictorial interest. The lower reaches of the Wye have the highest tides of any river in England, and when the tide is low, ugly mud-banks rise at each side of the river, nearly as steep as the roof of a house. Near the railway station at Chepstow is a picturesque cutting by the river and through the rocks; the heights are thickly wooded. Chepstow is reached *via* the Severn Tunnel, or if a steamboat be engaged, it could go down the Avon, under Clifton Suspension Bridge, then cross the Severn and proceed up the Wye to Chepstow. Once this was the regular means of communication between Chepstow and Bristol, but whether the opening of the tunnel has affected the old steamboat service we do not know. Evidently an excursion of this kind should occupy the whole day, and not be cut short, as was the case at Conway, because papers have to be read in the evening. Another excursion—this one close to Bath—will, no doubt, be along the valley from Bathampton to Bradford-on-Avon, which is picturesque the whole way, and includes subjects of historical interest. The ballast

used in the construction of the railway between Bradford and Trowbridge is rich in fossils, and in a bed of blue clay in a railway cutting this side of Trowbridge are numerous crystals of selenite, a fact which may interest those who are in the habit of experimenting with polarised light. A third excursion will probably be to Clifton Downs and Bristol. Bath itself, with its abbey, its architectural antiquities, and its picturesque surroundings, offers plenty of subjects for the camera. Here Beckford, the author of Vathek, lived, and the tower built by this remarkable man of fantastic imagination awaits the arrival of the Convention to be photographed.

The Photographic Convention may now be said to be upon a fairly permanent basis; it meets a want of the photographic fraternity in providing a summer outing, at which, also, many meet who otherwise would not make the personal acquaintance of each other. The Convention, practically speaking, was founded by Mr. J. Traill Taylor and Mr. J. J. Briginshaw. The former gave it its somewhat American title, and the latter told the listeners at the Convention dinner in the Grosvenor Hotel, Chester, that the organisation has now reached a stage at which "it can no longer be damned with faint praise." Mr. A. Pringle has done much in the nursing of the infant Convention, and the Mayor of Chester has given a good lift to the Association, which is likely to grow into something large in the future.

A marked feature of the meeting of the Photographic Convention at Chester was the absence of the general public at the meetings at which papers on photography were read, although some of the less technical utterances at such meetings were of general interest; Mr. Gambier Bolton's paper and lantern illustrations, for instance, were of a popular character. The question whether residents in the particular locality in which the Convention meets should be allowed to become associates for the week on payment of the nominal fee of a shilling towards the funds of the Convention, may be worth consideration. Such associates might join the excursions on the same terms as ordinary members.

The Photographic Club.—The subject for discussion on July 16th will be "Iron Printing Processes;" July 23rd, "Ceramic Photography."

Suggestions of Sitters.—A firm of photographers engaged in the production of a group which, they say, is considered successful, send the following suggestions sent to them by individual members of the group:—"Mrs. ——'s eyes might look larger, and her mouth have a bit taken off the corner. The body of her dress has very ugly creases. Please have them taken out altogether." "Mrs. ——'s eyes might be improved and the eyebrow put straight; the strong shade near nose much softened; the corner of sleeve taken out altogether." "Mrs. ——. Lines on the face still more softened, particularly between the eyebrows; the outline of cheek near the little girl could be improved." "The little girl's eyes look too small (particularly one of them)." "The little boy's ears are, by nature, too large. Can you please make them a proper size by shading part of them out altogether against that background; I should think it would be easy." Our correspondent may well wonder what next professional photographers will be called upon to do.

PHOTOGRAPHIC EXHIBITIONS.

BY GEORGE DAVISON.

No. VI.—Judges.

In the higher form of exhibition, for which I have indicated a few necessary regulations, a jury in the ordinary sense would not be required. The hanging committee practically takes some of its functions; indeed, the qualifications of a competent hanging committee are, to a great extent, those required for a board of judges, although the functions of the hanging committee are much broader. Taking the system of competition as we find it, however, the question of the jury becomes the most important to be dealt with. If prizes are given at all, they should at least be given only for such pictures as are truly deserving of some recognition, and in the art section should be given only to such as possess artistic qualities. It is safe to say that, under the present development of the classification and competition system, in five out of six cases the successful photographs are in no way qualified for the distinction they receive. This arises partly from the system itself, but chiefly from the characteristics of photographic judges. Faults from partiality, faults from vindictiveness, must be common to any system, but defects from ignorance ought to be avoidable. In many classes in which adjudication is made, the award has been given for no other reason than that the exhibit shows what has been held to be correct exposure, the result agreeing with a certain convention or standard of brightness and sharpness set up by a purely scientific consideration of photography. Mrs. Cameron, in writing of an early exhibition in Scotland, where she had shown some of her remarkable portraits, complained that the test of the judges was as to which photograph showed most the detail and pattern of table cloth, &c., and such has been the attitude of most photographers acting in the capacity of jurors.

In the May 30th issue of the Photographic News, there appeared an article contending that painters were not suitable or qualified judges of photographs because, it was averred,—1st. The means used by them were different. 2nd. They would give awards for what most resembled paintings. 3rd. They did not know the difficulties of photography. Now this contention simply means that there is no such thing as good art in photography, and that it is purely a matter of scientific motions. The writer speaks of roughness as charming in a painting, but as not even tolerable in a photograph, and he conducts his argument generally as though smoothness and sharpness were the essential characteristics of photography. Treatment in focussing is to him no power in the hands of the artist, and he holds the photographer's technique cannot be made obedient to the eye and will. It is impossible in the limits of these articles to discuss fully a comparison of the photographer's and the painter's technique, but the question of qualifications for adjudicating between photographic pictures does not depend chiefly upon whether the means employed by the judge and the competitor be exactly the same, but upon whether the judge has been trained to understand what constitutes artistic qualities. The aim of the painter or etcher or engraver is exactly the same as that of the photographer. If the photographer had been through the same art training as the painter, then he would be the best judge possible; but it must be remembered it is no question of deciding whether a plate is fogged or underexposed or done with a pinhole, and so forth, but whether

a picture is a spirited, complete representation of a natural scene and subject. A long cultivation upon the top of natural aptitude is needed to decide what is true in a pictorial representation. It is in subtle rendering of passages, simple or complex, in nature that much of the enjoyment of the true connoisseur consists. Composition, which the jury has to understand and appreciate, is not merely a detail of arrangement. In good composition is comprised the selection of what will most completely express a certain subject, and give the salient features under the most characteristic conditions, and the whole has to be translated in a way that shows knowledge of what constitutes truthful relations. It is because photographers have not had the needed training that they are not qualified to judge of pictures with the highest qualities. They decide merely from a few photographic conventionalities more or less guided by a taste which would certainly be altered by the study required for the production of pictures. All we can boast of in photography are two or three who are partly trained, but who have been compulsorily led away by business considerations to which they have had to give their chiefest attention; two or three whose hearts are entirely in their practice, but who have had no preparation, or have greater zeal than knowledge; and perhaps not more than one to whom it was possible to plan out life with photography and art as chief devotion, and to study it as rationally required. All this may at some future time be altered, but at present there is nothing left but to give the influence in our competitions to the right artists, and with a free hand. We do not want awards given for smoothness and sharpness any more than for roughness and blurriness, nor in an art exhibition for the overcoming of what are considered difficulties of exposure and the like. What is required is the distinguishing of the photographs that have some high artistic qualities, and only those who have learnt to know by practice can authoritatively do this. Artists have not been given a free hand. They have been subjected to petty interferences, so that it is no wonder that it is difficult to secure any further assistance from them. It has been thought necessary to associate one or more photographers with them, and the artists have frequently deferred to these technical assessors, or have been entirely influenced by the ready photographic opinion confidently expressed, but their reliance on these photographic colleagues is but a proof that they are unable to find anything amongst the exhibits which comes into the category of good art to which they can assign the medals. They then presume that it is for some other qualities that the distinctions must be given.

Captain Abney has recently suggested that every visitor to an exhibition should be a judge, and that in that way agreement with the public sentiment would most closely be attained. But it is hardly public sentiment that might satisfy the exhibitors. The public are apt to go chiefly from hearsay and for a name. In a matter of art a cultivated electorate is essential, and only those who know ought to be on a board of judges.

In conclusion, I am of opinion that the time has come when, if exhibitions are desirable at all, they should be made somewhat of the kind I have outlined and argued for. My contention in favour of exhibitions without awards, and if with awards without classification in the art section, has been to urge that such is a more dignified and rational system, rather than that it is essentially different in kind from those in vogue. If open exhibitions are to be held at all, the element of competition must more or less enter, but the less prominent it is the better. I do not say that a system in which acceptation is the award is perfect, but it is competition only in the broadest and most manageable form, and it passes by most of the defects of classified competition. Competition may tend to the multiplication of third-rate execution, but it is of no service in stimulating to good art; it stifles originality and encourages imitation. Something may be found to be said in favour of classified competition, but the arguments adduced are not based upon a consideration of the bearing of the best art-cultivation upon the question.

The exhibition required, then, is one in which in the art section the best, and only the best, shall appear, both from at home and abroad; where these best are fairly and judiciously displayed by a competent hanging committee; where there shall be no classifying, every distinction of amateur and professional being ignored; where the pictures shall be more uniformly framed; where the scientific department shall be kept distinct and be properly worked up, exhibits from meteorologists, from astronomers, microscopists and their societies, from photo-mechanical printing process workers, and from those interested in industrial applications of photography being effectively sought and secured. There have been generous offers of assistance in this direction, and some rumours of such an exhibition being accomplished, but our hopes still await realisation.

A NEGLECTED DRY PLATE PROCESS.

BY WILLIAM LANG, JUN., F.C.S.

A friend of mine who dabbles in photo-micrography consulted me recently as to whether he could obtain a collodion plate in the dry state, which he could use from time to time as the occasion presented itself. For some of his more highly magnified specimens, the gelatine film he found to be not altogether suitable; he wanted to have all the benefits of the collodion support, but he also desired to have a plate that would entail no abnormal length of exposure. The process which I recommended to my friend was one which, so far as I have been able to ascertain, has found almost no exponents, and, as it has met the requirements of the particular case I have referred to, it may be of sufficient interest to the readers of the Photographic News to have their attention called to it.

In the spring of the year 1861, the South London Photographic Society—a society no longer in existence, but which in its day did some good work—organised a committee to report on some dry plate processes then before the photographic world. The processes at that time known as "dry" were those where collodion had a preservative applied, and the preservatives recommended were simply legion. Dr. Russell's tannin process had been but recently given out; and the process which interests us in the present communication was likewise a recent contribution. Hence, the finding of the committee on the two processes in question was as follows:—"The tannin process and Dr. Hannaford's modification they consider promising, but would at present more particularly call the attention of the experimental members of the Society to them." The processes actually reported on by the committee were the following: The Taupenot (or original collodio-albumen process), the Fothergill, Petschler and Mann's, Mr. Davis's collodio-albumen, and the gelatine; the latter, as then understood, having nothing in common with what we now designate as the gelatine, for, the gelatine being poured on the collodion plate, played

only the part of a simple preservative. Briefly considered, the two principal processes here referred to consisted in having, in the first instance, the collodion plate duly sensitised, and afterwards thoroughly washed. The Taupenot plate was prepared by pouring iodised albumen over the washed plate, draining it, and drying rapidly before a bright fire; at this stage the plates were insensitive, but the necessary quality of sensitiveness was given to the plate by an immersion in a bath of aceto-nitrate of silver. The Fothergill process consisted in having albumen poured over the plate, the albumen having had a certain amount of ammonia added to it.

In order to avoid stains, which often made their appearance, an immersion in a weak bath 5 grains nitrate of silver to 1 ounce water was finally adopted. The modification which Hannaford introduced was pouring over the washed plate a solution of albuminate of silver in ammonia. The plate, after this application, was thoroughly washed before being set aside to dry. The preparation of the preservative is a simple affair; the white from a fresh egg is taken and thinned with an ounce or two of water, well mixed, and to the dilute albumen 1 drachm of a 60 grain solution nitrate of silver is added; this causes a flocculent precipitate of albuminate of silver, which is dissolved by means of ammonia added drop by drop and well stirred. It is desirable to add no more ammonia than actually required, and the resulting solution should be opalescent rather than clear. The solution will keep for some little time, and should be put away in a non-actinic light. The development of plates thus prepared is conducted as follows: First of all, should the plate not have received a substratum, it will be necessary to go over the edges either with a varnish or a solution of india-rubber in benzole; without this the tender film of collodion would not bear the strain of the subsequent operations. Say that the exposure has been made—and it may be as rapid as if we were employing the ordinary gelatine plate—the first thing to be done after removal from the dark slide is to pour some alcohol over the collodion surface, letting it remain on for some little time, and, before applying the developer, it is necessary to wash the plate, very gently of course, for we are dealing with a very different material from that now so generally employed in photography. Development is now proceeded with, and, until the advent of eikonogen, it had been my habit to use a formula similar to Beachey's—that is, pyro with excess of sulphite. Latterly I have had recourse to the one-solution formula issued by Marion's people in connection with eikonogen. The plate is generally immersed in a tray containing the developer, and the appearance of image closely watched. The moment it appears the plate is withdrawn and washed. A prolonged immersion will tend to veil the clear portions. It remains to be here stated that the picture at this stage looks unpromising, the image being little more than a ghost. To bring out detail, recourse is now to be had to the silver intensification method, as in the "old days" of acid pyro development. For the benefit of those whose acquaintance with photography is only limited to the gelatine period, I may state that the intensifying solutions, as they were called, were made up as follows:—

No. 1.—Pyro	... ...	10 grains
Citric acid	... ...	25 ,,
Water	... ...	2 ounces
No. 2.—Silver nitrate	... ...	10 grains
Water	... ...	1 ounce

Immediately before using, a few drops of No. 2 are added to No. 1, and the solution poured on and off the picture, when it immediately begins to gain strength. The intensifying solution, when it begins to discolour, or, rather, when it begins to show a deposit, should be at once discarded and fresh solution applied. In a short time the proper density will be arrived at, when, after washing, the image may be fixed either in the ordinary hypo or a bath of potassium cyanide. In practice it is necessary to be careful that the light employed be thoroughly safe. Being a collodion process, one is apt to think that the same care in this direction is not necessary, but I know that some failures by a friend who experimented with the process, and who was inclined to throw it up as worthless, were shown clearly to have resulted from this cause. The addition of some acetic acid to the intensifier above given was found to be beneficial. The process is thoroughly well adapted for making lantern transparencies, either by contact or by reduction in the camera. The tone given by the intensifying method is by no means a displeasing one for lantern work, but it can be still further improved by toning with a weak solution of palladium chloride. If all the operations be carried out as described in the foregoing, it is possible to produce transparencies that have all the appearance of having been made by the ordinary wet plate method. The rapidity of the plate is great; I have produced transparencies from a negative of ordinary density by simply passing the same, having the prepared plate behind it in a printing frame, in front of an ordinary batswing burner.

At the Birmingham Convention, Dr. Hill Norris announced that he had produced a dry collodion plate equal in sensitiveness to a gelatine plate. I rather think subsequent investigations did not bear this out, but here has been a collodion process lying more or less dormant all these years—since 1861—giving as great sensitiveness as it is possible to desire. It will naturally be asked, if that be so, how does it happen that it has not come to the front? Perhaps it may be accounted for in two ways. Hannaford's method may have been overlooked from the fact that collodion emulsions came shortly afterwards to engage universal attention, to be followed by the all-absorbing gelatine emulsion, or perhaps no one had thought of applying the alkaline method of development to be followed afterwards by silver intensification. Hannaford's method of development was the acid pyro, and with this the plate appears to possess no great rapidity. It would be interesting if some of the readers of the PHOTOGRAPHIC NEWS would take up the process for themselves, and give the results of their experiences. I think enough has been written to enable anyone having the knowledge necessary to produce a wet collodion plate ready for exposure in the camera, to prepare a dry collodion plate by Hannaford's neglected method.

THE project initiated long since by Captain Abney, of scientifically testing the optical qualities of any photographic lens sent to Kew Observatory, may possibly be carried into practical effect before long. A small fee will be charged to the sender for the testing.

ENFIELD CAMERA CLUB.—A society has been formed called the Enfield Camera Club. Its objects are to popularise the art of photography, and afford mutual help in photographic pursuits by the interchange of prints and lantern slides; field days, meetings, and discussions; and giving advice and assistance to beginners. Meetings are held on the first and third Wednesdays in each month, at the Lancaster Coffee Tavern, Enfield, and the hon. secretary (*pro tem.*) is Mr. James Dudin, Roseneath, Chase Green Avenue, Enfield.

NEW PHOTOGRAPHIC LENSES.*

BY DR. PAUL RUDOLPH.

In conclusion, I append to this specification of my invention four examples, which serve to illustrate the manner in which the principles set forth in the preceding pages may be applied to the construction of different types adapted to various purposes. All dimensions (radii, thicknesses of lenses, and air-distances) are expressed by proportional numbers, the focal length of the whole objective being taken as unity. A simple multiplication of these numbers, with the focal length actually required, will suffice for obtaining the dimensions of any objective wanted.

The letters of the following tables correspond to the letters marked on the drawings (see p. 525). The different kinds of glasses are determined by the indices n_D and n_{GI} relating respectively to the D line of the spectrum and to the Hγ-line of the spectrum of hydrogen. In order to render obvious the character of the pairs of glasses used in each system, I have appended to each kind of glass the value of the relative dispersive power $\left(\frac{\Delta n}{n-1}\right)$ where Δn has been calculated for the interval from the D to the Hγ-line of the spectrum, while the value of n_D is taken for n.

Examples.

TABLE I.

Objective of the kind shown by fig. 1, consisting of two positive systems having greatly differing focal lengths.

Effective aperture: 0·056. Angle of field about 110°.

Radii:	Thicknesses of Glass:
$r_1 = +\ 0{\cdot}2041$	$d_1 = 0{\cdot}013$
$r_2 = +\ 0{\cdot}0962$	$d_2 = 0{\cdot}025$
$r_3 = +\ 0{\cdot}3329$	$d_3 = 0{\cdot}067$
$r_4 = -\ 0{\cdot}1589$	$d_4 = 0{\cdot}013$
$r_5 = -\ 0{\cdot}0962$	Distances of diaphragm B:
$r_6 = -\ 0{\cdot}1798$	$b_1 = 0{\cdot}013$
	$b_2 = 0{\cdot}057$

Kinds of glass employed:

	n_D	n_{GI}	$\frac{\Delta n}{n-1}$	
L_1:	1·55540	1·57036	0·0269	normal pair of glasses;
L_2:	1·51900	1·53047	0·0221	focal length = + 1·1275.
L_3:	1·57360	1·58642	0·0224	abnormal pair of glasses;
L_4:	1·54763	1·56316	0·0284	focal length = + 3·3785.

(The objective of this combination, represented in full size by fig. 1, has a focal length of 24 cm.)

TABLE II.

Objectives of the kind shown by fig. 2, consisting of two positive systems having but slightly differing focal lengths.

Effective aperture: 0·166. Angle of field about 75°.

Radii:	Thicknesses of Glass:
$r_1 = +\ 0{\cdot}2559$	$d_1 = 0{\cdot}012$
$r_2 = +\ 0{\cdot}1029$	$d_2 = 0{\cdot}062$
$r_3 = +\ 0{\cdot}4122$	$d_3 = 0\ 012$
$r_4 = -\ 0{\cdot}2058$	$d_4 = 0{\cdot}029$
$r_5 = +\ 0{\cdot}4122$	Distances of diaphragm B:
$r_6 = -\ 0{\cdot}1897$	$b_1 = 0\ 0656$
	$b_2 = 0{\cdot}0656$

Kinds of glass employed:

	n_D	n_{G_1}	$\frac{\Delta n}{n-1}$	
L_1:	1·57973	1·59357	0·0239	normal pair of glasses;
L_2:	1·50546	1·51610	0·0210	focal length = + 2·325.
L_3:	1·53789	1·55250	0·0272	abnormal pair of glasses;
L_4:	1·57360	1·58642	0·0224	focal length = 1·426.

* Continued from page 525.

(The objective of this combination, represented in full size by fig. 2, has a focal length of 35 c.m.)

TABLE III.

Objective, such as shown by fig. 3, consisting of two positive systems, with nearly equal focal lengths.

Effective aperture: 0·180. Angle of field about 70°.

Radii:	Thicknesses of glass:
$r_1 = +\ 0{\cdot}3408$	$d_1 = 0{\cdot}015$
$r_2 = +\ 0{\cdot}1217$	$d_2 = 0{\cdot}044$
$r_3 = +\ 0{\cdot}6815$	$d_3 = 0{\cdot}015$
$r_4 = -\ 0{\cdot}3894$	$d_4 = 0{\cdot}044$
$r_5 = -\ 0{\cdot}8763$	$d_5 = 0{\cdot}019$
$r_6 = -\ 0{\cdot}1947$	Distances of diaphragm B:
$r_7 = -\ 0{\cdot}3213$	$b_1 = 0{\cdot}122$
	$b_2 = 0{\cdot}024$

Kinds of glass employed:

	n_D	n_{G_1}	$\frac{\Delta n}{n-1}$	
L_1:	1·55540	1·57036	0·0269	normal pair of glasses;
L_2:	1·51310	1·52461	0·0224	focal length = 1·741.
L_3 and L_5:	1·53984	1·55463	0·0274	abnormal pair of glasses;
L_4:	1·57360	1·58642	0·0224	focal length = 1·809.

(The objective of this combination, shown by fig. 3, has a focal length of 20 cm.)

TABLE IV.

Objective consisting of a positive principal system and a corrective system having a negative focal length.

Effective aperture: 0·056. Angle of field about 100°.

The letters correspond to those marked in fig. 1.

Radii:	Thicknesses of glass:
$r_1 = +\ 0\ 1928$	$d_1 = 0{\cdot}012$
$r_2 = +\ 0{\cdot}0938$	$d_2 = 0{\cdot}056$
$r_3 = +\ 0{\cdot}1251$	$d_3 = 0{\cdot}034$
$r_4 = -\ 0{\cdot}3127$	$d_4 = 0{\cdot}010$
$r_5 = -\ 0{\cdot}0834$	Distances of diaphragm B:
$r_6 = -\ 0{\cdot}1511$	$b_1 = 0{\cdot}084$
	$b_2 = 0{\cdot}034$

Glasses employed:

	n_D	n_{G_1}	$\frac{\Delta n}{n-1}$	
L_1:	1·51282	1·52421	0·0222	normal pair of glasses;
L_2:	1·57973	1·59357	0·0239	focal length = — 15966.
L_3:	1·51680	1·52755	0·0208	normal pair of glasses;
L_4:	1·56490	1·58215	0·0305	focal length = + 0·5956.

Having now particularly described and ascertained the nature of this invention, and in what manner the same is to be performed, I declare that what I claim is:—

In a photographic objective, the combination of two distinct systems of lenses, each composed of single lenses cemented together, the positive element of one system having a higher, the positive element of the other system a lower refractive index than the respective negative elements cemented thereto, and each system being in itself approximately achromatic, substantially as described.

INTERNATIONAL BIBLIOGRAPHICAL CONFERENCE.—An International Conference is to be held this summer in Antwerp, of publishers, printers, and others connected with or interested in books. Simultaneously, the Society of Industry, Art, and Commerce will organise in its rooms an exhibition which will include photographic presses and specimens of processes for the photographic illustrations of books.

BRITISH PHOTOGRAPHIC UNION.—The organising council of the above proposed union meets at the Polytechnic School of Photography on Wednesday evening, July 16th, at eight o'clock. Any workman who can get three or four of his fellow workmen to delegate him may attend. The subjects to be discussed are the form, rules, and methods of the union; the appointment of acting officers for London; the form of appeal for funds; arrangements for the institution of the examining body.

Notes.

Mr. Andrew Tuer writes pleasantly in the *English Illustrated Magazine* on "The Art of Silhouetting." One of the first and best silhouettists who practised in this country was Augustin Amant Constance Fidèle Edouart, who was born at Dunkerque in 1788, and found his way to London as a refugee in 1815. It was in 1825 that Edouart took to silhouette cutting as a profession. Spending an evening with some friends, he was shown profile likenesses of some of the family taken with a machine. These Edouart condemned, but the daughters pronounced them perfect. Challenged to do something better, Edouart seized upon a pair of scissors and the cover of a letter, and, putting the father in position, "in an instant I produced a likeness." The paper being white, the snuffers were resorted to for blacking it over. Natural skill triumphed over inexperience and difficulty.

The most interesting portion of the volume is that which foreshadows the experience of the photographer. When Edouart first began cutting out paper likenesses it was on the understanding that if they were not approved others would be taken. Some of his clients returned in a day or two saying they were dissatisfied with the old one, and they would destroy it at home. When Edouart afterwards insisted upon these old likenesses being returned and destroyed before a new one was began, complaints decreased. A young sitter highly approved his likeness, but on a friend pointing out that he would look better in a dress coat—he was taken in a frock—another was somewhat rudely demanded. This was refused, and the sitter ultimately refused to pay for the first and only likeness; so Edouart in revenge cut the body of the silhouette from the waist downwards into a screw, made an alteration in the top of the hat, and wrote underneath, "Patent screw for five shillings." In this altered condition the silhouette was exhibited in Edouart's window, where it was recognised by amused friends, and it was not long before satisfactory terms were made with the artist. How few photographers are there who have not had an experience of a "serew" of this nature! By the way, to have rendered Mr. Tuer's article complete, some mention should have been made of Mr. Francis Galton's photographic silhouettes, which he secures by placing the sitter in a long passage, at the end of which is an illuminated screen. The camera is, of course, stationed at the other end.

In the interesting book just published entitled "My Mistress, the Empress Eugénie," the authoress, Madame Carette, imparts a hint which the much photographed ladies of to-day might utilize with advantage. She gives an amusing account of one of the court ladies, the Countess de Wagner, who had considerably passed beyond the charms of her youth and even middle age, but who still fancied herself young. As a matter of fact, she was, although over seventy, exceedingly well-preserved. The Empress often went into raptures over her unfailing youth, and this pleased her greatly. One day, she brought her portrait to the Tuilleries, in which she appeared to be scarcely thirty years old, but it did really resemble her, and the Empress could not conceal her astonishment at its artistic flattery. "I wished to leave my friends a pleasing souvenir," said the Countess, "and I therefore instructed the photographer as to what he was to put in and what omit, and I think have succeeded in getting a pretty portrait."

This seems to us an admirable idea. Ladies who wish to please themselves should not fail to take advantage of the retoucher's art, and give their own instructions. There is only one doubt which crosses our minds. The Countess de Wagner's portrait, it is said, resembled her. Now we are inclined to think that the photographer, in spite of the lady's instructions, used his own discretion; but no doubt the Countess imagined that her directions had been faithfully carried out. The moral of this is, that the diplomatic photographer should listen to all the instructions of his fair sitter, but exercise his own judgment. They will not quarrel with him if he makes them look younger, and yet preserves some sort of likeness.

In the same interesting volume appears a reference to a certain photograph which played a mysterious and unexpected part in regard to the surrender of Metz. It will be remembered that when the Empress and the Prince Imperial fled to England, a M. Régnier visited them at Hastings. At his earnest request, M. Filon, the Prince Imperial's tutor, gave him a photograph signed by the Prince Imperial; and this little circumstance expanded to unexpected magnitude. M. Régnier presented this photograph to Marshal Bazaine at Metz, as a pledge of the powers with which he was charged to negotiate with him, though what these negotiations were was not known. The whole of this transaction has remained in obscurity, and it was only later, when events unravelled themselves, that the treachery of M. Régnier in presenting the photograph signed by the Prince Imperial was understood.

It would be a salutary caution to peopl who fill up cheques carelessly, if the photograph published in the *Banker's Magazine* of this month were reproduced and copies hung in every banking establishment. There is one numeral which is extremely useful to the dishonest person. All he has to do when he comes across a cheque made out for £8 is to add the letter "y" to the word "eight," and an "0" to the figure, and, with two strokes, he thus converts £8 into £80. This seems to have been the case with a cheque presented to the Birkbeck Bank. The original cheque was drawn for £8 5s., but when presented it appeared as £80 5s. The bank paid the money, and the drawer sued them for the amount over-paid. A photograph of the cheque is given, as we have already noted, in the *Banker's Magazine*, and proves conclusively that the cashier was not in fault, as there is no indication that the additions were made by a swindler.

It is taking the French papers a long time to discover that the Americans intend to do honour to the memory of Daguerre by raising a monument to him. Now that the discovery has been made, one of the lively Parisian journals suggests that at the foot of the monument should be placed a penny automatic likeness taker. As this is the lowest form of photography with which the world is yet acquainted, it is not quite certain whether the paper in question approves of the idea of a monument. Since it speaks elsewhere of Daguerre as *one* of the discoverers of photography, perhaps it wishes the names of Niepce, Davy, Wedgwood, Talbot, and even Scheele, to be included. If so, the argument is not without justification.

A Parisian paper gravely states that the automatic portrait-taking machine was anticipated by an enterprising jeweller who, on the first of April last, introduced his invention to the public. The apparatus is in the form of a clock which automatically marks the day, month, and year. On the side is an invitation to "Drop five centimes in the slot and see your likeness." When you have dropped your centimes in the slot as directed, an inscription, reading "Here it is," appears. At the same instant up bobs a donkey's head with large outstretched ears—your likeness! It is a new form of an old pleasantry, and if the apparatus does not take a photographic portrait, it certainly takes the public taste.

The *Chemical News* draws attention to a question which always troubles judges and juries, namely, the discrepancy which is invariably seen when scientific witnesses give their evidence. Our contemporary rightly points out that the disagreeable spectacle of men of equal scientific reputation disagreeing or appearing to disagree over some vital point, and the cross-examination of the scientific witness by a counsel who is totally ignorant of the subject under consideration, and who has been hastily and imperfectly coached, do damage, not only to the reputation of the witness, but bring science itself into contempt. This kind of thing has always been witnessed when any action turning upon a question of photographic chemistry comes before the law courts. The remedy proposed is that a scientific witness should make a written statement, but should positively decline to step into a witness box. We do not know whether this is a good way out of the difficulty, and judging by the light of recent photographic actions at law, probably the best plan would be for each scientific witness on either side to give his evidence, and let it be adjudicated upon by a scientific arbitrator. The scientific points settled, the legal questions involved would then be an easy matter to decide by the usual tribunal.

Photographers are, perhaps, as much interested in the state of the weather as any other class of the community, for it is certain that their incomes must fluctuate with its condition. No one cares to be photographed except when arrayed in the chief glories of her wardrobe, and such gorgeous vestments are not for rainy days. This midsummer will long be remembered for wetness, and the general stagnation of photographic work which it has brought about; for it is not only the photographer who suffers—the damp percolates through and affects every trade connected with the art. A wet fortnight at the end of June means that millions of plates are unexposed that ought to have been exposed, and that thousands of reams of paper which ought to have borne pictures remain blank. So the wet weather affects all, from the photographic monarchs of West End studios, to the poor fellow who holds himself in readiness to take your portrait on the sands for sixpence.

Writers who try to be comic have often tried to make fun of the circumstance that when two strangers meet, their conversation invariably opens with a remark about the weather. But in this country, at least, when the weather is so erratic in its behaviour that one knows not whether the morrow will bring forth scorching heat or icy cold, it is only natural that men should have the matter uppermost in their minds. The thing to wonder at is, that with so many millions of persons making remarks and observations of this kind every day of their lives, no one yet has proved himself to be a reliable weather prophet.

The number of persons armed with cameras one meets in the course of a day's outing is marvellous. It does not seem to matter in what direction you go, the ubiquitous photographer is bound to turn up. Of course there are favoured spots. For instance, up the river cameras "come not in single spies, but in battalions." The question naturally suggests itself, if anglers are allowed special privileges in the way of reduced fares, why should not amateur photographers? This is a matter which has been mooted at several photographic societies, and, for aught we know, the railway companies may have been approached on the subject; but certain it is that up to the present the photographer has to pay full fare. Probably he always will; for the argument may be that photographers are becoming so numerous that a reduction of fare to them would mean a reduction generally.

Let us hope that those photographers who are fortunate enough to get away to the sea this year may have a break in the clouds to look forward to, and that many seascapes, and glimpses of life on the shore, may compensate them for the wet season which they are now experiencing. Should any of them roam with their cameras in that part of our coast which borders "The Downs," they should take with them a book which has recently been published, "Memorials of the Goodwin Sands," by Gattie. This gives a full account not only of the treacherous sands, but of the coast near which they lie, and it is very pleasant reading. It always gives a zest to photographic touring when the worker knows something about the district in which his pictures are taken.

PHOTOGRAPHY IN FRANCE.

BY LEON VIDAL.

COLLOGRAPHIC PROCESS BY M. BALAGNY—COLOURED SCREENS FOR ORTHOCHROMATIC WORK—THE "CRISTALLOS" DEVELOPER—FLEXIBLE NEGATIVE FILMS.

Collographic Process by M. Balagny.—The fullest details of the divers phases of this process, which, as is known, is based upon the use of a pellicular printing surface, have been furnished by the author at a special conference. It is, in short, a sort of photo-lithographic process analogous to the Raymond autocopyist process, but with this difference, that the gelatinised paper which, in the autocopyist process, forms the printing plate, is covered with gelatine free from any other substance. In Balagny's pellicle the support is coated with gelatino-bromide of silver. According to our confrère, this substance, which, with regard to gelatine, is inert, has the effect of increasing the sensitiveness to the light of the film when bichromated. In our view this is a statement which remains to be proved, but what is true—a fact which has been already recognised by other experimentalists, notably by Husnik and Woodbury—is, that the presence of a pulverulent body plays the part of causing reticulation. We may, in this case, after insolation and rapid washing, take prints in fatty ink, whilst in the ordinary collographic process it is indispensable to dry the film in order to produce reticulation, after which it is moistened and impressions are taken from it. In support of his interesting explanation, M. Balagny offered to the Society, as illustrations for its *Bulletin*, 1,500 prints representing the installation of Class XII. at the *Exposition Universelle*.

Coloured Screens for Orthochromatic Work.—M. Stebbing, following the indications given by M. Vidal, has prepared some pellicular coloured screens for orthochromatic photography, and presented specimens of them. These screens are formed of discs of suitably coloured gelatine imprisoned between two coatings of normal collodion. There are four degrees of colouration. No. 4, which is the maximum, requires an exposure of from six to twelve times the normal duration—that is to say, of an orthochromatic plate employed without a screen. No. 1 is coloured to one-fourth that extent, and requires a correspondingly shorter exposure—that is, of from one and a-half to three times the normal exposure. These screens are very well prepared, and will render great service, seeing that they may be used in the place of the diaphragm, and inserted in a double diaphragm made of black paper. The interposition of an orange yellow film should not alter the focal point.

The "Cristallos" Developer.—This developer, presented in the names of Messrs. Jeannin and Jumeau, is one of great energy. It appears to be a mixture of hydroquinone and potash. According to M. Audry, who has tried it, it acts violently, and fogs the shadows. He finds it very energetic, but insufficiently restrained. It must be borne in mind that it has to be diluted with four times its volume of water.

Negatives on Flexible Films.—M. Morizet presented 300 negatives taken by him in Upper and Lower Egypt on flexible films. These negatives are very complete. Lantern slide reductions were projected on the screen, and I noticed particularly views of a square in Cairo, the rapids of the Nile, and the Place de Longsor.

The meeting was not large, a fact accounted for by the departure of many to the country and the seaside.

IMAGINING AND IMAGING.*

BY PHILIP H. NEWMAN.

THERE never was so much good painting as there is now; the present Royal Academy Exhibition is full of most admirable work; the *technique* gets higher and higher annually. But now go and ask the general public what they think of this Exhibition; the answer is, "The dullest we remember." The general public are not artists, but, as usual, they are very keen critics, and can generally tell when they see a good thing without the inspiration even of a newspaper. I walked through the rooms of the Academy the other day with a highly cultured girl—no painter, but knowing our National Gallery and some of the galleries of Europe, who could trace the influence of Veronese and Rubens in Makart, and Velasquez in Munckaksy, and could tell a Fortuny as well as she could tell a line of Shakespeare, or a bar of Beethoven.

"Well, my dear, how do you like the Exhibition?"

"Not at all; there is only one picture I would buy; I should like that."

It was a single figure, full of repose, and worthy of Greek art; the nature in it, like that art, had filtered through the passion of the painter. Here, at least, there was imagining as well as imaging.

Mr. Emerson has written other books besides the one I have been talking about, and published many photographs from original negatives. It would not be fair to him, having said so much, if we did not say something about these, and it is only fair to see how his wholesale repudiation of book-teaching in art, and his leaning entirely on nature, has helped him. In one of the books devoted to the Norfolk Broads, Mr. T. F. Goodall is a collaborator, and writes, in an article on landscape: "The roughest sketch, in which the ground and the objects against the sky are painted in a mass in right relation to it, is really more finished than the most laboured work wherein the essential truth is wanting." This may be granted at once, but then one looks to see it illustrated by the accompanying photographs. Unhappily for Mr. Emerson and Mr. Goodall, photography seldom gives objects against the sky in right relation to it; certainly, samples are sadly wanting in the book in question. This may be the fault of the copy, or processes of printing may have improved since. Let us pass on to another book, and look into the "Idylls of the Norfolk Broads"; plate 6, "Bathers." Here we have no question of printing, but of simple composition. The backs of two bathers rise out of the water side by side, one a little in advance of the other, however; the nearer one spreads his arms a little to lead up the angle of the bank and take away from the verticalness of the arrangement, the other bather keeps his arms down, one being partially hidden by his body. Now, all artists will admit that the human back is a beautiful object, delightful to draw and model, in its leading lines and subtle undulations, and Mr. Emerson missed a great opportunity here of showing himself both a photographer and an artist; anything more commonplace and less idyllic than the arrangement of these two backs it is difficult to conceive. I refrain from making fun; any one may do that where they cannot make sense; but one leaves the picture with a sort of suspicion that Mr. Emerson is making fun of us. We should like to ask him if the idyllism of the picture is supposed to lie in the backs, or in the background. I cannot determine; neither smudginess nor backs like these are idyllic to me. Plate 9, in the same collection, represents something going on with a hay waggon, which at first sight seems to be part of a tree; on the right-hand side of the picture a man is leading the horse towards us, and this emphasises the right angle made by the side of the waggon, and the ground cut clean against the sky; a little bunchy tree is near the horse and towards the horizon, while another man is near another small tree on the opposite side of the picture, and serves only to enforce the emphasis of the right angle already mentioned. I can only suppose that this arrangement is done in wilful defiance of any rules of composition whatever, and pass on to "Pictures,

* Continued from page 516.

in Field and Fen." "Ah!" you say, "how charming Mr. Emerson can be when he chooses." This "spring idyll," for instance, a girl peeling potatoes; note the turn of the girl's head in relation to the line of the shoulder, and its continuity in the branch of the tree: the very pail is ordered in its arrangement with the rest of the picture. But is this accident or design? It would be pleasant to give Mr. Emerson credit for this and several other pictures—"Ploughing" and the "Stickle-back Catcher" are excellent. But what are we to say when we find them in company with such wooden compositions as the "Dame's School" (which might have been so easily corrected, by the way), the atrocious "Winter's Morning" (look at the vaunted values here), and the hideous "Going to Market"? Well, there is nothing to be said but that if art is to be got by simply going to nature, Mr. Emerson does not show us enough of the way—at least, in the works I have referred to. Is there no sunshine ever in the fen country, that most of these photographs have such leaden skies? Or does our author belong to a school that enunciates the dogma that sunshine is unpaintable and brilliancy vulgar? If so, Fortuny, and some of the works of some of the greatest living painters, might teach him better. This last book I mention, "Pictures in Field and Fen," is prefaced, so to speak, with these lines from Browning:—

> "So British public, who may like me yet
> (Marry and Amen), learn one lesson hence
> Of many which whatever lives should teach:
> This lesson, that our human speech is naught,
> Our human testimony false, our fame
> And human estimation words and wind.
> Why take the artistic way to prove so much?
> Because it is the glory and the good of art,
> That art remains the one way possible
> Of speaking truths, to mouths like mine at least."

A more unfitting quotation to head such a book as this was never seen, save that it is capable of a double application, rich in its condemnation of the author. If Mr. Emerson has as much reverence for art as he pretends to for nature, we had been spared many of these so-called pictures, because many of them were not worth the taking. Many he would have re-arranged, and could have done so quite easily. One slight reference to the "Soldiers Bathing in the Arno" might have corrected those woeful backs; and many of the landscapists he has slighted would have saved him from the stumbles he has had elsewhere. I trust, for the sake of photographers, that his advice on technical matters is more reliable than his artistic guidance. As to his hints on art, I cordially agree with the man who called them "Tupperisms." His pictures, at least as printed in his folios, do not bear out his standard of excellence or teaching. Let us dismiss this disciple of nature as quickly now as he has affected to dismiss time-honoured names in art, and let him know and bear in mind that while in characterising a learned reverend, if oft enthusiastic criticism, as "splendidly false," his own has too often the latter quality, but never the former. I unhesitatingly say that he has written on art without adequate knowledge and reflection, as he has frequently imaged nature without refined taste or imagination.

There has been much discussion lately on the subject of beauty; it may be difficult to exactly define it, or how much of it is necessary in the constitution of a work of art. It is too wide a question to more than mention now. It may be worth saying, however, that beauty lies more in order and consistency than is often allowed, and works that do not possess these qualifications proportionately fail to charm us. Beauty, moreover, is an individual perception, more or less, but it is distinctly capable of wider appreciation, the more apparent is the consistency and order I allude to. Thus, in a picture or photograph of a group of figures there must be a principal figure or a principal group, and it is essential for our satisfaction that that principal figure should be principal in every respect—force of light and shade, mass, &c. If there is a story to be told, it gains immensely in directness by such means. These things are exceedingly difficult to talk about, but beauty in composition is so dependent upon them that they must not be passed over. I am the more sensible of this because of some recent terrible examples of photography that have come before me, where there were several women in white aprons; and some that were smaller in size and more in the background were as white as that which should have been principal. Perhaps I am rather urgent on this point of ordination and subordination. I fail, however, to see good composition without it; it is my *ism* or idiosyncrasy. One artist of our own time is accused of this shortcoming, and one is accused of that. One artist of the greatest poetical insight and refinement, a very Achilles equally in his retirement as when he is moved to put out his strength, is accused of soft, waxy texture. The public and the critics seem quite oblivious of the fact that his aim is not to imitate nature in his textures so much as to move us with his design. It would be heart-breaking to think of the future of art in this country were it not that one knows the tide of fadisms is at its flood, and while it rushes on, the poet painters who see art, and beauty, and consistency, are as firm as the rocks they rest upon, until the tide has turned, and when their voices will again be listened to. The young men who have any real art feeling in them will have made their studies from nature, and will have been as dissatisfied with them as were their great predecessors with theirs. It may be that the foundations laid will be the more solid from the long continuance of the realistic and naturalistic craze, so good coming out of evil; for certainty of draughtsmanship and knowledge of light and colour will be at the facile command of those who, ceasing to make unsatisfactory images, will develop their imagination and give us works of art. We will at least hope so.

But you ask, What has all this to do with the Photographic Convention of Great Britain? Much, everything, because it is to you that art looks in the present day to be in the van of this desirable movement; to you who, having many sins of omission and commission to answer for in the past, whereby you have in a great measure been responsible for this unstudied naturalism which is sapping the foundation of the finest taste; you, by your multiplying processes and waistcoat-pocket cameras, who have been tempted to photograph everything you have seen—good, bad, and indifferent. I am speaking plainly but generally (of course, there are grand exceptions). It is to you I say—artists, photographers, and photographic artists—in the cause of art I appeal; you have a great future before you if you will only exercise a dignified reserve that a dignified profession demands, and never photograph anything, under any circumstances, that shall not, when it is printed, be a joy because of its beauty.

I am certain that in the present all who have the real interests of art in England at heart will uphold me in this appeal, as I am equally persuaded that Rejlander and the greatest names in the past, and those who are yet in the future, will approve of your doing your utmost with these high aims in view. Pray believe me, I am not ignoring much, very much, good work that has been done, and I know is being done. I should like to mention names, but must not do so for fear of invidious comparison. If I have been unjust in anything I have said, it has not been with intention, and I beg forgivenesss. The book I have so often alluded to was put into my hands for the first time just as I was asked to write this paper, that I might have some knowledge of some of the things that had been said on the art side of photography. I was amazed when I had read the book at its audacity, and more amazed when I heard that its teachings were gaining ground. I was told that photographers, however, would be glad to be spoken to on the art question, notwithstanding. I have spoken to the best of my power and belief. If I have spoken loudly, I may be pardoned for art's sake at finding its temple shattered and its gods dispersed, that Mr. Whistler or Mr. Anybody else should occupy the site. Not a word against Mr. Whistler, who has shown himself often and often a great artist. All I contend for is, that "naturalism" is not the only nor the highest art in the land. Let us, indeed, be termed Philistines and rejoice in the honour thereby conferred on us; the rather keeping to our own gods than falling down and worshipping stocks, and stones, and nature unanimated by the divine gift the soul of man has the privilege of conjuring up and

investing it with. I would rather go back a hundred years and more; I say it seriously. It would be better for art, better, far better for us all, to go back to the sickly sentimentality and bathos of the last century, that culminated in the lachrymatory effusion of uncle Toby's recording angel, or, more practically, to the primary artistic principles of our great grandmothers' samplers, than reach the logical bourn of naturalism where imagination dies in imaging, and over whose portals might well be written, "Abandon hope all ye who enter here."

DEVELOPERS USED BY GERMAN PROFESSIONAL PHOTOGRAPHERS.*

BY JULIUS F. SACHSE.

ANSELM SCHMITZ, Königl. Hof. Photograph, Koln.—Developer—The sulpho-pyrogallol-developer. Advantages—The developer furnishes brilliant negatives of superior detail. Composition—(A) Water, 64; sulphite of soda, 16; citric acid, 1; pyrogallol, 1. (B) Water, 64; sulphite of soda, 8; carbonate of soda, 32. Developer—Equal parts A and B, diluted with 20 parts water. Equal results have been attained with other formulæ; the advantages which I claim are not the result of this formula in particular, but of pyrogallol in general. I have tested all other developers as they appeared, among others the much vaunted eikonogen, but soon came to the conviction that pyro is far superior. For short and instantaneous exposures, eikonogen in its various combinations has been persistently praised, as it was claimed that greater results and detail were to be obtained with the new agent than any other. I have, however, obtained results far greater with pyrogallol. Accelerator—None.

A. Stock, Hof Photograph, Guben.—Developer—Pyrogallol. Advantages—Very rapid development, complete in three minutes; at the same time, vigorous results. In a few minutes every grade of strength can be attained. Composition—(A) Pyrogallol, 15 g.; sulphite of soda, 30 g.; water, 500 g. (B) Pure soda, 100 g.; water, 1,000 g. For use, equal parts A and B, diluted with one-third water with several drops of bromide. For under-exposed plates, use with bromide or water.

It will be seen by the responses given that one-half of the whole number still adhere to the favourite German stand-by—ferrous oxalate—their main reasons given being the simplicity, uniformity of action, cheapness, cleanliness, and freedom from fog. Seven of the whole number have become converts to the new candidate for photographic favour—viz., eikonogen—on account of the quicker action, allowing of shorter exposure, together with finer grain and detail; the factor of price is also an item in its favour.

Three are equally enthusiastic in their praise of pyro, which we in this country can agree to. One is a convert to hydrochinone, while another promulgates the questionable formula of mixing hydrochinone and eikonogen. It will be noticed that ten photographers only approve of an occasional preliminary bath (accelerator).

The attention of both professionals and amateurs is called to the fact that the foregoing all relate to the department of studio portraiture only.

C. Baumann, Hofphotograph, Dortmund.—Developer—Eikonogen. Advantages—Cleanliness and clearness of plates, wealth of fine tones, combined with strong high-lights, when extra rapid plates are used. Composition—The usual formula: (A) Sulphite of soda, 200 g.; water, 3 litres; eikonogen (dissolved warm), 50 g. (B) Cryst. soda, 150 g.; water, 1 litre. For use, 3 parts A, 1 part B. In the fixing bath no sulphite of soda is used, as it is superfluous, and in my experience the plates are destroyed by leaving them in a bath of that kind any length of time. Accelerator—None.

J. H. Brasehoss, Cöln.—Developer—Eikonogen. Advantages—Saving thereby half of the exposure. Solution can be used repeatedly, is lower in price than all others, and is absolutely non-poisonous. Composition—(1) Eikonogen, 50 g.: sulphite of soda, 200 g.; water, 3,000 g. (2) Soda, 300 g.; water, 2,000 g. Accelerator—None.

Julius Dörstling, Hofphotogr., Eisenberg i. A.—Developer—Until within three months ferrous-oxalate, since then, with preference, eikonogen. Advantages—Shorter exposures, detail in shadows and high-lights, and transparency at the same time. Strong negatives, therefore more rapid printers; greater permanency. Composition—Dissolve 200 g. of sulphite of soda in 2½ litre of rain-water, then rub up 50 g. of eikonogen in a mortar, and pour into an earthen pot in which there is half a litre of hot water. After both are dissolved, pour the hot solution into the 2½ litres of soda; then shake up well. No. 2—Dissolve 150 g. of soda cryst. in one litre of water. Three parts No. 1, one part No. 2. Accelerator—None.

Otto Faltz, in Eberswalde.—Developer—Eikonogen. Advantages—Quick and active action. The picture develops brilliant and complete detail in the deepest shadows. The developer can be used repeatedly. Composition—Water, 600 g.; sulphite of soda, 100 g.; potash, C.P., 40 g.; eikonogen, 20 g. Dissolve and boil in a Florence flask: use when cold. Accelerator—None.

W. Gilles, Unna.—Developer—Eikonogen, since six months ago, with good results. Advantages—Detail in the shadows; much quicker printing negatives than oxalate; shorter exposure; shading of certain portions of the negative in printing lessened. Composition—(1) Distilled water, 1,500 g.; sulphite of soda, 100 g.; eikonogen, 25 g. (2) Distilled water, 1,000 g.; ordinary soda, 150 g. For use, three parts No. 1, one part No. 2. Both solutions keep; No. 1, made in December, was without change in February. Accelerator—None.

F. Hundt, suc. to Hülswidt-Münster i. W.—Developer—Eikonogen. Advantages—The enormous reducing power of the agent, with a finer silver grain than, in our experience, is attainable with any other developer. We use extra rapid plates exclusively, which, with pyro and oxalate, give a very coarse grain. With eikonogen, however, the grain is so fine as not to be perceptible. Shorter exposures than with any other developer; cleanliness. Composition—(1) Sulphite of soda, 200; water, 3,000; eikonogen, 50. (2) Carbonate of soda, 150; water, 1,000. For use, three parts 1 and one part 2, bromide 1-2 drop 1 : 10. When the high lights stand out strong, pour off the developer and finish with fresh (without bromide). In this manner we obtain exceedingly brilliant, harmonious negatives. Accelerator—None.

Specifications Published.

11,555. *July 19th*, 1889.—"Coating Photographic Plates." JOHN HENRY SMITH, Ph.D., Photographic Chemist, 9, Merkur Strasse Hottingen, Zurich, Switzerland.

My invention for improvements in apparatus for coating photographic dry plates and other plane surfaces with an emulsion or viscous liquid, has for its objects to deliver the liquid at a uniform rate, to vary the rate of delivery of the liquid according to the size of the surface to be coated or to the desired thickness of the coat, to distribute the liquid in a regular stream of the width of the surface to be coated, to construct the surface down which the liquid flows on to the surface to be coated, so that it readily adjusts itself to the different thicknesses of the articles whose surfaces are to be coated, and to provide means for traversing the surfaces to be coated at a regular speed and in a horizontal plane past the coating apparatus until the liquid has set, and for cooling the plates in order to set the coating liquid.

The liquid is delivered at a regular rate from a holder placed at a suitable height above an overflow trough by means of one or more bent tubes or syphons into the trough. The delivery orifices of the tubes are arranged in a horizontal plane immediately above the trough. The holder is made broad and shallow, and is raised to such a height that the differences in the level of the liquid in the holder do not materially affect the pressure, and consequently the regularity of the flow. Where greater accuracy is desired these differences in level are compensated for by making the delivery tubes partially or wholly of india-rubber, and altering the height of the holder; or preferably by employing a closed bottle provided with a delivery or syphon tube, and an air tube extending into the bottle to near its bottom, so that the liquid is deliverd under a constant head equal to the vertical distance between the lower end of the air tube and the exit orifice of the delivery tube.

The rate of delivery of the liquid is varied by means of a graduated tap in each of the delivery tubes, or by altering the height of the holder in relation to the exit orifices of the delivery tubes, or by adjusting the air tube of the closed bottle, or by a combination of these methods, or the ends of the delivery tubes are drawn out, and the quantity of liquid which each nozzle delivers per unit of time when the holder is fixed at the height indicated is marked upon a fixed vertical scale at convenient distances apart. The holder is raised and lowered by means of a rack and pinion, or other equivalent mechanical arrangement, and its height regulated according to the desired delivery of the liquid. The flow of liquid is stopped by means of a tap or clip applied to the delivery tube or tubes.

The delivery trough, by means of which the liquid is delivered in a uniform stream of the width of the surface to be coated, is provided with an overflow lip, and is divided by a partition extending nearly to the bottom into two divisions. The liquid flows from the holder into one division, and underneath the partition into the other or second division, where it assumes a perfectly level surface. The liquid is painted by means of a small brush over that portion of the lip which is immediately above the plate to be coated, and overflows only over that painted portion, and falls upon the plate in a uniform stream. The form of the trough can of course be varied, but in order to obtain a uniform distribution of liquid, the lip over and down which it flows must be formed of surfaces including obtuse angles only. Where the liquid overflows over a horizontal surface instead of over an edge a better overflow is obtained, and this form possesses the additional advantage that the trough can be very accurately adjusted and levelled. The partition of the overflow trough runs in grooves, and can be removed in order to clean the trough. The trough is fixed to the coating table and levelled by means of screws.

In order to adjust the surface down which the liquid flows to the different thicknesses of the articles whose surfaces are to be coated, the liquid is arranged to flow over a curved movable piece hinged to the trough at some distance back in the direction in which the surfaces move. The curved piece may rest directly upon the surfaces, or be separated therefrom by short wires, and is of any suitable shape containing only obtuse angles. It is so constructed that in its vertical motion it remains in easy contact with the front edge of the trough throughout its whole length, and is bent or curved backwards at the bottom. Its back portion is only slightly inclined to the horizontal in order that when a thicker plate succeeds a thinner one, the upward motion of the piece is very slow. Where large plates have to be coated it is with advantage made jointed at one or more points.

The surfaces to be coated are traversed past the coating apparatus, and the liquid afterward set by supporting them in a long trough upon drums or rollers floating on water or other liquid in the trough, and free to rise, and fall, and to rotate, but all motion in the direction of traverse of the plates is prevented. The drums or rollers are covered with cloth or felt to absorb the cold liquid in the trough, and apply it to the backs of the articles whose surfaces are being coated; or the articles may lie upon a traversing and stretched endless band, the underneath portion of which is either immersed in the cold liquid, or passes underneath the trough containing the liquid; and the upper portion of which is supported at a constant level, and kept constantly wet by means of the rotating drums or rollers already referred to. It will be evident that this arrangement will serve the double purpose of a levelling table and a cooling apparatus.

The inventor makes five claims.

7,747. *May 9th*, 1889.—"Rendering Cardboard Impervious to the Action of Photographic Chemicals." WILLIAM FRIESE GREENE, Photographer, of 92, Piccadilly, London.

This invention relates to a new or improved process and means for rendering cardboard and the like innocuous as regards any action on, and suitable as a basis to or upon which any suitable sensitising medium with which it may be desired to coat the same may be directly applied, and innocuous as regards any action on and impervious to the action of photographic developing chemicals or solutions, and suitable for photographic purposes, as hereinafter referred to.

The special object of the invention is so to prepare ordinary commercial cards, such as those whereon photographic prints as ordinarily produced on sensitised paper are at present mounted, as to enable the same to be sensitised with mediums suitable for the production of permanent photographic prints of the highest excellence and artistic value, so as to enable such prints to be produced directly on such cards, so as to avoid the tedious process of mounting and the subsequent process of rolling the prints, whereby the cost, time, and labour required for the production of such prints will be materially lessened.

Cardboard, and such cards and the like as ordinarily manufactured and without suitable preparation, such as that contemplated by the present improvements, is or are not suitable for the reception of such sensitising mediums, or for the production directly thereon of such prints, on account of the absorbency thereof, and of the chemicals or ingredients used in the manufacture thereof and contained therein, and of the liability of such chemicals to effect a deleterious action on such mediums if applied thereto directly, and on developing solutions and on prints if obtained thereon directly, causing such mediums to become unreliable and such prints to become discoloured and to fade and to be quickly destroyed so far as the artistic merit or value thereof is concerned.

To avoid all such disadvantages, and to obtain the aforesaid object and the important advantages attendant thereon, I cause, in accordance with the present improvements, the cards or the like to be subjected to a process or treatment which will be effective in rendering the same innocuous as regards any action on, and suitable as a basis to or upon which any suitable sensitising medium with which it may be desired to coat the same may be directly applied, and innocuous as regards any action on and impervious to the action of photographic developing solutions, so as to render the same suitable for the printing directly thereon of any desired photographic representation, either by exposure under any suitable negative to daylight, or artificial light, or in the camera or otherwise, in any ordinary manner of obtaining photographic prints or representations.

I attain such objects firstly, by destroying all organic matter at the surface of the card which would be deleterious to sensitising mediums or to developing solutions, and, as it were, parchmentising the surface of the card, and rendering it specially suitable for the subsequent operation hereinafter described, and this is effected by dipping the card into or otherwise subjecting it to the action of a mixture of about two measures of strong sulphuric acid and about one measure of water, subjecting it to such treatment for a time dependent upon the quality of the card, after which I thoroughly wash the card to free it from all acid, and dry it.

I then render the card or the like impervious to the action of developing solutions and otherwise suitable as aforesaid for photographic purposes, by brushing or otherwise coating the card by hand or by suitable mechanical means once or more times, according to the relative fineness of the texture of the surface of the card, and according as to whether a dull, or matt, or a glossy surface is required, with a mixture prepared by gradually pouring about three parts by weight of spirits of turpentine into about one part by weight of zinc oxide, stirring the mixture the whole while, and by gradually adding to such mixture about one part by weight of pale gold size, continuing the stirring all the while, and for a sufficient time subsequently to ensure homogenity in the product.

All such operations should be conducted in perfectly clean containers, preferably formed of glass, and with glass stirring rods, and they may be conducted at ordinary atmospheric temperatures.

After being thus coated the card is dried, and will be suitable as aforesaid as a basis to or upon which any suitable sensitising medium may be applied directly, and it will keep suitable for such use so long as it is kept free from the access of dust and under appropriate conditions, and after being sensitised it should also be kept until required for use under usual appropriate conditions; and may then be used and treated as if it were ordinary sensitised paper, but will possess the advantage of dispensing with the operations of mounting and rolling and of consequently effecting a material saving in the cost, time, and labour involved in the production of the required prints.

If the cardboard or the like is of a sufficiently good quality as to be innocuous as regards any action on sensitising mediums or developing solutions, then the aforesaid preliminary operation may be dispensed with, it then only being necessary to render the same impervious to the action of the developing chemicals and solutions as set forth.

If any particular colour of card be required, there may be added to the zinc oxide, before the admixture therewith of the spirits of turpentine, any suitable colouring matter innocuous as regards any action on sensitising mediums or developing solutions.

The inventor makes ten claims.

10,930. *July 6th*, 1889.—"Photographic Objectives." Dr. RUDOLPH KRUGENER, Bockenheim, Germany.

The objectives heretofore used in photography consist almost exclusively of two halves or parts, each of these halves or parts being made of two lenses (crown glass and flint glass) which are cemented together.

The progress made in the science of photography during the last few years has considerably increased the requirements with regard to optical apparatus, whilst by the momentous undertaking of the Glastechnische Laboratorium at Jena, the calculator or the designer of optical apparatus has had placed at his disposal kinds of glass enabling conditions to be fulfilled which were formerly altogether unknown.

In photographic objectives the aforesaid conditions bear more especially upon the evenness and lightness in focal depth of the picture on the plate, as regards the arrangements of the spherical surfaces.

The present invention is the result of a research which has been carried out with much labour spent in calculations, and in which many modifications have been taken into consideration.

In this research it has been found that the circumstances are most favourable if the front part or system is made of a single flint-glass lens of positive focal length, whilst the rear part of system, which may be composed in any desired manner, annuls the faults caused by the flint lens in front, and, together with the former part or system produces a picture which is planatically and chromatically correct.

As an example may serve an aplanatic device in which the rear part or system consists of a negative flint glass lens cemented to a positive crown glass lens.

The constants of the same for the following kinds of glass are :—

n D = 1·506 crown.
n D = 1·583 flint.
R 1. 43·25 + } front lens, flint glass.
R 2. 78·69 — } central thickness, 6·19 millimetres.
Longest distance between the front lens and rear lens = 8·26.
R 3. 76·89 } rear lens, flint glass.
R 4. 22·56 } central thickness, 1·34 millimetres.
R 5. 22·56 + } crown.
R 6. 50·74 + } central thickness, 19·38.

n designating the index of refraction of the glass.
D the spectroscopic line.
R R, &c., the several radii of the lenses.

The system has a free opening of 33 millimetres, and a focal length of about 200 millimetres.

In the present case + signifies convex and — concave.

The herein described improvements in photographic double objectives in which use is made of a simple flint-glass lens of positive focal length, for the purpose of concentrating in the plate picture a larger quantity of light with a considerable focal depth.

Correspondence.

SPHERICAL ABERRATION AND FOCUSSING.

Sir,—Your correspondent, Professor W. K. Burton, has fallen into an error in describing the position of best visual definition when positive spherical aberration is produced in a lens. I have before now pointed out that the position of best definition is not that of the least circle of aberration, but *beyond* it, and not nearer to the lens, as stated by Professor Burton. Referring to fig. 2, reproduced in your last issue, the best definition *will lie beyond* i_1, and not between I and i_1.

The image-forming rays are those near the axis, and are clustered very nearly in one point for an aperture up to *f*/15 in *ordinary* landscape lenses; beyond this aperture the rays, as they approach the edge of a non-aplanatic lens or system, become rapidly refracted towards the lens without concentration on the axis, and introduce round the more or less definite image the "halo" referred to. The greater the amount of spherical aberration in a lens, the greater is the measurement of the locus of partial definition; and if the locus of longitudinal aberration is much or little, common sense alone must show that that partial definition is a *fact* within the limits of that locus, and settle the "much-vexed question."

In ordinary landscape lenses it is *not* necessary to readjust the focus if the aperture be *opened up* and spherical aberration introduced; but in the portrait lens, by removing the flint element in the back combination slightly from the converging crown, the *focus alters*, and therefore it *is* necessary in this case to readjust the focus. Thomas R. Dallmeyer.

25, *Newman Street*, W., *8th July*, 1890.

WEIGHTS AND MEASURES AT THE PHOTOGRAPHIC CONVENTION.

Sir, —The last issue of your valuable paper was anxiously looked for in order to read the news from Chester, knowing that among other important questions submitted to the Convention, was the report of a Committee on Weights, Measures, and Formulæ.

The able Secretary of the Committee, with his usual lucidity, described in the preamble the superiority and convenience of the metric system, and to increase its value by strong contrast, explained also the negative beauty of the English system. From this portion of the report we learn (what was not generally known), that the apothecaries' ounce of 480 grains, after all, is not legal, and that the legal one of 437·5 grains is divided into 480 parts, which greatly increases the already inextricable chaos.

Arrived at this point of the report we exclaimed, "Bravo Convention! that is a good blow at that horrible system!" But alas! our joy was of short duration. The commission, according to the report, after informing us that "the metric system is *exclusively* used for scientific purpose," declares that photographers are not intelligent enough to understand it; they require long education before they will be able to use it.

Throwing this gratuitous insult at the heads of thousands who, with good reason, consider themselves fully competent to use the methods of their brothers occupied with other branches of science, the commission then commits an error in proposing a modification of the condemned system—and what a modification!

Till now we had to deal with a bad system, but with one only. The Convention imposes on us two—the metric and a modified one—in which ounces and grains differ from the old ones (they are divided into decimal parts), forgetting that "photographers do not possess the knowledge of decimals sufficient to enable a decimal system to be used easily and accurately."

Scarcely twelve months have elapsed since the Photographic Club passed a resolution that the metric system, *pure* and *simple*, should be adopted by photographers. The communication sent to other societies inviting them to co-operate in view of the general introduction of the system was sympathetically received.

Why put obstruction in the path of the useful progress of our art by introducing another bad system, and thereby increasing the chaos? No doubt we have arrived at the conclusion that the existing system of weights and measures is so bad that we cannot use it any longer. It is also known that the metric system is good, is already introduced all over the world, and even adopted by scientists in this country. Let us adopt it too. By doing this we shall secure uniformity in our expressions and simplicity in our calculations. Let us protest against the insinuation that we are too ignorant to understand decimals, and less intelligent than the mass of the population of Germany, and the inhabitants of the Balkan Peninsula, and other countries of the world, who, two months after the introduction of the metric system, became thoroughly conversant with it. L. Warnerke.

Silverhowe, Champion Hill, London, S.E.

NEW GELATINE FILMS.

Sir,—In your article on the "New Gelatine Films" you speak of "Obernetter's Films." This is, so far, correct, as the films are coated with the well-known Obernetter emulsion. The support, however—that is, the films proper—are entirely the make of Otto Perutz, of Munich, who also does the coating both of plates and films with the said emulsion.

J. R. Gotz.

19, *Buckingham Street, Strand, London, July 9th*, 1890.

Proceedings of Societies.

London and Provincial Photographic Association.

The annual meeting was held at Masons' Hall Tavern, Thursday, July 3rd, Mr G. W. Atkins in the chair. The chairman called upon the hon. sec. to present the annual report, which ran as follows:—

"In presenting the eighth annual report, your committee is pleased to be able to congratulate the members on the work done by the Association during the past year. The general meetings have been fairly well attended, and the discussions have been interesting and well supported. In accordance with a suggestion made in the last report, your committee recommended the giving of lecturettes and demonstrations monthly. These have been very successful, and the best thanks of the committee and members are due to those gentlemen who have given them. Among the most interesting subjects introduced on these special evenings should be mentioned:—"Glass Blowing as Used in our Chemical and Physical Laboratories," A. Haddon; "The Action of Ferricyanide of Potassium on Developed Plates," P. Everett; "Selecting Focal Distance with Detective Cameras," W. E. Debenham; "Etching on Glass," A. Haddon; and "The Ethics of Photography and Photographers," J. Traill Taylor." The lantern meetings have been well supported, and the competitions in connection with slide making, silver and platinum printing and developing have been productive of much pleasure and beneficial discussion. Monthly out-door meetings have been again recently introduced, and bid fair to be very popular with those members who have Saturday afternoons at liberty. There have been a few resignations from various causes, and your committee regrets to have to record the death of Mr. J. T. Collins, who had been a member since 1884, and was for some time a member of the committee. In thanking all those who have in any way helped the success of the meetings of the Association during the past year, your committee would specially urge the desirability of increasing the number of members. The amount of subscription is very small (only 5s. per annum), and it is only by keeping up the number of members that the Association can be made to pay expenses. Finally, the financial condition of the Association (as will be seen on presentation of the balance sheet) is thoroughly satisfactory. All accounts and liabilities have been paid, and there is a balance in hand."

The balance sheet was then read, and, with the report, adopted.

The election of officers for the ensuing year was then proceeded with. The result of the ballot was as follows:—

Trustees—Messrs. J. Traill Taylor and Mr. J. B. B. Wel-

lington ; *Curator*—Mr. A. Haddon ; *Committee*—Messrs. H. D. Atkinson, F. A. Bridge, J. J. Briginshaw ; F. P. Cembrano, E. Clifton, W. E. Debenham, T. E. Freshwater, F. S. Pask ; *Hon. Sec. and Treasurer*—Mr. R. P. Drage.

Mr. P. EVERETT proposed, "That a special vote of thanks be given to the retiring hon. sec. and treasurer, Mr. F. A. Bridge, for the efficient way in which he had carried out his duties." This was seconded by Mr. A. Cowan, and carried by acclamation.

Mr. F. A. BRIDGE briefly responded, thanking the members for their good feeling, and regretted that the limited time at his disposal had necessitated his resigning the secretaryship.

A vote of thanks to the other officers was proposed by Mr. W. H. Harrison, seconded by Mr. A. Cowan, and carried unanimously. Mr. W. E. Debenham responded.

The Saturday outing was fixed for Wanstead Park, July 12th. Trains from Liverpool Street to Ilford at 2·17.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

A SPECIAL meeting was held at the Masonic Hall on the evening of July 8th, Mr. B. J. TAYLOR in the chair, when Mr. SMITH, the representative of the Eastman Company, gave a lecture and demonstration on their latest Kodak hand-camera, and their new films, after which he developed some film negatives exposed during the day at Chesterfield, which all came out splendidly.

The SECRETARY announced an invitation from the Rotherham Society to join their excursion to Haddon Hall on the 17th inst.

AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE annual meeting of the council of this society was held on Wednesday, July 2nd, at 58, Pall Mall, the Right Hon. the Lord DE ROS in the chair. H.R.H. the Duke of Cambridge was elected a vice-president, and Mr A. Newton Melhuish was, on the proposition of Mr. Glaisher, appointed assistant-secretary.

Mr. ARTHUR JAMES MELHUISH, the hon. secretary, then laid before the council the pictures for the current year, which had been arranged and classified by Mr. Glaisher. After a careful examination, they were pronounced by the council to be far in advance of any previously received. They were arranged in four classes. The first class comprised 128 pictures. The following prizes were awarded :—To R. O. Milne, the first prize, a large silver goblet ; to F. S. Schwabe, a silver goblet ; to W. Vanner, an oil painting in frame by McEvoy ; to R. Murray, a handsome portrait album with silver plate ; a handsome portrait album to F. Griffith, W. S. Hobson, and F. Wrigley ; to the Vicomte de Condeica, a large silver medal ; to Dr. Drew, W. Gaddum, Miss J. Wilson, Miss Mahon, J. C. Cohen, Rev. G. J. Perrain, F. G. Smart, General Kaye, and R. Leventhorpe, a medal each ; to H. O. Hutchinson, a picture in frame ; to M. De Dêchy, a portrait album.

A vote of thanks was given to Mr. Glaisher for the time and attention he had bestowed on the arrangement and classification of the pictures.

THE SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting was held at the Masonic Hall on Tuesday evening, July 1st, Mr. B. J. TAYLOR in the chair.

After the routine business of the meeting, prints were shown by the president, secretary, and Mr. Crowder of views taken at the recent excursion to Bolton Abbey.

Mr. E. BECK then read a humorous paper on "Bolton," written by one of the members.

It was arranged that the Society should purchase three American stereoscopes for use at the meetings, as many of the members now take stereoscopic views ; and arrangements were made for a half-day excursion to Ashopton and Derwent Hall on July 19th.

THE HOLBORN CAMERA CLUB.

THE usual weekly meeting was held at the headquarters of the Club, 100, High Holborn, on July 4th, when a lecture on "Developers and Development" was delivered by Mr. A. Jones, and a discussion followed, which was joined in by Messrs. Smith, Bayston, and Dear.

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and Communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

W. H. M. (Stoke-on-Trent.)—*Photo-Etching Process.* The bitumen process is more easily worked on zinc plates than upon copper, and the etching with ferric chloride solution does not then present so much difficulty, half-tones being more readily obtained.

CASTILE.—*Astronomical Photography.* Eclipse phenomena, spots on the sun, the phases of the moon, the occultation of planets with their satellites, may be enumerated as some of the more important applications of photography. To these may be added the splendid results of Mr. Isaac Roberts in mapping the starry heavens, and representation of the nebulæ. Colour photography seems as far off as ever, but even if realised, it remains to be seen how this will help the main problems of astronomical science.

W. M. (Mainz).—Received, and answered by post.

E. G. S.—*Selection of Lenses.* The rapid rectilinear ought to do most of your work. Try the front lens of your portrait combination, reversed and suitably stopped down, before procuring another landscape lens.

IN TROUBLE.—*Ancient Lights.* You are not the only sufferer. This is often a very serious question for the professional photographer, and you should at once consult your solicitor. If we rightly understand you, there was a chimney stack before, but it has recently been raised in height, so as to obscure much of your available light. Did you make a representation whilst the work was in progress ?

J. P.—*Wooden Washing Trays.* Lance wood, sycamore, and alder are said to be very close-grained woods, but this quality is not all-important provided they be well coated with shellac varnish, or basted with melted paraffin. For the glass bottom, mixed red and white lead makes a better joint than ordinary glaziers' putty.

B. J. L.—*Actinometer.* We have referred to the patent of a year ago, but fail to see any element of novelty. It is based on the assumption that ordinary silver sensitised papers are always of uniform rapidity, which is questionable.

VEILED.—*Ferrous Oxalate Development.* The whitish deposit you complain of may be only a thin layer of oxalate of lime, in which case a short immersion in very dilute hydrochloric acid ought to remove it.

S. W.—*Perished Rubber.* We are not aware of any use to which you can put it. The best plan would be to offer it cheap to some india-rubber manufacturer.

F. I. C.—*Weights and Measures.* The case is well put in the Convention Report (see page 523 of last week). The nine recommendations ought to meet with universal acceptance, and it is immaterial whether French or English measures be adopted, so long as the decimal system is adhered to.

M. G. (Preston).—*Sulphate of Silver.* Your proposal to add free sulphuric acid to the silver sensitising bath is open to the objection that the comparatively insoluble sulphate of silver would be formed, and this is not affected by light. The employment of citric or acetic acid would certainly be preferable.

N. READ.—*Isochromatic Patents, &c.* The specifications are numbered A.D. 1883, No. 101 ; A.D. 1886, Nos. 7,963 and 15,532. Rhodamine is procurable at the Atlas Dye Works, Hackney Wick, N.E. Its use is not covered by patent.

J. W. (Leeds).—Wishes to know the formula for developing Seed plates (American). Can any of our correspondents oblige us with the information ?

J. A. C.—*Sensitometer.* Mr. A. Watkins has recently described a new exposure meter depending upon the use of a bromide paper sensitised with nitrite of soda. This was shown at the Hereford Society, and likewise at the meeting of the Camera Club on May 22nd last.

THE PHOTOGRAPHIC NEWS.

VOL. XXXIV. No. 1663.—*July* 18, 1890.

CONTENTS.

THE METRIC SYSTEM IN PHOTOGRAPHY.

WHILE two such champions as Mr. Warnerke and Mr. Bothamley are in tournament in our correspondence columns about the introduction of the metric system of weights and measures among English photographers, far be it from us to interfere while the case is *sub judice* before the court of public opinion; but some use may be served by introducing a new element into the case which may tend to accentuate or to calm the strife. Washington Irving told a story, setting forth how, in an early American hall of legislation, a hole was found in the wall of the Parliament House, admitting the winds of heaven, and making certain law-givers more stiff-necked than they were before. Week after week was passed in discussing the question to what department of the executive staff of the government fell the lot of repairing the hole in the wall, until one fine morning a member, out of his private purse, gave a bricklayer a dollar or other sum to block up the hole, and when the members assembled the following evening to resume the heated debate the bone of contention was found to have disappeared.

By analagous line of action, we venture to offer a possible practical explanation of a chief reason why British photographers have been slow to adopt the metric system, namely, that being convinced by the utterances of the Convention and of other photographic bodies that they ought to take the system up, they found in looking through most photographic dealers' catalogues, that the said weights and measures were not on sale by the firms from which they ordered their ordinary photographic goods, except, perhaps, in the instance of a small minority; moreover, upon calling upon the said dealers, it may have been found that they had no more of such weights and measures in their stocks than they had in their catalogues. The idea, in short, is, that the unfamiliar weights and measures are less readily obtainable than might be the case, and that many photographers do not take the trouble to get them from special sources. This simple explanation may reveal what has more to do with the matter than the alleged influences mentioned in the Convention report; if so, dealers have much influence in the matter.

All over France, the metric weights, from a gramme upwards, to such a height as photographers are likely to require when making up small quantities of developer, are sold for ordinary trade purposes, sticking something like cribbage pegs into a little bit of wood, and are easier to handle than the flat, small weights in ordinary use here.

The metric system, which has spread all over civilized Europe, and into the scientific section of English society, had its origin in the French Revolution, which the recent Exhibition in Paris was established to celebrate. The ambitious French philosophers then discarded arbitrary standards, and on first principles laid down standards for the whole world, taking a portion of the meridian of the earth as their unit of measurement. The ten-millionth part of a quarter of the earth's meridian is the unit from which all the other measurements are made, and this unit is called a metre; it is 39·371 inches, or a little more than our yard; one-hundredth of the metre is a centimetre. A cubic centimetre of distilled water at its maximum density—39·5° F.—is the unit of weights, and called a gramme. This gramme in English weight is about 15½ grains, and it is just as easy to mix a developer by so many grammes of each ingredient as it is to mix a developer by so many scruples of each ingredient—an intellectual feat which, in our humble opinion, the English photographer is capable of achieving, especially when aided by weights which he can handle more readily than those which he had previously used.

Yesterday afternoon, after the preceding lines were written, we opportunely received a new catalogue from "The Blackfriars Photographic and Sensitising Co." in which are quoted "Decimal weights for photographic use, as proposed by the various societies," but in the index we can find nothing about measuring-glasses on the same system.

ABOUT WEATHER FORECASTS.

THE state of the weather is of so much importance to those who depend upon light as the first necessary for their daily work, that the question whether or not our Meteorological Office is able to give us reliable advice as to what the morrow may bring forth in the way of sunshine or rain is to them a very serious one. For some years past weather forecasts have formed a notable feature of our daily newspapers, and in the *Times* and some of the other papers we have placed before us, in addition to the forecasts, a small map or chart of the British Islands and the countries contiguous thereto, marked with certain curved dotted lines, with arrows pointing in different directions, and with other hieroglyphics to which certain meanings are attached. The curved lines are "isobars," or lines of equal barometrical pressure, and the figure at the termination of each gives its value. The arrows show the direction of the wind in the particular locality where they fly, and the number of barbs upon the messenger denotes the strength of the breeze. In addition to this information we are also given the temperature at various stations all over the area covered by the chart, and a knowledge of the state of the sea, that is, whether it be rough, smooth, or in a state of calm. It is from a study of this chart, coupled with a knowledge of the actual state of the weather at various stations on a given day, that the Meteorological Office is enabled to indicate the kind of weather which may be reasonably looked for during the next twenty-four hours.

The isobars of the chart represent the most important feature of it so far as weather forecasting is concerned, for all such predictions are founded upon barometrical readings. This will at first seem difficult to believe, for we have all had experience of household barometers, and know full well that often when it points to "set fair," the weather outside is rainy, and *vice versâ*. Hope never yet told such flattering tales as these barometers do with regard to fair weather when all is foul. But we must not be too hasty in blaming a valuable instrument, when we should rather blame the maker for attaching to it words which are altogether useless and misleading. In one sense the barometer may be said to have come before its time, for its value could never be fully appreciated before it was possible, as it is now, to compare its readings at a given moment over a large area. This is done daily by means of the electric telegraph, and on the faith of the messages so received by the Meteorological Office, the charts and forecasts are prepared.

In order to give a general outline of the manner in which this is accomplished, it will be necessary to point out that the curved lines, or isobars, represent parts of two great barometrical systems, and that one is known as a "cyclone," and the other as an "anti-cyclone." The first may be regarded as indicative of bad weather, for it is usually accompanied by rain or snow, according to season, and by leaden skies and gusty wind. Its centre is marked by an area of low pressure, and the rotatory movement of the winds round about it are in a direction contrary to the hands of a watch. The anti-cyclone is the reverse of all these things. Light breezes circulate round a high pressure centre, and we have those bright, balmy days so valued by good people in general, and photographers in particular. It is the relation which exists between these two systems, which travel slowly or quickly over the face of our part of the globe, which enables the weather forecasts to be tabulated. It is true that they are very often wrong, but experience shows that, in the aggregate, they are correct to the extent of about 66 per cent.; or, to put it in other words, two forecasts out of three are borne out by the weather which afterwards comes to us. There are many difficulties in the way of making reliable forecasts, and the chief one is due to our insular position. Most of the cyclones which bring us such bad weather travel across our country from west to east, and therefore find their origin in the Atlantic ocean. How they are formed no one can say; all we know is that they are due, like all other atmospheric phenomena, to solar radiation. If it were possible to dot signal stations at distances of a few hundred miles all over the great western ocean, and to place them all in electrical communication with London, the forecasts would become far more reliable than they are now, and the idea of establishing at least one such station in mid-ocean has more than once been ventilated. The difficulties in the way of such an enterprise may, however, be looked upon as insuperable.

Some months ago a correspondent of the *Times* wrote a very amusing letter to that journal on the subject before us, and while he admitted that the "clerk of the weather"—*i.e.*, the Meteorological Office—was correct in his forecastings to the extent which we have already stated, he more than hinted that it was all guess work, and that the money which it cost could be more profitably applied. He based his strictures on certain experiments which he had made, which were certainly ingenious, but hardly scientific. In the first case he pasted each published forecast for one summer month on a separate piece of card, placed them all in a bag, shook them up, and on each day of the following month he took out a card and compared it with the state of the weather which prevailed at the time. He says that, so far as results went, it was a neck and neck race with the clerk of the weather, but the latter won by a short length. By which he meant that by this "lucky bag" system his forecasts were correct in almost as many instances as those published by authority. In another case he tried the system of forecasting for the morrow by adopting the weather record for the previous day at sunset, and this plan he also found to be moderately correct. Upon these data he founds his belief that the present system of weather prediction is as amusing as a game of pitch and toss by reason of its uncertainty.

We do not agree with this writer. The official observations are taken with great care, and are founded upon a scientific basis, and although it is common for

some persons to laugh at anything which they cannot readily understand, particularly if its imperfections are manifest, the thoughtful will feel glad that some steps have been taken towards the solution of a very difficult problem. Because the predictions are wrong once out of three, it does not follow that they always will be so. A child crawls with difficulty before it can walk upright, yet no one is so foolish as to scold it for incapacity.

READY-SENSITISED PAPER WORKS.

A New Hygrometer.

Mr. Otto Scholzig having kindly sent us an invitation to inspect his works at Stockwell Green, London, now established six years, and wherein he prepares ready-sensitised papers for the market, the following particulars may be of interest. There are four sensitising rooms on the premises, each containing thirteen large baths, on which girls float the sheets; each sheet, when taken off its bath, is put between blotting-papers, or rather blotting-boards—for they are exceedingly thick—then "mangled" through the wall into the adjoining drying room; the object of the rolling is to remove all superfluous liquid. The blotters are used over and over again, to the extent of thirty or forty times; they are then burnt, and the ashes containing the waste silver are saved for reduction. There is a reducing furnace on the premises, and the silver thus recovered is sold to refiners, as it is not remunerative to make one's own nitrate salt of that metal. The metal thus obtained is, on an average, 17½ dwts. per ounce purer than standard silver, or but ½ dwt. per ounce less than pure silver. The crucibles are of such capacity as to produce a lump of about 16 lbs. weight of metal. Mr. Scholzig says that he cannot account for it, but it is a fact that the chloride of sodium forming most of the soluble residue in the reducing pots is better than ordinary table salt for precipitating the silver from old baths; it throws the chloride down more quickly, and leaves the liquid in brighter condition.

The drying room is at a relative humidity of less than 55 per cent., and this is regulated by varying the temperature and ventilation of the room. Girls hang the sheets over wooden rods to dry; after the drying each sheet is brushed with a pad of green baize to remove any fluff, and the sheets are afterwards packed ready for sale.

As Mr. Scholzig naturally will not furnish the formula of the sensitising solution he employs, we turn to the next leading feature in the works of interest to the public, namely, a new hygrometer.

An important point in drying ready-sensitised paper is that it shall not be dried too much, which would give it a horny character; hence the warm drying room has to be kept at a particular degree of humidity. This end is attained by means of a new hygrometer invented by Dr. C. Koppe, made by Usteri-Reinacher, of Zurich, and in use by order of the Government at certain Swiss meteorological observatories. Mr. Scholzig prefers it to the wet and dry bulb instrument, for it indicates exactly what percentage of aqueous vapour is present in the air. In ceramic photography by the dusting process, a good hygrometer is useful for the obtaining of uniform results, and the instrument is of value in other departments of photography, so a description of the new one may be of interest. It consists of a frame to which one end of a human hair, carefully freed from grease, is fixed; the other end of the hair is wound round one groove of a pulley wheel with two grooves. Round the second groove a filament of silk is wound in a reverse direction to that of the hair, and at the lower end of the hanging silk filament a little weight is attached, so that the hair is kept constantly under tension. An index needle attached to the wheel in front of a scale of 90°, divided into 100 parts, shows the amount of any elongation or contraction of the hair. When the hair grows drier the needle turns to the left, and when the hair grows more damp the needle turns to the right. When the surrounding air is completely saturated with water the needle points to 100 on the scale.

To use the instrument, a little sliding frame covered with muslin is soaked in water, then put in position at the rear of the little case, the front of which is then closed by a sheet of glass. In a short time the air in the case becomes saturated with water, and the needle travels nearly to 100; then by turning a key it is regulated by being brought exactly to 100. The instrument should be tapped a little every now and then when regulating it, in order to overcome any inertia.

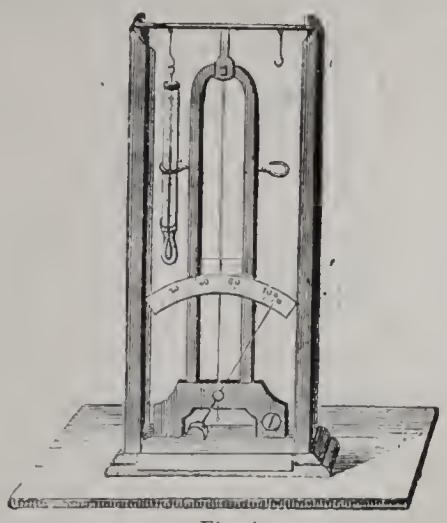

Fig. 1.

A metal back behind the muslin frame prevents the escape of moisture. When the air in the case is saturated with water, the metal back, the muslin, and the glass are removed; the hair then begins to dry so far as the air in the room will permit it to do so; the index needle turns as the hair grows drier, and when the needle comes to rest it indicates the relative humidity of the apartment or locality in which the hygrometer is placed.

If drops of water have formed at the bottom of the hygrometer, they should be wiped off before taking the reading. In order that the hair may sustain no damage when subjected to transport, its tension is taken

off, the needle is guided to the left extremity of the frame, and there fixed by means of a little hook. The small weight is then pushed under a spring which holds it tight against the middle of the frame.

By the aid of the diagram, fig. 2, it is easy to ascer-

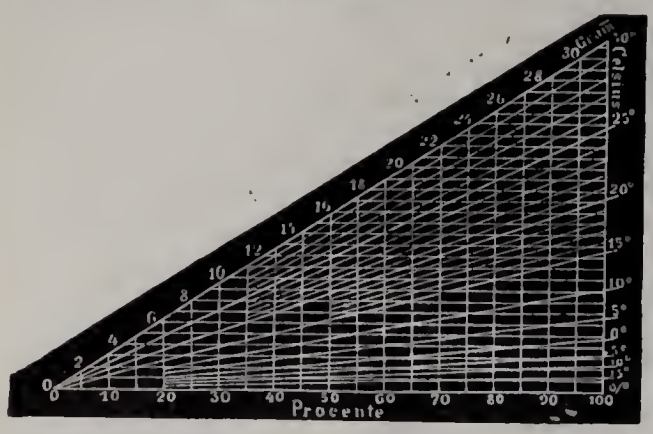

Fig. 2.

tain without calculation the absolute humidity and the condensing point of the aqueous vapour, by observing at the same time the temperature of the air. For instance:—

Indication of the hygrometer ...	... 65 per cent.
Thermometer	... 10° Cent.

The observer then follows the horizontal line upon the diagram till he reaches the point where the two lines 65 and 10 cross each other, and finds at the left side six grammes marked; this means that a cubic metre of the air under observation contains six grammes of vapour of water. Upon following the same line to the right, the condensing point 3° is found; that is to say, the air may be cooled from 10° to 3°, or seven degrees, before the moisture in it begins to condense. For example:—

Hygrometer indication ...	... 65 per cent.
Thermometer	... 25° Centigrade
Absolute humidity	... 15·3 grammes
Condensing point	... 18° Centigrade

Whilst in the first case the air only contained six grammes of vapour with relatively equal humidity, in the second case this quantity of vapour of water increased to fifteen grammes, because the temperature was higher. The higher the temperature of the air, the greater is its power of absorbing vapour of water.

AN Australian photographer has recently made up an album containing 700 portraits of the pioneer colonists of Victoria, reproduced from original photographs or paintings by photo-mechanical means.

PHOTOGRAPHIC TERMINOLOGY IN AMERICA.—A new science brings with it new words, and if one language is too weak to supply them they must be taken from another language. Photographers who use a preliminary bath before developing a plate are adopting the word "Vorbad," from the German "vor," meaning "before," and "bad," meaning "bath." The photographic journals were all prompt in accepting the word, never for a moment considering that a noun like "prelavation," a Latin derivative, would answer just as well or better. The word which we suggest means a preliminary bath, being derived from the Latin *præ lavare*, to wash or bathe beforehand, or rather from *præ*, beforehand, and *lavatio*, a bath or washing.—*Photographic Globe.*

THE PROGRESS OF THE PHOTO-MECHANICAL PRINTING PROCESSES.

BY HERMANN E. GUNTHER.

No. III.

AFTER the asphalt powder has been gathered on the white paper, it is moistened, and, on a glass plate, rubbed down finely by the aid of a rubber, which manipulation is repeated several times, the powder being dried each time.

The finely-powdered asphalt is now placed in the dusting-box, which may be made either revolving on an axis, or stationary, and provided with a blast arrangement, but which, at all events, should have a sufficiently powerful moving force, so that the particles of the dust are thrown up to the cover of the box. R. Maschek uses a box about seven feet high and three and a-half feet wide, which, as he asserts, suffices for the coarse powder as well as for the fine one, for the reason that by the time which lapses between the whirling up of the dust and the introduction of the plate into the box, the size of the falling asphalt particles may be ascertained. Strips of sheet rubber should be nailed round the inside of the door of the box, so that it will shut up nearly hermetically.

After the asphalt has been placed in the box, the door is closed tightly, and the powder shaken up violently. After a lapse of a minute or two, if it be supposed that those asphalt particles are falling which are intended to be used in order to produce the required degree of granulation, the door is opened, and the previously thoroughly cleaned plate is placed therein, poised on the points of a few double-pointed nails driven into the base of the box, all being equal in height. The plate remains in the box until, if removed and held obliquely against the light, it shows a velvet-like appearance. In looking at it, only a shade, but better still, no plain copper at all, should be observed. Until this state is attained, about five to seven minutes will be required. The longer the plate remains in the box, the greater will be the quantity of powder deposited, and the finer will be the resulting granulation. The plate should be removed very carefully from the box to prevent any dislocation of the particles.

To melt the dusted-on asphalt powder, the plate is held with the reverse side in contact with the flame of a spirit lamp until the brown velvet-like tint of the asphalt has changed to a beautiful bluish-violet tone. It is then laid aside to cool down, and then placed for about one minute in a bath of vinegar, common salt, and water, until it becomes copper-coloured. After the plate has been rinsed in this bath it is ready for receiving the negative pigment impression, which can at once be squeezed on and developed with warm water in the ordinary way. As I have mentioned in the previous chapter, the etching of the copper plate is done with solutions of chloride of iron of different concentration. Previously, however, the edges and the reverse side of the plate must be coated with asphalt varnish, to prevent their being attacked by the etching solution.

The four dishes containing the solutions of different consistencies are now placed in a row, and at last a fifth one is added containing clear water. Dish No. 1 contains the strongest; dish No. 4 the weakest solution. Not too large a quantity of the etching fluid should be poured into the dishes, so that the picture is still distinctly visible through the solution. A plate-lifter is necessary to manipulate the copper plate easily in the solutions without handling it with the fingers. Kiewning uses a curved

rack of copper wire, which is also coated with asphalt varnish to render it indifferent to the etching fluid, and which is provided with two handles. Masehek recommends an arrangement consisting of six single bars, which can be screwed separately on either side of the plate. At the upper end of each bar there is a perforated tail, through which tie-rods can be passed and fixed by screws. This arrangement has the advantage that, in the case of large plates, these can be transferred from one bath into another one by two persons at the same time.

In the first etching bath the parts of the plate are attacked which are covered with the weakest film of gelatine, representing the deepest shadows; the second and third bath successively produce the gradations of the tones, while the fourth bath etches the light tones. The plate is then transferred to the water bath, and it is important that this be done at the very moment it is observed that the solution begins to attack the high lights. If this moment be allowed to pass, the parts of the plate which should be represented by plain copper, and which in printing should be entirely free from colour, will be slightly etched, consequently will retain the colour in the printing press. It is well to transfer a small quantity of the etching fluid from the fourth solution into the water bath together with the plate, so that a very dilute chloride of iron solution is produced, which completes the etching process.

When thoroughly washed the plate is taken out of the water bath; the gelatine is removed by means of a piece of soft linen, and the asphalt dust by aid of benzole. Also the cuprous chloride which has been formed during the etching process must be removed from the plate, and this is done by means of a mixture of spirit and ammonia to which some finely powdered chalk has been added.

Printing plates obtained by the above process will generally require retouching, though it should be applied only to a slight degree. It is achieved similarly to mezzotint engraving, the high lights being put in with a burnisher, and the shadows, if not deep enough, or if the grain has disappeared through the prolonged action of the etching fluid, are passed over with a "roulette," in order to give a bite for the printing colour.

If a large number of prints is to be taken from an etched copper plate, it is necessary to steel it previously. This is done by attaching it to the negative pole of an iron bath, and providing it, by the action of the galvanic current, with a fine coating of iron, which protects the plate against wear and tear. After the plate has been taken out of the galvanic bath, it is quickly washed with water, then with a solution of soda, when it is carefully wiped by means of a linen cloth, and rubbed in with some oil to prevent oxidation.

The Photographic Society of Great Britain.—Monthly technical meeting Tuesday, July 22nd, at 5A, Pall Mall East, at 8 p.m.

Conjugal Likeness.—It is a theory like another that by moral pressure you can change the shape of your nose; and a Genevese society (photographic) has succeeded in showing that the pressure aforesaid need be neither conscious nor direct. It has secured the likenesses of eight-and-seventy couples old in matrimony; has contrasted the same with the likenesses of eight-and-seventy pairs of brothers and sisters; and has come to the conclusion that the resemblance induced by the habit of association is stronger than the resemblance which is an effect of consanguinity. It is a pleasant result, and the developments of which it would seem to be susceptible are pleasant in likewise.—*The Scots Observer.*

EXPRESSION.

BY J. MEW.

It has been said that to write in defence of the claims of photography to be an art, is to admit it not to be an art. If this position were true, many writers are ill-sped, for it is difficult to meet with a single volume of any book dealing with photography without finding several pages written, well or ill, with the avowed intention of affirming and supporting this exact position. But it does not seem to be true that to defend the claims of photography to be an art is to to prove that it is not one. Could it, for example, be said truly that to defend the claims of the heliocentric system of our little world to correctness, is to demonstrate them to be incorrect? or that to maintain the sacred truths of our holy religion is to declare them to be false? Such a notion would, indeed, sadly distort and pervert the views hitherto held by the vulgar of such men as Paley and Butler, who have ever been regarded by the public at large as amongst the most doughty defenders of Christianity. These ecclesiastical champions, these Amadises of orthodoxy, would, by a parity of reasoning to that adduced to show photography to be not an art, be changed into fellow-labourers with Tom Paine and Denis Diderot, with Ingersoll and Voltaire.

Because the claim of photography to be an art has been disputed, does it follow that it must, of necessity, be disallowed? It is said that painting is an art because it has never laid claim to be one. But in the kind of painting known as pre-Raphaelite, which is, perhaps the nearest approach to photography, there seems to be about as much reason to question the existence of art as in the ordinary photograph. The painter may place his art in the region of imagination, a region to which the photographer has, as a photographer, but a straight and narrow path of access. The broad and wide field of truth in which the latter chiefly labours admits, on the contrary, somewhat unwillingly any approach to art or artifice. But painter and photographer may both be artists in the matter of expression.

From the first meaning of expression—squeezing out by pressure, as, for instance, the juice of a fruit—are derived the other two meanings, one of the utterance by the tongue, or the representation by words of mental emotion; the other, of the change which takes place in the face under the influence of feeling. The term expression has been also analogically applied to the grouping of figures and the character of a landscape, but with these the present article has nothing to do.

Expression, as used in the present paper, regards only the specific conformation of the human features. To take a homely and well-worn instance of photographic expression, it is only necessary to open an old photograph album. There confronting you, in the great majority of pictures, is the semblance of weary resignation and enforced repose commonly attributed to the use of that modern instrument of torture called the head-rest. This sad expression seems to be squeezed out of the head as the juice out of an orange, but it is not nearly so nice. It is the outcome of an agony, a mental and capital distress perhaps too great for words. It is not into this expression that art enters. Nor does it enter into what is known as physiognomy. Expression and physiognomy are, moreover, distinct; the latter is permanent, the former transient. Expression varies in the same person according to circumstances in different times. Physiognomy in the same person is always

the same. They probably are, in their origin, identical, expressing the physiological relations between the hidden movements of the brain and the many manifestations of the muscles of the face; but in physiognomy this relation is frozen and stereotyped, while it is momentary and fugitive in expression. Perhaps the nearest approach to art in photography is the transference to the paper of such of the fleeting expressions as are most characteristic of the person whose portrait is to be taken. It is not infrequently the case—a case partaking of the nature of a riddle—that in a picture otherwise good, well worked, and exact in most technical particulars, a something is, by the spectator, discovered to be absent which may be found in another portrait upon which not nearly so much labour has been expended—a portrait, too, which is decidedly inferior in general accuracy and scientific detail.

The key to this riddle consists in the fact that, in the latter picture, the operator has managed to seize a characteristic expression which, in the former, has been absent or unnoticed. It is this peculiar expression which really constitutes the likeness; it is the representation of truth; it does not depend on the camera, like the annihilation of freckles, or on position, like the shortening of a nose; it requires little aid from the retoucher, and it can scarcely be comprised in the vast catalogue of "dodges." The photographic portrait, possessing this beauty of truth, is a joy for ever.

Some famous painter—perhaps Stodhart—said that there was nothing so difficult as to paint people doing nothing. By this sentence he did not perhaps mean to imply that those who sit for their portraits should be employed in some manual exercise, but rather that their faces should not be idle. In other words, he found it not easy to obtain a good portrait without expression. If the ladies who come to our photographers expended less artistic pains on their furbelows, and allowed nature more room in their faces, disappointments and heart-rendings in the matter of their portraits would be less frequently the result. It is, however, perhaps as idle to hope for the extinction of what has been not inaptly designated the mongrel smile as of the many coloured clothing. The smile will probably always be with us, unless, indeed, it be banished by the application of the head-rest, when it commonly leaves in its place something worse, that expression of resigned agony mentioned above, and commonly known as the "photographic look;" and for the many coloured clothing, the prolonged discussion about the power of photography to represent colour interests not the majority of ladies in the least, and that majority would probably say that if the camera could not reproduce colour, why—it ought to.

Let nature work unrepressed, uncribbed, uncabined, unconfined. Get rid of the "smile," the "look," and their many unnatural congeners. Seize upon the expression which gives the hall-mark of individuality, and you gain that which is of more importance than much sharpness of finish, or softness of lighting, or dexterity of manipulation, or beauty of pose, the supreme photographic excellence, which gives the operator the title of artist, the virtue of expression, without which all the other technical virtues are as sounding brass and a tinkling cymbal.

The mouth is probably the most expressive of all the features. It is well-known that much of the expression which is attributed to the eyes is really due to this organ only. For sad eyes, for instance, we should read sad mouth. It is a fatal mistake for an artist in photography to attempt to control this feature. It is, we repeat, the chief seat of expression, which, again, is the index of the soul. Suppose a sitter comes to be photographed, to take an extreme case, with his mouth open; not, by any means, merely with parted lips, but a man of whom an open mouth is the normal facial condition; the photographer by telling him to shut it, will lose his likeness. His resultant picture may be more decent, but it will be nothing worth as a presentment of the original. Nor are the muscles of the eyebrow less worthy of attention than those of the lips. Four distinct muscles, as readers of anatomy are well aware, govern the motions of the brow. The varied expressions of sadness, surprise, fear, admiration, disdain, and other emotions produced by these, have been ably treated of by Duchenne in his "Mécanisme de la Physionomie Humaine," a kind of electro-physiologic analysis of the expression of the passions, illustrated with numerous photographs of interest, if not of profit, to every photographer.

Duchenne studied photography for the sole purpose of executing these pictures himself. "Photography, which," he says, "faithful as a mirror, will allow the reader to assist at my experiments, and to form a judgment of their value." The photographs are none of them retouched. Some taken in full sunlight recall the manner of Ribera; others, of the darker passions, such as fear and hatred, remind the spectator of the chiaroscuros of Rembrandt. The whole volume impresses upon the student the power of the subject of our article, so that we may, with a well-known artist in his profession, apply to expression and individuality what the author of the Book of Proverbs said of understanding and wisdom. Individuality is the principal thing; therefore get individuality, and with all thy getting, get Expression.

ALUMINIUM.—There is no other metal on the earth so widely scattered and occurring in such abundance as aluminium, yet it is never found metallic, says an American contemporary. But the combinations of aluminium with oxygen, the alkalies, fluorine, silicon and the acids, are so numerous, and occur so abundantly, as not only to form mountain masses, but to be also the bases of soils and clays. Especially numerous are the combinations with silicon and the other bases, which, in the form of felspar and mica mixed with quartz, form granite. These combinations, by the influence of the atmosphere, air, and water, are decomposed; the alkali is replaced or carried away, and the residues form clays, the clays form soils, and thus the surface of the earth becomes porous to water and fruitful. It is a curious fact that aluminium has never been found in animals or plants, which would seem to show that it is not necessary to their growth, and perhaps be injurious. Most of the aluminium compounds appear dull and disagreeable, such as felspar, mica, pigments, gneiss, porphyry, and trachyte; yet there are others possessing extraordinary lustre, and so beautiful as to be classed as precious stones. Among these are the ruby, sapphire, garnet, turquoise, and topaz. One would suppose that since aluminium occurs in such abundance over the whole earth that we literally tread it under foot, it would be extracted and applied to numberless uses, being made as abundant and useful as iron. But such is not the case. Beauxite and cryolite are the minerals most used for producing aluminium, and their preference lies mainly in their purity. Native alums generally contain iron, which must be removed by expensive processes. Beauxite comes from Austria and France, and has only been found in this country in Floyd county, Georgia. Cryolite comes from Greenland. It has been found in Colorado in very small quantity. Native sulphate of aluminia has been found on the Gila river, Socorro county, N.M.—*Invention.*

DEVELOPERS USED BY GERMAN PROFESSIONAL PHOTOGRAPHERS.*

BY JULIUS F. SACHSE.

Theodore Schafgans, junr., Bonn.—Developer—Until a few months ago, oxalate; now I have adopted eikonogen, and use it exclusively. Advantages—With eikonogen the film remains wonderfully clean and clear, the plate shows greater plastique, and beautiful high lights. With the dexterous use of old developer over-exposed plates may be brought to the proper density, and per contra, greatly under-exposed plates may be saved by use of the strong developer. Composition — With normal and properly exposed plates I use the developer exactly according to the formulæ of Dr. Krugener. With doubtful exposures I commence with old developer, and, according to circumstances, finish with fresh developer. The development must only be done by a weak red light, or the plates are apt to fog and the fine lights disappear. I have also found that the two solutions must be kept separate until just before use; also that if two solutions are mixed in large quantities, the developer loses its power after two days. Accelerators—My experiments prove that they do not hasten development.

E. Lassen, Ratzeburg. — Developer — Eikonogen. Advantages—Since six months ago I have worked with eikonogen, and am well satisfied. We obtain brilliant negatives, high lights, middle tones, and clearness of shadows, with rich detail. Time of exposure is shortened one-third in relation to oxalate, and it is cheaper. Composition—(A) Distilled water, boiled, 600 g.; sulphite of soda, 100 g.; potash, 40 g.; eikonogen, 20 g. When the water boils, dissolve first sulphite, then potash, and lastly eikonogen. Accelerator—None.

C. Westendarp, Cöln.—Developer—Eikonogen. Advantages—Surety, simplicity, cheapness. Composition—I use the formula of the manufacturer. When developing, however, I take half old developer; the plates remain clearer, and any desired grade of strength can be obtained thereby. Accelerator—None.

Wm. Bergmann, Moers.—Developer—Ferrous oxalate. Advantages—Surety, simplicity, cheapness. Composition—(A) Iron, 1 : 3. (B) Oxalate potash, 1 : 3. One part A, three parts B. Accelerator—With extremely short exposures, hyposulphite of soda 1 : 2,000.

Aug. Classens, Aachen. Developer—Oxalate. Advantages—The constancy. Composition—In summer, 1 : 5; exposure 1 : 1½ seconds. Winter, 1 : 5; exposure 2 : 3 seconds. Accelerator—With drop shutter exposures of $\frac{1}{6}$ to $\frac{1}{4}$ seconds, a few drops of dilute hypo in developer.

F. Courte, Püttlingen. — Developer — Iron oxalate. Advantages—Simplicity and constant properties of development. Adaptable to all kinds of exposure. Cheapness. Composition—Saturated solution of oxalate of potash. (A) Iron, 30 g.; water, 100 c.cm. A few drops of 2 per cent. solution of tartaric acid. (B) Old developer with a few drops of above tartaric acid solution added. For use in normal exposures: Iron (A), 1 part; old developer (B), 1 part; saturated solution of oxalate, 2 parts. For over-exposed plates: Iron (A), 1 part; old developer (B), 2 parts. For very short exposures: Iron, 1 part; oxalate, 3 parts. Accelerator—None.

Joh. Freund, Schliechtron. — Developer — Oxalate of potash and iron. Advantages—Simple manipulation and sure results. Composition — (A) Oxalate of potash, 30 parts; distilled water, 100 parts. (B) Iron vitriol, 30 parts; distilled water, 90 parts. Just before use: 3 parts A and 1 part B, with a few drops of bromide of potassium, 1 : 10. Accelerator—None.

H. Haberlandt, Berlin.—Developer—After all developers have been tried, I have left all, even eikonogen, and return to the iron developer. Advantages—Iron acts quicker than eikonogen. I would prefer pyro on account of its finer detail if I only had portrait plates to develop; further, iron and pyro—unless through carelessness—never fog, while eikonogen easily does. This, however, may be the fault of the unequal quality of even the best sulphite. Composition—(1) Oxalate of potash, 300; water, 1,000. (2) Iron, 300; water, 1,000. One part iron to three parts oxalate. I make both solutions with hot water, and filter. In No. 2, I pour two drops concentrated sulphuric acid to every 100 g. of hot water, then dissolve the iron, and filter. Accelerator—One part hypo to 8,000 to 10,000 parts of water, only with drop-shutter exposures.

Louis Hermestroff, Metz.—Developer—Iron oxalate. Composition—Potash, 1 to 3½; iron, 1 to 3. Three parts of potash and one part of iron, both dissolved in hot water. Accelerator—With drop-shutter exposures, hypo 1 : 1,000.

J. F. Klinger, Braunau ob. Oesterreich.—Developer—Iron oxalate. Advantages—The always even results with Monckhoven dry plates, with fine modulation, close grain, and high-lights. Composition—(A) Neutral oxalate of potash, 300 g.; distilled water, 1,000 g. (B) Iron vitriol, 300 g.; distilled water, 1,000 g. Three to four drops of sulphuric acid. For use, 4 parts potash, 1 part iron. Reduction if necessary. Hypo, 200 g.; water, 1,000 g.; red pruss., 1-5. Accelerator—Children with advantage: Water, 3,000 g.; hypo, 1 g.; citric acid, 3 g.

A. zur Mühlen, Magdeburg.—Developer—Oxalate. Advantages—With accelerator, soft and clear shadows. Composition—Oxalate 1-4, iron 1-3. For use, 1 part iron, 3 parts oxalate. Accelerator—Hypo.

Alfred Person, Lahr.—Developer—Oxalate. Advantages—Clear plates. Grey colour and rapid printers. Composition—(1) Oxalate, 300 g.; water, 1,000 g. (2) Iron, 100 g.; water, 3,000 g. For use, 1 three parts, 2 one part. Consider the developer the best. Have developed shortest drop-shutter exposures with success. Accelerator—None.

Prof. C. C. Schirm, Berlin.—Developer—Ferrous oxalate, with accelerator (250 water, 1 part hypo), and an addition of weak solution of hypo and bromide to developer. Advantages—Evenness in appearance of lights and shadows, and the correct relation to each other, gradation and beauty in detail. Composition—(A) Oxalate of potash, 1; water, 3. (B) Iron vitriol, 1; water, 4. One part of B to three parts of A with the addition of one drop of solution. Hypo, 0·5; bromide, 3 g.; water, 100 g. to every 10 c.cm. of developer. Also two-thirds of old developer to one-third fresh. Accelerator—One of hypo to 2,500 of water.

L. Schmidt, Freiberg. — Developer — Iron oxalate. Advantages—Works not too slow, gives clear shadows with all detail and high-lights, when suitable dry plates are used. Composition—(A) Oxalate of potash, neutral, 300 g.; distilled water, 1,000 g. (B) Sulph. iron, 100 g.; distilled water, 300 g. Sulph. acid, c.p., two to three drops immediately before use, three parts of A to one of B, with under-exposed plates, to every 100 g. of developer one or two drops of hypo 1 : 100. Over-exposure, 1

* Continued from p. 540.

regulate the development with the addition of bromide 1 : 10, drop by drop. Accelerator—None. [Note.—Have tried eikonogen in various ways, but prefer iron oxalate to all others. I, however, think the time will come before long when, with different combinations, the eikonogen developer will be deemed the best.]

L. Stuting, Hofphotograph, Barmen.—Developer—Oxalate of potash with iron. Advantages—I have found that it works clearer and stronger than all others. Composition—Saturated solutions of oxalate and iron, 3 parts of ammonia to 1 part of iron. Accelerator—With drop-shutter and interiors 1 part of hypo, 2,000 of water, to which add a few drops of 10 per cent. bichloride of mercury.

George Muller, Eltville.—Developer—During the last six months a prepared hydrochinone developer, which has kept well and remains clear. I use it fresh for instantaneous, and old for time exposures. Advantages—Softness combined with fine lights, and especially fine detail in the shadows—good colour of the negatives. Composition—(A) Water, 400 g.; sulphite of soda, 45 g. (B) Water, 450 g.; soda, 45 g.; potash, 45 g.; sulphite of soda, 45 g. For a plate 13 by 18 cm. take A, 40; B, 5; 10 drops of bromide. After these are in the developing glass, add just before use a small thimble-full of dry pyro. Accelerator—None.

Hubert Koch, Kevelaer.—Developer—Pyrogallic acid. Advantages—It gives strong negatives with soft modulation, develops strongly and quickly. Negatives are easy printers on account of the bluish colour of the plates; extreme cleanliness. Excellent results can be obtained. Composition—(A) Water, 500 g.; sulphite soda, 100 g.; 10 drops sulphuric acid. (B) Soda, 50 g.; Water, 500 g. Before use—4 parts water, 3 parts A to 3 parts B. (Note—pyro not given.) Sulphite of soda added to fixing bath. Accelerator—None.

These replies will suffice to show the general trend of the German portrait artists. We find that the publishers of the *Photographishches Archiv* sent out a total of one hundred and forty-five queries throughout Germany and Austria-Hungary. Eighty replies were received, forty-eight of which have been reproduced in these columns for the benefit of our readers, both professional and amateur. From the great stretch of territory covered by these responses, they may be accepted as fair representatives of the whole body of photographers who are scattered throughout the Fatherland. The result arrived at shows that ferrous oxalate is still the most generally used agent in the development—more than one-half (44-80ths) still adhere to the old stand-by; twenty-five per cent. (20-80ths) have become converts to the latest candidate for photographic favour, viz., eikonogen. Next comes hydrochinon or fifteen per cent. (12-80th), and finally pyro (8-80th), or 10 per cent. of the whole number of replies received.

In analyzing the total replies, we find that in the advantages claimed for the ferrous oxalate, seventeen claim simplicity and surety, nine claim equality of work, nine claim capabilites of modulation, seven claim clearness of negatives, seven claim rapidity of development, seven claim cheapness of price, three claim cleanliness, two claim greater latitude of exposure, two claim value of copying properties.

Of those in favour of eikonogen, thirteen claim that the new developer is superior to all others in producing soft and clear, yet at the same time strong negatives, ten claim that the time of exposure is much shortened, eight claim greater detail in the shadows, seven claim rapidity of work, seven claim brilliant middle tones and high lights, four claim advantages of repeated use, two claim negatives that are easy printers and cleanliness in development.

Hydrochinon: five claim keeping qualities of developer, three claim soft and strong negatives, and convenient for application, three claim surety of work, two claim fine modulations.

Pyrogallic acid: four claim superior brilliancy and detail in negative, with good colour for printing; further, great latitude of exposure, that it keeps well in separate solutions, and acts quickly. The developer, however, requires great cleanliness in all manipulations.

As to the accelerator, it is apparent that with the use of eikonogen and pyro it is unnecessary, with hydrochinon only occasionally, while with ferrous oxalate it is requisite in half the normal cases, while it is always required with drop shutter exposures or in cloudy weather; the usual formula is hypo in a very dilute solution 1 to 1,000 to 10,000, and occasionally with the addition of a few drops of solution bichloride mercury.

The editor of the *Archiv* closes the subject with the statement that although the returns make no pretension to completeness, he is yet convinced that the imparted information from practical experience will prove of great service to the craft in general, giving many valuable hints and points to the professional as well as the intelligent amateur.

A MISCONCEPTION.—Clara: "Well, Aunt, have your photographs come from Mr. Snappeschotte's?" Miss Maydeval (angrily): "Yes, and they went back, too, with a note expressing my opinion of his impudence." Clara: "Gracious! What was it?" Miss M.: "Why, on the back of every picture were these words: 'The original of this is carefully preserved.'" —*Pittsburg Bulletin.*

MESSRS. EGLINGTON AND CO. announce that the August number of *Men and Women of the Day* will contain three panel photographs (10 by 7½ inches) of Mr. and Mrs. Stanley (Miss Dorothy Tennant), and Lieut. Stairs, together with authentic biographies. The publishers state that the photographs have been specially taken for this publication, which is a national photo-biographic journal, and that the portrait of Mrs. Stanley is one of the few authorised photographs published.

AN INTERNATIONAL EXHIBITION.—An Exhibition, promoted by the Edinburgh Photographic Society, is to be held in the Galleries of the Royal Scottish Academy, Edinburgh, November, 1890, to January, 1891. The object of the Exhibition is stated to be to direct attention to the development in recent years of photography, and to stimulate further advances by encouraging artistic skill and invention. In addition to the ordinary character of photographic exhibits, it is intended to illustrate historically and technically the processes connected with the art in their various stages, and the council will regard it as a special favour if those having unique specimens, especially of the earlier processes and apparatus, will kindly lend them for exhibition. Besides the above-mentioned exhibits, the council have thought it desirable to embrace in their operations a scheme of lectures, in which the different processes in connection with photography will be practically explained and illustrated. These lectures will be given by speakers thoroughly qualified in the treatment of their subjects, and it is contemplated to have one in each week during the continuance of the Exhibition. A series of awards will be granted, and the council will appoint, to act as judges, five qualified persons, whose names will be announced at an early date. A gold medal and silver and bronze medals will be awarded for pictures according to merit. The secretary is Mr. Thomas Barclay, 180, Dalkeith Road, Edinburgh.

HOME PORTRAITURE.

BY H. H. SUPPLEE.

It seems to be generally admitted that the amateur begins by undertaking the most difficult branches of work first, and after meeting with divers discouragements, either abandons the whole affair or else gradually discovers the error of his ways and gets hold of the right end and moves on to success and satisfaction. The beginner's idea of a photograph is a picture of somebody, and of a camera as an apparatus for taking people's pictures with, and in many cases that is all he wants it for; and when he is carefully advised to start with slow plates, and essay only well-lighted views, he naturally resents such ill-timed suggestions, and generally goes home immediately and proceeds to "take the baby."

This proceeding, however, is rarely a success, and usually it is only after many tribulations that really satisfactory home portraits are produced; but there really seems to be no good reason why some of the trials and failures might not be avoided, or why one may not profit by the hard-bought experience of others in this most desirable and pleasant branch of amateur work.

To make fairly good portrait work, however, requires suitable tools; but these need not necessarily be the most expensive. The lens should be of fairly long focus—about twelve inches—and the rapid rectilinear type will generally be found most available. If the cost of this be found too high, good work may be done with a single achromatic landscape lens of about fifteen inches focal length, in which the fixed stop has been reamed out to a size of not less than one inch to one and a-quarter inches. This enlargement of aperture will of course materially reduce the marginal definition of the field; but when that is wanted smaller diaphragms may be inserted, and for portraits, where only the very centre of the field is to be employed, the increased opening will give the desired speed, while with this length of focus and limited field the spherical distortion is so small that it may be neglected. For portraits great depth of focus is not needed, and, indeed, in many cases is undesirable, and if good definition is obtained upon the features, so that the true expression is secured, the sharpness may well be permitted to diminish for the remainder. Of course the possession of a fine portrait combination is much to be desired, and where the expense of this is prohibitory the intermediate types, such as the Steinheil anti-planet or the new Voigtlander euryscope, are nearly as good.

As far as the camera goes, anything which is steady and light-tight will answer, and it is unnecessary to spend money in that direction. For cabinet portraits, 5 by 7 holders are about right, giving a moderate margin for centreing and trimming.

The amateur is generally limited in his supply of screens and backgrounds, but sometimes the extemporised affairs are more pleasing than the orthodox professional pilasters, balustrades, or gates, and if care and taste are displayed in handling the subject, the less conspicuous the background the more satisfactory the result is likely to be.

A framework somewhat resembling a large clothes-horse can readily and cheaply be made at a neighbouring carpenter's shop, and should be about eight feet high by ten feet wide, and, for convenience of storage, it may be pinned together so as to be readily knocked down, and stood away when not in use. Upon this frame various things may be draped, and often very effective results obtained. There should be one curtain of grey flannel, giving, when photographed, a neutral tint just right for vignetting, and soft enough to hang in easy folds without looking harsh or stiff. This may be hung from the top by hooks and rings, or may be smoothly drawn when the picture is to be vignetted and the folds are not desired. Many styles of shawls produce effective backgrounds, especially when far enough back from the sitter to be somewhat out of focus; while, in most cases, the easy chair which does duty for a posing chair is less obtrusive and more effective if entirely concealed under drapery whose apparently careless folds are not altogether accidental.

When the floor at the feet of the sitter is to appear in the photograph, it should be kept subordinate to the other details, and a brilliant carpet pattern is best covered by some quieter rug or mat. Skin robes or mats are often quietly effective, and seem to hold the light they receive in a way which has shown itself serviceable.

The great point, however, in amateur portraiture is the illumination. The absence of a skylight, and the difficulties in the way of controlling the light which is to be had—these are the common causes of the defects to be seen in most home portraits. A room should be chosen with as high a ceiling as possible, and with a projecting bay window whose openings extend as high as can be secured. If there are other windows, let them be closed, so that the light shall come approximately from one direction. Never mind the exposure; west or south will do, if only the quantity and direction of the light can be controlled.

Place the camera close to the middle window, leaving only room enough to get behind it, and close the lower shutters behind the camera, leaving the upper ones above it partly open to secure a slight front illumination. Upon one side the shutters of the bay window should be opened entirely, so that the most brilliant light falls upon the sitter from that direction, and then by regulating the amount of opening upon the other side the shadows may be softened to any desired extent. At first the effect should be examined upon the focussing screen of the camera, which should be of the finest ground glass obtainable. Use the full opening of the lens, and focus upon the eyes of the model, and the definition of the rest will take care of itself. A microscopic sharpness, by which every thread in the garment may be counted, is readily obtained by using a smaller aperture; but such precision is not wanted.

Never mind about head-rests or their substitutes, but try to place the sitter in such an easy and comfortable position that such supports will not be needed. Avoid straight lines in the composition, and if the lens is of sufficient focal length there need be no fear of undue distortion of points nearest the camera. Standing just behind the camera, direct your sitter to glance in the direction which, in your judgment, gives the best effect, and then selecting some object upon which the eyes may rest, the exposure may be made. With rapid plates, such as Seed 26, or Cramer 35-40, two or three seconds with bright daylight will be sufficient, using an aperture of F8; but the beginner must expect to waste a few plates in gauging the light of his extemporised gallery. After having arranged the details of this part of the work, however, the amateur will soon find the photographic side of the work a matter of routine, and be able to devote his thought and attention to the higher and more artistic matters of posing, draping, and composition, in which, if he will, he may find a source of endless delight.—*Amer. Journ. of Photography.*

Notes.

Mr. J. R. Gotz has sent us some half-plate specimens of flexible films of gelatine rendered insoluble and coated with the Obernetter emulsion. They are thinner and more flexible than those of celluloid, but in the developing solutions absorb water and increase considerably in thickness, acquiring at the same time a leathery, slippery feel, and increasing much in weight. They are not so "horny" when handled as celluloid films. Despite their thickness, we found no difficulty in using them in an ordinary dark slide, simply by placing them therein with a piece of black cardboard behind. They are coated with the Obernetter emulsion, and the latter works well. The negatives require aluming. Full instructions for use accompany each packet.

The statue to Daguerre about to be erected in front of the Smithsonian Institute at Washington is nearly completed in the artist's studio, and will be erected on the 12th August next. The bronze portion is sixteen feet high, and upon the granite beneath is the following inscription :—"To commemorate the first half-century in photography, 1839-1889. Photography, the electric telegraph, and the steam engine, are the three great discoveries of the age. No five centuries in human progress can show such strides as these. Erected by The Photographers' Association of America. August, 1890." All photographers must be pleased at the erection of this monument, and the only criticism we have to make is, that it would have been well if, before selecting the subject, its promoters had instituted some real, sound, historical research as to the rival merits of Niépce de Chalons and Daguerre. The general tendency of comparatively recent research has been to show that the merits of Nicephore Niépce exceed those of Daguerre in relation to the founding of photography. A chief point in Daguerre's favour is the discovery of mercurial development. A school of historical criticism in photography is desirable at the present time, for the few who consult original documents are aware how numerous are the historical errors which rapidly become popular, and which can afterwards be eradicated from the public mind only with difficulty.

There is little of a photographic nature at the French Exhibition in London. Messrs. Haret Frères, of Paris, have erected an oak stand for exhibiting a considerable number of large photographs in wooden frames, which frames are hinged to a central pillar. The principle is not new, but the design is of interest, because it is the one selected by the authorities of the Musée du Louvre as the best brought before them for displaying large pictures in a limited amount of space. The pictures in the frames consist of some subjects in the national art galleries of Europe, photographed by Braun and Co., of Dornach. Messrs. A. C. Vasseur and Co., of Paris, exhibit a considerable number of French photo-mechanical prints, some of them in colours. Mr. Reitlinger, a Hungarian, with a manufactory in France, exhibits some artistic frames of white metal, to hold photographs; and Mr. Rosenmann some remarkable metallic pens for writing, sketching, or other purposes, the nibs of which can be bent in any direction without breaking, and the pen then restored to its original form. Among the amusements at the Exhibition, the driving of the lions is a great attraction; a "Japanese" conjuring entertainment is of an elegant and refined character, and a burlesque of Robinson Crusoe contains poetry of the following type :—

> *Crusoe* :—"Friday! There's cannibals on this isle;
> They've just put a black man on to bile."

In the grounds is a cosmorama, containing photographs of scenes in France.

The English amateur photographers who make a speciality of instantaneous work missed a chance on Sunday morning, when the *Sans Peur* Bird Society, of Brussels, contested its annual race from London. The members of the *Sans Peur* Society are pigeon-fanciers, and on this occasion an enormous number of birds were liberated from the Thames Embankment adjoining Millbank Prison. When a similar contest took place in Paris, a few months ago, the President of the French Photographic Society invited amateur photographers to attend, as this monster flight of pigeons offered a good opportunity of showing of what instantaneous photography was capable. The English societies apparently are not alive to this, for, so far as we know, no representative was present on the occasion mentioned above.

The ingenious photographer who keeps a sharp eye upon the "hatched, matched, and dispatched" column of the *Times* has been distanced by a still more ingenious rival. The method of the first-named is to photograph every morning the column in question, divided into three sections, and send a copy to the persons concerned, with the request for sixpence for his trouble. The new man haunts cemeteries, and with his camera photographs all the new grave-stones that are erected. Then, having obtained the address of the relatives of the deceased person, he posts a copy of the photograph with the intimation that he is willing to supply "a dozen *souvenirs* of the departed for 5s. 6d." The number of orders the photographer receives is stated to be surprising.

Of a kindred nature is the crematory urn just patented in America. This is an arrangement by which the ashes of the defunct person are always on view. The bowl is made of the finest crystal glass, mounted in elaborately decorated silver. A crest surmounts the urn, which shows, in addition, masonic emblems and two shields for inscription. Above all is a space for a photograph, which, of course, gives a very realistic

touch to the whole affair. Despite its completeness, we doubt whether this transparent urn will be agreeable to English taste.

It is sad to read of the death of Mr. Payne, headmaster of Harrington School, near Preston. He was an enthusiastic amateur photographer, and was spending his holidays at Ingleton, and in endeavouring to get a good photograph of a rustic bridge, he fell from a considerable height to the rocks below and was killed on the spot. We are inclined to think that amateurs frequently incur a risk of accidents in similar fashion. They allow their enthusiasm to run away with them for the moment, and in their anxiety to get some view they fancy, are perfectly heedless of danger. In some respects the amateur photographer, especially if he be a beginner, is like the youthful angler, who is apt to think that the more inaccessible the spot, the more likelihood of sport, and he strains every nerve to get to some particular point which older men with cooler heads would have the philosophy to leave alone.

Mr. Samuel Plimsoll is quite alive to the advantages of photography. In the most recent of his pamphlets, which have done so much to raise the condition of the sailor, he deals with the question of cattle ships, and what may be rightly termed their "horrors." It would be out of place to enter into any discussion of the revelations which Mr. Plimsoll details so graphically; all we need draw attention to is, the assistance which he has derived from photography. Dealing with the meat supply question, as regards London, he gives the consumer a mass of valuable information, by means of reproductions from photographs, of all the market operations of Smithfield, and one can only regret that he overlooked photographing what would convey most important hints to materfamilias when she buys the Sunday joint. He gives representations of the hind quarters of cattle dressed in the American and English fashion, and these are all very well as far as they go, but, unfortunately, they are drawn, and not photographed. This seems an unaccountable omission, as photographs could have been easily obtained, and would have shown the difference between the two in a forcible manner.

Still, we are grateful to Mr. Plimsoll for what he has done, and especially in regard to the photographic operations carried on in America, in regard to the cattle ships. He says that, in the outset of the investigations, he sought the aid of his brother in New York, and requested him to employ a photographer in that city to obtain photographs of vessels loading and loaded with live cattle. This was done by a professional photographer, Mr. Barrett, an amateur assisting him. The photographs, reproductions of which are given in the volume, are twelve in number, and depict most graphically the conditions under which the sailors have to work. It seems that the decks are formed simply by the roofs of the cattle-sheds, are full of openings, and have not the least vestige of a bulwark. As for the way in which the cattle are stowed, the less said about it the better. It is significant that, in some cases, permission to photograph was refused, and it is clear that the people concerned had a wholesome dread of the evidence of photography.

A new use has been found for our old friend pyro by Dr. Gautrelet, of Vichy, who lays claim to the discovery that it renders tobacco harmless to mouth, heart, and nerves, without in any way spoiling the soothing effect or the aroma of the seductive weed. The proper way to bring about this desirable result is to plug the pipe or cigar holder with a pledget of cotton wool which has been soaked in a ten per cent. solution of the pyrogallol, so that the smoke drawn through this filter may be robbed of its bad qualities, and the noxious weed may be noxious no longer. With this precaution the tongue will not fur, the head will not ache, and everyone will be able to smoke with impunity. We are not quite sure, but we fancy that if every smoker were to take the trouble to insert in his pipe a wisp of cotton wool as a bed for the tobacco to rest upon, all the evils with which the weed is credited would be obviated without any aid from pyrogallol. It must be remembered that the latter, from its poisonous nature, might possibly prove to be more dangerous than the nicotine.

Hand camera work must have been, during these last two months of cloudy skies and general darkness, quite at a standstill, and the detective agency whose novel advertisement we quoted a fortnight ago must have found their efforts to secure compromising pictures severely handicapped. Even in the best of weather such pictures will present great difficulties. Let us, for instance, take the case of some unfortunate couple whose portraits a paid spy armed with a camera is anxious to secure. The picture must be taken in sunlight, with the faces of the victims turned towards the instrument, so that there may be no doubt as to identity, and at the same time the operator must be careful that he himself is not detected. With all these things opposing him, the chances are ten thousand to one against success, and glad we are that this is the case.

The actual difficulties of instantaneous portraiture with hand-cameras may be guaged from the circumstance that such portraits of well-known public characters are never seen. If they were easy to procure the market would teem with them, for they would find a ready sale. The only case of the kind of which we are cognisant is an extremely unflattering portrait of her Majesty the Queen smiling in her carriage. This was exhibited in the shop windows about a year ago. Her Majesty's countenance is so well known to everyone that the picture can be recognised, but if it had represented any one of less note it would have been almost useless; at any rate, as a means of identification.

ILLUSTRATING POEMS BY PHOTOGRAPHY.*

BY CATHARINE WEED BARNES.

As the Venus of Milo stood before her sculptor-creator saying to his inner consciousness, "You have made me visible to men, but among them, as on Olympus, none shall question my sovereignty"; so poetry says to her various adorers, "No one shall be able to say he has sounded the depth of my soul." One approaches nearest her inmost shrine in closely following nature, and it is the part of true wisdom to study her under all the ever-changing conditions of life with a reverend worship which will richly reward every faithful worshipper. Not to those who deny her power, or to those who try to force themselves into her most sacred penetralia, are its mysteries discovered, but to those who in spirit and in truth wait before its altar. Painters and sculptors have sought through all ages to reveal poetry by means of form and colour with all the varying expression of her changeful features, but there is no reason, it seems to me, why, among those who seek to translate into visible shape her spiritual beauty, only those should be numbered to whom heretofore the world has given the name of "artist." Why should the fact of using brush or pencil presuppose in its user the possession of artistic power or appreciation? The world does move, and people are beginning to understand that after all it matters little what tools are used if into the finished work is breathed the breath of artistic life. Our friend Dr. Emerson seems to think that by the blending of art and science in photography each is thereby weakened, that each should keep to its own sphere. Is it not possible to study science in this connection as one does the steps in dancing, very important to follow closely at first, but gradually becoming a second nature, so that one, so to speak, forgets the letter in the spirit?

Let your work be so much a part of you that while not conscious of moving according to fixed rules, you are nevertheless largely guided by them.

Travellers abroad can purchase the poems of Scott, Burns, or others, illustrated by photographs of scenery and buildings, but few and far between are the photographic illustrations designed to specially bring out the spirit of the poem as the painter or etcher designs his special work. The photographer must, of course, labour within limits, but I believe they are more flexible than generally supposed. While it is not always possible to make one's model fit the picture, it is possible to make the picture fit the model. In other words, I believe that, after careful choice of lines to be illustrated, the intended picture should be evolved from one's brain by thinking of it, brooding over it, dreaming of it, until all is ready for the realisation. Take plenty of time to absorb into your very soul the thoughts of the poem before you. Then carefully decide on the accessories, and, if practicable, discard those which are readily recognised as being in ordinary studio use. Have real curtains, chairs of wood or brass, or other material not made to simulate something else. I make an exception in favour of using artificial flowers and vines, but sparingly. If the operator is not a carpenter, one can be found to construct temporary doors and windows. They are better than the painted article, and *papier-mache* is so glaringly a false deceiver. If the deception could be well done it would be allowable, but the average rocks, walls, trees, &c., are only too visibly unrealities. These things need not be necessarily expensive if the camerist is possessed of dramatic taste and is something of a mechanic. The professional is usually assisted during an exposure by some one to focus while he is posing, and has everything ready for the work, while the amateur portraitist has to be almost omnipresent, so that he works under much greater difficulties than his professional brother, and if he did not really deserve the name "amateur," never would have courage and patience to continue, but the camera fever when it reaches a certain stage is incurable.

It should be the exception when pictures of out-door scenes are taken by indoor light, even the light of the studio. It conveys a wrong impression to the uneducated eye, and, in the branch of photography under consideration, does more harm than good. There is no need either of all the pictures being made in the studio. But where interiors, fancy figures, or portraits are needed, the studio is the place wherein to make them. No hard or fast rule can be laid down on the mode of studying out or realising illustrations. To a great extent the artistic operator must be a law unto himself or herself, but, while working in limits, I believe in stretching them as far as possible and taking advantage of everything within them. If the model, when found, does not entirely suit the character desired, it is often well to slightly vary one's conception of it and gain thereby, it may be, a finer effect than the one intended. There should be, and I say it from experience, a magnetic relation between sitter and operator, their minds should work together, and the words to be wrought out in the picture should occupy their thoughts to the exclusion, for the time being, of all else. As the actor or opera singer best realises a character by utter forgetfulness of self, so ought the ideal sitter to think so fully of the part to be represented that the idea never occurs to him or her that it is a "portrait" which is being taken. "You are only a part of a whole," I say in such cases, "it is not you any more than the chair you sit upon that is being photographed."

It requires a certain amount of histrionic ability to sit for an ordinary portrait, but infinitely more for an ideal subject. This is not common, but where it exists the camera can be sure of extra credit which should be shared with the sitter. The various difficulties incident to taking small heads and figures greatly increase when it comes to taking large ones, and justly the camerist who takes good ones is proud of them. Do not try to get a *likeness* of your model. The point is to have the picture tell a story; make it do that at any cost, and it matters nothing at all if the face is not shown or is utterly unrecognisable. Let imagination dominate your thoughts, and your work will have originality, character, not be like that of any one else. This means, however, putting enough labour and thought on one picture to take a dozen ordinary portraits. The artistic camerist should also bear in mind by what process his work will be reproduced, and keep that thought ever before him from the instant of exposure until the negative is developed. Training in some branch of art is capital preparation for illustrating, and every picture designed is an education for the next one. The eye becomes more and more accustomed to realising in a picture certain stanzas or lines, and new ones will be constantly suggested.

There is one point more that I never have heard mentioned. In taking an interior for illustration, if done in the studio, it is possible to arrange a ceiling over the sitter so that the effect of a room can be better preserved, and the light come, as it naturally would do, from the side.

* Read before the Society of Amateur Photographers of New York.

It is a good plan, also, where an out-door scene is desired, to arrange either by means of a mirror, or water in a tank, to simulate a stream or lake, and prevent reflections from the roof by stretching painted canvas over it.

This subject of illustrating poems is destined to bring about some striking changes in the world of art, and "weary, stale, flat, and unprofitable" will gradually seem to the ambitious amateur all other branches of camera work. It is inconceivably fascinating, and one's brain becomes bewildered at what seems to be its destiny. The various new and beautiful reproducing processes constantly claiming attention seem created for this very purpose. The camera has a wonderful future before it, and you will need all the inspiration you can possibly gain in entering a field of work filled with so many opportunities, but which others claimed to have owned long before you. Remember first, last, and all the time, these words from Longfellow's "Kavanagh":—"We judge ourselves by what we feel capable of doing, while others judge us by what we have already done."

THE PHOTOGRAPHIC IMAGE.*

BY PROFESSOR RAPHAEL MELDOLA, F.R.S., M.R.I.

The history of a discovery which has been developed to such a remarkable degree of perfection as photography has naturally been a fruitful source of discussion among those who interest themselves in tracing the progress of science. It is only my presence in this lecture theatre, in which the first public discourse on photography was given by Thomas Wedgwood at the beginning of the century, that justifies my treading once again a path which has already been so thoroughly well beaten. If any further justification for trespassing upon the ground of the historian is needed, it will be found in the circumstance that in the autumn of last year there was held a celebration of what was generally regarded as the jubilee of the discovery. This celebration was considered by many to have reference to the public disclosure of the Daguerreotype process, made through the mouth of Arago to the French Academy of Sciences on August 10th, 1839. There is no doubt that the introduction of this process marked a distinct epoch in the history of the art, and gave a great impetus to its subsequent development. But, while giving full recognition to the value of the discovery of Daguerre, we must not allow the work of his predecessors and contemporaries in the same field to sink into oblivion. After the lapse of half a century we are in a better position to consider fairly the influence of the work of different investigators upon modern photographic processes.

I have not the least desire on the present occasion to raise the ghosts of dead controversies. In fact, the history of the discovery of photography is one of those subjects which can be dealt with in various ways, according to the meaning assigned to the term. There is ample scope for the display of what Mr. Herbert Spencer calls the "bias of patriotism." If the word "photography" be interpreted literally as writing or inscribing by light, without any reference to the subsequent permanence of the inscription, then the person who first intentionally caused a design to be imprinted by light upon a photosensitive compound must be regarded as the first photographer. According to Dr. Eder, of Vienna, we must place this experiment to the credit of Johann Heinrich Schulze, the son of a German tailor, who was born in the Duchy of Madgeburg, in Prussia, in 1687, and who died in 1744, after a life of extraordinary activity as a linguist, theologian, physician, and philosopher. In the year 1727, when experimenting on the subject of phosphorescence, Schulze observed that by pouring nitric acid, in which some silver had previously been dissolved, on to chalk, the undissolved earthy residue had acquired the property of darkening on exposure to light. This effect was shown to be due to light, and not to heat. By pasting words cut out in paper on the side of the bottle containing his precipitate, Schulze obtained copies of the letters on the silvered chalk. The German philosopher certainly produced what might be called a temporary photogram. Whatever value is attached to this observation in the development of modern photography, it must be conceded that a considerable advance was made by spreading the sensitive compound over a surface instead of using it in mass. It is hardly necessary to remind you here that such an advance was made by Wedgwood and Davy in 1802.* The impressions produced by these last experimenters were, unfortunately, of no more permanence than those obtained by Schulze three-quarters of a century before them.

It will, perhaps, be safer for the historian of this art to restrict the term photograph to such impressions as are possessed of permanence. I do not, of course, mean absolute permanence, but ordinary durability in the common-sense acceptation of the term. From this point of view the first real photographs, *i.e.*, permanent impressions of the camera picture, were obtained on bitumen films by Joseph Nicéphore Niepce, of Châlons-sur-Saône, who, after about twenty years' work at the subject, had perfected his discovery by 1826. Then came the days of silver salts again, when Daguerre, who commenced work in 1824, entered into a partnership with Niepce in 1829, which was brought to a termination by the death of the latter in 1833. The partnership was renewed between Daguerre and Niepce de St. Victor, nephew of the elder Niepce. The method of fixing the camera picture on a film of silver iodide on a silvered copper plate—the process justly associated with the name of Daguerre—was ripe for disclosure by 1838, and was actually made known in 1839.

The impartial historian of photography who examines critically into the evidence will find that, quite independently of the French pioneers, experiments on the use of silver salts had been going on in this country, and photographs, in the true sense, had been produced almost simultaneously with the announcement of the Daguerreotype process, by two Englishmen whose names are as household words in the ranks of science—I refer to William Henry Fox Talbot and Sir John Herschel. Fox Talbot commenced experimenting with silver salts on paper in 1834, and the following year he succeeded in imprinting the camera picture on paper coated with the chloride. In January, 1839, some of his "photogenic drawings"—the first "silver prints ever obtained—were exhibited in this Institution by Michael Faraday. In the same month he communicated his first paper on a photographic process to the Royal Society, and in the following month he read a second paper before the

* This is the full text of Professor Meldola's recent lecture at the Royal Institution, of which we gave a brief report.

* "An Account of a Method of Copying Painting upon Glass, and of making Profiles by the Agency of Light upon Nitrate of Silver. Invented by T. Wedgwood, Esq. With Observations by H. Davy." *Journ. R.I.*, 1802, p. 170.

same society, giving the method of preparing the sensitive paper and of fixing the prints. The outcome of this work was the "Calotype" or Talbotype process, which was sufficiently perfected for portraiture by 1840, and which was fully described in a paper communicated to the Royal Society in 1841. The following year Fox Talbot received the Rumford Medal for his "discoveries and improvements in photography."*

Herschel's process consisted in coating a glass plate with silver chloride by subsidence. The details of the method, from Herschel's own notes, have been published by his son, Prof. Alexander Herschel.† By this means the old 40-foot telescope at Slough was photographed in 1839. By the kindness of Prof. Herschel, and with the sanction of the Science and Art Department, Herschel's original photographs have been sent here for your inspection. The process of coating a plate by allowing a precipitate to settle on it in a uniform film is, however, impracticable, and was not further developed by its illustrious discoverer. We must credit him, however, as being the first to use glass as a substratum. Herschel further discovered the important fact that while the chloride was very insensitive alone, its sensitiveness was greatly increased by washing it with a solution of silver nitrate. It is to Herschel, also, that we are indebted for the use of sodium thiosulphate as a fixing agent, as well as for many other discoveries in connection with photography, which are common matters of history.

Admitting the impracticability of the method of subsidence for producing a sensitive film, it is interesting to trace the subsequent development of the processes inaugurated about the year 1839. The first of photographic methods—the bitumen process of Niepce—survives at the present time, and is the basis of some of the most important of modern photo-mechanical printing processes. [Specimens illustrating photo-etching from Messrs. Waterlow and Sons exhibited.] The Daguerreotype process is now obsolete. As it left the hands of its inventor it was unsuited for portraiture, on account of the long exposure required. It is evident, moreover, that a picture on an opaque metallic plate is incapable of reproduction by printing through, so that in this respect the Talbotype possessed distinct advantages. This is one of the most important points in Fox Talbot's contributions to photography. He was the first to produce a transparent paper negative from which any number of positives could be obtained by printing through. The silver print of modern times is the lineal descendant of the Talbotype print. After forty year's use of glass as a substratum, we are going back to Fox Talbot's plan, and using thin, flexible films—not exactly of paper, but of an allied substance, celluloid. [Specimens of Talbotypes, lent by Mr. Crookes, exhibited, with celluloid negatives by the Eastman Company.]

If I interpret this fragment of history correctly, the founders of modern photography are the three men whose labours have been briefly sketched. The jubilee of last autumn marked a culminating point in the work of Niepce and Daguerre, and of Fox Talbot. The names of these three pioneers must go down to posterity as co-equal in the annals of scientific discovery. [Portraits by Mr. H. M. Elder shown.] The lecture theatre of the Royal Institution offers such tempting opportunities to the chronicler of the history of this wonderful art, that I must close this treatment of the subject by reminding myself that in selecting the present topic I had in view a statement of the ease of modern photography from its scientific side only. There is hardly any invention associated with the present century which has rendered more splendid services in every department of science. The physicist and chemist, the astronomer and geographer, the physiologist, pathologist, and anthropologist will all bear witness to the value of photography. The very first scientific application of Wedgwood's process was made here by the illustrious Thomas Young, when he impressed Newton's rings on paper moistened with silver nitrate, as described in his Bakerian lecture to the Royal Society on November 24th, 1803. Prof. Dewar has just placed in my hands the identical slide, with the Newton rings still visible, which he believes Young to have used in this classic experiment.

Our modern photographic processes depend upon chemical changes wrought by light on films of certain sensitive compounds. Bitumen, under this influence, becomes insoluble in hydrocarbon oils, as in the heliographic process of the elder Niepce. Gelatine mixed with potassium dichromate becomes insoluble in water on exposure to light, a property utilised in the photo-etching process introduced in 1852 by Fox Talbot, some of whose original etchings have been placed at my disposal by Mr. Crookes. [Shown.] Chromatised gelatine now plays a most important part in the autotype and many photo-mechanical processes. The salts of iron in the ferric condition undergo reduction to the ferrous state under the influence of light in contact with oxidisable organic compounds. The use of these iron salts is another of Sir John Herschel's contributions to photography (1842), the modern "blue print" and the beautiful platinotype being dependent on the photo-reducibility of these compounds. [Cyanotype print developed with ferricyanide.]

Of all the substances known to chemistry at the present time, the salts of silver are by far the most important in photography, on account of the extraordinary degree of sensitiveness to which they can be raised. The photographic image, with which it is my privilege to deal on this occasion, is that invisible impression produced by the action of light on a film of a silver haloid. Many methods of producing such films have been in practical use since the foundation of the art in 1839. All these depend on the double decomposition between a soluble chloride, bromide, or iodide, and silver nitrate, resulting in the formation of the silver haloid in a vehicle of some kind, such as albumen (Niepce de St. Victor, 1848), or collodion on glass, as made practicable by Scott Archer in 1851. For twenty years this collodion process was in universal use; its history and details of manipulation, its development into a dry plate process by Colonel Russell in 1861, and into an emulsion process by Bolton and Sayce in 1864, are facts familiar to every one.

(To be continued.)

* For these and other details relating to Fox Talbot's work, necessarily excluded for want of time, I am indebted to his son, Mr. C. H. Talbot, of Lacock Abbey.

† *Photog. Journ. and Trans. Photog. Soc.*, June 15th, 1872.

The Photographic Club.—The subject for discussion on Wednesday, July 23rd, will be "Ceramic Photography"; July 30th, "Printing with the Salts of Chromium." Bank Holiday outing to Guildford.

Mr. R. Harris, of Sydney, writes that, wishing for a pinhole camera, he extemporised one rapidly simply by pressing a piece of black wax into the smallest stop which he was in the habit of using with his ordinary lens, and then making a small hole in the centre of the wax with a pin.

THE PHOTOGRAPHIC CONVENTION AT CHESTER.

The Report of the Photographic Club Delegates.*

The fifth annual Photographic Convention of the United Kingdom was opened at the Town Hall, Chester, on June 23rd with a conversazione given by the Mayor of Chester. Certainly the reception was a most cordial and hospitable one, and it is flattering to note that, in the opinion of a local newspaper, well capable of forming an estimate, "never before had so much artistic skill been employed in the decoration of the main corridor of the building as was brought to bear on the present occasion." After the formal reception by the Mayor of the members of the Convention, the retiring president, Mr. Andrew Pringle, in the presence of the members and guests, introduced his successor, Mr. C. H. Bothamley, who, in the course of his most eloquent presidential address, while admitting that no discoveries or inventions of far-reaching importance had startled the photographic world, pointed out what minor advances have been made. With regard to photography in natural colours, there are differences of opinion as to whether the results of Herr Verescz, of Vienna, which, it is understood, are founded on the experiments of Carey Lea, are in advance of those of previous experimenters; at any rate, so far we can only say, that the direction in which the solution of the problem is to be looked for is not yet apparent. No marked advance had been made in orthochromatic photography, and the general adoption of such methods is impeded by, among other causes, the fact that the commercial products upon which many have to depend do not at present represent the maximum possibilities of the methods. The appreciation of eikonogen and the introduction of guaiacol as developers were alluded to. The application of photography to science, the president did not hesitate to say, is the direction in which photography has won, and probably will win, its greatest triumphs, and he instanced the remarkable astronomical photographs of Mr. Ainslie Common, F.R.S., and Mr. Isaac Roberts, F.R.S. On the other hand, he deplored the fact that the number of competent investigators, apart from experimenters, was very few indeed, and strongly advocated the cultivation of scientific method, which could only be inculcated by long and careful training. Turning to the art aspect of photography, he pointed out how we have advanced in our knowledge of science and art since Mr. P. G. Hamerton's well-known criticism of the claims of photography to rank as a fine art appeared in 1873 in the *Portfolio*, and he agreed with those who would fix a limit to subjects which may be considered to come within the legitimate scope of photographic treatment. Lastly, after alluding to the efficient school of photography at Berlin under Dr. Vogel, and the splendid institute at Vienna under Dr. Eder, he advocated the development of a desire for better training, and the provision of means to satisfy the desire. Whether this could be brought about by founding a photographic institute would depend on whether it is founded on a right basis and conducted on right lines; but, after all, the future of photography would depend on the work of individuals, and every one must see to it that his own work is honest and thorough, and the best that he can do.

Our minds having been thus strengthened, the remainder of the evening was, with a clear conscience, devoted to indulgence in the Mayor's hospitality, the admiration of lantern pictures illustrating former conventions, and to general sociability. The apparatus was scanned with attention, especially the splendid photo-micrographic instrument constructed for the Royal Veterinary College by Messrs. Swift.

Tuesday—a glorious photographic day—was well spent in excursions (1) to Little Moreton Hall, unfortunately in process of necessary repair, but one of the finest examples of half-timbered, moated mansions in the country; (2) to Llangollen, and by the valley of the Dee to Berwyn and Valley Crucis Abbey. The Photographic Club was well represented at both places, and you will no doubt see them fully illustrated. The first business of the evening was the presentation of the report of the Committee on Lens Standards, which was prefaced by a lucid explanation by Mr. Haddon of the means taken to arrive at a decision. The report recommends the adoption of the Photographic Society's Standards, with some few additions in the nature of amplification and explanation. It is satisfactory to note that there was no opposition expressed to the standard diaphragms, which, since they were first recommended, have been very extensively adopted, and now seem to be well established; but with regard to the flanges, it was evident that that portion of the report did not commend itself to those opticians who have been manufacturing lenses with mounts screwed to a different gauge, and who naturally consider the matter in the interest of those who use such lenses, and of which many thousands are stated to have been issued. In view of the fact that the decision of these opticians to abide by their own gauges had not been brought before nor considered by the committee, it was proposed and carried that the report be once more referred back to the committee, in order that they may confer on this point with the opticians and with the Photographic Society of Great Britain committee. The only point now in dispute is whether the standard flanges should be 1 inch, 1·5 inch, 1·25 inch, 1·75 inch, 2 inch, 2·25 inch, &c., with 24 threads to the inch, as recommended by the committee, or whether the 1·5 inch and the 2 inch should be superseded by the 1·52 inch with 32 threads, and the 2 inch with 30 threads at present in use. But whatever the final result may be, the Convention may fairly be congratulated on having aroused the opticians to a sense of the importance of coming to some agreement on this question, which is one that more or less affects all users of lenses.

Mr. Gambier Bolton, in his paper, "Animal Photography: Its Difficulties, Uses, and Abuses," told us of the trials he encountered in securing scientific and artistic qualities in zoo-photography; how he succeeded in giving, with the expenditure of from thirty to fifty plates, the exposure of two seconds, which was necessary to show the object in all its detail, on an animal which was never still for an instant. He considered that instantaneous exposures were of little or no use, and was severe on detective camera animal photographers, though he would admit the occasional use of a hand-camera with twin lenses. The perfect animal photograph should have had sufficient exposure to bring out all possible detail in the hair or feathers, and in the shadows; should be full of life, yet unrestrained; natural in position and expression (not as a man would look who had just sat down on the business end of a tin tack); all four legs and the tail should show distinctly, and the mane, if any; nostrils, ears, eyes, and the hairs round them should be microscopically sharp. He urged on photographers, especially those who travel, the importance of securing faithful, scientific, and artistic representations of birds or animals which are either rare or fast becoming extinct, and implored them not to waste plates on such childishly easy subjects as swans, deer, cattle, and sheep. Mr. Bolton then illustrated his paper by lantern pictures, first showing the kind of representation to be avoided if results of any permanent value were aspired to, and then his own pictures showing the way to do it. These proved to the satisfaction of his audience that the immense patience and perseverance he had exercised had not been in vain, and went far to justify his own estimate of their importance and scientific value.

The next paper was an important essay by Mr. Philip H. Newman, entitled "Imagining and Imaging," which proved to be an attack by an experienced art critic from the conventional standpoint on the doctrine and dogmas of Mr. P. H. Emerson, contained in his "Naturalistic Photography." It is comforting to find at the outset the rival combatants agree in paying tribute to photography as an art, and in admitting its claims to be a legitimate means of artistic expression. The combat seems mainly to resolve itself into one of mere words. Each sees individuality in Van Eyck's "Jean and Jeanne Arnolfini," though the one calls it conventionalism, while with the other it is the absence of that quality. Perhaps Mr. Newman's strongest point is where he charges Mr. Emerson with not permitting the freedom to others he takes himself, especially when he is taken at his word and his principles judged by his own works, though it must be observed that they can shake hands when treating of the expression of detail by photography, and pre-

* Read before the members of the Photographic Club, June 9th, 1890.

sumably also on the questiou of composite photographs, nothing belng said on this latter subject. As these two last are the points which have most agitated photographers, and as the treatment of historical aud mythological subjects is by common consent determined to be beyoud the range of legitimate photography, we, as spectators, canuot but feel that Mr. Emerson's positiou is, on the whole, not materially weakened by this clever onslaught.

The annual meeting of the members was held on Wednesday morning, when it was resolved that the next Convention (1891) be held at Bath. It having been generally felt that provincial members should, in the interests of the Convention, be more largely represeuted on the council, an alteration of rules was made to the effect that the council shall consist of forty members, of whom not more than twenty shall be London members, and five members from the locality where the Convention shall be held in the following year. Power was also given to alter or amend the rules at any special general meeting called for the purpose. In spite of the rain, most of the members proceeded by steamboats up the river Dee to Eaton Hall, where they assembled on the terrace and were successfully photographed, in the face of the adverse conditions which still prevailed, by Mr. Watmough Webster. In the evening the President (Mr. Bothamley) explained that the detailed results of his receut experiments with rhodamin would be deferred until they are more complete than he has at preseut had time to make them. Mr. Paul Lange then gave an interestiug account of a recent visit to Norway, interspersing it with valuable hints to intending visitors, and illustrating it by a number of fine lantern pictures taken with a hand-camera.

On Thursday the excursious were to Couway and up the valley of the Conway River as far as Llanrwst aud Trefriw. The weather during the day was all that could be wished, and your delegates deterumined to join the Trefriw party. Each started with the impression that the other had found salvation through Mr. Gambier Bolton, F.Z.S. Imagine, therefore, their mutual surprise when, easting away their crowns, they found themselves childishly hurrying after a trivial group of cattle, which they suddenly resolved to image. This trip into North Wales involved the loss of the evening's papers, the first being the report of the Committee ou Weights and Measures drawn up by the president. The feature of the report is that it recommends, in dealing with formulæ, "a method which is independent of the system of weights and measures used, provided that the relation of the unit of weight to the uuit of measure is the same as that which exists between the gramme and the cubic centimetre, or the ounce and the fluid ounce." It is recommended that formulæ should give the number of parts of the constituents by weight or measure, to be contained in some definite number of parts by measure of the solution. The mixture can then be made up according to the unit selected, either in (1) grammes and cubic centimetres, or (2) graius and fluid grains, or (3) ounces and fluid ounces. The report, we understand, was well received, and, without dissent, adopted.

Mr. Andrew Pringle's "Record of Photo-micography" pointed out the difficulties that had been encountered in rendering baeteria ou account of their colour. This difficulty had led more than one eminent bacteriologist to abandon the use of photography for the purpose ; colour-correct photography, however, is now removing this stumbling block of the earlier workers. Reviewing the optics of the subject, he pointed out the advantages derived from the immersion system, and from the later Zeiss objectives, aud looked for the time when every candid investigator would employ photography, the ouly scientific method of delineation.

Mr. Friese Greene's paper, "Suggestions," was, at his desire, taken as read. He exhibited his magazine camera ; but, owing to some hitch in the optical arrangement, he was unable to show the results on the screen to his satisfaction.

On Friday mauy of the members might have been seen with their cameras busily securing reminiscences of Chester architecture, ancient and modern, the projected excursion to Liverpool beiug evidently considered less attractive. Later in the day Hawarden Castle was the object of attraction.

The annual dinner at the Grosvenor Hotel, at which about sixty members were present, happily completed the programme.

The Chester Conveutiou of 1890 was thus practically brought to an end, and although, perhaps, the number of members from the Chester district was uot so large as might have been desired, there was no question as to the success of the meeting. All who did attend, we cannot but feel are considerable gainers both meutally and physically. It is one thing to attend such a meeting and have the events indelibly impressed on the memory; it is quite another thiug to read or, perchance, merely skim the papers as they appear in the journals, or to listen to such an imperfect report as can be brought before you on an occasion like the present. It is good to be in a position to exercise our own iudividual judgment on the interesting matter put forward for consideration, and thus to bring our influence to bear to direct the future course of the development of what, at present, are little more than the germs of photographic knowledge. In photography less, perhaps, than in most other pursuits, can any one afford to take up an entirely independent position. Each must recognise the principle of inter-dependence, and it is for these reasons that we would urge you to support the Convention, seeing that it has no other aim or claim to encouragement than in so far as it tends to advance the interests of our chosen occupation.

THE EXHIBITION OF THE PHOTOGRAPHIC SOCIETY.

THE hon. sec. to the Photographic Society, Captain A. M. Mantell, R.E., announces that the next Exhibition of the Society will be inaugurated by a conversazione, open to members and their friends, at 8 p.m., on Saturday evening, the 27th of September, and that the Exhibition will remain open daily (Sundays excepted) from Monday, the 29th September, until Wednesday, the 12th of November; admission (from 10 a.m. till 5 p.m.) one shilling. It will also be open every Monday, Wednesday, and Saturday evening; admission (from 7 to 10 p.m.) sixpence. Members have free admission at any time, and will be supplied with tickets to admit their friends.

Medals will be placed at the disposal of the judges for artistic, scientific, and technical excellence of photographs, and for lantern transparencies and apparatus, and the following are the judges: Capt. Abney, R.E., C.B., D.C.L., F.R.S., Valentine Blanchard, W. England, J. Gale, Henry Moore, A.R.A., H. P. Robinson.

A copy of the regulations may be obtained on application to the assistant-secretary.

Foreign exhibitors are specially invited to contribute. The Society will pay the carriage of photographs one way, and provide frames during the exhibition for photographs approved by the judges. There will be no charge for wall space. Exhibits sent in packing cases (carriage paid) must be addressed to the "Photographic Society of Great Britain," care of Mr. James Bourlet, 17, Nassau Street, Middlesex Hospital, London. Packing-cases must arrive not later than Monday, September 15th ; they will be too late if received after that date. No packing-cases can be received at the Gallery. Exhibits (including pictures, negatives, transparencies, lantern slides, apparatus and appliances) sent by hand will be received at the Gallery, 5A, Pall Mall East, on Monday only, September 15th, until 9 p.m. Delay will prevent exhibits coming under the inspection of the judges.

Lantern transparencies sent in competition for a medal, not less than six, should be fitted (removable) in a frame

to stand upon the table, and it is desirable that duplicates be sent for exhibition in the optical lantern. They will only be eligible for award when both the negatives and slides are the work of the exhibitor. Photographic lantern slides will be shown with the Society's optical lantern during the Exhibition. The loan of slides for this purpose is invited; they must not exceed 3¼ inches in height, and, to enable the committee to select and arrange them, must be delivered at the Gallery not less than one week before the evening of their being shown in the lantern.

It is to be distinctly understood that the sending of exhibits signifies acceptance by the exhibitor of the decision of the council upon all matters connected with the Exhibition as absolute and final. The council do not hold themselves responsible for any damage that may happen to the pictures or other exhibits whilst in their custody, but they will take every precaution to insure their safety and prompt return to the owners at the close of the Exhibition. To avoid damage to frames, exhibitors are requested to have sunk backboards to their frames, with the fastening nails not projecting, and the whole covered with thick brown paper. The regulations as to the removal of exhibits can be had on application to the assistant-secretary, Mr. Edwin Cocking, 5A, Pall Mall East, London, S.W.

UNIFORMITY IN LENS MOUNTS.

Considerable interest is now being manifested in England in regard to an uniform system of mounting lenses, to be adopted by the different lens makers. For many years the microscopists have had the comfort and great advantage of the so-called society screw for their objectives. This society screw has a thread which is of such a character that an objective bought of any maker will always fit upon the tube of a microscope already fitted with objectives made with this screw. As a consequence, no extra fittings or adapters are necessary, and every microscopist can use a lens of any other maker than the one he already possesses, without having to make special changes for the purpose.

This same idea is now being discussed in regard to photographic lenses. It is argued that all photographic objectives of the same lens diameter, or even slightly smaller, could be fitted in mounts having screw-threads working into the same flanges for all makers. At the present time even lenses of the same diameter will not fit into the flange if they are made by different opticians. What a comfort and convenience it would be if all lenses, say from 6½ by 8½ down, had screws that fitted into one flange, and that every make of lens of these sizes, 6½ by 8½, 5 by 8, 5 by 7, 4¼ by 6½, and 4 by 5, could all be used with one flange. At the present time, if one wishes to use a different size of lens within the above limits, there are only two clumsy and troublesome methods available. First, to have as many separate front boards fitted to your camera as there are lenses you wish to use with it; or second, to use a series of brass adapters, one for each lens available for the camera. The first method is clumsy in the extreme, the extra front boards always being in the way when packing the lenses for transportation or storing them for safe keeping. The second method, while less objectionable than the first, is very expensive and troublesome after the adapters have been made. What is wanted is a series of screw-threads of such a standard character that every lens maker can use them, and with one screw for a series of lenses. Of course it would be out of the question to have one mount for all lenses. But two or three lenses, that differ only slightly in diameter, could be fitted with threads that all screw into the same flange. For example, lenses covering 11 by 14, 10 by 12, and 8 by 10 plates could all be made to fit into a flange that carries an 11 by 14 lens tube; and lenses that are smaller than 6½ by 8½ could all be fitted with threads to fit into a 6½ by 8½ flange. Perhaps these might be divided differently, and the 8 by 10 and lower sizes could be separated into two groups; but this is a matter of detail for the opticians. What we need is a series of screw threads and flanges so arranged that several lenses of nearly the same size will fit one flange, and every lens of the same size made by different opticians will fit the same flange.

Yet another source of annoyance, especially to the travelling photographer, is the tripod screw. Up to the present time there seems to be no easy method of securing the camera upon the tripod except the screw, and every camera manufacturer seems to take a special delight in making every new camera box with a new plate having a thread that is different from every other tripod screw ever before made, and especially different from that of any other maker. There are no other manufacturers using screws that have such an apparently unnecessary diversity of those exceedingly useful means of securing parts of apparatus together. And the time has come when those who will pay attention to these matters and the wants and needs of those that use their wares, will succeed and prosper, while those who do not will most certainly be ignored.

What we need is uniformity in the mechanical parts of photographic apparatus, uniform and simple lens mounts, uniform and correct diaphragms, and uniform tripod screws. And we are very glad to note that such men as Dallmeyer, Ross, Beck, and others are trying to come to some agreement in the matter as far as lenses are concerned. We also hope that American opticians will see that it is to their interest also to take the same action and let us have an international system.—*Anthony's Photographic Bulletin.*

Non-actinic White Light.—Dr. E. Liesegang says, in the *Photo Archiv*, as translated for *Wilson's Magazine*, "The expedient of covering a window with a fluorescent solution of quinine sulphate has not proved sufficient to keep out all actinic rays. This is better accomplished thus:—It is known that an aqueous solution of three parts green chloride of nickel, and one part red chloride of cobalt, is colourless by transmitted light, and quite clear when dilute. The two colours are complementary, and completely neutralize each other. Hence the light passing through the mixed solution has no effect on the salts of silver. Although it is quite white it is perfectly non-actinic, and does not any longer affect the sensitive film. To completely neutralize any possible rays in the ultra-violet, another glass is coated with a solution of quinine sulphate in collodion somewhat acidified with sulphuric acid. The quinine cannot be used in the same solution because it is precipitated by the cobalt salt. As the cobalt chloride, red when containing water, becomes blue when free from it, the mixture must not be allowed to dry. It may be made with gelatine and glycerine, but even a high temperature around the window may dry it. Silver paper which was left exposed for a week behind a thin layer of the cobalt-nickel solution thus prepared, did not show the slightest alteration. I have not as yet experimented with plates, but with sufficiently concentrated solution these also should not suffer change."

PHOTOGRAPHIC ESTABLISHMENTS.

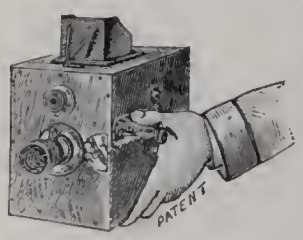
THE London Stereoscopic Co. invited newspaper repretatives and others to visit their new premises at 106, Regent Street, London, last Monday. At the top of the premises they have a special studio for those who will give any amount of time for the obtaining a likeness with the best possible resnlts. It has none of the artificial furniture sometimes used in studios, and is intended for those who will give the photographer a fair opportunity of doing the highest work, without taking turn in a hurried manner with a waiting crowd of sitters, and who will remnnerate him accordingly.

In the developing rooms they have the electric light with glow lamps, and two-way switches for obtaining light from the lanterns or for illuminating the room at will.

In one of the dark rooms is a little piece of apparatus by Mr. Fletcher, for obtaining nearly boiling water in five minutes, or less warm water in a shorter time. The chief merits of it are, that it is of small compass, and all the parts are under the observation and within the reach of the possessor, so that if any parts get out of order they are not boxed up so as not to be available for immediate repair.

With one of the cameras on the premises the operators can take portraits measuring 30 inches by 24 inches direct.

A novelty, just introdnced by the Company, is a quarter-plate "artists' camera," measuring exteriorly 6 inches by 5 inches by 4½ inches, strongly made, so that it looks as if it might stand a kick anywhere without damage. The lens works at $f/5\frac{1}{2}$; it has a large finder, and a shutter to give varions speeds at will. They have also a new camera with twin lenses for stereoscopic work, and photographs taken with it were exhibited at the Photographic Convention at Chester by Mr. Gambier Bolton.



Mr. Edgar Clifton has charge of the amatenr-teaching branch of the bnsiness, and we hope that he will write a book abont his experiences. Mr. Humphreys is in charge of the business section of the amatenr department. The Company has been awarded a certificate of merit by Ally Sloper.

Mr. Friese Greene has just opened new stndios at 162, Sloane Street, London, and a day or two ago invited the press and others to inspect them. Afternoon tea was served and carried round among the guests by two waiters dressed as English gentlemen of the Garrick period, with powdered hair and everything complete. The varions storeys of the bnilding are fitted up in artistic style, and Mr. Greene advertises that they are "open as an exhibition and a lonnge between the honrs of three and five."

He has a good artist in oils constantly engaged upon the premises—Miss Kate Pragnell, who is well known in Bath and the West of England, who recently illustrated the catalogue of paintings in the great private collection of Sir Greville Smith, of Ashton Court, Clifton. Her photographic colouring is executed in snbdned colonrs, and with artistic skill. She says that she finds that celluloid will not bear loading with oil colours, also that Mr. Greene's opal cards will bear such treatment; this resnlts in the exhibition of two classes of coloured photographs.

A SUPPLEMENT TO THE "PHOTOGRAPHIC NEWS."

ON the sixteenth of August we shall issue as a supplement a highly artistic photo-etching of the house of the late Charles Kingsley, at Eversley, photographed from a painting. As this jonrnal is usually kept by its subscribers for binding, we recommend them not to part with their copies until they are snre that they can get others.

Correspondence.

WEIGHTS, MEASURES, AND FORMULÆ.

SIR,—In your issue of the 11th inst. Mr. Warnerke inveighs against the report of the Convention committee on weights, measures, and formulæ, and since his letter is a most extraordinary, though doubtless unintentional, misrepresentation of the report, I will ask you to allow me to reply.

Mr. Warnerke says: "We learn (what was not generally known) that the apothecaries' ounce of 480 grains, after all, is not legal, and that the legal one of 437·5 grains is divided into 480 parts, which greatly increases the already inextricable chaos." Why "after all"? The avoirdupois ounce of 437·5 grains has been the only legal ounce for ordinary buying and selling in this country for many years; no special apothecaries' ounce has been included in the *British Pharmacopœia*, at any rate since 1864, and if these facts were not generally known to photographers, they were, of course, well known to everyone really acquainted with the English systems of weights and measures. How can a state of things which has existed for more than a quarter of a century fairly be said to "greatly increase" anything at this time of day, and is it not desirable that, in discussing a scientific question, we should avoid applying such extravagant terms as "inextricable chaos" to the comparatively simple problem of distinguishing between an avoirdupois ounce and a troy ounce, a gram and a minim? Mr. Warnerke obviously does not fully recognise the difference between the mode of division of the ounce and that of the fluid ounce.

We never said that the metric system was exclusively used for scientific purposes, because that would not be true. In certain branches of applied science the English units are constantly used.

We are charged with throwing a gratuitous insult at the heads of thousands by stating that photographers are not intelligent enough to understand the metric system! We never said anything of the kind. We did state that "a knowledge of decimals sufficient to enable a decimal system to be used easily and accurately is by no means so widely diffused as is desirable," but that is a very different thing from what we are asserted to have said. The statement is unfortunately quite true; we did not make it without first being sure that it was in accordance with the facts; and we did not limit it to photographers, because it applies to all sorts and conditions of men.

We are also charged with trying to impose on photographers two systems of weights and measures, "the metric, and a modified one, in which ounces and grains differ from the old ones (they are divided into decimal parts) forgetting that 'photographers do not possess the knowledge of decimals sufficient to enable a decimal system to be used easily and accurately.'" In the first place, Mr. Warnerke puts between inverted commas, and passes off as a sentence from our report, a statement which does not occur in it at all. In the second place, the ounces and grains which we speak of are not new; they are the same ounces and grains that we have been using for years and years. Neither is the use of decimal parts of grains and ounces in any way a novelty; it has been the practice in many chemical laboratories, and with some photographers for a long time. Surely Mr. Warnerke does not share the common misbelief that a decimal system is inseparable from the metric system, and that metric units are the only units which can be or are used decimally? Finally, in

this connection, we make no attempt to impose any units on anybody; we recommend no new units. We do recommend that certain sub-units in fluid measure should *not* be employed; and we endeavour to show how well established and familiar units can be used in the simplest and most intelligible manner.

Mr. Warnerke's grievance against us, obviously, is that we did not insist on the adoption of the metric system pure and simple. Several of us, like many other scientific men, whilst fully recognising the advantages of a decimal system, are by no means so enamoured of the metric units as Mr. Warnerke seems to be. The committee endeavoured to recommend a scheme which should, in the first place, be practicable, and in the second, likely to secure general adoption.

We regard our recommendations relating to formulæ as the most important part of our report. It seemed to us to be undesirable to insist upon the adoption of any particular units, and it is quite of secondary importance whether any individual chooses to use in his own practice ounces, or grains, or grammes, so long as his units satisfy the condition of relation between weight and measure which we specify, and provided always that he expresses his quantities or formulæ in "parts" when he wishes to communicate them to others. The fact that our recommendations as to formulæ are quite independent of the particular units employed seemed to us to be one of their strongest claims to general favour and acceptance.

The whole of the concluding and longest paragraph of Mr. Warnerke's letter has very little bearing on the question under discussion; it certainly has no foundation on anything contained in the report of the Convention committee.

C. H. Bothamley.

AN ELECTROSCOPIC MIRROR.

Sir,—An experimenter has seen occasion to arrive at the conclusion that, under certain attainable conditions, and by the employment of a conducting wire of a selected metal—the same to be *flattened out at each end into a highly-polished mirror-surface*—it becomes possible to transmit to a distant station the perfect image of any face, picture, or document thrown, under a proper arrangement of light, upon the transmitter. This may, possibly, be true; but it remains to be demonstrated. ———.

Clifton.

[Because of a pencil note on the original, we are not sure whether the writer intended this to be published with his name attached, so omit his name.—Ed.]

EALING PHOTOGRAPHIC SOCIETY.

Sir,—A meeting of the above Society will be held at the Victoria Hall, Ealing, on Thursday, the 24th inst., at 8 p.m., to approve the rules, enrol members, and elect officers for the year. I am instructed by the provisional committee to invite the attentance on that occasion of all those who are interested in the subject. H. W. Peal.

2, *Craven Terrace, Ealing, W., July 15th.*

German Amateurs.—A German amateur states that he has made excellent portrait photographs in his garden, even in high winds and on rainy days, by using a large white umbrella, such as is used in out-door sketching, to control the light and act as a curtain. He also uses a reflecting-screen made of light muslin, stretched upon a rigid wooden frame. One of the worst stories yet of the budding amateur is told by a German journal. The youth in question wanted some 9 by 12 cm. plates. The dealer to whom he went, having none in stock, gave him a package of the next larger size, telling him he could cut them down to suit—this, by the way, is also somewhat characteristic. The amateur forthwith went off to a neighbouring glazier's shop, unwrapped his plates, and had them cut down to the proper dimensions in the ordinary daylight of the shop. He then repacked them, took them home, and filled his plate-holders in his dark room. Strange to say, those plates turned out almost the worst cases of fog he had ever seen.—*Wilson's Photographic Magazine.*

Proceedings of Societies.

London and Provincial Photographic Association.

At the weekly meeting on the 10th inst. Mr. T. E. Freshwater occupied the chair.

Details of a lantern slide competition to be held during the lantern season were discussed. It was decided that the conditions of the competition should be similar to those of the last one held, three negatives to be selected, each competitor to have them in turn. The slides may be made by any process, one set of slides from each competitor to be an exact reproduction of the negative, without dodging, or masking, or addition of skies.

At the request of the members, Mr. A. Cowan promised to bring some quarter-plate negatives to the next meeting for selection.

A member said that after toning, fixing, and washing prints on gelatine paper, in some instances the surface of the prints became very tacky, and if touched a part of the image would adhere to the fingers. Could any member state the cause of this?

Mr. A. Cowan suggested as a remedy putting the prints in an alum bath for a short time.

Mr. H. M. Hastings showed two prints on Hardcastle's platinum paper printed out.

Replying to a query whether drying negatives with alcohol increased their density, Mr. J. J. Briginshaw said that some time ago Mr. A. L. Henderson showed some results of experiments he had made, which proved the affirmative.

Mr. W. E. Debenham said drying negatives quickly with heat would have a tendency to increase their density.

Mr. W. H. Harrison described a simple photo-mechanical process for printing coloured designs. Orthochromatic plates are used, and an exposure made to suit each colour; the remainder of the design on each plate is then blocked out and the negative printed on a collotype plate. A separate plate is used for each colour in the design.

The subject for discussion on the 24th will be "Printing through Coloured Media."

Photographers' Benevolent Association.

A committee meeting was held at 4, Great James' Street, Bedford Row, on the 11th inst., Mr. W. Bedford chairman. Messrs. R. P. Drage, G. C. Audsley, and P. J. W. Wapp were elected members. Votes of thanks were passed to the Mayor of Chester for allowing the boxes to be placed in the Town Hall, also to Mr. Briginshaw for his kind help. A vote of condolence to Mrs. T. J. Collins was passed on the death of her husband, who had always been to the fore in helping the Association, of which he was the deputy-chairman. The money collected at the convention was £2 1s. 7½d. The committee trust that employers requiring assistants will write to the hon. sec., as there are numerous persons on the books requiring situations.

Croydon Camera Club.

On Thursday, July 10th, a meeting was held at the Public Hall, Mr. G. R. White in the chair. A vote of thanks was accorded to Mr. A. H. Smee for allowing the members to have an excursion to his estate at Wallington.

The Secretary read a financial statement showing that the affairs of this young Club are in a highly satisfactory condition.

Mr. De Clercq notified the council's views and decision in reference to acquiring a permanent home for the C. C. C. From his statement it appeared that the council had in contemplation the acquisition of premises situated at 56, George Street, Croydon, as being in every way suitable for the purpose.

The Secretary proposed and Mr. Cheshire seconded a resolution approving the decision of the council. After a few remarks in favour of the scheme by Mr. Alfred Underhill, the assistant secretary, the resolution was carried unanimously, and the Secretary was authorised to call a special general meeting on July 16th to take possession of the rooms.

The premises consist of one large room which will be used

as a club room for meetings, demonstrations, and lantern exhibitions; there are two smaller rooms, one of which will be used as a store room, and the other as a dark room fitted with every convenience and appliance. The council will allow the club to be used by tourists, cyclists, and others.

The assistant secretary (Mr. A. Underhill, 23A, Clarendou Road, Croydon) will be glad to receive the names of candidates who intend joining, or to give any required information.

HACKNEY PHOTOGRAPHIC SOCIETY.

THE ordinary meeting was held on Thursday, July 10th, at Morley Hall; the chair was occupied by Mr. C. F. HODGES.

The SECRETARY reminded members that the monthly outing would be on the 19th, that a competition would be held in November, and that Messrs. H. P. Robinson and J. Traill Taylor had consented to act as judges.

Mr. CARPENTER handed round some negatives which had holes iu the films.

Mr. ACRES said that they were air-bells, arising iu development.

Mr. HODGES said he had found that with rapid exposures he was troubled with them.

Mr. ACRES said that it was through the developer being too strong.

Mr. BIRT ACRES then read a paper on "Exposure and Development." He said that he did not altogether agree with exposure tables, and explained that exposures varied, and gave as an exaunple the angle of 45°, when the exposure would be increased one half, and if at right angles it would be trebled. The lecturer advocated the backing of plates with either burnt sienna or Bates' black. He preferred dull weather when photographing on glass. Some people complained of not beiug able to develop isochromatic plates through their foggging by red light. Mr. Acres said the fogging was geuerally caused when the plate was held up to the light. He made two very interesting experiments, one of which was as follows: Taking an isochromatic plate, he made a positive by exposing the negative for thirty seconds to the ruby light of the screened candle; the result was an exposure. The other experiment was that the development was carried on by white light, the only change being that he held the developing dish above the light. There was no fogging with either of these plates.

Various questions were asked by Messrs. Hodges, Heusler, Capel, Poulson, and the Secretary, to which Mr. Acres said that soure makers would back their plates if a sufficient number were ordered, that plates ranged generally from 16 to 25 on the sensitometer, and that he preferred as large a stop as compatible with good definition.

DR. LIESEGANG, in *Photo. Archiv*, states that he has utilised the known fact that the sensitiveness of silver salts is affected by pressure in making prints. Any relief, such as a Woodbury-type on glass, is pressed upon the paper under a sheet of glass. Naturally the highest parts of the relief make the strongest impressiou, the paper under them becomes less sensitive, and on exposure to light a negative of the subject is obtained.

FLASH-POWDER.—We learn from our exchauges that a new flash-powder has been worked out by Dr. James Taylor, of the United States Department of Agriculture, which is obtained from the down of the milk weed couverted into charcoal, and which is said to be almost entirely free from ash, aud to burn with a remarkable freedom and rapidity, and it is expected that this new substauce uay largely supersede many of the daugerous flash compounds now in use.—*Anthony's Bulletin.*

RECEIVED.—The first number of "The Gentlewoman," an illustrated journal. Under the heading "Art and Artists," is chronicled what is called "another artistic advauce iu photography," and the following are the terms in which it is spoken of:—"Mr. Vanderweyde is now producing what he terms 'Diaphanous Effects' in his new daylight studio, which apartment is built on entirely new principles as an addition to his famous electric light studios in Regent Street. Mr. Vanderweyde secures, under the most novel conditious of lighting by means of patented appliances, a subtle atmospheric and truly diaphanous effect never before attained. The results are extremely beautiful and artistic, and this new invention lends tself most delightfully to portraits of ladies and childreu."

Answers to Correspondents.

All Communications, except advertisements, intended for publication, should be addressed to the Editor of the PHOTOGRAPHIC NEWS, 5, Furnival Street, London, E.C.

All questions requiring a reply in this column should be addressed to Mr. John Spiller, F.C.S., 2, St. Mary's Road, Canonbury, London, N.

All Advertisements and communications relating to money matters, and to the sale of the paper, should be addressed to the Publishers of the PHOTOGRAPHIC NEWS, Messrs. Piper & Carter, 5, Furnival Street, London.

W. D. B.—*Preparation of the Nitrate from Old Silver.* There are two methods of working: either to evaporate the mixed nitrates to dryness, and heat to incipient fusion, whereby the copper salt becomes decomposed, and converted into the insoluble black oxide; or throw down the silver as chloride, wash until free from copper, and reduce to pure metal by fusiug the dried chloride with three times its weight of dry carbonate of soda. If you intend to use the nitrate of silver only for printing, the first plan will be found to answer; but, for the better purposes, it is always safer to go the length of purifying the silver in the way mentioned, and then dissolve this again in pure nitric acid.

E. O. C. (Boston, U.S.A.).—*The Photogravure Process.* Dr. Gunther, in his letter of the 20th of Juue, was merely quoting from the two German periodicals, *Deutsche Photographen Zeitung* (Berlin), and *Photographische Correspondenz* (Vienna), the first containiug a practical article by E. Kiewning, and the latter one by Rudolf Maschek. Both of these separate numbers can be obtained by applying to their respective publishers. Mr. W. T. Wilkinson's manual is out of priut just now; enquire of Messrs. Eugland Brothers, Charles Street, Notting Hill, London, W., for a new edition is said to be in the press; but a brief report of Mr. Wilkinson's mode of working the photogravure process was published in the NEWS of March 28th last, page 237.

G. F. W. (Erith).—*Alpha Paper Developer.* Without experimental trial it is difficult to give an eikonogen equivalent for the ferrous oxalate developer you now use. You speak of the "complication" of formulæ in cubic centimetres and grammes, but nothing can be simpler, remembering that one c.c. of water weighs a gramme. Take them as *parts or units* by weight and measure, and then all will go right, whether the English or Continental system be adopted.

J. W. (Leeds).—*Seed's Developer for Dry Plates.* This was given in the NEWS of March 15th, 1889, top of page 170, as follows:—

No. 1.—Sulphite of soda	...	...	...	1 ounce
Water	...	...	...	8 ounces
No. 2.—Carbonate of soda	...	...	...	1 ounce
Water	...	...	...	8 ounces

Normal developer, No. 1, $1\frac{3}{4}$ ounce; No. 2, $\frac{1}{4}$ ounce; pyro, dry, 4 grains.

H. H. B.—(Reading).—*Toning of Aristotype Paper.* Your difficulties are increased by the unscientific practice of toning and fixing in the same bath. Why not separate these processes, using a borax or sulpho-cyanide toning bath, and fixing with hypo as usual? We have heard several complaints of late about the muddy tones given by some samples of this paper, but treated as proposed the defects may be to a cousiderable extent obviated. See Mr. H. O. Hughes's article in the YEAR-BOOK, page 111.

L. N.—*Fixing Prints with Chloride of Magnesium.* The strength of solution does not appear to be a matter of very great consequence, provided that enough is employed to dissolve out all the chloride of silver. We have searched the journals for several months without finding any specific formula for a fixing bath made with this new agent. Probably two baths in succession would be best.

M. P. S.—*Judges at the Forthcoming Exhibition.* From the list of persons nominated, we were led to infer that the Royal Academicians would be in the majority; but with Mr. Henry Moore in association with six of the most talented art-photographers of the day, we may still say that it would be impossible to empanel a better jury.

THE PHOTOGRAPHIC NEWS.

PERMANENT HISTORICAL PHOTOGRAPHS.

THE production of small photographs for historical purposes in such a manner that they are likely to resist the attacks of deteriorating influences for centuries, is a problem which well deserves the attention of the photographic world. Many years ago we gave a considerable amount of attention to the problem, and came to the conclusion that one good method was to cement with heat a collodion transparency between two plates of glass, by means of a resinous substance not likely to crack or otherwise deteriorate with lapse of time. In short, the idea was to preserve the photographic film like a fly in amber, and between two sheets of glass. The insects found in amber lived ages ago, and most of them belong to now extinct species. In those early times many an unfortunate insect, while crawling upon a hot day beneath the shade of certain pine trees, particularly the *pinites succinifer*, found itself entombed for ever in a mass of resin which had fallen from above as an exudation from the tree. The essential oil in the resin slowly evaporated in course of time, the resin itself hardened correspondingly, and the body of the insect became so protected from the ravages of time as to be preserved through geological periods.

On this principle we once set to work to make a kind of artificial amber so far as properties were concerned, that is to say, a transparent, resinous cement, free from volatile oil. A sample of pure and old Canada balsam was taken, and placed for several days in an oven with the door open, to slowly drive off the essential oil without the application of much heat; it was stirred occasionally during the operation. Afterwards a few drops of castor oil were added to the melted balsam, and well stirred in; care was taken not to add too much castor oil, otherwise the mixture would not have become sufficiently hard when cold. When the proportions—which must be discovered by the system of trial and error—are nicely adjusted, the mixture when cold is somewhat tough, and not so brittle as amber. Castor oil is not a volatile oil, and may almost be classed with the drying oils, for after the lapse of great length of time a thin layer of it will dry into a film. The mixture just described is virtually a tough resin, practically free from volatile matter.

A plate of iron, with short, firm legs and some minute gas jets a little below it, was then taken, and some sheets of smooth blotting-paper laid thereon, so that the transparency should not come into direct contact with the hot iron. The heat was regulated by means of small taps governing the gas flames; too much heat discoloured the resinous mixture, and gave the transparencies a yellow tinge. The transparency was laid face upwards on the blotting-paper, and when it became sufficiently hot some of the melted prepared balsam was dropped upon it; the warmed covering glass was then laid upon the balsam, and the excess of the latter worked out at the edges of the two plates by means of thickly gloved fingers. Air bubbles were troublesome, but with patience could be worked out; this was all the more practicable because plates larger than the lantern slide size were not employed. Uneven glass was troublesome and sometimes useless for the purpose; patent plate, or other glass with a truly plane surface, should alone be used.

The hot iron arrangement was not a good one for working always at uniform temperature, or for yielding a steady heat. A better plan would be to use a brazed rectangular vessel of copper, filled with olive oil and with gas jets beneath; a thermometer with its stem projecting from the oil bath would serve as a guide to the temperature, and the manipulations should be performed on the upper copper surface of the bath.

The operations already described were performed by us about a quarter of a century ago, in the old collodion days, and the various portraits—heads and busts only—thus preserved were altogether unchanged, so far as memory could be trusted, when we saw them last, upon turning out the contents of an old box a year or two back. One of the portraits thus preserved was that of Faraday, and it is probably the most life-

like and interesting one of him at present in existence; another was a likeness—and not a flattering one—of Professor Tyndall. The two collodion transparencies were originally obtained from two professional photographers, who furnished them to us at the request of Professor Tyndall.

When Mr. York photographed the last of the quaggas, little did he think that he was earning immortality for his name, and causing it to be emblazoned for ever in the annals of zoological science, just as would have been the case with another man had that other person been the only one to photograph the last living dodo. Mr. York has five negatives of the quagga, and it is desirable that positives from them should be made as soon and as perfectly as possible by the most permanent process available, and one yielding abundance of delicate detail. On considering these points, it will be seen that much is to be said in favour of the method just described, and that it is one which deserves the attention of the historian and the antiquarian.

Some microscopic slides cemented with Canada balsam are found to lose their covering glasses by the balsam hardening and allowing the glasses to chip off. The process of cementing lenses, photographs, and so on by means of Canada balsam and castor oil is as old as the hills, and we are told that the ready-prepared transparent cement can be had in the market. For historical purposes, however, it is essential that the photographer shall conscientiously make the cement himself at the lowest suitable temperature from the best materials, and shall take care that all the volatile oil has been driven off; he must also take care that enough castor oil is employed to guard against an adverse amount of brittleness. The arborescent markings which sometimes appear between cemented lenses are due to a residuum of volatile oil in the cement used, which oil evaporates in course of time after the cementing.

The Convention at Washington.—The Photographers' Association of America will hold its annual convention at the Smithsonian Institute, Washington, August 12th to 15th inclusive. The grand prize is offered for the best print from a negative suggested by Tennyson's "Enoch Arden." During the convention week the memorial to Dagnerre will be unveiled.

Matting Lantern Slides.—A trustworthy universal form for cutting out openings of various sizes and shapes in slide mats is still a desideratum, notwithstanding the fact that there are one or two mat-trimmers in the market. Without wishing to reflect upon their usefulness, we may express the wish that some ingenious amateur would give us some better way. A fairly satisfactory method is to keep a stock of strips of thin black paper of various widths, and to gum these to the face of the slide as the subject may require, care being taken to make perfectly square corners. Another method, which does away with the square corners, objectionable to many, is to cut a piece of thin, hard card-board to the size and shape of the opening, and bend it over squarely across the middle. The mat paper is cut to size, folded across the middle, and placed between the two halves of the doubled card-board, which acts as a clamp. The opening is easily cut out with a pair of sharp scissors. Cards of various sizes and shapes are easily made, or thin sheet brass may be used.—*American Amateur Photographer.*

PHOTOGRAPHIC GRUMBLERS.

There are some men who are never content with their surroundings, and seem to have a notion that their fellow-creatures, and the universe generally, are in conspiracy against them, in order to render all their schemes abortive. It is, of course, natural that photography should have among its votaries a few men of this kind, although it is a misfortune to them that they ever undertook the business or pastime of picture-making with a camera; for this art of ours is full of pitfalls and quicksands of trouble and disappointment, and unless the worker be of easy temperament he will most surely quarrel with it, and attribute his want of success to everything but the true cause.

It so happened that a few weeks ago we had the opportunity of spending some time in the company of one of these grumblers, and we were certainly amused at the way in which he met every little trivial occurrence as if it were a foregone conclusion, and one which had been especially prepared for his discomfiture. We reminded him of the well-known lines:—

"The best laid scheme o' mice and men
Gaug aft a-gley,"

and told him that it was silly to make so much of trivial misfortunes; but he replied in a despondent tone, and although he did not actually say that

"From childhood's hour
I've seen my fondest hopes decay,"

he looked it, and evidently meant it. As there may be others among our photographic friends who occasionally allow despondent thoughts (and their livers) to get the better of them, we have thought it worth while to dot down some of the complaints of our dyspeptic friend, in order that they may see how ridiculous such complaints appear to be when "made a note of."

The weather naturally furnishes the greatest amount of matter for grumbling about, and if our friend had confined his vituperations to this terrible month of July, we could not but sympathise with him. But he has quarrelled with the weather ever since he began to photograph; indeed, some of his acquaintances go so far as to say that he took up the art in order to enlarge his opportunities for grumbling at the elements. If the sun shines brilliantly and it is seasonably hot, he will tell you that he had set apart this very day for sensitising carbon tissue, or for making gelatine emulsion, or for doing something else where coolness was required. Or he will tell you endless stories of how he went to a particular place to take a certain photograph with an ash tree or a birch tree in the foreground, and how that particular tree could only be taken in the absence of wind; how he had chosen a muggy, sultry day for his work, and how a gale sprang up directly he put up his tripod on the spot. "Just like my luck," he always says at the end of one of these painful narratives. "If I were a farmer," he told us, "and my crops needed rain, I shouldn't worry myself at all. I should arrange to print a few photographs, for I am certain that directly I got out my frames,

and prepared for a good day's work, the rain would come down in torrents; it always does whenever I want to print." He also tells a remarkable story of returning home from a morning's work in the open country, and coming upon a wonderful group of cattle standing knee deep in a river, and forming a most perfect picture. The animals were motionless, and he had everything in his favour for taking a fine picture. He had only one plate left unexposed, and that he was to use for this splendid work of art. Gold and silver medals already dangled in imagination before his eyes, and this picture he was determined should be the picture of the season. He focussed with extra care, and made his exposure, but only just in time, for the cattle presently moved out of the water. Packing up his camera, he made the disgusting discovery that he had never drawn the shutter of the dark slide. He, of course, does not attribute this accident to any fault of his own, but to some persistent flies which would swarm round his head while he was focussing the picture. He is not a very pleasant companion to go out photographing with, because if you make a remark, or sneeze, or cough, and he happens at the moment to expose a plate a second time, he blames you as much for the loss of his two pictures as if you had caused him to sacrifice as many bank notes.

But it is in the dim obscurity of his dark room that this grumbling friend of ours is seen, or rather heard, at his best. If a picture is over or under-exposed, or if no developer or combination of developers will bring out any trace of an image—and this is often the case with our friend—there is heard through the door sounds of quarrelling, which generally finish up with a smashing of crockery. It is only our friend grumbling at his results, and smashing his plates by way of emphasizing his disgust. The storm for the moment appears to have past, but presently you will see our friend emerge from his dark-room with a frowning expression of determination upon his face. He makes for the nearest table, sits down, and writes a letter to the unfortunate plate-makers of such a character that they would be fully justified in bringing an action against him for slander, if they cared to do so. On one occasion this dyspeptic individual bought, on the recommendation of a friend, a new changing-box, and on the first occasion of using it returned without it. Upon asking what had become of it, he acknowledged that one of the plates having stuck in it, he had been so exasperated that he threw the box down in the road and jumped upon it. The jumping he owned had not cured the evil—but had smashed the apparatus to splinters. Our friend's experiences of toning silver prints are too sad for description, neither will we harrow the feelings of our readers by telling them more of the many difficulties which beset him. We endeavoured lately to point out delicately to him that some at least of these evils are of his own creation, and may possibly be traced to an abnormal condition of his digestive organs. He differed with us, and we have not been on speaking terms since.

INDIAN NOTES.

BY COLONEL J. WATERHOUSE, B.S.C., ASSISTANT-SURVEYOR-GENERAL OF INDIA.

Eikonogen Developer for Bromide Prints and Enlargements.—The following developer, given in Eder's last *Jahrbuch* by Dr. Just, as Dr. Krugener's, has been found to answer well for bromide paper enlargements. In 20 ounces (or 600 c.c.) of distilled water, 320 grains (or 20 grammes) sodic sulphite, 240 grains (or 15 grammes) sodic carbonate, crystals are dissolved; and then 80 grains (or 5 grammes) of eikonogen added with potassic bromide, as required, up to 10 drops (1 : 50) per 1,000 c.c. of developer. Very short exposures are required with this developer, and if the exposure be correct, the image is well detailed, and of a good colour. It is said that old eikonogen developers work better for bromide prints than fresh ones; but with old developers there seems to be a tendency for the paper to stain round the edges, especially if it also is old, and therefore it may sometimes be better to use freshly-made developer in small quantities for each print, with a little once used added, in preference to developing a batch of prints one after the other in the same solution. It may be noted that developer that has been repeatedly used becomes strongly fluorescent or dichroic, appearing a bright dark green by reflected light, and a dark olive yellow by transmitted light, very much like petroleum oil.

Preserving Eikonogen.—Eikonogen seems to be very readily decomposed by air and moisture, more so than pyrogallol or quinol, and it would be a great thing if some means could be found for keeping the crystals free from discolouration. They seem to be quite insoluble in alcohol, and it might answer to fill up the bottles containing them with this fluid, or some not too volatile hydrocarbon from which they could easily be freed by evaporation when required. The brown colouring matter, which results from the oxidation, has a certain staining action on the gelatine film, and in preparing solutions it is well to wash the crystals once or twice with a very little water to remove the colour, and then to dissolve the clean remainder in the proper quantity of distilled water. This, however, involves a certain loss of material, which is better avoided if possible. The solution with sodic sulphite gradually darkens if exposed to air, and therefore the stock solutions should be kept in bottles well filled up and closed. In a recent number of the *Journal des Societes Photographiques* a very ingenious method of keeping a bottle filled up is reported as brought before the Versailles Photographic Society by Monsieur Fourtier. It would seem that a hydroquinone developer is sold ready prepared, accompanied by a box of glass beads, which are to be put into the bottle to replace the fluid taken from it from time to time, and thus keep it filled up. The plan will be useful for all stock developers, and if glass beads are not available, clean glass (old plates) broken into small pieces, pounded quartz, or small pebbles, would answer equally well. The dodge is by no means new, but I do not recollect seeing it used in this connection before, and it is certainly worth noting.

Eikonogen for Instantaneous Work.—Further experience with eikonogen seems to show, as already recognised in Europe and America, that it is likely to be particularly valuable for instantaneous work, and that not so much from the mere shortening of exposure, as for the power it gives of using a very much smaller stop in the

lens. Hitherto, when working with the ordinary pyro developer, I have generally found it necessary to use nearly the full aperture of a 7½-inch focus rapid symmetrical lens to cover a 5 by 4 plate fairly to margin. With this aperture, and using extra rapid plates, not drop shutter, over-exposure was rare, and the plates more inclined to be under-exposed than otherwise. With the eikonogen developer recommended by Dr. J. Nicol, in the last *Photographic Times Almanac*, and working in the same way, I found that my plates were considerably over-exposed, and further trials have shown that the working aperture may be very considerably reduced, the smallest stop being sufficient for open, bright subjects with sky and water, and the medium for close work with foliage; there is the further advantage that, if desirable, a shorter focus lens (6-inch) can be used to cover the same sized plate. It seems probable that before long all out-door work in fine weather will be done instantaneously, and this new developing agent will undoubtedly be a very great aid in this direction. There does not seem to be the same tendency to excessive density and hardness as with hydroquinone or pyro in cases of under-exposure, and there is a greater tendency to weakness and want of density by over-exposure, or by too quick development. The image should come up slowly, gathering density as it goes on, and plates may be given a prolonged development without showing the fatal mottling which is observable with hydroquinone. For studio work and interiors where it is possible to effect a substantial reduction of exposure, eikonogen will also be found useful. For vigour and delicacy of gradation it seems at present inferior to pyro, but with it, as with other developers, the result depends very much on the strength of the solutions, and the relative proportions of eikonogen and alkali, as well as on the lighting and exposure given.

Eikonogen Developer without Sulphite.—In nearly all the published formulæ the addition of sodic sulphite in varying proportions, usually from twice to four times the eikonogen, is recommended, and no doubt it is valuable for preserving the solution in good order. Unfortunately, like many sulphur compounds, sodic sulphite readily decomposes, and there can be no doubt that partially decomposed or impure sulphite in the developer is a fertile source of surface stains and discolouration, especially if the sensitive gelatine silver coating of dry plates, films, or paper has itself become decomposed by keeping, as those sent out to this country often are found to be on arrival. In Europe there need be no great difficulty about obtaining supplies of fresh sulphite as required, but in this and other distant lands dependent upon Europe or America for chemicals and other products of civilisation, there can be no certainty as to this material being fresh and pure, though its purity as regards freedom from sulphate may easily be tested with a little baric chloride or nitrate. Even if fresh and good when received, it soon spoils by keeping in the corked bottles it is usually put up in, and should be kept in well-stoppered bottles. It seems, therefore, desirable, if possible, to dispense with the sulphite, at any rate for home work, and use freshly made-up solutions of eikonogen, adding the requisite quantity of alkali, with a little restraining bromide to give density if necessary. Some experiments have been made with this object, but the weather is unfavourable at present, and I have not yet ascertained the best proportions for general use. A solution containing 1 to 1½ parts of eikonogen and 1 to 2 parts of sodic carbonate crystals to 100 parts of water, seems likely to work well, the relative proportions of eikonogen and alkali being modified to suit the exposure and type of plate used. Potassic carbonate has also given good results, but further trials are necessary. I hope to have more to say on this subject at a future time, as well as upon other preservatives than sulphite for the eikonogen solution.

Keeping of Erythrosin-Silver Plates.—Some Swan's plates which had been prepared by Mallmann and Scolik's erythrosin-silver bath process for orthochromatic work, on the 19th of October, 1888, or about twenty months ago, and had since been kept in a cardboard box in a light temporary dark-room, made of Willesden paper, out in a verandah, were lately exposed. Though they had somewhat lost sensitiveness, they developed quite clear and free from any fogging round the edges, and were only slightly marked by finger spots. This would seem to show that the erythrosin-silver compound acts beneficially in preserving orthochromatic plates in this climate. The English orthochromatic plates, though working admirably when fresh, soon deteriorate under similar circumstances. The erythrosin-silver plates referred to have been kept wrapped up in pairs, face to face, and it has been found that plates kept in grooved boxes, tin, wood, or card, very soon become decomposed round the edges. Some other plates (Wratten's and Ilford's) prepared with æsculin and ammonia, with salicin and ammonia, and with a certain resinous chlorophyll solution, upwards of a year ago, backed in the same way, and also left through the monsoon in the little paper dark-room, seem none the worse. They developed quite clearly with eikonogen, and barely show a speck of fungus.

Acid Fixing Bath.—Several Continental writers have lately recommended an acid fixing bath as being more permanent, and tending to clear plates from stains, as well as hardening the film. In Eder's *Jahrbuch* for 1890, Herr Lainer has recommended the following:—

A.—Hyposulphite of soda	...	...	160 grammes
Dissolved in water to	...	...	800 c.c.
B.—Sulphite of soda	...	...	20 grammes
Water	...	...	80 c.c.
Hydrochloric acid	...	...	10 ,,

Mix A and B; the result is a clear solution, with a very strong smell of sulphurous acid, which soon goes off. This solution has been used with the eikonogen developer for plates and celluloid films. It kept clear at first, but after a week or so a copious black precipitate was formed, and the sides of the bottle were thickly coated, just as with the ordinary fixing bath. The solution has, however, only a very slightly sulphurous smell, the smell of camphor from the films predominating, and it is quite free from colour. The hardening effect claimed for the bath has not been very noticeable. Trials have also been made with another similar bath containing chrome alum, recommended by Cramer for use with the American plates made by him. The formula, as given in *Anthony's Bulletin*, is—

Sodium sulphite crystals	...	4 ounces (120 grammes)
Water	...	1 quart (1 litre)
After being dissolved, add—		
Sulphuric acid	...	½ ounce (15 c.c.)
Chrome alum powder	...	3 ounces (90 grammes)
Dissolve, and pour into a solution of—		
Hyposulphite of soda	...	2 pounds (1 kilo)
Water	...	3 quarts (3 litres)

The bath, when first made up, was clear, but soon became

turbid, and deposited a yellowish-white precipitate. It is claimed for this, also, that it remains clear after frequent use, does not discolour the negatives, and forms no precipitate upon them. It also hardens the gelatine to such a degree that the negatives can be washed in warm water, provided they have been left in the bath a sufficient time. It is recommended that they should be allowed to remain in the bath from five to ten minutes after the bromide appears to have been dissolved, in order to secure the permanency of the negative and its freedom from stain, as well as the hardening of the film. This bath has a strong green colour, and the negatives fixed in it all show a greenish tint when laid upon paper, though it is not perceptible by transmitted light. It has also precipitated, but not so much as the other bath. It certainly does harden the gelatine film very strongly, but if the film is hopelessly soft to begin with it will not save it; the outside skin gets tanned, and is liable to separate from the lower one, or it becomes wrinkled all over. A solution weaker in chrome alum would probably be better for such films. After about ten days' moderate use it has only a very slightly sulphuretted smell, not nearly so strong as the ordinary bath would have. It has been used almost exclusively with the eikonogen developer. So far, the advantages to be gained by these acid fixing baths are not quite apparent, but further use, in comparison with the ordinary bath, may bring them out. In this country, a fixing bath which would remove stain, and effectively harden soft films without reticulating them, would be very valuable.

FLEXIBLE SUPPORTS FOR PHOTOGRAPHIC FILMS.*

BY J. S. FAIRFAX.

Heretofore it has been customary to form the sensitised gelatine film used in the production of photographic negatives, commonly known as "dry plates," upon transparent glass. The increasing use of the dry plate process for out-of-door photography has added to the demand for a light plate, which will reduce to a minimum the weight to be transported.

Paper has been used as a temporary support; the sensitised film being laid upon it in long strips, and apparatus provided by which rolls of this film can be placed in the camera, unrolled without opening the camera, and successive plates exposed. This improvement has lessened weight, but on account of the want of transparency in the paper, it has been found necessary, after exposure and development, to separate the film from the paper, and coat the film with collodion. The pyroxyline support, thus provided, requires skill to apply, and an accident may destroy the picture on the negative; while it has been found impracticable to thus secure anything but a very light and unsubstantial support.

Attempts to substitute pyroxyline for paper in the first instance have not proved successful, the strips of celluloid or plastic compounds of pyroxyline (either rolled or split thin) having insufficient flexibility for use on rolls. It has also been found impracticable to form these pyroxyline supports by means of ordinary collodion, the film which could be formed from a single application (unless the liquid when applied was too thick to flow) being too unsubstantial, while subsequent applications injuriously acted upon or dissolved the previously formed film. Moreover, the great contraction of collodion in drying was objectionable, as it caused the film to buckle.

The improved film or support may be made from a thin solution of pyroxyline flowed upon a smooth surface, called a "carrier," and the thickness regulated by the number of coats, when, by using a nearly saturated solution, I am enabled to apply successive coats of this pure pyroxyline compound, which, heretofore, has not been done. It may be made also from a very heavy solution of pyroxyline, and spread upon the carrier, the thickness being regulated by the spreader. In practice I prefer to use the heavy solution and spread it, as it is more quickly done, and cheaper than by flowing. In making these solutions, I use as a solvent any liquid or solvent which will thoroughly dissolve the pyroxyline, and will not give the film a greasy surface—to which the gelatine emulsion will not adhere—nor injuriously affect the gelatine emulsion when applied. In the heavy solution it is preferred to use gum camphor as one of the solvents, and I mix with the solution any of the miscible non-solvents, such as amyl alcohol, butyl alcohol, and petroleum naphtha, which, while having little or no solvent power in themselves, are often desirable ingredients in these solutions from their water repellant qualities and cheapness.

Having thus outlined the invention, I will proceed, more particularly by way of illustration, to describe some methods of applying it. I do not, however, wish to be understood as confining myself to the particular methods of application mentioned, as there are various other ways which involve merely such modifications of the solution as will be readily suggested to those skilled in the art.

For a thin solution to be flowed upon glass, or other polished carrier, the following is found to be a good formula:—

Methyl (or wood) alcohol	40 gallons
Amyl, propyl, or butyl acetate, or mixtures thereof	20 ,,
Amyl alcohol	40 ,,
Soluble pyroxyline	50 pounds

The solution is so nearly saturated that the second application thereof (which is frequently necessary to secure a sufficiently thick and substantial support) will not destroy nor injure the previously formed film. The solution is allowed to flow upon glass (preferably first coated with a thin solution of india-rubber in benzine, or other suitable coating, to prevent adhesion), and when dry it is stripped from the glass or other carrier and cut to desired sizes, or into long strips to be used from rolls, for which the invention is especially well adapted.

For a heavy solution, to be spread upon the carrier by a spreading knife or straight edge, the following formula is a good example:—

Methyl (or wood) alcohol	55 gallons
Amyl alcohol or fusel oil	20 ,,
Amyl acetate	25 ,,
Gum camphor	50 pounds
Soluble (photographic) pyroxyline ...	100 ,,

For amyl alcohol in the foregoing formulas, butyl alcohol or its isomer may be substituted, and for the amyl acetate, the acetate of butyl or other ethers of butyl alcohol and amyl alcohol which are known solvents of pyroxyline may be substituted. Also, the proportions in which the liquids are mixed will somewhat depend upon the amount of dampness in which they are to be worked,

* This is the substance of a patent of general interest to photographers, issued last Wednesday. The invention is that of Mr. Frederick Crane, of New Jersey.

the degree of solveney of the pyroxyline employed, the consisteney of the solution desired, and the amount of susceptibility to water required in the film.

The solution given in the last example is too heavy to flow, but it is distributed upon the glass or other polished carrier (prepared as before mentioned) by means of a knife or other equivalent device, as is well understood, and when the film has set or hardened, I strip it from the carrier and cut it into plates or long strips to be used from rolls.

After taking the pyroxyliue film from the glass or other carrier, I distribnte upon it the sensitised gelatine emulsiou from cylinders revolving in a trough contaiuing the emulsion, or in any of the well-known ways of distribnting the emulsion upon its support. Or I may distribute the sensitised gelatine emulsion by spreading it upon the pyroxyline film before its removal from the glass or other carrier. After being coated with the gelatine emulsion, the strips of coated films are placed in holders, or rolled upon rollers, aud are then ready for use in the camera.

If, for any reason, it is found desirable to use less pyroxyline, or to use stronger or more energetie solvents in any of the solutions named, the surplus or too aetive solvent power may be reduced by the substitution of miscible non-solvents in sufficient quantity to neutralize the excess of solvent, the amount of these non-solvents to be used in any case depending entirely upon the amount of unemployed solvent power which is desirable to reduce.

It is to be understood that I do not confiue myself to the particular solvents named which are enumerated as examples. For instance, in place of, or iu conjnnction with, amyl alcohol, or fusel oil, or butyl alcohol, or their isomers, I sometimes use benzoline or petroleum naphtha or benzoline.

It is necessary, however, to use about the proportions named of non-hygroscopic menstrua to prevent clouding the resultant film; but in general, any of the well-known solvents and well-known non-solvents may be employed, provided they are not of such a greasy nature as to prevent the adherence of the sensitised emulsion to the finished film; and the choice of these depends upon the time required for the film to set or dry.

This invention may also be used as a support for photographic prints, especially in the production of transparencies.

MAGNESIUM LAMP.—Mr. R. Robert is placing on the market a small apparatus which has been patented in France as "Le Tison Eclair," to be known here as "The Lightning Fusee." The advantages claimed are its portability, its safety, the brilliancy of its light (serving to illuminate objects within a radius of ten yards), and the ability to use it in the open air in any weather. The magnesium powder, of which the little apparatus carries twelve charges, is driven by pneumatic pressure through the flame of a fusee-vesta placed in a holder in front of the instrument.

A CAMERA-STAND ADJUNCT.—Messrs. Watson and Sons have just introduced a device for rendering a tripod stand more stable on slippery surfaces, such as polished wood or stone, or the deck of a ship. It consists of three little brass thumb-screws for affixing at any desired level to the three legs of the stand. From each thumb-screw proceeds a cord to a light, peculiarly-shaped piece of brass which the three cords hold in suspension horizontally beneath the centre of stand-head, and to which piece of brass the cords hold on firmly by friction. The legs are thus "tied," so to speak, at any desired angle to each other, and when accidentally kicked underneath are not likely to fall or to allow the camera to be upset.

Notices of Books.

DIE ORTHOSKIAGRAPHISCHE PHOTOGRAPHIE. Bemerkungüber Misserfolge und deren Abhilfe, und Sammlung von Receptеn. Ludwig David and Charles Scolik. *Halle: W. Knapp.*

THIS work, forming the second volume of David and Scolik's Manual of Photography with bromide of silver gelatine, is itself divided into three parts. The first part treats upon orthochromatic photography, and will be found to possess great interest to those who either propose to prepare plates giving what is known as orthochromatic effect, or to use such plates prepared commercially, with an understanding of the amount of effect that they should expect, and of the extent to which that effect may be modified and controlled by the use of coloured screens or other artifices.

On the vexed question of the ultimate reason why the addition of certain dyes to an emulsion should render it sensitive to certain rays, we do not find a great deal written. Doubtless the authors reasoned that it would be a mistake to devote much space in a work intended principally for the use of the practical photographer, to the consideration of the polemics of the question, respecting which such wide differences of opinion prevail amongst those who are entitled to be considered authorities on the subject. Concerning a practical method of ascertaining the effect of particular sensitisers, and reasoning therefrom with regard to their use with the sensitive silver salts, we find the following summarised remarks.

In order to discover a suitable dye stuff for sensitising the photographic film for rays of any particular colour, an image of the solar spectrum is projected by means of a prism, and a vessel containing a solution of the substance to be examined is placed in the path of the rays between the slit and the prism. It is then found that certain rays disappear, and their place in the spectrum is occupied by dark lines (absorption lines). It is noted what are the lines thus absorbed and extinguished. If, for instance, the interposed vessel contain aniline red or napthalin red, as those dyes absorb the yellowish-green rays, we find in the spectrum band a dark strip between the solar lines D and E. We can then form a judgment, from the influence which a dye stuff has upon the visible spectrum, of the effect which it may be expected to produce in sensitising for colour the photographic salts.

There are two coloured plates in the work, one of which shows the spectrum, both continuous and solar, accompanied by photographs of the spectrum taken, with the silver salt affected by various of the recognised colour-sensitisers. Here may be noted the effect of cyanin and of a mixture of cyanin and chinoline red in carrying the photographic action considerably beyond that effected by eosin or erythrosin, the image in the latter case stopping short at the yellow line D, whilst with cyanin the action is carried well into the yellow orange, a colour which, from its luminosity, absolutely requires to be rendered if the plate is to approximate to a real orthochromatic effect.

The other coloured plate is one which will be appreciated, especially by those practical workers who do not care to go into the question of spectrum photography, but like to see the direct effect of sensitising for such colours as they meet with in nature and on the palette of the painter. Here we find squares covered respectively with two shades of red, orange, yellow, two greens, one yellowish, and the

other inclined to blue; two blues, and purple. The colours appear to be well and fairly chosen; the blues, for instance, though different, are both bright, and do not partake of that dark, heavy character which we have sometimes seen in such examples, when the difficulty of making blue come out dark in the resulting orthochromatic photographs appears to be met half-way by special manipulation of the colour selected. On the next page are three photographs of this sheet of colours—one taken on an ordinary plate, one on a colour-sensitised plate without, and one with, the addition of a yellow screen. This set shows the advantage to be derived from each of these aids. A pair of photographs of a landscape subject, taken one under ordinary, and the other under orthochromatic conditions, strikes us as being the least satisfactory portion of the work. It is not that the difference is not manifest, for it is so in a very marked degree; but—a fault that we have before observed in similar productions—the best does not appear to have been done with the ordinary plate. Buildings and other objects in the foreground which are almost lost in general blackness might, we are convinced, have been brought out much better with a somewhat longer exposure. It is no doubt possible that in that case the distant mountains would have suffered from over-exposure, but we think it would be better to show the best that could be done on an ordinary plate with the subject as a whole, leaving the orthochromatic to beat it, perhaps, at both ends of the scale of light gradation, rather than to present for comparison a picture which strikes the observer as deficient in point of exposure.

To the illustrations and descriptions of the effect of various orthochromatising additions is added what will doubtless be the most useful and interesting part of the work to the practical photographer, formulæ and methods of using shown by experience to yield the most satisfactory results. Although few photographers now make their own emulsion and coat their own plates, there is an increasing number of those who like to orthochromatise plates themselves by the simple bath process, requiring no special installation beyond a dark cupboard, who will appreciate a work like the present, in which not only are the various methods and formulæ stated and explained, but the reason is given for the selection of one or other sensitising agent, according to the effect desired in the plate.

The second part of the work is devoted to an explanation of the various causes of failure likely to be met with in working the gelatine process. Here not only are failures described, but cuts are given illustrating most of the spots and markings to be met with in gelatine plates. A glance at these wood-cuts brings an unpleasant reminder of the failures that most have experienced in the early days of gelatine photography.

The third and concluding part of the volume contains a valuable collection of formulæ for use throughout the practise of photography with gelatino-bromide of silver. In addition to these is a short description of the effects and characteristics of most if not all of the various recipes. There is, moreover, a special chapter furnished with several illustrative wood-cuts of the various manipulations connected with printing by the enlarging lantern upon gelatino-bromide of silver paper.

New Holidays in Essex, by Percy Lindley. (*London: 125, Fleet Street*, 1890.)

This is another of the cheap little guide-books by Mr. Percy Lindley about districts connected with the Great Eastern Railway system, and is likely to be useful to photographers, so many of the short excursions of London photographic societies being to places in the Eastern counties. Essex may not be so rich in picturesque scenes as some other counties near London; nevertheless, it has its beautiful forest, and abounding objects of interest, as set forth in guide-books, and in the records of the Essex Field Club. Mr. Lindley's book is well illustrated, and will give its possessor, when he is travelling in Essex, an amount of information which will add considerably to his interest in the the places which he visits. The book contains a map of the county.

THE "CROTONWANZE" ONCE MORE.

When we sounded our note of warning in the January *Journal* respecting a fresh danger that threatened the American dry plate industry, we had but little idea that the matter would become one of international importance; therefore it is with pleasure that we inform our readers on both sides of the ocean that the incipient danger has passed, the dark clouds have been dispelled, and once more the photographic horizon is clear and bright without the least sign of fog. In reply to our query in the March *Journal*, Dr. A. Miethe, of Berlin, the well-known editor of the *Photographisches Wochenblatt*, in No. 17 of present volume, answers:—

"Our friends in America have shown much pleasure that we so well understood their Cimex joke, as set forth in our Letterbox notice—as our readers will no doubt recall the fact, that at the time we referred in our 'Repertorium' to an article from an American newspaper, in which mention was made of a mythical insect which had developed an especial appetite for the American dry plate. Under these circumstances we could not refrain from warning our readers against the use or purchase of any American dry plates, so as to prevent the introduction of this dreadful insect, which threatened to prove more destructive than the Colorado potato beetle, and, if possible, to obviate this great danger. Immediately afterwards there appeared in an American magazine* a well-meant sally against German thoroughness and credulity.

"In reply, we mentioned seriously as the occasion offered, that an organism outside of the Crotonwanze did exist—a fungus, which formed on damp gelatine dry plates, and that in the process of formation, growth, or existence, so changed or affected the photographic properties of the affected plate that, after exposure and development, such plates showed numberless transparent spots, and, consequently, were rendered useless. We suffered heavily during the past summer by the appearance of these organisms," writes Dr. Miethe, "and only overcame the difficulty by a thorough disinfection of our dark chest with carbolic acid and fumes of bi-chloride of mercury. The plates which had been thus affected, as a matter of course were lost or spoiled, and herein the friendly editor of the *American Journal of Photography* has misunderstood us (vide *American Journal of Photography*, March, 1890, p. 89).

"We hope," continues the *Wochenblatt*, "that the little bug which threatened to assume the proportions of an immense sea-serpent has been scotched or decapitated, a 'prozedur' that we are glad to have aided in accomplishing." We of the *American Journal of Photography* also

* *American Journal of Photography*, January, 1890.

claim a share of the glory in bringing about this end, and thank Dr. Miethe for his courtesy and information, and close with the good old motto, "*All's well that ends well.*"—J. F. S., in *The American Journal of Photography.*

PHOTOGRAPHY IN CRIMINAL JURISPRUDENCE.

BY JULIUS F. SACHSE.

No sooner was photography discovered than it was recognised as one of the greatest aids to the police authorities, and became a medium for the detection of criminals and evil doers, and the consequent prevention of crime. To obtain an exact likeness and the duplication of prints or pictures, which could be sent out broadcast over the country at a comparatively small cost, thus familiarising the various local police authorities with their lineaments, was a menace to the criminal classes greater than anything which had so far been discovered for their suppression.
