New Bingham Bee Smoker

In 1878 the original direct draft bee smoker was invented and patented by Mr. T. F. Bingham, of Michigan. Mr. Bingham manufactured the Bingham Smoker and Bingham Honey Knife for nearly thirty-five years, and in 1912, becoming a very old man, we purchased this business and joined it to our established business of beekeepers' supplies and general hardware. Those who knew Mr. Bingham will join us in saying that he was one of the finest of men, and it gives us much pleasure to help perpetuate his name in the beekeeping industry.

Bingham Smokers have been improved from time to time, are now the finest on the market, and for nearly forty years have been the standard in this and many foreign countries. For sale by all dealers in bee supplies, or direct from the manufacturers.

Smoke Engine, 4-inch stove.....28 oz. \$1.25
Doctor, 3 1/2-inch stove26 oz. 1.00

Hinged cover on the two larger sizes, postage extra.

NEW BINGHAM
BEE SMOKER

A. G. WOODMAN CO.
Grand Rapids, Mich.

WOODMAN'S SECTION FIXER

A combined section press and foundation fastener of pressed steel construction. ONE OF THE GREAT ADVANTAGES this machine has over all others on the market in the putting in of top and bottom starters is, YOU ALWAYS HANDLE LARGE PIECES OF FOUNDATION. You know how hard it is to set small, narrow pieces for bottom starters. With this machine a large piece of foundation is set and the hot plate is again used to cut it off, leaving the narrow bottom starter. What is left of the large piece is then set for the top starter.

Price of machine, \$3; with lamp, \$3.40. Weight, 5 lbs.; postage extra.

THIS IS THE ONLY MACHINE ON THE MARKET from which the section always comes away right-side up, with the large piece or top starter hanging down. It does not become loosened in reversing, as with other machines.

A. G. WOODMAN CO., Grand Rapids, Mich.

Tin Honey Packages

YOU WILL MAKE A MISTAKE if you do not ask for our Low Prices on Friction Top Pails and Cans. We are Saving money for car load buyers and others of smaller lots. Why not you?

Our three-year contract is enabling us to make prices considerably under general market quotations. Let us hear from you, specifying your wants.

Friction Top Tins

	2-lb. Cans	2 1/2-lb. Cans	3-lb. Cans	5-lb. Pails	10-lb. Pails
Cases holding	24	24	---	12	6

THE GUARANTEE THAT MADE "falcon" Bee Supplies Possible

The "falcon" GUARANTEE. Every hive, every super, every crate of sections, every pound foundation every article, and every queen leaving the "falcon" plant goes out with our "absolute satisfaction or money back" guarantee. For more than a third of a century we have stood behind everything we sell. If anything is wrong or not just what you thought it would be, we'll appreciate it if you write us, and we'll make it absolutely right at our expense. Our satisfied customers are to be found everywhere and are our best advertisement. "Once a customer always a customer," is synonymous with the name "falcon"

The beekeepers' past experience when "short" should have taught him that it's a "wise move" to get hives, sections and supplies ready in the next two months. We will be glad to quote on "falcon" supplies if you will send us an approximate list of what you will require for the coming season.

POULTRY, FRUIT, BEE PAPER COMBINATION \$1.50

Poultry and fruit are allied pursuits for the beekeeper. Here is a special combination of three papers which gives excellent reading at a low cost:

- The Fruit Grower \$.50
- American Poultry Advocate \$.50
- American Bee Journal 1.00

Our price for all three for one year is only \$1.50. Or, if you want two poultry papers, add 25c to the above offer and get your choice of the following one year:

- Reliable Poultry Journal, Poultry Success, American Poultry World, Big Four Poultry Journal, Poultry Tribune, Poultry Item.

Send all orders to
AMERICAN BEE JOURNAL, Hamilton, Ill.

Why Order Early?

With the exceedingly high price of honey and the urging on the part of the State Department for production of every ounce of produce possible, you, as a beekeeper, are going to do your part and have probably already made up your mind to increase your holdings in bees to the limit of your capacity in caring for them.

Possibly, however, you have lost sight of the fact that it is greatly to your interest to get in your orders for bee supplies now.

Freights are Slow The congestion of last year may be repeated. Many beekeepers who ordered their supplies in February were barely able to get delivery in time for the white clover flow. Others had to cancel orders, and still others had supplies arrive after the critical storing period was past. *You cannot afford to let your bees wait a day on delayed freight shipments.*

Early Order Discounts We want as many early orders as possible. This gives us less of a rush in spring, when a too large proportion of beekeepers order their supplies. This is why we can make a closer price for an order sent in before the new year opens. If your banker were to offer you 15 per cent interest on your deposits you would certainly grab the chance. A three or four per cent discount on supplies for ordering them three months earlier than usual means sixteen to twenty per cent interest on your money for the year, and you have your goods on time, without fail.

Save You Money

*Send us a list of your requirements.
We are in a position to give you a
very close estimate for early order.*

Are You Throwing Money Away?

No? But are you throwing away old combs, small lots of cappings, or else beeswax scrapings and propolis from the tops of your frames when you clean them? If not, perhaps you are melting up your combs in an old-fashioned way and getting only about half the wax out of them.

Many beekeepers this year secured their season's supply of

DADANT'S FOUNDATION

by sending in their combs and cappings to be rendered into beeswax and made up into foundation. Our high-pressure steam outfits get all the wax possible, save these same beekeepers an unpleasant job and return more beeswax in the shape of foundation than they could get by the extra work themselves. If you prefer, we will pay you *Highest Cash Price* for all beeswax rendered.

SWEET CLOVER AS A FARM CROP

Items of Interest About a Plant Which Was Formerly Regarded as a Weed,
Now Generally Grown for Forage---Photographs From
U. S. Department of Agriculture

WHEN our older readers were beginners in the beekeeping business it was a popular thing for the beekeepers to buy sweet clover seed and stealthily sow it along the roadsides after night. So general was this practice, that, whenever the plant appeared in a new locality, it was generally charged up to the beekeepers living near by, and they were very often guilty of having sown it. So great was the prejudice against the plant that much ill feeling developed in some places because of it. It even went so far that in some States it was placed on the list of noxious weeds and its eradication required by law. When Frank Coverdale, the well-known Iowa farmer who has done so much to popularize sweet clover, first sowed it in his own fields, neighbors called on the county attorney to enquire whether he could not be prosecuted for sowing weed seed. For a generation the beekeepers kept up the fight, and constantly preached that sweet clover was not a weed, but a valuable forage plant. It remained for men like Coverdale, who were both beekeepers and farmers, to prove the assertion and convince an unwilling public, by making as much profit from sweet clover pasture or forage as the neighbors could make from other farm crops.

It was on poor lands which had been worn out by bad tillage, that the plant made the best showing. When lands which had been lying idle, because no other crop could be raised profitably, were made to produce good yields of milk, butter and beef from sweet clover, the neighbors were inclined to give it a trial on their own poor lands. The change in

sentiment has been very marked during the past five years, and now the demand for sweet clover seed is greater than the supply, and will continue so for several years, since the area where it is being grown is constantly being enlarged. There are large areas where sweet clover is grown generally as a farm crop in Kentucky, Nebraska and Kansas, and to a lesser extent in many other States. The increased acreage of this plant will double the possibilities of honey production in most any locality, and, in numerous instances, will treble and quadruple it, sometimes twice over. In the early years of his experience, Coverdale kept bees in several out-apiaries, so that much travel back and forth was nec-

essary. Since sweet clover has become so generally grown in his locality, he is able to keep three hundred colonies in one yard in his orchard, where they are under his immediate care at any and all times. After traveling over much of the central west, it has become apparent that within a few years the beekeeping possibilities of parts of Kansas, Nebraska and South Dakota, will be almost inexhaustible because of the increase of this plant.

Last spring, on visiting Falmouth, Ky., I was amazed at the stories they told of what sweet clover had done for that region. One of the pioneer growers was E. E. Barton, and his experience with it sounded like a fairy tale. Mr. Barton said that following

THE SWEET CLOVER LEAF

the civil war, most of Pendleton county was given over to tobacco growing, with little live stock, and not much rotation of crops. It was a hill country and although it had a fertile soil over a clay subsoil, the heavy rains soon washed away the shallow surface soil, and one farm after another was abandoned. Hundreds of farms were abandoned and many of them were sold for taxes, because no buyers could be found. More than a third of the population left the county, and the farmers who remained had hard lines to make ends meet. Sweet clover was stealthily sowed, probably by beekeepers intent on increasing the bee pasturage. At first it was regarded with distavor and fought as a dangerous weed.

Mr. Barton told me how he came into possession of a farm somewhat against his will because the owner could not pay the mortgage. He tried renting it, and the tenant was unable to make a living, much less pay the rent. After it had been abandoned, he went to great trouble to keep down the weeds, especially sweet clover. Then came a year of drouth, when there was very little feed for the cattle and they were turned into the roads to graze. Even there, there was but little except the sweet clover, which by this time was rather common along the roadsides. It was soon noticed that the cows were eating the sweet clover with relish and doing well. Then somebody tried an experiment by sowing it in a field. It thrived, the cows liked it and the milk flow was increased. Mr. Barton by this time was quite ready to profit by the experience, and within five years the farm which would not grow grass, was producing good crops. He bought more abandoned farms and sowed them to sweet clover, and his neighbors began to do likewise. One by one the farmers came back to their abandoned farms, new settlers came in, and everybody began to grow sweet clover. Now there are fifty thousand acres of it in that county. Ask any farmer you meet on the streets of

A FIELD OF SWEET CLOVER JUST BEFORE BLOOM

Falmouth what he thinks of sweet clover, and he will tell you such tales of rebuilt fortunes from a combination of dairy cows and sweet clover as you never expect to hear. There are now shipped from the county about half a million pounds of seed yearly, besides thousands of dollars' worth of dairy products every week. They find that an average of 300 to 600 pounds of hulled seed per acre can be secured from the white variety and 500 to 700 pounds of the yellow. An average yield of from \$40 to \$100 per acre is the return from the sweet clover, according to local reports picked up on the street. Now one finds evidences of prosperity on every hand. The farmers have fine homes, automobiles, and money in the bank.

Soil Requirements

There is no forage plant that will succeed on such a wide range of soil conditions as will sweet clover. It will succeed under unfavorable conditions on the heaviest clays and on light sand. It will grow on hardpan

and on gravelly and stony land unsuited for general cultivation. It does well on soils too wet for either alfalfa or red clover and on soils so dry that neither of these will succeed. It will grow on land so poor and devoid of humus that no other clover or grass will grow. It is the greatest soil builder known, and now that the public has finally accepted the fact that it is not a noxious weed, it will shortly be used to redeem untold thousands of otherwise waste land. It grows all the way from sea level to the mountain sides, and is spreading in the semi-arid sections of Colorado and other western States, where the annual rainfall is very light.

In the October number of this Journal has already been told the story of the sweet clover region of Alabama and Mississippi. In those States sweet clover has spread over thousands of acres of land, which had been abandoned for agricultural purposes; and it is not only furnishing abundant pasturage to the bees, but is restoring the fertility of these worn out plantations.

The growth of the plant, however, is no longer confined to the roadsides and worn out fields; but farmers are growing it successfully and profitably on lands worth \$200 per acre in Iowa and Illinois, because it pays them to do so. In some cases, the railroad companies have discovered that sweet clover growing along the right of way is the best possible insurance against erosion of the roadbed. A heavy growth of sweet clover protects the banks from the washing of heavy rains, as no other plant will do. In places, one can see a continuous strip of sweet clover for miles and miles along the railroads. It would seem the part of wisdom for the beekeepers' associations to bring this fact to the attention of the men in charge of keeping the lines in repair, wherever possible. Once established along the railroads, it is bound to spread more or less along the byroads and into the fields, thus in-

The Field in the foreground has just been grazed by stock which is now being turned into the field of sweet clover in the background.

creasing the supply of forage within reach of the bees.

One of the most useful purposes which sweet clover serves is to smother out noxious weeds. So persistent is the plant where sowed in waste places, that there are few weeds which can compete with it. Where bad weeds are present in old lots, along roadsides, etc., the easiest way to eradicate them is by sowing sweet clover freely. Within a few years the sweet clover will generally crowd them out. In spite of this fact, sweet clover is itself one of the easiest plants to destroy. Since it only lives two years and must come again from the seed after that time, all that is necessary to clear the ground of sweet clover is to cut it low when in blossom and before the seeds are formed.

Where there is difficulty in establishing alfalfa, sweet clover is often grown in advance to establish the nitrogen gathering bacteria, which are peculiar to the leguminous plants. Following sweet clover, there is usually little difficulty in getting the alfalfa to grow, if the seed bed is carefully prepared. However, many farmers who have been growing both plants, are of the opinion that sweet clover is the more profitable of the two, and that it can be handled successfully with less difficulty.

There is no pasture crop which will support as many cattle or other livestock as will sweet clover during the second season of its growth. This year a small experimental plot of little more than an acre yielded two big loads of hay. The plants were permitted to get a good start after the hay was cut, before pasturing, then two cows and a horse were turned in for the rest of the season. In addition to furnishing abundant pasture for three, more than twenty bags of seed were secured. Allowing \$15 a ton for the hay, \$1 a month per head for pasture, and \$3 a bag for the seed, all very conservative figures, the crop returned about 96 per acre. While this small plot was experimental in the nature of things,

there are numerous farmers who have received more than \$100 an acre for seed alone.

The next article will give details of seeding, cutting for hay and harvesting the seed crop.

Inversion

Interchange of letters on Inversion in transferring, between J. F. Diemer, of Missouri, and the Editor.

Liberty, Mo., Sept. 9, 1917.

Friend Dadant: I am experimenting a little on transferring bees from box-hives to 8-frame hives and I want your guess as to what they will do. I bought 38 colonies in box-hives 14x14x16 inches high. White clover flow was over, but the boxes were full of honey and brood. On top are some holes, which I covered with wire screen to give them air, as my plan was to use these box-hives for hive-stands for the 8-frame hives by turning them upside down, which puts the honey at the bottom and the brood at the top. I bored a 1-inch hole in the middle of the bottom-board of the 8-frame hive, and after turning the box-hive top down I placed the 8-frame hive on top; placed therein one frame of brood and seven drawn combs and full sheets and closed all cracks. The bees will be compelled to use the regular entrance to the 8-frame hive. These bees are 16 miles from home, in the Missouri River bottom. The best fall flow we have ever had is on now and I believe they will carry or move the honey to get it above the brood. This is my guess. What's yours?

Yours very truly,

J. F. DIEMER.

Sept. 17, 1917.

Friend Diemer: I would make a guess similar to yours on those hives and affirm that they would carry the honey up to the movable frame hive. But the experience of the old country beekeepers is rather against such a conclusion. In a province of France which they call "Gatinais" they tip their skeps over in the same way, placing another skep on top of the

inverted skep, "mouth to mouth," as you might say. The result is that they fill the lower skep full of honey. Probably the result with you will depend some upon how much flow there is. If you have a very good flow, they may fill both. Of course, if you use full sheets in the upper hive it may be filled first.

Since you have told me all this and have asked for my guess, I wish you would write me when the season is over and let me know just what they did. We hope you are having some flow now. We have a flow from heartsease and Spanish needles just now, and the honey they store is just like liquid gold.

Your old friend,

C. P. DADANT.

Liberty, Mo., Nov. 4, 1917.

Friend Dadant: Twenty of those colonies transferred themselves from the box-hives to the movable-frame hives, but left the box-hives nearly full of honey. The first cold spell we had here, (16 degrees above) drove them all up into the frame hives, so it was easy to remove the box-hive, all clear of bees. Eighteen colonies not only stayed in the box-hives, but removed nearly all the honey from the frame hives down to the box-hive. I suppose the queen stayed below, because there was plenty of room to lay.

Yours truly,

J. F. DIEMER.

Nov. 8, 1917.

Friend Diemer: Your letter to hand. This shows that the old-time beekeepers of the Gatinais were right in expecting the lower hive to remain full of honey. This operation was called "culbutage," or inversion. Some forty years ago the pages of L'Apiculteur were full of this method. But they had to acknowledge that it left very weak colonies in the upper story. The men who practiced it usually bought a fresh lot of bees every spring to replace those they lost by that method. We hope you will winter yours well.

Of course, at the time when this method was followed they had only straw skeps. If the colonies did not have enough left in the upper hive for winter there was no practical way of supplying them. With movable frame hives the case is different. But your experiment may prove of some use to many of our readers.

Best wishes,

C. P. DADANT.

(Mr. Diemer now writes that he is going to try to transfer those bees to movable frame hives by turning them, bottom up, in January, under a hive partly full of combs of honey. We will report on this later.—Ed.)

Death of W. M. Whitney.—We regret to inform our readers of the death of Mr. W. M. Whitney, which occurred in Chicago two weeks ago. Mr. Whitney was a very familiar figure at the annual meetings of the Chicago Northwestern Association. A retired lawyer, in 1892 he began to keep bees and has since been exceedingly interested in them.

THE EDITOR'S VIEWPOINT

We are just now making plans for an extended trip through Texas by our staff correspondent, Mr. Frank C. Pellett. He expects to start in the latter part of February and be gone six or eight weeks. We are anxious to have him visit as many beekeepers as possible and see every important honey-producing region of our largest State. His journey will be entirely planned by the Extension Department of the Texas Agricultural College, under direction of Prof. F. B. Paddock, the State Entomologist at College Station.

Sugar for Feeding Bees

A few days ago Mr. E. R. Root, editor of *Gleanings*, wrote Dr. E. F. Phillips, Apiarist in charge at the Department of Agriculture at Washington, mentioning the inability of beekeepers to secure sugar for feeding bees where there was a shortage of honey and suggesting possible relief by interviewing the Food Administrators. Dr. Phillips immediately replied with the following telegram, both to Mr. Root and our editor:

"Food administration, realizing importance of saving bees, has willingly endeavored to help beekeepers secure sugar in urgent cases reported, but no announcement of this made, as shortly after January 1 sugar should be generally available. Beekeepers can save colonies by using hard candy or syrup on warm days.
 "E. F. PHILLIPS."

This is satisfactory information for the beekeepers who may need to buy sugar for spring feeding. The colonies that were not fed in fall, if short, would be in poor shape to take food by this time.

The United States cannot afford to do less for the beekeepers than the governments of Europe. We see by the European magazines that France allows 3 kilograms per colony (6½ pounds) and Switzerland 8 kilograms

(17½ pounds.) The French were paying 1.50 francs (30 cents) per kilo and the Swiss 2.50. We are much better off and the shortage is more imaginary than real.

Carniolan and Banat Bees

We have a request from an experimental station for the addresses of parties in the South having pure Banat bees, also for Carniolans and Caucasians.

It is the intention of the experimenters to test ten or a dozen colonies of each kind of bees side by side for honey gathering, swarming, wintering, etc.

We would be glad to have subscribers who are able to furnish pure bred queens of these races early write us so that we may give their addresses to the parties in question.

Russian Beekeeping

The high value of the gray Caucasian bee as a producer of honey is quite readily shown by the large number of bees kept in the several States of Southern Russia. The cuts which we are reproducing from time to time from this region show that the honeybee has been, from time immemorial, one of the resources of that country.

We have been in correspondence with Professor Gorbatcheff, manager of the experimenting apiary of the "Station Sericicole" (silk culture station) of Tiflis. But at this time, while the world is aflame, postal intercourse between America and Russia is rather slow. A letter addressed to this scientist, from here, April 18, was 104 days on the way. His reply took 86 days to reach us. At this rate only about two letters a year could be sent and the reply received. But ought we not to consider our-

selves lucky that the letters did arrive at all? However, it is noticeable that very few letters get lost, in spite of the Kaiser's piratical undersea war.

Professor Gorbatcheff sends us his explanations in the French language and we translate them for our readers. He remarks that "in Tiflis the people well acquainted with the English language are about as rare as Russian scholars in the United States." French, for them as well as for many other nations, is the international tongue.

We are glad that our Tiflis correspondent seems quite optimistic regarding the Russian position. He says: "We thank you for the compliments you pay us concerning our revolution. We are proud of having shaken off the autocratic yoke and to have stepped up to the ranks of free people. We are delighted with the position of America in this terrible conflict. Your wonderful country is showing the force of its clan and the greatness of its soul, well-known qualities of the American nation. We are not the enemies of democratic Germany, but we despise and hate the sanguinary despot and his militarism which is trying to oppress the world."

Let us hope that the time is not distant when we may have peace and commercial intercourse with the breeders of the Caucasian bees. The contribution of Professor Gorbatcheff will be found in another column.

The Chicago Northwestern Meeting

The editor and his wife left home on November 28, with two purposes in view. They wanted to spend Thanksgiving with their youngest daughter, Harriette, who is now Mrs. F. A. Bush, wife of a lieutenant in Uncle Sam's army, stationed at Camp Grant, near Rockford. Thence the editor went to the Chicago meeting, to return again to Rockford and from there reach the Des Moines Convention. It had also been his intention to get to Michigan, at Saginaw, and to Wisconsin, at Madison. But his endurance in travel was not equal to the task and numerous occupations at home also compelled him to shorten the trip.

The Chicago Northwestern meeting was only fairly attended, some 35 beekeepers being present. But they were all in great earnest. A very interesting talk on honey sales was given by our old friend and honey

merchant, R. A. Burnett, of Chicago. Mr. Burnett, who for probably forty years or more has handled shipments of honey, stated that he had never known the honey market to be so cleanly swept as it was during the present fall. Remnants of honey from previous crops which had been thought unsalable had been cleaned out for export. But the high price was to some extent lessening the demand.

The consensus of opinion was that there is going to be quite an increase in the proportionate amount of extracted honey produced, because of the proportionately greater advance in the price of it.

In a discussion upon the use of feeders above the brood chamber, objections were made to them because of the deperdition of heat. Br. Bull, the secretary, explained that he avoided any loss of heat by using over the brood frames a piece of roofing paper, cut of the exact size of the top, with a hole in it just sufficient to enable the bees to reach the food.

A number of resolutions were passed urging the building of a Honey Building at the Illinois State Fair grounds, the increase of State support to the beekeepers' associations and the greater advertising of honey as food.

The election of officers resulted in the selection of the same men as before, E. S. Miller, President; Edward Hassinger, Jr., Vice President; John C. Bull, Secretary-Treasurer.

Although the crop was reported as very meagre among the members, the high price of honey has evidently worked in favor of more production and the general tendency proved to be in favor of the cultivation of a greater number of bees. During the coming years beekeeping will be in the ascendency.

The Iowa State Meeting

The meeting at Des Moines was as well attended as any previous meeting. This evidences the advisability of thorough advertising. The efficient secretary, Hamlin B. Miller, kept the matter before the public for several months and did not spare printer's ink.

One of the most interesting features was the address by E. R. Root on the Demuth plan of wintering mentioned in both November and December numbers of *Gleanings*. The Demuth plan, described in a few

words, is the putting of the seven best combs of a colony into a box in which they stand on end. This box, which is inexpensive to make, is then put inside of a two and one-half story ten-frame hive. This practically makes a winter packing body, as there is room for several inches of forest leaves between the two, and in spring the bees can be readily re-transferred into the ten-frame hive. Instead of an expensive winter case, the beekeeper supplies only a small box of thin lumber. The advantages of the system are apparent, the only objection possible being the necessity of transferring the bees in fall and spring, which ought to be done without much loss of time.

Dr. H. E. Ewing, professor of entomology at Ames, gave a very interesting talk on the anatomy of the bee.

J. W. Tinsley gave an address on "painting foundation with hot wax" which convinced us still more of what we have said in the December number of the *American Bee Journal*, page 410, that the proper weight of foundation to use, in order to supply the bees with all the wax they need to build the entire comb would be about six sheets, Langstroth size, to the pound. The weight required by the trade is 7 or 8 sheets.

Another scientific address was given by Professor H. R. Werner, also of Ames, upon the determination of sex in bees, showing the development of the egg and the manner in which fertilization changes the sex of the undeveloped eggs. We should very much like to give a detail of this very scientific address, but it was accompanied by chalk drawings, without which the matter could hardly be made intelligible. Such an address must be heard to be appreciated.

Still another address by a scientist of Ames College was given by Professor Atkins, Assistant at the Experimental Station. This was a description of the three best methods of queen rearing, the old Alley method, the Doolittle cell-cup method and Dr. Miller's latest method described by the *American Bee Journal* in August, 1912. Never before have we heard so thorough and exhaustive a description of the best practical ways of rearing queens.

Professor F. Eric Millen, apiarist in charge at Ames, described and announced several short courses in beekeeping and secured the promise

of the editor of the *American Bee Journal* to attend the May short course, to address the students. Those interested in these short courses should write him to enquire about the dates and particulars.

Papers were read by Dr. Bonney and others. A most interesting short paper by a lady, Mrs. Clara T. Noel, was secured for our *Journal*. It will be found in the *Woman's* column.

Mr. Pellett gave a lecture on "Beekeeping North and South," with lantern slides in the evening of the first day.

The election of officers resulted as follows:

President, Professor F. E. Millen, of Ames; Vice President, W. S. Walker, of Iowa Falls; Secretary, Hamlin B. Miller, of Marshalltown; Directors, C. H. True, Mrs. Clara T. Noel, Bert Brown.

The advancing price of honey was discussed at length, and while the unusual war conditions are known to be in great part responsible for the advance, yet it is the general opinion that honey will gain in public favor through the temporary shortage of sugar. The beekeepers are therefore generally planning to increase their holdings and the teaching of apiculture in the colleges is considered as more and more necessary, especially in order to do away with ignorance among owners of apiaries. This ignorance is held to be one of the greatest obstacles to the eradication of foulbrood.

Beekeepers, join your State Association. It will not only help you in producing a greater amount of honey, it will also help you in securing fair prices for it.

New Zealand Beekeeping

The *New Zealand Farmer Stock and Station Journal*, in its October number, contains a number of articles on beekeeping and, among others, a description of sacbrood after Dr. G. F. White. This is written by one of the old veterans, I. Hopkins, of Auckland. Mr. Hopkins writes us: "I intended to have visited my native country, England, in 1915, had war not been on. My wife and I were going via Canada, and I had a very kind invitation to visit Dr. Phillips at Washington, who was to take me to some of your principal beekeepers. I am afraid if the war don't end soon I shall be too old, as I passed into my 81st year last month."

Experience With Package Bees 1917

By C. W. Aeppler.

THE spring of 1917 was a very trying one to beekeepers in most parts of the United States. The pound package men in the South experienced great difficulties in filling orders for package bees. On account of the late, cold spring, the colonies did not build up normally, necessitating a delay in filling orders. As a result, many packages were received in the north too late to yield a surplus, or even enough for stores to winter on.

Our packages were ordered to arrive not later than a certain date. However, on account of the weather conditions it was impossible for the shippers to fill orders when promised. Consequently, packages were received all the way from April 20 to June 18. Packages that arrived early were received in good condition. Those that arrived after May 15 arrived with a high percentage of dead bees. Warm weather en route was undoubtedly responsible.

As soon as the packages were received, they were taken into the cellar and the cages thoroughly painted with thick sugar syrup. The bees took this up readily and were therefore in good condition to release onto drawn combs.

All hives had been prepared in advance. Each hive contained ten frames, some of which contained honey and pollen. The latter is as important as the former, since little pollen is available as early as the middle of April in this part of Minnesota. These combs of pollen and honey saved from the previous season, serve as a regular bonanza in getting packages built up. A great deal of fussing with sugar syrup is eliminated and a more balanced ration is available for larval development than where sugar syrup is provided, and the chance taken by the beekeeper that pollen may be available when his pound packages arrive.

In releasing the bees onto the combs, the following method was employed: An empty deep super was placed over the brood-chamber. One side of the package was opened where the wires came together. The directions that come with the package usually do not advocate this method, but it was found that the bees left the cages more readily, especially early in the spring. Sometimes it happens that the bees begin to build comb within the package and several were found where the queen had begun to lay en route. In the latter case it is invariably true that the bees will not desert the package and go below. It is then necessary to shake the bees out of the package onto the combs. This should be done late in the day, as the excitement may bring on robbing in the apiary. Package bees received early in the season are not nearly so apt to build comb enroute as those received later in the season. The empty supers can usually be removed within 24 hours.

It is unwise to examine the bees to make sure that queens are present until they have had time to lay. Little is gained and the bees are more quiet on the combs after two or three days' rest. If any queens are found missing, the shipper should be notified immediately and they will be replaced free of charge. It is unwise to purchase packages without queens. The bees are restless en route and in every case arrive in poorer condition than when queens are present.

Shipments of two-pound packages were received on the following dates: April 20, May 15, May 30 and June 18. The following results were achieved with these packages. The

results given are averages of the packages in terms of surplus extracted honey:

Date Received.	Surplus Honey.
April 20 -----	75 pounds
May 15 -----	30 pounds
May 30 -----	10 pounds
June 18 -----	0 pounds

Those received June 18 gave no surplus, and in every case not enough was stored to winter on. As there was no fall flow this year in this part of Minnesota, these colonies had to be fed to prevent their starving in September and enable fall brood rearing to go on. These last packages also did not build up to

Mrs. Aeppler beside a big swarm which issued Aug. 7, from a two-pound package bought on April 20.

proper strength for most successful wintering.

Our experience with one-pound packages is not so extensive, as it was assumed that they are not quite populous enough to build up in the cold spring, such as we have here in Minnesota.

The one-pound packages were received on the following dates: April 20, May 15 and June 15. The following results were achieved in the way of surplus extracted honey:

Date Received.	Surplus Honey.
April 20	25 pounds
May 15	0 pounds
June 15	0 pounds

The packages received May 15, although yielding no surplus, gathered enough to winter on. Packages received June 15, in addition to gathering no surplus were supplied with brood from other colonies after the honey flow in order to build them up properly. In other words, they were not worth very much more than the queens that came with them. Nuclei made up of two frames of brood with adhering bees about June 10 and supplied with a virgin queen reared in our own apiary, gave better results than one-pound packages received at about this date.

The reader must not be misled and be made to believe that every season would give the same results. As stated heretofore, these results were obtained in 1917. The spring was abnormal in every way and the weather cold up to July 1, so much so that corn at this date was no farther advanced than it is June 15 in normal years, and clover in almost like proportion. So from the experience of the past season it is safe to conclude that the two-pound package is a better proposition than the one-

pound. At least from a dollars and cents standpoint this is true, and when the northern beekeeper cannot realize a fair margin of profit on the venture, he is not apt to be a supporter of the package business in the future, which in turn means a lessening of orders received by the package men of the south. On the average, the two-pound package costs one dollar more than the one-pound package. However, this extra investment of one dollar means the production of several dollars' worth more of surplus honey. Furthermore, the two-pound packages build up to good-sized colonies more quickly than do the one-pound. Unless the packages build up to good-sized colonies they are a poor investment at their best. Our experience is that about 15 per cent of the queens received with the packages fail and are superseded within the first month. This, of course, lessens the profits from such a colony to a marked degree. It is highly probable that a certain percentage of queens are injured in transit, even in combless packages.

As stated before, slightly different results might be obtained in a normal season, but it is improbable that the results would vary radically.

Conclusions

The combless packages have come to stay. It is highly important to receive them early, as near the middle of April as possible at this latitude. The financial returns per package are in direct proportion to the earliness of arrival. A two-pound package with a good queen received the middle of April is about equal to one of our cellar-wintered colonies, and in some cases will actually yield more surplus honey per colony. In our experience this is, however, only true

when a very prolific queen is present, as we aim to have good queens present in every colony wintered over.

Supplying combs saved from the year before, containing pollen, is worth quite as much as supplying combs containing honey. The latter are, of course, essential, or their equivalent in sugar syrup, but the former are very valuable in securing rapid brood-rearing. As it takes time to build up a package of bees to a full colony, this feature should not be overlooked, provided combs of pollen are available for the purpose.

Forreston, Minn.

Shamrock Versus White Clover

YESTERDAY, while glancing through the pages of an encyclopedia, "The New Practical Reference Library," I noticed among the pictures of National Flowers the "shamrock" as the emblem of Ireland. This was represented, in the colored plate, by white clover leaves and blossoms. The question at once arose in my mind: Is the shamrock a real clover and a honey-producing plant?

Although I well knew the shape of the shamrock leaf, I had never thought of it as a possible honey-plant. Some of our readers perhaps do not know that the shamrock's reputation and its adoption by the Irish as a national flower are due to the legend that St. Patrick, while preaching to the heathen followers of Druidic faith, 1500 years ago, used the three leaflets on a single stem as the exemplification of the Christian Trinity.

Three plants, besides the white

DEMUTH'S WINTER CASE
(Gleanings in Bee Culture)

THE OXALIS ACETOSELLA, COPIED FROM BONNIER'S "FLORE"

clover, are credited with the reputation of being the original shamrock, the *Trifolium minus*, a very small clover; the water cress or *Rudicula Nasturtium-aquaticum*, and *Oxalis acetosella*, the plant which, we suspect, is the true shamrock.

But why should we contradict the "New Practical Reference Library" and its very positive picture of a white clover shamrock? The Standard Cyclopedia of Horticulture, a very modern and apparently accurate work, says that half of the world calls the white clover "shamrock" and the other half calls the oxalis by that name. It quotes Sowerberry as stating that the oxalis "is in perfection on St. Patrick's day."

However, Gaston Bonnier, in his immense and admirable work, "Flore Complete" of France, Switzerland and Belgium, of which only three volumes have so far been published, says that the trifoliate leaf of white clover appears in the arms of Ireland, although St. Patrick used a trifoliate leaf of *Oxalis acetosella* as a symbol of the Trinity.

The most weighty argument in favor of the latter plant as the true shamrock lies in its being a native of Ireland, while white clover was introduced there, they say, much later than the time of St. Patrick, which was about the year 430. So we shall take sides against the New Practical Library until we find out better.

This must be of interest to the people of Ireland, especially the beekeepers. White clover is a honey-plant, but the little oxalis, though pretty, has no reputation for sweetness, but rather for sourness, as would indicate its denomination "acetosella" and its popular name of "wood sorrel." What do our friends of the Emerald Island have to say on the subject? Does the shamrock yield honey?

By the way, it may not be amiss to say that Bonnier's "Flore Complete" gives descriptions and colored photographs of 60 different clovers (*trifolium*), while our Gray's Manual describes only 14. Bonnier's Flore, of which only three volumes have yet appeared, will be a wonderful work, if a cessation of present abnormal European conditions ever permits its full publication, in ten or twelve volumes.

A Feeder for Cell-Building Colonies

THE queen breeder must be able to control the activities of his bees to a much greater extent than the honey producer. From the time the first batch of cells are grafted in spring until the last cells are finished in the fall he must turn out queens at a fairly steady rate. It is a rare locality where honey will be coming in from natural sources through all this long period. The queen breeder, accordingly, must be prepared to feed whenever there is no nectar coming from the field in order to keep his plant in continuous operation.

In this connection we show a cor-

FEEDER FOR CELL-BUILDING COLONIES USED BY THE PENN COMPANY.

ner of the queen breeding yard of the Penn Company of Penn, Mississippi. Mr. J. D. Smith, manager of the company, uses ordinary Mason fruit jars for feeders. By boring a round hole in the top of the cover there is no danger of robbing, since the feed is given above the cluster. At the same time he can see at a glance when passing through the yard whether any feeder is empty. An empty can can be removed and a full one given in its place without disturbing the bees. A few small holes in the jar cover enable the bees to take the feed without its running too fast. On the corner of the hive in the foreground will be noticed the record board on which the queen breeder keeps his notes.

Is Co-Operative Marketing Practical for Beekeepers?

By Chilton Gano.

THE writer discussed in these columns over a year ago, the subject of national advertising for honey through a co-operative plan. It was argued that though beekeepers, unlike the California orange growers, are scattered over an entire nation, this really constitutes no obstacle to co-operation. Several readers of The American Bee Journal were, however, inclined to take issue on that point, and they had quite a weight of authority back of them. For example, the general manager of the great California Fruit Growers' Exchange has himself stated in his book on co-operative marketing that one of the most desirable conditions, where co-operative marketing is planned, is that the crop in question be produced in a restricted area. Mr. Powell, however, says in his book, that this is only true because of the inborn independence of farmers and

their natural instinct against trusting strangers.

A most interesting case directly in point has come to light in the past year, however, and has proved that farmers, if they have been distrustful in the past, are getting over it, and that in our Twentieth Century America a farmer in Maine can co-operate with a farmer in Arizona and not feel any grievance over the fact that one is a Yankee and the other a wild and woolly westerner. The cranberry industry of this country furnishes the very interesting case in question.

Cranberries do not, like apples, grow in every State in the Union. They grow in bogs unfit for the production of almost any other crop, and the industry has flourished in only three States which have boggy sections especially adapted for their production—Massachusetts, New Jersey and Wisconsin. While the former States are almost within a stone's throw of each other, Wisconsin is a thousand miles from the others. Yet the cranberry growers of these three States have one of the finest and best co-operative marketing organizations in existence today, and are marketing through it about 60 per cent of the country's total cranberry crop. This exchange has just completed its first year's advertising campaign, which was an experiment, of course, but highly successful. It is now practically agreed that advertising is to be a regular policy of the American Cranberry Exchange.

The organization movement in this industry first bore definite fruit in Wisconsin in 1906, when, under the leadership of Judge Gaynor, of Wood County, the Wisconsin Cranberry Sales Company was formed. Judge Gaynor's influence was also a primary factor in the organization of cranberry growers in the other two important cranberry States, where were formed the New England Cranberry

AN EFFECTIVE ADVERTISEMENT FOR CRANBERRIES

Sales Company and the Growers' Cranberry Company of New Jersey.

A federation of the three State organizations was immediately engineered, under the name of the National Fruit Exchange. This Exchange was re-organized in 1911 as the American Cranberry Exchange, whose purposes are stated as "the securing of higher standards of grade and pack and direct shipments from the grower to the jobber also for the purpose of advertising, selling and distributing at actual expense, Cape Cod, New Jersey and Wisconsin cranberries."

A word about the State organization with which the writer happens to be most familiar may be of interest here. The Massachusetts organization was formed in 1907 for the purpose of increasing "the sale and use of cranberries, to reach a wider market for the same, to improve the packing of cranberries, which * * * shall be maintained to the standard * * * so that purchasers may rely on the quality of the same." The original capital stock was \$5,000 in ten-dollar shares; voting is by the one-man, one-vote rule, and no honest grower is excluded from membership. Each member agrees to sell his entire crop to the association and not to withdraw during the harvesting and selling season.

Try Advertising

Up until this past year the Exchange had made rapid progress in all of its aims except that of advertising, and had secured a membership all told of about 1,000 growers in the three States. Last fall, with everything ship-shape and an experience with badly glutted markets during several years past, it was determined to put consumer advertising to the test as a remedy for cranberry overproduction.

An assessment of 7 cents per barrel secured \$25,000 with which to put on a trial campaign in a single city. General Manager C. M. Chaney, of the Exchange's central office in New York, is authority for the statement that it was no easy matter to secure the growers' consent to this campaign. They argued that cranberries are only cranberries and that their competitors would benefit as much as

they did. The campaign was finally undertaken with the definite understanding that in the city where it was tried consumption must be quite measurably increased by the advertising or there would be no second attempt.

Chicago was selected, because it has long been a primary market for cranberries from all three producing territories and because one of the Exchange's two sales offices is in Chicago. The campaign followed much the same ideas which have been used in advertising fruits. Posters and painted signs, street car cards and newspaper space were used, supplemented with recipe folders in colors, window display material for grocers, and cards for restaurants. The two primary appeals were to appetite, with inviting illustrations in natural colors, and to household pride and economy through the advertising of new and appetizing ways in which cranberries can be used, as for garnishing steaks and chops, as well as turkey and chicken, for cranberry ice, blanc-mange, tapioca, jelly roll, etc.

The campaign was a pronounced success. The volume of business done by Chicago retail stores increased 76 per cent, and sales of carload lots by the Exchange in Chicago, in the first few months, had increased 5 to 7 per cent. In addition to this immediate result it is figured that due to the educational work done and the booklets distributed, Chicago will continue for years, even in the absence of additional advertising, to consume more cranberries per capita than in the past.

However, the campaign is to be continued steadily. A short crop this season prevented immediate expansion, but an appropriation of \$50,000 has been voted to be used as soon as the supply warrants.

The brand-name used, "Eatmor Cranberries," is affixed at present only to the barrels. But the Exchange has under consideration a plan for packing in pound packages which will bear the trade-name and more closely identify it with the product.

As one campaign after another is tried and succeeds, the mystery in exploiting successfully various food products is gradually disappearing.

A good brand-name, appetizing illustrations, new recipes that tempt the ambitious housewife, and a sufficient volume of publicity to impress both consumers and retailers—in practically every case proves a simple success formula.

Now that producers in so widely separated territories have successfully combined and successfully applied the formula, it would seem as if the last doubt has been swept away that it could be beneficially applied in the honey industry.

Chicago, Ill.

Bees in the Far North

By F. Dundas Todd.

ON page 335 of the October issue you say "On the Western Continent there are probably no bees kept as far north as the latitude of Kazan, which is a trifle north of the 55th degree."

British Columbia comes pretty close, as this summer I shipped a nucleus to the Rev. Father Allard, at Ft. St. James, on Stuart Lake, which is just a trifle south of the same degree of latitude. Stuart Lake is on longitude 120 degrees W. Ft. St. James is on the S. E. corner and is located about 100 miles N. W. of Ft. George, which is probably on your map. Ft. George is on the Fraser River just where it takes its big turn from the east. Quite a number of rivers join it near that point; one, the Nechacko, being helped by a river from Stuart Lake.

Father Allard writes: "George, my beeman, entertains no doubt whatever of succeeding with bees. When he left he told me had we had those bees in the early season we could have gotten a hundred pounds of honey." (A three-frame nucleus arrived at Ft. St. James on June 25.) "And I wish you were here to taste it. It's grand!"

This region along the Grand Trunk Pacific is, from a beeman's standpoint, a most interesting one. On the map you will find Aldermere. Close by, say ten miles away, is Smithers, a division point. I shipped bees there, which also did well. This town, you will notice, is still further north than Ft. St. James.

From Hazelton to Ft. George is about 300 miles. North and south of the railroad, for at least ten miles each way, there is a solid mass of fireweed in the fall, while in fall and early summer there are all kinds of wild fruits in bloom. On the face of it, we have a beeman's paradise of about 6,000 to 10,000 square miles area, which is just being tapped. I dream that this Bulkeley Valley will some day become the biggest and most productive honey section of the North American continent. The flavor of our B. C. honey is exquisite.

I wish you could visit this western coast some summer, for I know you would enjoy it. The scenery is wonderful and from a bee standpoint most fascinating.

We in British Columbia, I think, can claim the most northerly record on this continent and we assuredly

have got the most westerly, which is situated at Sandspit, on the Queen Charlotte Isles, the longitude being about 132 degrees west.

Victoria, B. C.

The Apiaries of the Caucasus

By C. A. Gorbacheff.

BEEKEEPING has been a leading industry in the Caucasus since prehistoric times and, according to tradition handed down, this has been its cradle.

The indigenous apiaries and hives present a great variety of types and an originality of construction, as they all bear the stamp of their locality and of its population.

Since the dissemination of movable-frame hives, these characteristic apiaries diminish in number annually and the time is not far distant when they will entirely disappear.

The Society of Apiculture of the Caucasus, since the first days of its organization, has considered it a duty to gather together the most characteristic pictures of these indigenous apiaries. It has therefore taken advantage of the excellent photographic collection of Mr. K. M. Saniss, member of the association, as well as of the collection of the "Sericole Station." These views were gathered together to the number of forty-eight.

Apiary Constructions. The majority of the indigenous apiaries are installed near homes; sometimes in special quarters; oftentimes they are placed against the house walls.

In the district of Akaltzikhe, Tiflis, and in some villages of the State of Daghestan, they establish apiaries on the flat roofs of houses.

An interesting feature of some of indigenous apiaries is the placing of skulls of domestic animals on stakes, roofs or fences, about the apiary. They are popularly believed to preserve the apiary against the "evil eye."

In the north of Caucasus, where

nomadic beekeeping is very common, the "sapetki" (hives made of reeds, withes or wicker basket-ware) are placed in regular rows and covered with hay. In Kakheti, in the Province of Sakatali, Kutais State, they are placed in enclosures and sometimes sheltered under projecting sheds. Usually they are set pell-mell and rarely in regular rows. In the Transcaucasus, in the oriental part, they are installed in enclosed sheds made of boards or reeds, with small holes in the walls through which the bees take flight.

In the districts of Djibrail and Choucha, the apiaries are installed under earthen roofs; the hives are either piled up or placed upon shelves made of poles or boards.

In the State of Elizabethopol, at the foot of the mountains, the hives are ranged in rows against the walls of houses and in cold weather they are covered with felt or rugs.

In the district of Akhaltzikhe, they keep the apiaries on the roofs of the houses, or to protect them against thieves they are surrounded with poles and stakes weighted down with rock piles.

The principal types of Caucasian hives may be divided in two types, to wit: 1. Wooden hives made of logs hollowed out and standing vertically (stoiaki) or lying down (lejaki); 2. Hives made of basket or wicker ware, both stoiaki and lejaki.

1. Hives of hollowed logs are found as follows:

(a) The Kutais hive: The trunk of a tree split in two, the two halves being hollowed out and put back together. At the sides or ends, several bee openings (letki) are made, and the cracks of the joints are closed up with a mixture of soft clay and manure. The hives of this style are often placed on forked stakes which have been driven into the ground.

(b) The Akhaltzikhe hive is similar to that of Kutais, but they are usually piled up.

(c) The Nouka hive is like a trough, formed of two wooden halves narrowed down at their extremity. It is laid on the ground or supported on low stone bases and covered up with bark.

(d) The Lencoran hive is made of a whole piece of log bored through and through. The extremities are closed with round wooden disks, one of which is fitted with entrance holes. A layer of grass serves to protect them against the sun.

(e) The Elizabethopol hive resembles that of Lencoran, but it is much larger and longer and wrought with greater care. It is also found in some villages of Erivan State.

2. The mountain hives are made of wicker, measuring about 1 arshin by 6 or 8 vershok (about 30 inches in length by 10 to 14 inches in diameter). The top of them ends in the shape of a cupola (like the straw skeps of England and France). The joints of the wicker are always closed with clay and dung mixed. They are set on boards and covered with straw or woolen quilts.

The Tartar hive is cylindrical, with a flat top. It is set up on boards and sheltered with boards.

The "Lejaki" hives are narrow cylinders of wicker or walnut, closed at each end with a wooden disk. The cracks are closed as in the others with a mixture of clay and manure. They are usually set in tiers and sheltered under sheds. They are common in the State of Erivan.

The hives made of bark are to be found in the districts of Gory and Tioneti. They are also long cylinders closed at both ends with wooden disks, with small holes for the bees' entrances.

Tiflis, Caucasus, Russia.

The Texas Fair Exhibit

By T. P. Robinson.

THE Texas Beekeepers' Association has just closed one of the most successful apiarian exhibits at the Dallas State Fair in the history of the association. The honey on display was of the finest to be had in the State and came from all parts of the State. There were entries made from Arkansas, as well.

The wax art displayed bananas, peaches, apricots, figs, apples, pears, oranges, crackers, light bread, fried eggs, a baked chicken, a beef heart, and nearly a dozen choice cuts of meat, both pork and beef. The eggs were so perfect that they would have been accepted at any cafe as part of the menu. The beef heart would never have been taken for beeswax at all. The artist was not contented to make a peach and color it perfectly, but put the fuzz on the peach.

The exhibit, as an educational factor, is of the greatest merit to the beekeepers of the State. Thousands of people come and visit the apiarian department at the fair and are fast becoming educated to the merits of honey as a food, its granulating propensities, the reason for its varied colors and tastes. Many would at

APIARY IN DAGHESTAN TERRITORY, TIFLIS, CAUCASUS.—The hives are made of clay.

first suggest that the honey in the grocery stores was adulterated. These parties were allowed to have their opinion, but were quickly told of the different flavors of honey, its various colors, and its granulation. I have long ago learned not to argue with people who are certain about a thing, for this makes them more positive in their belief. Merely tell them that you could not think of anyone adulterating honey, especially with the stringent food laws. I always treat them as if I did not care a whit about their contention. These contentions are growing less year by year, as the people become more enlightened on honey. This continuous education is having a great effect towards the larger use of honey. We had honey of the various colors and flavors, also granulated honey, and any argument could be clinched by a real demonstration if necessary. Not only are the people awakening to the importance of the exhibit at the State Fair, but the beekeepers are awakening also to its great importance as an educational factor.

I must mention in this connection the honey cooking that was on exhibition. We had three show cases full of cakes, cookies, fruits and preserves that our good ladies had prepared with honey to show in an educational way the great value of honey in the culinary science.

Mr. W. H. Laws, of Beeville, Texas, was elected by the association to judge the bee exhibit, but the culinary department is a little out of Mr. Law's line, and three ladies judged the cakes and cookies. Miss T. Walker, of Dallas, Texas, is one of the greatest cooking experts in the South; cooking is her hobby. She has carried off many premiums. Miss C. Weimer, of Denton, Texas, the second judge, is the director of foods for the College of Industrial Arts. Miss Elois Berry, of College Station, Texas, was the third judge for this department. She is at present engaged in the exhibition of culinary science for the A. & M. College of Texas.

Mrs. C. G. Hickox, of Dallas, won six first prizes, three second prizes and three third prizes. Mrs. T. W. Burluson, of Waxahichie, Texas, won two first prizes, three second prizes and four third prizes. Miss Madie Hickox, of Dallas, Texas, won one first prize. Mrs. E. G. LeSturgeon, of San Antonio, Texas, took two first, two second and three third prizes. Mrs. Geo. W. Shoemaker, of Dallas, won one first and one second prize. Mrs. W. N. Wiggins, of Dallas, won one first and one second on candy. Bartlett, Texas.

Apiary Experiences and Weather Conditions

By D. Queen.

AT the end of the season the beekeeper may well review his management and experiences, and learn something which may be profitable in the season following.

The writer is impressed more and

more with the necessity of knowing his territory, and no less, the kind of weather to be expected at certain periods. These things can be learned only by careful observation through a number of seasons, and by listening to older residents who are themselves thoughtful observers.

As I am entirely dependent upon a fall flow for surplus, my observations will apply to similar localities. The early-flow man has his troubles in relation to winter stores, and the late-flow man also has his, although they may be less expensive. Late stored nectar is likely to be not well cured or capped. The prejudice against aster honey is most likely due to the weather conditions immediately after it is stored, rather than to the real character of the honey.

The bees are not good weather forecasters. In proof of this, I have never seen combs so generally built out to biscuit form as is the case this fall, and seldom so many not capped, nor even two-thirds full.

Everything was booming. A week or more of favorable weather could have been profitably employed, when, without warning, came cloudy, raw days one after another until the bloom was over. The bees foresaw the work to be done, and made their storage preparations, but they could not foretell the weather.

I must confess to some responsibility for the failure to cap. I also saw the big flow in prospect, and put on supers rather recklessly, at the same time making the serious mistake of putting these late supers next to the brood-chamber. The result was honey stored in small quantity in about every comb. I should have known better. Next time the supers go on top, if at all.

Another effect of this excessive supering was, in the case of colonies none too strong, to crowd the brood-chamber with honey, and nothing done in the supers.

These colonies evidently realized their inability to fill the big space

overhead, and did the next best thing, which was not exactly what I was hoping for.

Queenlessness late in the fall is a rather puzzling problem. If the queenless colony is left alone it may pull through until a queen can be obtained and introduced in the spring, if not, count one colony less.

On the other hand, if united to a queen-right colony, count one less right from the drop of the hat. As an experiment, I have a case of each, and don't know which is to be preferred. The newspaper method of uniting worked all right. One colony had a lot of drones, and the other had the queen. I am curious to know how social affairs stand in the living-room.

Equalizing of brood persistently as long as it seemed desirable was a great aid in lifting weak colonies, and probably controlled swarming. This was my first season without at least one swarm.

The "putting up" of brood sometimes fails to work out well. This is the case where there is a dearth of nectar until late in the season. After the brood is hatched out above there is that large empty space all summer staring the colony in the face, and it proves a real discouragement to any but a rousing big colony. Half-depth supers given as part of the brood-chamber until three weeks before the expected honey flow have kept down swarming, and are not discouraging to a weak colony.

New Jersey.

Report on Apiary Inspection and Demonstration in Ontario for 1917

By Morley Pettit, Provincial Apiarist.

A CONFERENCE of the Ontario Apiary Inspectors was held at the office of the Apiculture Department, Ontario Agricultural College, on May 16. As few changes had

WICKER HIVES IN LENKORAN STATE, RUSSIA

A whole piece of log is bored through and the ends closed with discs. The hives are on boards and sheltered with bark.

been made in the list of inspectors, the discussions were of an advanced nature which made them very helpful in systematizing the work and bringing about uniformity of methods. Perhaps the most important action taken was the framing of a resolution asking for a change in the foulbrood act calculated to control the sale and shipping of diseased bees from one locality to another. The proposed change would substitute for clauses 5 and 6 of the act the following clauses:

5. Any owner or possessor of diseased colonies of bees or of any infected appliances on beekeeping who sells or barter or gives away or removes from the premises such diseased colonies or infected appliances, or who exposes in his bee-yard or elsewhere any infected comb, honey or other infected thing, shall incur a penalty of not less than \$50 nor more than \$100, or he may be imprisoned for any term not exceeding two months.

6. Any person who sells or offers for sale or barter or gives away any bees on combs or used appliances for beekeeping, before being authorized by the inspector so to do, shall incur a penalty of not less than \$50 nor more than \$100, or he may be imprisoned for a term not exceeding two months.

It will be seen that the purpose of this desired change is to prevent the moving or disposal of bees which may be diseased and still have not been inspected. It has been found that there is a great deal of traffic in colonies of bees and used appliances and that disease is spread by this means. At present the law only allows the inspector to prevent this when the apiaries have previously been inspected and found diseased. Many apiaries are advertised for sale at a season when they cannot be inspected, and under the act as it now stands the sale cannot be prevented unless the bees have previously been found

diseased, even when they are known to be in a diseased district and are very likely to be infected.

The following is a list of inspectors and the counties in their charge: Angle, W. B.—Wentworth, Brant, Victoria, Hastings, Peterboro.

Armstrong, Jas.—Lincoln, Welland, Frontenac, Grenville, Leeds, Lennox, Christian, J. E.—Muskoka, Simcoe. Denison, Alf.—Dundas, Prescott, Russell, Gloucester, Carleton, (Os- goode.)

Devins, C. J.—Grey, Dufferin. Fowler, R. A.—Perth, Waterloo. Gowan, L. B.—Norfolk, Haldimand. Hunter, R. M.—Oxford. Hutchinson, E.—Wellington. McCauley, J. H.—Halton, Peel. Robertson, N.—Essex, Kent, Elgin. Rumford, S.—Lambton, Middlesex. Schrank, J. S.—Bruce, Huron. Scott, W.—Northumberland, Prince Edward.

Selwyn, H. H.—Glengary, Stromont, Lanark, Renfrew, Carleton (Ex-Glout. Osg.)

Weir, W. A.—Durham, York, Ontario.

The backward spring and frequent rains in early summer made the inspection work very difficult. It also held back the home work of the inspectors so that in many cases they refused to leave home when the weather became favorable for inspection work. On this account the money available for inspection and demonstration work was not all used and not nearly all of the known cases of disease were attended to. This is one of the worst features of our system of inspection by men who are not devoting their whole time to the government work.

Because all beekeepers in the Province cannot receive attention the policy of this department in apiary inspection has been to give the services to those who appreciate it most. This also, coupled with the fact that at no time have we been in a position to take care of all known diseased

areas renders any sort of statistical report of little value. A statement of the percentage of inspected apiaries found diseased under such a system, while it might be expected and has usually been given in a report, is of no value under the circumstances. Unfortunately, comparatively few apiaries infected with either disease have been found to be entirely cured, yet it might safely be said that the expenditure of time and money from year to year has not been without benefit in the same way as the expenditure of life and ammunition which has merely held entrenchments against an enemy without making very great advances. Our leading beekeepers are convinced and have stated publicly that great headway is really being made by the education of beekeepers who are learning to act as their own inspectors and are learning to regard either variety of foulbrood as no less an enemy, but one which can be kept very much under control.

Seven hundred and seventy-eight apiaries were inspected and 203 of these were found to be diseased with either American or European foulbrood. Eight thousand five hundred and fifty-seven colonies were examined and 1,132 were diseased. Two hundred and seventeen colonies were destroyed or treated by the inspector. The owners of the other diseased colonies were instructed as to methods of treating them and most of them reported afterward that they had followed out instructions.

The legislation referring to the disposal of bees was frequently enforced by inspectors and in several instances sales were stopped. As far as possible all intended sales and removal of bees were discovered and examination made before bees were removed.

One unfortunate feature of the season was the shipping of some bees infected with European foulbrood from Niagara district to Kenora district. This district of New Ontario is becoming famous as a clover seed producing area and the district representative has been encouraging the keeping of bees. As soon as the presence of the disease was discovered he communicated with the Provincial Apiarist and our most experienced inspector, Mr. Armstrong, was sent up to look over the case and reports that he has hopes that through the prompt action of the District Representative and of local beekeepers the infection has been practically wiped out.

In addition to the personal visits of inspectors, instructions were carried to beekeepers by means of local apiary demonstrations to a greater extent than ever before. Eighty-eight of these meetings were held in all parts of the Province.

The total attendance at these demonstrations was 2,686, or an average of 32 persons at each. Considering the highly specialized nature of the subject and the fact that comparatively few in a community are interested in bees, also that these demonstrations have been held exten-

ANOTHER APIARY IN TIFLIS

sively throughout the Province for seven years, it must be admitted that they are meeting the desires and requirements of Ontario beekeepers.

These meetings are conducted in almost every case by the inspector for the district. Some of them were interfered with by unfavorable weather, but the people have learned that bee demonstrations will be conducted punctually as advertised, regardless of weather conditions, and that they will not be postponed under any circumstances. The inspectors were instructed this year to make the demonstrations as practical as possible and to reduce public speaking to a minimum. They also agreed that wherever possible the actual manipulations of hives and combs in the apiary under natural conditions would be most acceptable and profitable to those in attendance. Wherever it seemed advisable the demonstrator was supplied with a trunk containing a great number of beekeeping appliances of the most modern design. One of the bee supply firms has also supplied District Representatives with exhibits of this nature, and in some cases these were used.

Evolution of Wintering in British Columbia

By W. J. Sheppard

YEAR 1915—Single-wall hives on trial

YEAR 1916—Double-wall hives on the "Buck-eye" principle being tried.

YEAR 1917—Hive-cases that take ordinary single-wall hive-bodies, permanently packed as far as the brood-chamber and covered in, have been found an improvement on the double-wall hives for this section of British Columbia.

"KOOTENAI" HIVE CASE

Permanently packed. There are 3 inches of packing below the floor and on all four sides. The flat cover is 3-8 inch larger all around than the top of the case, and small triangular blocks nailed in each corner inside raise it and ensure permanent ventilation. The stories or "lifts" are all alike, and as supers are put on are added as necessary. In this hive-case the bees are warmer in winter and cooler in summer. When packing for winter all that is necessary is to add the top covering over the frames.

Notes From Switzerland

By C. W. Aeppler.

IN the September number of "Schweizerische Bienen Zeitung" (Swiss Bee Journal) I find the following of interest:

"Night and day from the nearby boundary one can still hear the thundering of thousands upon thousands of death-dealing cannon. Our importations (sugar) are endangered more than ever; but we live in happy confidence that the interests of Swiss beekeeping will nevertheless be preserved for the future. Should this fatal war be the cause of rationing all foodstuffs, as has already been done in the case of sugar, we will surely set aside a ration for the little bees, even though it must be a modest one.

"Therefore, let us, even though it is with a weary heart, look into the

dark future with hope. The war has convinced every Swiss beekeeper that behind him stands a watchman who looks after him. Who is this watchman who endeavors to safeguard our interests? It is the Swiss Beekeepers' Association—the Central Association, which, with its 117 affiliated associations has established itself like a mighty tree which neither storm nor weather can harm, and beneath whose shade over 10,000 beekeepers feel themselves safeguarded."

We can learn a great lesson from the above. The Swiss beekeepers are organized—in comparison we are not. During the past year the Swiss Beekeepers' Association imported 70 carloads of sugar for winter stores for the thousands of colonies of bees in Switzerland, while only 52½ carloads could be delivered by private firms for the same purpose. There are in the neighborhood of 200,000 colonies of bees in Switzerland today. Although we are not surrounded by enemies, as is Switzerland, their success through organization should serve as a lesson to the beekeepers of the United States. The Swiss Government has allowed 8 Kg. (17.6 pounds) of sugar per colony. The Swiss Beekeepers' Association has recommended to all its members to unite all weak colonies and winter only the very best, so that each of these strong colonies can be given more than 17.6 pounds of sugar in the form of sugar syrup, and thus insure the beekeeping industry for 1918.

The average production of honey per colony in Switzerland in 1917 is 5 Kg. (11 pounds) and little or no swarming is reported.

The average price of honey in Switzerland today is 4.50 francs per Kg. (2.2 pounds.) Not knowing whether or not the value of Swiss money has been lowered during the war, I wrote to a large bank for the necessary information. They advise that 100 francs is worth \$21.50, or one franc is worth 21½¢, so that today honey is selling for 99¢ per Kg, or 45¢ per pound. This is an increase of about 25 per cent over 1916, caused by a corresponding increase in the price of sugar and all beekeeping supplies.

More or less speculation in honey seems to have gone on of late, so that today the Swiss Beekeepers' Association is attempting to prevent any further increase in the price of honey. If such a procedure should ever become necessary in the United States, would other foodstuffs be necessarily higher in price? Not so; but such a condition might be brought about if the people at large once learn to know the real food value of honey.

Forreston, Minn.

Winter Cases for Single Hives

THERE are many modifications of the winter case for wintering outside. Aside from the extra cost of making a separate case for each hive, none are more practical than the case used by W. R. Hemple, of Bagley, Wis. The picture

shows the cases piled up at the corner of the apiary in summer. Mr. Hemple produces comb honey with 125 colonies in one yard. His average was seventy-five pounds of comb honey from basswood in 1917, which is a record for comb honey seldom excelled the past season. In this winter case he provides five inches of bottom packing, five inches on four sides and eight inches on top, all packed with planer shavings. He removes the covers from the hives when packing for winter and places burlap over the frames. An examination in cold weather will often show ice under the cover of the packing case, but all dry over the hive. Mr. Hemple also has a very ingenious swarm catcher which we hope to be able to show at some future time, as our photo was a failure.

WINTER CASES FOR SINGLE COLONIES USED BY W. R. HEMPLE, BAGLEY, WIS.

Store-House for Comb Honey

THE question of caring for comb honey in cold weather has puzzled many a beekeeper. Once it granulates in the combs the value of the product is materially reduced and the man who produces in large quantity must market early or be prepared to keep his comb honey warm.

Hubbard Brothers, of Boyne Falls, Mich., are large producers of fine comb honey. For a few months in the fall and winter of 1916 comb honey was a slow sale and many beekeepers sacrificed their crop rather than risk keeping it until cold weather. The Hubbards did not worry, for they are prepared to carry a big crop through any kind of winter. The picture shows their concrete store-house for comb honey. The building is ceiled inside with matched lumber and a very little fire maintains an even temperature and requires little attention. At the end of the building can be seen an ordinary iron stove for burning wood, which is encased in a brick case. From this case a pipe to conduct the warm air

enters the building. They can thus care for the fire without opening the building. There is another pipe leading out at the side to provide for a circulation of air. By holding the one crop for a few months until the market was stabilized, they were able to get a fair price for their honey and thus save the price of the building several times over in one year.

A Texas Beekeeper--T. W. Burleson

By T. P. Robinson

AT the close of the Dallas State Fair, and where my services had ended as superintendent of the apiarian department, my good friend, Mr. T. W. Burleson, gave me a kind invitation to go home with him and I accepted.

Mr. Burleson is one of those very enthusiastic beekeepers. He is full of the malady of beekeeping and as a result is making a great success. I

must say, in the first place, that Mr. Burleson was the greatest, or I might say the largest exhibitor, at the fair this year and he won many prizes, both on honey and bees. The money won by him amounted well beyond \$100.

He is a believer in the motor truck for apiary work and has a fine truck which he uses with great success. At the close of the fair he used it to take back to his home all the honey and other show things that he had not sold. We started for his home, 35 miles south, at Waxahachie.

This beautiful town is located on the M. K. & T. R. R. and is a most ideal place in which to live. The wind was blowing strongly from the north, with a temperature of about 45 degrees, and was chilly. We made the run in about two and one-half hours, leaving Dallas about 2 o'clock p. m., and arriving at Waxahachie at 5 o'clock. A half hour was lost in a detour from our course to visit one of Mr. Burleson's apiaries. Upon arriving home we found Mrs. Burleson busy with the cares of her house. She is perfectly at home in her husband's apiaries and a splendid homekeeper besides. His home yard is kept in his back yard, right in the heart of town. He told me that the bees did very well in this location.

His honey house is two stories high. In the upper story were stored cans and momentarily unneeded hives, frames and the like. The lower story is used for the extraction room and honey storage. This house is tightly constructed and is used as a heating room to liquify granulated honey. The house is equipped with a hot water system and artificial gas is used as the heating agent. Mr. Burleson's idea was to construct the house so that he could cater to fancy comb honey trade, keeping it heated up to near 100 degrees so as to have this honey in tip top shape for the fancy market. Cotton honey gathered in this district will granulate in ten days with a temperature ranging near 40 degrees. There has been very little use for the house for the last three years, as the demand for

HUBBARD BROS.' CONCRETE HOUSE FOR STORING COMB HONEY

honey has outrun the supply, and no honey was held over, but the house was used very successfully in 1914.

We visited several of Mr. Burleson's apiaries and found them in good condition and doing well. The bees are kept with the hives in pairs. For hive-stands two 2x4 scantlings are cut 6 feet long and nailed together with cleats, a separate board about 14 inches square is used for an alighting board just in front of the hive. In taking the honey he makes it a rule to extract a yard a day and return home with the harvest and visit a different yard the next day, and so on until he is through all his apiaries.

He is very enthusiastic about pound packages. He made large shipments

of the pound packages last spring and was uniformly successful.

Massachusetts Meeting.—Wednesday, January 9, at 1 p. m., the beekeepers of Massachusetts will meet in the library of Horticultural Hall at Worcester to discuss matters of general beekeeping interest. At 3 o'clock, in the same day, Mr. E. R. Root, of Medina, Ohio, will talk on "Importance of Honey Production."

There will also be exhibits of honey, wax and apiary appliances, in Horticultural Hall, during the three days, to which the public will be invited. It is intended to emphasize the value and uses of honey in the home. B. N. GATES.

entirely just. Accordingly when a shipper takes the short cut and presents his case directly he is quite likely to receive both courteous and fair treatment. It is necessary, however, to send along all the papers so that the claim department can see at a glance the history of the shipment.

It sometimes happens that a local agent is inclined to be surly and unreasonable. I have even known cases where the agent himself was at fault, and he then used his influence with the road against the settlement of an

T. W. BURLESON AND CREW READY TO EXTRACT

T. W. BURLESON

LEGAL SERVICE DEPARTMENT

Shipping Honey—Claims for Damage

"In November, 1913, I shipped a crate of four cases of comb honey to — by — railroad. A week later two cases of comb honey were shipped back to me. It was badly broken and leaking, and I would not accept it. He wrote that it was broken by the railroad company. It was in first-class condition when I got the bill of lading. Can you help me collect the damages?"

ILLINOIS.

Answer: We can only give advice through this department and cannot undertake to look after any kind of legal case.

Where an article is delivered to the railroad company in good condition and is lost or damaged en route the company is liable for the amount of damages. There is usually very

little trouble about settlements in cases of this kind if properly handled. A shipper should never accept damaged goods without having the fact of the damage noted on his shipping receipt by the agent. Where the agent is friendly and reasonable the easiest way to make a collection for damages is through him. If he is disposed to take the matter up with the claim department of the road and to make a fair statement of the case, the settlement is usually prompt. Railroads dislike having claims of this kind placed in the hands of attorneys, since there are lawyers who make a specialty of damage cases against railroads. It too often happens that the railroad company is compelled to pay claims that are not

honest claim, apparently to shield himself from blame. In a case of this kind it becomes necessary to disregard the agent and take the matter up with the claim department of the road or employ an attorney to do so.

Where the damage occurred as long ago as 1913 there may be some delay in getting a settlement, as everybody will have forgotten about it by this time and it will be harder to prove the facts in the case. All claims for damages to goods in transit should be filed promptly.

Under present tariff regulations the freight rate on comb honey in unprotected cases is double the first-class rate, while cases properly crated in carriers go at a much lower rate. This applies to all points west of the Mississippi River. The large number of claims for damaged comb honey brought about the higher rate on unprotected shipments.

BEE-KEEPING FOR WOMEN

Conducted by MISS EMMA M. WILSON, Marengo, Ill.

Thirty-five Years of Service

Volume 58 of the American Bee Journal begins with this number. Fifty-seven years have brought a succession of editors, beginning with the great Samuel Wagner, its founder, through his son, Geo. S. Wagner, W. F. Clarke, Thos. G. Newman and Geo. W. York, to the present management.

In continuity of service and extreme devotion to the self-assigned task none can equal the record of Miss Mattie C. Godfrey, whose photograph we reproduce.

Miss Godfrey has been compositor for the American Bee Journal continuously for 35 years. During this

MISS MATTIE GODFREY

time practically all the material used in the Journal has been set up by her. We have the word of former editors, and we can vouch for it ourselves, that the major credit for absence of typographical errors in the columns of the American Bee Journal during this period can be directly traced to her. Her proofs have always been extremely clean and her judgment in revising doubtful copy very accurate.

Although it was with a feeling of regret that we accepted her resignation, which takes effect immediately, she has certainly earned her retirement. Such devotion to duty should have a greater reward than is in the power of the American Bee Journal to bestow. We know that we can combine the appreciation of all our older readers, at least, with our own in extending hearty good wishes for many years to come to the one who has been so faithful to the American Bee Journal.

My Bees

Read at the Iowa Convention by Mrs. Clara T. Noel.

I am one of the little beekeepers. My apiary has never numbered 40 colonies, yet my enthusiasm is not to be measured by my size or the number of colonies I operate.

My interest in bees began in the early seventies, when my honored father, a retired farmer, became interested in bees and made them his special study. He had the idea of movable frames and for his own amusement made hives of various shapes, but always with movable frames. I was his assistant and companion in operating an apiary located in the woods along the Des Moines river, where basswood was plentiful. This apiary consisted of a large number of log gums and boxes filled with bees that the owner had long neglected. My father and I transferred these into movable frame hives for a consideration. The long days that I operated the smoker and the many queens I helped to find that they might be clipped, my father transferring, uniting, robbing as he thought best, gave me my first experience in beekeeping.

It is only in the last dozen years that my love for bees has had an opportunity to indulge itself and to put in practice the lessons I learned in early girlhood. A colony of bees came into my possession in a modern, up-to-date hive, in June, when white clover was in bloom, and the pastures and roadsides were as white as if carpeted with snow—that swarm, the beginning of my apiary, gathered over 100 pounds of beautiful white clover honey that season. Since then I have had much pleasure, some profit and many stings in my beekeeping experience.

My apiary grew very slowly, but it was always self-supporting, supplying the home table with choice honey. I used up-to-date hives, building a substantial bee-house for storage and work. The last few years there has been an income that I call "my traveling fund." Through its existence a few years ago I was enabled to make a visit to some of my children living in the far West. In giving parting instructions to the girls who were to care for the home during my absence, one asked, "What about your bees? What must be done to them?" Knowing they were never known to molest them in any way, I felt safe in saying: "You may have for your own all the honey you take off and sell." Many supers were on and the white clover harvest was in full swing. After a delightful trip through California's fine valleys, over snow-capped mountains, a day and night ride on the ocean, home by way of Glacier Park and Montana's

wonderful wheat fields, I found my bees had been tampered with and appeared in a decidedly disordered condition. After a little questioning I found those girls had robbed my bees of over 100 pounds of choice white clover comb honey, although they had said they would rather face the German guns than my bees. While I wear neither veil nor gloves, those girls went mother one better and went forth to conquer with low-necked and short-sleeved dresses. They daintily used the smoker and hurriedly took off the supers and rushed them to a place of safety, bees and all. The astonished bees did not at once protest, but soon other sounds than laughter came from those girls. Brothers came hurriedly to the rescue, but beat a hasty retreat, even the sedate father disappeared around the buildings in undignified haste. The hired man and the dog came in for a share of fiery darts. Not until dark did those bees desert their stores. The next day, with swollen hands and disfigured faces, those girls prepared their plunder for market. But they said "Never again will we play a joke on mother through the agency of her bees." The hired man would eat no honey while he staid with us, and the dog to this day disappears when the smoker starts.

I have been stung many times, but not always by the bees. Once I bought a red clover queen and had visions of gathering all the honey for miles around, but instead, her workers cared little to fill honey sections with any kind of honey; they swarmed early and late and poorly prepared for the winter.

Oh the talking it took to convince the irate woman who said the bees were ruining her grapes; they were all my bees, because they all had "Clara T." on their wings. You beekeepers know how hard it is to convince some people that the bees were saving what had been laid waste by other insects and birds.

I never could control swarming, but one year an article in one of the bee journals said "Swarms always settle a certain number of feet from the hive before taking their long flight." I believe it was fifty feet. I was delighted. No more swarms should get away from me. But the writer did not say in what direction those fifty feet would be. My prime swarm settled fifty feet from the hive all right, but straight up to the swaying branch of a tall ash tree, where I found it impossible to get them. Just why so many swarms chose that particular place I do not know, but practically every swarm went to the same swaying branch, just fifty feet away.

When white clover blooms, I do not enjoy the Ladies' Aid nor the Missionary Society as a good member should. When a paper is being read describing the good work in India or South Africa, I have caught myself wondering if by any chance I had overlooked a queen-cell in No. 10, or hoping No. 6 could wait till tomorrow for another super, or if the clipped golden queen would be lost

should No. 13 swarm while I was away.

The best the Good Father had to give the children of the earth was a land flowing with milk and honey. Nectar is found in practically every flower and there is no other way to obtain this sweet for man's use but through the agency of the bees. Think for a minute of the many trips afield for the raw product and the mysterious work in the hive that must be done before it is ready for man's use, then have some consumer wonder why the bee man wants more than 10 cents per pound.

In these troubled times when we are all urged to do our bit in the great struggle for universal peace, we housewives, in answering the call, have canned nearly every known food product, from dandelion greens to beef, pork and chicken. The bees knew the art of canning their stores long before the Mason jar and the cold-pack method were known, and every can keeps, the secret of their canning no one has found out, but if the seal is not broken it seems to keep indefinitely. When supplies are scarce the bees go on scant rations and no one murmurs; their stores are so carefully guarded, supplies issued in such just manner that the colony often lives through a severe famine. But when the harvest is ripe and white clover in bloom, how the bees do work. They let no opportunity pass to bring in supplies, even from the humblest source. There are no strikes for shorter hours. The beekeeper is happy as he watches the heavily laden workers returning to the hive, knowing that the surplus stores will enrich himself. There is not a slacker in the hive, no one asks for exemption from the duty at hand. The future need of the colony is at stake, the life of their home depends upon each doing her bit, and all cheerfully rally to the call.

Oskaloosa, Iowa.

Bees Wintering on Honey Stored Below Brood-Nest

I ran my bees this summer for extracted honey, using the 5 $\frac{3}{4}$ inch super containing the regular shallow extracting frames, but when I was ready to set on my chaff trays for winter I found in eleven of my colonies that the cluster of bees was partly in the shallow extracting super while the bees of the lower part of the cluster hung in the main hive. I found that if I would remove the super they would not have enough honey below to winter on, so I took the supers, bees and all, and set them below the hives, wrapped them with slaters' felt, a sort of tar paper, put my chaff trays with packing on top of the main hives and then the telescope covers.

I have my bees in 8 and 10-frame standard double walled hives, and if I left the supers on top I could not use a chaff tray, for there would be nothing to protect the rim of the hive from rain, and water would leak through at the corners and wet the packing in the spaces at sides and ends.

Now the question is, will my bees starve after they have eaten all the honey out of the main hive, and not go below?

I was afraid they would not go below, because it is more natural for them to travel up after stores, and the heat of the cluster would be at the top of the warm hive. They might not be able to keep up the right temperature if they went below on account of too much space above.

I have the eleven packed this way.
MISS BIRDIE M. HARTLE,
Reynoldsville, Pa.

The likelihood is that the bees will take care of their stores all right without any interference on your part. Since your last handling there have probably been days warm enough so that the bees would carry

up from below the honey; since, as you say, it is natural for them to travel up after stores, it is also natural for them to carry up any stores that may be below. There is, however, a chance that some one of the colonies has been a bit sluggish, and has not been as active as it should about carrying up. At any rate, it will do no harm, the first day it is warm enough for any of the colonies to fly fairly well, to see that all are doing so. If you find any colony that is quiet while others are flying, pound on the hive until the bees are thoroughly stirred up and flying. When they become thus active you may count that they will be sure to give their attention to carrying up any honey that may be beneath the cluster.

Will Change to Extracted Honey

I am contemplating changing from comb honey to extracted honey. The prospects are bright for 1918.

FRANK COVERDALE,
Delmar, Iowa.

Price is Good

This has been a good year, and the honey is retailing for 25 cents per pound. The old crop is gone.

J. E. RIDLEY, Douglas, Wyo.

Crop a Failure

The bees will not make enough honey to do them around here. There has not been a pound of honey taken off, as far as I have been able to learn. About 50 per cent of the bees were lost last winter on account of continuous cold weather. Many starved in the cluster with plenty of honey in the combs. White clover was mostly killed last winter.

J. H. WARREN,
Elliott, Iowa.

Gets a Fall Flow

We got a little honey from white clover in the spring, but our fall flow from Spanish needle was fairly good. I had eighteen colonies and increased to twenty-one, all in good winter condition. I had 825 pounds of honey all sold at 18 and 20 cents.

PAUL PIERSALL,
Robinson, Ill.

Another Change to Extracting

I have 400 colonies of bees and have turned them over to extracted honey.

LESTER K. KEISTER,
Wisconsin.

Good Crop and Good Price

As far as I can learn from beekeepers in this part of Oklahoma, they have all done extra well this year. My bees have filled two supers. We

never lose any from wintering. They are out nearly every month in the year. I have sold my honey at 20 cents in 50-pound lots and 25 cents per pound in small lots of five and ten pounds.

AL. PORTER,
Page, Okla.

A Colony of Hustlers

The queen of this colony, a leather-colored Italian, distinguished herself during the season of 1917. Her Keeper heeded the editor's advice, page 124, and she did the rest. At swarming time she attended strictly to business instead of following the foolish fashion of her neighbors. Super after super was added and nicely filled until the pile was nearly five feet high. Where the nectar was found, when other colonies found

A COLONY OF HUSTLERS

barely enough to keep from starvation remains a puzzle. Two hundred and ten pounds of honey has been extracted from the five upper supers and sold for 12½ cents per pound. Mary, who keeps a store at the fifth cross roads, paid \$27.25 cash.

L. L. APIARY, Wisconsin.

Good Times in Wisconsin

The past season in Northern Wisconsin has been below the average. An apiary that averaged 193 pounds per colony in 1916 fell to 104 pounds per colony this year.

In July we had a very interesting meeting with about 25 beekeepers present. Professors Ball and Wilson, of the University of Wisconsin, were with us for two days. The first day was spent in inspecting apiaries; 391 colonies were examined. Professor Ball pronounced them the freest from disease and best kept of any in the State. On the second day a field meet was held at the apiary of James Cheif, who has an up-to-date apiary of 68 colonies. Interesting and in-

structive talks and demonstrations were given.

There are about fifty beekeepers in Langlade County, with from 1 to 200 colonies of bees, producing about 100 pounds of extracted honey per colony and 35 pounds of comb honey per colony. A year ago we organized a beekeepers' association with a present membership of 30. We are establishing one brand of honey for all members, known as "Arctic Honey." We are offered 18 cents per pound for extracted honey in carlots now.

We had 3,500 pounds of honey on display in our booth at the county fair, also swarm of bees in glass hive, beekeeping equipment, and pies, cakes, etc., made with honey.

E. H. MARSH.

He Does Not Agree

In the September Journal Mr. Pellett explains the ancient custom of making a noise when the bees swarm. Not all see it in this way. When a swarm is out and on the wing we cannot fail to see that the bees are

directed by the sound of the wings of the queen and the leaders stay near the queen.

They have a sound in issuing, another on the wing, another when a place has been selected to settle. The sounds lead them. A small entrance is often the cause of swarms alighting, since it takes longer for a swarm to issue from a small entrance.

Bees issue from the hive in an organized way, following the sound of the queen and leaders. Ring a bell or make any noise loud enough to drown the sound of the queen and you disorganize the body, so they settle.

VIRGINIAN.

California Cold and Dry

Rains are still holding off, but I have hopes for a wet winter for the reason of summer and fall rains in adjoining States. November has started in cold.

M. MENDELSON,
Ventura, Calif., Nov. 12.

Approves Big Hives

In connection with your advocacy of large hives it would probably be of interest to you that we have in this county a veteran who is no doubt among the oldest in the country, with an actual experience of over fifty-five years of keeping bees in several States. He now has an apiary in Pennsylvania and one in North Carolina. Mr. A. G. Lyman, with his wealth of experience, now keeping bees in two widely separated States, after a trial of all sizes of hives and kinds of equipment, says: "Use nothing less than the equivalent of twelve Langstroth frames, and it is doubtful whether fourteen is too large."

L. E. BEBB,
Morgantown, N. C.

Beginner Gets Good Returns From One Hive

This is my first year. One colony gave me 128 filled sections of fancy comb, none less than 14 ounces. They were sold at 25 cents per section.

C. M. KOPT,
W. New Brighton, N. Y.

Gets a Good Crop

We have had the largest crop of honey we ever harvested, and are selling it at \$1.50 per ten-pound pail. This price looks low, no doubt, but it is about all we think the people here will pay. It has been a great season for buckwheat, but the corn failed to mature, the weather was too cold.

GILLETT BROS.,
Postoria, Iowa.

Wide Spacing of Frames

Probably you have forgotten me and the pleasant day we had at Mr. Crane's last summer, in Middlebury, but I have not. I have had another pleasant summer with the bees, got nearly 2,000 pounds of honey from 15 colonies, spring count; 1,500 extracted and 500 comb. My best colony gave me nearly 400 pounds of extracted honey. I had only 2 or 3 swarms and they all came back.

BEEKEEPERS' DISPLAY AT ANTIGO, WIS.

How did I do it? By following your wise suggestion of wider spacing of frames, with plenty of ventilation and abundance of super room.

To get the wider spacing of frames—mine are all 10-frame Hoffman spaced $1\frac{3}{8}$ inches—I just pulled out

one and divided up the room with the others. I wonder if I can succeed again. But I feel very grateful to you and the Journal for the advice you gave me.

C. H. CROFUT,
Arlington, Vt.

The next annual meeting will be held at Battle Creek.

B. F. KINDIG, Sec'y.

North Carolina Meeting.—The State Beekeepers' Association of North Carolina will meet in convention at Newbern, N. C., on Thursday, January 10, in the Chamber of Commerce of that city. The editor of the American Bee Journal has promised a paper for that meeting and will bring it in person if it is possible for him to be there.

Information concerning the meeting may be secured by addressing the President of the association, Professor Franklin Sherman, State Entomologist, Raleigh, N. C.

It is a pleasure to see the South-eastern States coming to the front. President Sherman states that their membership is now 127 beekeepers, owning 7,869 colonies.

Northern Pennsylvania Beekeepers Organize.—At the Inter-State Fair at Athens, Pa., on Sept. 19, 1917, there was organized a Northern Pennsylvania Beekeepers' Association with 35 members, representing about 1500 colonies. The following officers were elected:

Chas. N. Green, President, Troy, Pa.; W. H. Allen, Vice President, Wysox, Pa.; Harry Beaver, Secretary-Treasurer, Troy, Pa.

The Northern Pennsylvania Beekeepers organized a few years ago at Williamsport, Pa. Either for lack of interest or more interest and more beekeepers in the southern part of the State, the association moved to Philadelphia, Pa.

The National Meeting.—The annual meeting of the National Beekeepers' Association will be held Feb. 19, 20 and 21, 1918, at Burlington, Iowa. Remy Hall, one of the finest in the city, will be the meeting place. Do not forget the dates. A full program will appear in February.

JOHN C. BULL, Sec.-Treas.

Tupelo Honey Exchange.—Beekeepers are taking an increased interest in organization, the best evidence of which was the Tupelo Honey Exchange, which came as the result of the meeting held at Wewahitchka, Fla., by Georgia and Florida beekeepers of the Apalachicola river. J. J. Wilder, of Cordele, who was elected President, was the principal mover in the work and was assisted by Kenneth Hawkins, of the U. S. Department of Agriculture. It is understood that Mr. Hawkins plans to spend several weeks in the State, working on the organization of the beekeepers for foul brood eradication.

The officers who were named were J. J. Wilder, Cordele, Ga., President; L. L. Lanier, Dalkeith, Fla., Vice President; J. R. Hunter, Wawahitchka, Fla., Secretary; J. O. Hallman, Helena, Ga., Treasurer, and J. K. Isbell, Wewahitchka, Fla., manager. The directors are: J. J. Wilder, G. G. Hensler, C. F. Glenn, H. E. Rich, R.

MISCELLANEOUS NEWS ITEMS

New Jersey Meeting.—The annual meeting of the New Jersey Beekeepers' Association will be held at Trenton, N. J., on Jan. 24 and 25, 1918. Among the speakers will be Dr. Phillips, editor Root, S. D. House and N. L. Stevens. The meeting is held during Agricultural Week and in conjunction with the Allied Agricultural meetings, and a large attendance is expected.

E. G. Carr,
Secretary-Treasurer.

Ontario Bulletin on Wintering Bees.—"The Wintering of Bees in Ontario" is the subject of Bulletin 256 of the Fruit Branch of the Ontario Department of Agriculture. It is a 24-page booklet written by Morley Pettit, who has just resigned as Provincial Apiarist for Ontario.

The need for such a bulletin is very evident, since Mr. Pettit, in his opening remarks, states that the loss of bees in Ontario from winter and spring dwindling is yet from 10 to 50 per cent each year.

In his estimation the prime factors in successful wintering are: plenty of young bees, with a young and vigorous queen; plenty of good stores; a well-made and well-adapted hive; a good, sunny location, well protected from winter winds, and extra outside protection from extreme cold and piercing winds.

The major part of the bulletin is taken up with a thorough description of different methods of outdoor wintering, of cellar wintering, of setting out celled bees in spring, their protection, and spring feeding.

The bulletin is a compact source of information for any beekeeper confronted with similar wintering conditions.

The Indiana Meeting.—The meeting of the Indiana State Beekeepers' Association, held in Indianapolis, though not overly large, was certainly an enthusiastic one. The sentiment seemed to be against trying to put the price of honey too high, 25 to 30 cents being considered a fair retail price. After going into the matter very carefully, Prof. D. A. Rothrock gave the opinion that the production of honey in Indiana last season was not nearly so large as reported in the Government Crop Bulletin.

State Inspector Wallace reported a large number of cases of American foulbrood, due mainly to the fact that most of the inspections were

made in answer to requests from beekeepers having trouble with disease.

The following are the officers:

Mason J. Niblack, President; F. N. Wallace, Vice President; E. A. Ditttrick, Treasurer; R. B. Scott, Secretary.

Notes From the Michigan Beekeepers' Association Meeting Held at Saginaw, Nov. 27 and 28.—The number of members attending was small for Michigan, owing to poor train service, nearness to Thanksgiving and the short crop of this year.

Mr. Floyd Markham, of Ypsilanti, won the manufacturers' gold medal for the third time and it thus became his, permanently.

Upon solicitation of Mr. Tyrrell, of Detroit, a committee was appointed which will have charge of making an exhibit of bees and honey at the State Fair. The exhibit will be furnished by members and after the fair it will be sold and the money returned to those who furnish the exhibit. All exhibits of honey will be made in uniform containers which will be furnished by the committee.

The organization of County Beekeepers' Associations was authorized. Any persons interested in securing local organizations should correspond with the Secretary at once.

A committee was appointed to make an effort to secure an extension specialist in beekeeping for Michigan.

Mr. Cremer, an advertising specialist from Theo. McManus, Inc., addressed the convention on the subject of advertising and showed that co-operative advertising is successful. He advised that the annual production be increased to a point where a demand created for honey by advertising could be satisfied. He made it clear that the first step beyond production would be the formulating of a plan for selling after a demand is created by advertising.

Mr. E. R. Root spoke on the future of the honey market. His belief is that the prices will not drop during the war, and that after the war the prices will not become as low as they previously have been.

The paper on the "Proper Spacing of Frames," by C. P. Dadant, was read by the Secretary in the absence of Mr. Dadant.

A banquet was enjoyed on the evening of November 27.

J. Read, F. T. Branch and W. B. Bradley, of Florida and Georgia.

The Kansas Meetings.—A member of the staff of the American Bee Journal enjoyed the opportunity to attend the meetings of the Arkansas Valley Beekeepers' Association, which met at Wichita Nov. 23-24, and the Northwest Kansas at Manhattan on Nov. 26. The beekeepers of Kansas are wide awake and propose to keep their State in the front rank. Three sectional meetings are held which make it possible for many to attend who would not attend the State meeting, as well as stimulating interest in the State convention.

Dr. A. D. Raffington was elected President of the Arkansas Valley Association, J. A. Nininger Vice President, and Prof. A. W. Jones Secretary-Treasurer. O. J. Jones and E. W. Jewell were elected Directors. The Northwest Kansas Association elected Prof. G. H. Failyer President, W. E. Axtell Vice President and Harry A. Huff Secretary.

A feature of the Wichita meeting was a honey luncheon served by the class in cookery at the Friend University. Everything served was cooked with honey or seasoned with it in some way. It was a most delightful occasion.

Animated discussions followed the various papers, which indicated a lively interest in the subjects discussed. In some sections of the State the beekeepers have secured a good honey crop, which is selling readily at good prices. Both meetings were well attended.

Make Bees Comfortable.—Failure to insulate the bottom of the hive largely offsets the value of insulation around the hive in the outdoor wintering of bees, according to the Chief of the Bureau of Entomology of the United States Department of Agriculture. Experiments conducted with a number of insulated hives

THE WRIGHT APIARY, where the Eastern New York meeting was held. Large honey house in the middle, house for combs on the left, with a background of basswoods.

showed that much heat was lost from the unprotected hive bottom.

Beekeepers have repeatedly claimed that excessive insulation is even more detrimental in winter than insufficient insulation, because of the failure of the colony to warm up on bright days. To test this theory, a colony was packed in the fall with 16 inches of sawdust on all sides, top and bottom. Temperature records were made at frequent intervals every day throughout the winter and spring. The colony remained in excellent condition in every respect throughout the winter, being little affected by high winds, and after brood rearing began it built up with great rapidity. Then, to continue observations on the effect of insulation on the building up of the colony, the packing was allowed to remain all summer. Except for the impossibility of manipulating the colony, it remained in excellent condition. It

seems clear, therefore, that beekeepers need not fear detrimental results from abundant insulation at any season of the year.

Kansas State Meeting.—The Kansas State Beekeepers' Association will hold their annual meeting in Topeka, January 8 and 9.

O. A. KEENE, Sec'y.

Price Committee of Chicago-Northwestern Association.—At the convention of the Chicago-Northwestern Beekeepers' Association held in Chicago Nov. 30-Dec. 1, the following important resolution was unanimously adopted:

Whereas, The committee appointed at the 1916 meeting of this association for the purpose of investigating conditions for marketing honey and for recommending to producers a schedule of minimum prices for the season 1917, has performed its work to the satisfaction of the association, resulting in more fair and more uniform prices to the producer; therefore, be it

Resolved, That the work of the committee be continued throughout the season of 1918 and extended as far as the funds of the association will permit, and that the President be empowered to appoint the members of such committee.

The following were appointed as Committee on Prices for 1918:

John C. Bull, Secretary-Treasurer Chicago-Northwestern Beekeepers' Association, Valparaiso, Ind.; E. D. Townsend, Northstar, Mich.; L. C. Dadant, Hamilton, Ill.; Edward Hasinger, Jr., Greenville, Wis.

In discussion of the resolution it was shown that the purpose of the committee is not to boost prices to an unreasonable or exorbitant figure, but to keep producers informed in regard to reasonable retail prices for their product and in this way to endeavor to overcome the practice among uninformed beekeepers of retelling honey at or below wholesale

W. D. WRIGHT ADDRESSING THE EASTERN NEW YORK MEETING

or jobbing prices. A canvass of the members of the association present at the convention showed that nearly all were obtaining for their honey prices not less than those recommended by the committee, whereas, a year ago a similar canvass showed selling prices varying from 10c to 25c a pound.

All interested in receiving reports and price recommendations of the committee should write to Mr. Bull.

E. S. MILLER, Pres.

Meeting of Ontario County Beekeepers.—The Ontario County Beekeepers' Society of New York will hold its regular meeting in Canandaigua court house on Tuesday, Jan. 15, 1918.

F. GREINER, Sec'y.

Missouri Apicultural Society (Incorporated)—The fifteenth annual meeting of the Missouri Apicultural Society, being the third as an incorporated body, will be held in Columbia, Mo., during Farmers' Week, Jan. 15 to 18, 1918. The following program has been prepared and important business will be transacted. All members are urged to attend and to bring others interested in beekeeping.

Tuesday, Jan. 15—"Spraying and Bees," T. J. Talbert; "Some Adversities in Beekeeping," E. E. Tyler; "Extension Beekeeping," K. C. Sullivan; "Fruit Growing and Bees," E. H. Favour. Inspection of Department Apiary.

Wednesday, Jan. 16—"Extracted vs. Comb Honey," J. F. Diemer; "History of Missouri Beekeeping," R. A. Holkamp; "Missouri Honey Plants," H. B. Parks; "Commercial Production of Comb Honey," A. B. Crandall. Demonstration in handling bees under screen, extracting honey and preparation of hives and hive fixtures, E. E. Tyler, L. Haseman, A. H. Hollinger and K. C. Sullivan. "Commercial Beekeeping," C. P. Dadant. Business meeting.

Thursday, Jan. 17—"Thirty-three Years in Beekeeping," Wm. J. Preston; "Beekeeping in Japan," George

O. Shinji; "Using Honey to Save Sugar," Louise Stanley; "The Chemistry of Honey," Prof. W. G. Brown; "The Anatomy of the Honey Bee," A. H. Hollinger. Demonstration in handling bees under a screen, E. E. Tyler. Question Box, W. C. Campbell. Business meeting and election of officers at 3 p. m.

Friday, Jan. 18—"Wintering Bees," H. M. Fort; "Shipping and Marketing Honey," George Conaway; "Queen Rearing," A. V. Small; "Farm Beekeeping," L. Haseman; "Missouri Beekeepers," A. D. Wolfe. Annual Farmers' Week banquet at 8 o'clock, at which a special table for beekeepers will be reserved.

UNITED STATES DEPARTMENT OF AGRICULTURE

Bureau of Markets

Semi-Monthly Market News Bulletin
Honey arrivals since last report:

Keokuk, Iowa—20 Pounds Missouri.
Hamilton, Ill.—2,500 pounds Minnesota.

Medina, Ohio—5,995 pounds Michigan, 11,040 pounds New York, 30,900 pounds Oregon, 3,016 pounds Ohio.

Telegraphic Reports From Today's Markets—Jobbing Prices

(In many markets in the honey trade the term "jobber" is commonly applied to the original receiver who buys direct from the grower in carlot quantities. However, in these reports we use the term "wholesale carlot receiver" to designate the carlot purchaser, while the term "jobber" refers to the dealer who buys in less than carlot quantities from the carlot receiver and who sells direct to retailers. The prices quoted in this report represent the prices at which the "wholesale carlot receivers" sell to the "jobbers.")

Note: Arrivals include receipts during preceding two weeks. Prices represent current quotations.

Chicago—Receipts and supplies very light. Demand good, market firm. Stock from nearby States:

Comb honey, fancy clover and basswood, 22-24c per pound; off grades as low as 18c; extracted in tins, best 15½-16½ per pound; California, amber mostly 16½c per pound. Beeswax: Supplies practically exhausted, no sales reported.

Denver—Approximately 900 cases comb, 15,000 pounds extracted. Demand and movement good; market firm. Comb honey: Colorado, white, quality and condition generally good; 24-section cases No. 1, \$4.05, No. 2, \$3.65. Extracted honey, white to light amber, 16c per pound. Beeswax: Receipts light. Price to producer, 40c.

Kansas City—No fresh arrivals; light demand, movement moderate, market firm, few sales. All sales in small lots. Comb honey: Colorados: white, quality and condition good, No. 1, \$4.35; No. 2, \$4.20 per 24-section case. Extracted honey, Colorado, quality and condition generally good; white and extra light amber, mostly 15c per pound; dark, no sales reported. Beeswax: Receipts light; light demand, market firm; all sales in small lots; few sales, 30-35c per pound.

Minneapolis—Local receipts very light; supplies moderate; demand moderate; market firm; all sales in small lots. Comb honey: Minnesota and Wisconsin, white, 24-section cases, \$4.50-5.00; 12-section cases mostly \$2.25. Extracted honey: Minnesota, white in 10, 20 and 60-pound pails, mostly 19c per pound. Beeswax, no sales reported.

St. Paul—Receipts, one box, and one crate Minnesota comb honey (total weight 140 pounds), and two casks of Wisconsin extracted honey weighing 1,530 pounds. Demand moderate, market firm; few sales reported. All sales in small lots. Comb honey: Minnesota and Wisconsin, white, 24-section cases mostly \$4.50. Extracted, no sales reported. Beeswax: no sales.

New York—Arrivals, 256 barrels Porto Rican, 6 barrels Florida. Supplies light; market steady. Extracted honey: West Indies, \$1.50 1.60 per gallon. Beeswax: 40 bags Porto Rican arrived. Demand good; market steady. Yellow, 37-38c per pound; dark, 36-37c per pound.

St. Louis—No fresh carlot arrivals. Supplies light. Practically none being sold. Extracted honey: In cans, light amber, 12c per pound; in barrels, 11½c per pound. Comb honey: No sales reported. Beeswax: Supplies practically exhausted; no sales reported.

Philadelphia—23 kegs, 2 barrels, mostly from New York, and approximately 300 cases local comb arrived. Practically no sales. Very active demand; market very strong. Comb honey: Few sales; light amber, 22c per pound. Beeswax: No sales; no offerings.

Cincinnati—Extracted honey: One car California, 4 barrels from Florida. Comb honey: 1 car Colorado. Demand and movement good; market very strong. Extracted honey: Domestic light amber, 16-17c per pound; orange and white sage, 18c per pound. Comb honey: Fancy white, heavy, \$5.00-5.75; No. 1, white, heavy, \$4.75

PART OF THE APIARY OF A. L. BEAUDIN IN QUEBEC. BEGINNING WITH 250 COLONIES IN THE SPRING, MR. BEAUDIN FINISHED WITH 400 COLONIES AND HARVESTED 26,000 POUNDS OF EXTRACTED HONEY.

per 24-section case. Beeswax: Demand moderate; market steady; average yellow, 38c to 40c per pound. Extracted honey from Porto Rico: dark amber, 15c per pound.

There was an old man named Miller, (Dr. C. C. for a filler). He was filled with bee lore 'Till he couldn't hold more; He's a regular bee-lore distiller.

Western New York Honey Producers' Association Meeting.—The fourth annual meeting of the Western New York Honey Producers' Association was held at the Genesee Hotel, Buffalo, N. Y., Nov. 13 and 14, 1917. After the various reports were read and approved the following subjects were ably handled by their respective supporters.

"Wax Rendering," by O. L. Hershiser, of Kenmore, N. Y. He pointed out as the best way intermittent pressure under hoiling water. He also advised using very small amounts of sulphuric acid to help cleanse the wax.

J. L. Byer, of Markham, Canada, spoke on beekeeping as a business and showed that beekeeping was not a get-rich business, but rather one of modest inclinations. A man to be a good beekeeper must be a nature lover, a keen observer, have patience, and, last but not least, must like his work.

Mr. S. D. House, of Camillus, N. Y., spoke on "Producing Fancy Comb Honey." He likes to have a queen of the previous season's autumn rearing, preparedness of both man and bees to the best possible point, and prefers a super of a lesser number of sections than is ordinary, for his hive only containing 21 sections. He produces some extracted honey at the close of the season rather than a lot of unfilled sections.

Mr. Charles Stewart, of Johnstown, N. Y., spoke on "Rearing Good Queens." Beekeepers do not appreciate the value of having a few queens in the yard to draw on at any time to use. He emphasized that good breeders be used, some that are good honey gatherers, gentle, resistant to foulbrood, and always to select the best.

Mr. H. H. Root, of Medina, Ohio, spoke on "Shall We Keep More Bees, Better Bees, or Keep Bees Better?" He laid stress on the point that we should keep as many bees as possible for profit and to produce as much honey as possible, especially in these times of National Conservation. He thought there was a limit to the amount of bees a man can keep profitably.

Mr. J. L. Byer spoke on "Preparing for a Crop of Honey." Young queens, young bees, hive solid with stores to go into winter quarters; these will cause good wintering, which must precede the crop. He does not advise uniting weak colonies in spring, but rather build up medium ones with them if possible, to get as many as possible strong for the honey flow.

"Bee Diseases" were taken up by

Mr. Chas. Stewart and Mr. House. Discussions and questions followed each speaker.

The following officers were elected: Mr. J. H. Sprout, Lockport, N. Y.,

President; Dr. G. J. Hearne, of Buffalo, N. Y., Vice President, and Mr. Howard Myers, of Youngstown, N. Y., Secretary-Treasurer.

WILLIAM VOLLMER.

DR. MILLER'S ANSWERS

Send Questions either to the office of the American Bee Journal or direct to

DR. C. C. MILLER, MARENGO, ILL.

He does NOT answer bee-keeping questions by mail.

It is inferred that all readers have access to the book "A Thousand Answers to Beekeeping Questions." This will avoid duplication in answering, as the book contains answers to practically all questions ordinarily asked on beekeeping. Subjects not specifically treated, or which are not clear to the reader will be further explained in this department at the request of any subscriber.

Shake Swarming—Natural Swarming

1. Aside from the advantage of being able to attend to the work at a more convenient time, what advantage is there in shake-swarming as compared with natural swarming? In other words, does the artificial method give better results, and if so, will you please tell us just why?

2. In natural swarming is it a safe proceeding and entirely practical to return to the parent hive both prime and after-swarms in order to prevent increase of colonies?

3. In natural swarming, when returning the bees to the parent hive, should either queen-cells or issuing queen be destroyed, and at what stage of the proceeding?

MICHIGAN.

ANSWERS.—1. Aside from having things under your own control and avoiding the necessity of watching for swarms, I'm not sure there is any advantage in shaking swarms.

2. Yes, if you return the swarm as often as it issues, there will finally be left in the hive only one virgin, and there will be no more swarming. This plan was formerly the orthodox thing to do, but it may involve a good many times returning, provided no cells are killed.

3. At the time of returning the swarm, kill the old queen and all but one queen-cell. A better way, although a little more troublesome, is this: Kill the old queen upon returning the first swarm (if the queen is clipped you will likely find her on the ground, and the swarm will return itself). Then, beginning a week later, put your ear to the hive each evening until you hear the young queen piping, and the next morning kill all the cells in the hive.

Queen Rearing, Etc.

1. In Iowa how late will a swarm leave the hive and fly away?

2. If you take the queen and a small bunch of bees out of the old hive, will the bees build a queen-cell and rear a queen all right?

3. I want to increase my colonies just so they get enough honey for themselves; what would be your plan to increase them?

4. Will any worker-egg put in a prepared queen-cell hatch out a queen?

5. Would it be all right to put a queen-excluder on top of the hive and drum out all the bees but the queen and a small bunch, and divide up the ones you drum out? Would the queen stay and rear a queen all right?

6. Which would be the best honey location, on rolling land with quite a little white clover and dandelions, a few fruit trees and quite a few willows; or down by the river with lots of willow and basswood and very few fruit trees and white clover?

7. Do colonies rear their own queens when the old one dies?

8. How do you switch the hives around to make the bees build a queen-cell and rear their own queen?

IOWA.

ANSWERS.—1. As a rule a colony is not likely to swarm in Iowa after July, but there may be an occasional swarm in August, and in rare cases a fool swarm will issue even in September or October.

2. Yes, at a time when eggs and brood are present.

3. I don't know. In some places, in some seasons, there is no plan by which you could increase without loss, for there is not enough harvest to supply the colony for winter, let alone supplying any increase. I suppose your idea is to get the largest increase possible. You might divide each colony into a number of nuclei, but that's a risky business, for if the season should be poor they would not get enough to build up for winter. A safer plan would be to make up colonies having as many as four frames of brood at the start, drawing the brood and bees not from any one colony, but from different colonies, in no case leaving any colony with less than four brood. Then if the flow should stop at any minute, you would have no weaklings on hand.

4. Not always. You are likely to have many failures, and will probably succeed better with young larvae than with eggs.

5. Yes, the queen would be likely to do the best she could with what she had left. But whether it would be "all right" would depend on what you did with the bees you took away, and I'm just a little afraid of what you might do.

6. As you put it, it would be hard to say, but in general it would be better to go for the most clover.

7. Yes, if she dies at a time when eggs or young brood are present.

8. No switching is needed. Just take away the queen at about swarming time, and the bees will do the rest.

Natural Comb Brittle—Queen Laying—Nurse Bees

1. Why is natural comb more brittle than manufactured comb-foundation, at the same temperature?

2. What is the relative conductivity of heat of beeswax, water being taken at 1. as a standard?

3. Assuming that a strong colony be made queenless and ripe queen-cell be given; that the queen hatch an mate and prove normal in every way; and that there be emerging brood sufficient to nurse the brood of a vigorous queen; how long from the time of her hatching would it be before the queen would be at her full capacity at egg-laying? In other words, when would she be at her full maturity?

4. Assuming that I give a pound of newly-hatched bees and a strong, vigorous queen to a queenless colony with a large force of field bees, would the pound of nurse-bees be enough to nurse all the brood she could produce, say until the first of it be sealed? If not, can you give a fair estimate of the approximate number or measure nurse-bees required, either in number, pounds or any other way?

WASHINGTON.

ANSWERS.—1. I don't know. You know iron is annealed, making it soft and tough; perhaps was gone through some process when used for foundation, having the same effect.

2. Beeswax is poor conductor of heat as compared with water; but I don't know that I ever saw exact figures given for it.

3. Under the conditions you name, the queen would begin laying hardly later than ten days after emerging from her cell; possibly in eight days. I don't know how long after she begins laying she reaches her maximum, and wish some one would tell us. My guess would be not more than one day. That would make her at full maturity when nine to eleven days old. But that guess of "one day" may be considerably off:

4. I don't know enough to answer definitely. I'm inclined, however to the opinion that all the brood an average queen could produce up to the time of the sealing of the first of the bees would be properly fed if a pound of newly hatched bees were added. At that it might be hard to prove that some of the feeders did not turn in and help on the feeding.

Bees in Frost-Proof Building for Winter

An old patriarch in our town dreamed of an idea concerning a bee-house, so he began. Being somewhat of a carpenter, he did his own work. He built a house 6x13x10 feet, but set 8 inches of sawdust all around it to make it frost proof. He left a bee-entrance at the side, entire width up near the eaves. The bees also contained 8 inches of sawdust, in other words his door is as thick as his walls. He worked for weeks putting in frames that were stationary. Then he placed five hives of bees up near the roof, removed the covers and thought his task was over, the bees would do the rest, and after the bees had filled it full he would swing back the huge door and cut great chunks of pure white honey. His hopes were futile. The bees refused to leave their brood-chambers to any great extent.

Recently I rented his bee-house and stored 25 swarms for the winter. Now tell me if I made a mistake. I placed a thermometer inside and he writes me it stands at 53 degrees when it is 36 degrees outside. We believe the house to be frost proof. There is a bee-entrance five-eighths of an inch by four feet near the eaves and a small space one-third of an inch under the door. Will that give them sufficient ventilation? The hives at 53 degrees and on warm days he will open it so they can get a flight. Or do they need it? They had a good flight November 22. They can't get out at the five-eighths in, by four ft. entrance and the room is perfectly dark with door closed. This is near Baker, Ore., where it gets 36 degrees below zero at times, but not of long duration, but there will be no weather now for three months. We generally have a Chinook wind in February; then the bees get a flight.

I averaged 90 pounds of extracted honey to the colony this year. I beat Dr. Miller; sold it for 25 cents a pint.

We have white clover, alsike, alfalfa, sweet clover and Rocky Mountain bee plant. The alfalfa meadows are covered with dandelion all through May and until the middle of June. The bees are generally carrying pollen from the alders by the middle of March with a snowdrift behind the hives four feet high. But they didn't do it this year. It was not the first of May before they got any pollen. A friend of mine in Baker averaged 176 pounds extracted honey, or had 6,000 pounds from 34 hives. We beat Idaho Mine would have done as well had I stayed at home and given them room. I am working in a gold mine. I even worked at mine from the time I put the supers on until I extracted. We lost 60 per cent of our bees last winter; gave them no protection. OREGON.

ANSWER.—I don't know how your bees will come out. December 2 the temperature was 53 degrees, and if the building is frost-proof, as stated, it should stand at that. As the bees usually gather pollen by the middle of March, the confinement would probably be no later than that, making the time of imprisonment three and one-half months or less. My guess would be that at a steady temperature of 53 degrees they should stand nicely three and one-half months' confinement without need of a flight. I am skeptical, however, about that "frost-proof" business. Even with your thick walls, the temperature will inevitably become

lower until it reaches the average of the outside temperature, and I'm afraid that in considerably less than three and one-half months it will be down to a point where it will be hard for the bees to keep up the proper temperature in the cluster.

If the temperature stands at 53 degrees the bees should be so nearly dormant that the ventilation will be abundant. If it gets colder, so that the bees will be quite active, I'm not so sure. If the bees have a flight while in the building, that will help, provided you can get them to fly and return to their own hives, as to which there may be question.

In the past such buildings have been used, sometimes with success, perhaps oftener with failure.

Keeping Queen Below Super—Swarm Prevention

1. I have fifty colonies of bees and am running my apiary for comb and extracted honey. I have one shallow extracting super for each hive, with Hoffman frames; top-bars are one-fourth of an inch thick. In the spring, when the honey flow is starting, I give each colony one extracting super, then when they have made a fair showing gathering honey I raise the super and give each one a super containing one-pound sections with full sheets of foundation in each section. The important question to me is, will the bees carry pollen into the section, or will the queen get into the comb-honey super and raise brood there? I don't use queen excluders and thought perhaps this comb-honey super would keep the queen from going into the extracting super. Would it be better to leave the extracting super next to the brood-chamber and put the comb-honey super on it? Would the bees be more apt to put pollen in the one-pound sections over thin top-bars than the over thick ones? If you were running my apiary, equipped as I am, state just how you would manage it.

2. When one doesn't want any natural swarm, how would this plan work? When you find a colony preparing to swarm, catch the queen and put her in a cage; then remove all queen-cells containing eggs or anything else; leave the queen caged for ten days, then examine the colony and kill all queen-cells, then release the queen. Would this prevent swarming? Or would it be better to let the queen remain in the cage for a longer period than ten days? If so, how long?

3. How long can a fertile queen be left in her own hive without injury to herself or to the colony. Also, when would you advise leaving the caged queen just inside the entrance under the frames, or between two frames of brood, or elsewhere?

ANSWER.—1. I'm not sure just how it would work to have sections over extracting supers and no excluders, having had no experience in that line. The queen is less likely to go up into shallow extracting-combs than into deep ones, so you have an advantage at that point. She rarely goes up into a section-super, provided the sections are filled with worker-foundation. So, if the queen has not already gone up into the extracting-super when a section-super is placed under it, I think the chances might be good that she would not enter the sections. If, however, there should be brood in the extracting combs when they are put up, the queen would likely enter the sections. If the sections were put on top of the extracting combs, I should not expect the queen to go up. In any case pollen is not likely to be carried up if the queen does not go up.

You ask how I would run your apiary. In these days, when the government is urging food conservation and the greatest amount of production, I should run for extracted honey entirely, or if I should want some sections I should run one or more of the strongest colonies for comb honey entirely.

2. Caging the queen for ten days (which is better than a longer or shorter time) would at least delay swarming, and in a large number of cases prevent it entirely.

3. A queen might be caged probably a month without harm to her, but it would hardly be so well for the colony to have her caged more than ten days.

Feeding Fullbrood Honey

1. I have some honey taken from fullbrood hives. It has been boiled hard for half an hour with equal amount of water. I understand this is perfectly safe to feed back to the bees. I also understand that it is not safe to feed it in the winter, as it is likely to cause dysentery. When and how can I feed this with safety?

2. Should this be sealed the same as extracted honey for keeping some time, or would it keep in an ordinary jar with paper cover? ILLINOIS.

ANSWERS.—1. Boiling does not make it unsafe for winter food, unless it is burned. But unless absolutely necessary to prevent starvation, it is best never to feed in winter. After bees get to flying in spring it may be fed the same as any honey.

2. It will keep as well as any honey without sealing, unless so thin as to sour. After you have boiled it if it is thinner than ordinary honey, allow it to continue with moderate heat until it is as thick as good honey should be, taking care that it does not burn. A safe way is to use a double boiler.

FOR SALE

FOR RENT—My home of 2½ acres, 1½ miles south of Bureau, Ill., on the I. V. W. road; 6-room dwelling, work shop and storeroom; barn, corncribs, chicken house and outdoor cement cellar; good well and cistern; plum orchard, grapes, apple, cherry, peach and pear trees; two good garden plots. Fine chicken farm and one of the best bee locations in Illinois, and home of the late R. A. Elliston, who was a large honey producer. For information address Mrs. R. A. Elliston, 357 Grand Ave., Aurora, Ill.

FOR SALE—Wishing to retire from active business, I offer for sale 300 colonies here in 8 and 10-frame L. hives; 750 full depth extracting supers, with combs; 400 section honey supers; 300 honey boards; 75 escape boards; eight-frame power extractor, with honey pump; four H. P. gasoline engine; saw with dado, planer heads and attachments for making supplies; a complete apiary in No. 1 condition; good location. 1917 crop was 14 tons honey. Will also sell my home place of ten acres, 5-room house and No. 1 schoolhouse, near to a \$5,000 schoolhouse. Will sell home separately and give terms. J. K. Marlow, R. D. No. 1, Weiser, Idaho.

Bigger Fruit Profits

The fruit grower of today is reaping his greatest profits by keeping in close touch with the progress of the industry and developments.

Green's American Fruit Grower

"The National Fruit Journal of America"

through its many articles on growing, marketing and related subjects, points the way to bigger fruit profits. A sample copy will be sent you on request; better still, take advantage of our rate of

3 Years for \$1.00

which brings you 36 copies of Green's American Fruit Grower—filled from cover to cover with money-making suggestions.

QUEENS

BEES

QUEENS

Three Banded and Golden Italians; the best of either

They are hustlers; gentle to handle; cap their honey white; are very resistant to European foulbrood. We have added Mr. B. M. Carraway's queen-rearing outfit to ours and have with us one of his assistants, so can fill all orders promptly. Had fine success shipping bees last season in our newly devised cage and method of feeding, a number of shipments going as far as Idaho and Wyoming. Mr. R. B. Mills, Corinth, N. Y., wrote, "Bees arrived in fine shape, not 50 dead bees to the cage, 2-lb. size." Satisfaction and safe delivery guaranteed. Get your order in early. Reference: The Guaranty State Bank, Robstown, Texas, or the City National Bank, Corpus Christi, Texas.

Paint Without Oil

Remarkable Discovery That Cuts Down the Cost of Paint Seventy-Five Per Cent.

A Free Trial Package is Mailed to Everyone Who Writes

A. L. Rice, a prominent manufacturer of Adams, N. Y., has discovered a process of making a new kind of paint without the use of oil. He calls it Powderpaint. It comes in the form of a dry powder and all that is required is cold water to make a paint weather proof, fire proof, sanitary and durable for outside or inside painting. It is the cement principle applied to paint. It adheres to any surface, wood, stone or brick, spreads and looks like oil paint and costs about one-fourth as much.

Write to Mr. A. L. Rice, Manufacturer, 23 North Street, Adams, N. Y., and he will send you a free trial package, also color card and full information showing you how you can save a good many dollars. Write today.

Save Money

Let me figure on your wants in Bee Supplies. Let me order them shipped from factory direct to you at less than wholesale prices. Send me list of wants.

BEEES AND QUEENS

BEEES AND QUEENS from my New Jersey apiary. J. H. M. Cook, Latf 84 Cortland St., New York City.

TESTED leather-colored queens, \$2.00; after June 1, \$1.60; untested, \$1.00; \$10 per doz. A. W. Yates, 3 Chapman St., Hartford, Conn.

VIGOROUS, prolific Italian Queens, \$1.00; 6, \$5.00, June list. My circular gives best methods of introduction. A. V. Small, 2303 Agency Road, St. Joseph, Mo.

GOLDEN QUEENS that produce Golden workers of the brightest kind. I will challenge the world on my Golden and their honey-getting qualities. Price, \$1 each; tested, \$2; breeders, \$5 and \$10. 2Atf J. B. Brockwell, Barnett, Va.

THREE-Banded and Golden Italian Queens and pound packages in spring, from the Sunny Southland. Grant Anderson, Rio Hondo, Texas.

FOR SALE—1 to 100 strong 8-frame colonies extra fine strain Italian bees, \$4.50 to \$5.00 each; all free from disease, with stores for winter; standard full-depth, self-spacing Hoffman frames; all straight combs in new one-story single-wall hives, f. o. b. here. Wilmer Clarke, Earlville, Madison Co., N. Y.

MY BRIGHT Italian queens will be ready to ship after April 1 at \$1.25 each. Send for price list. Safe arrival and satisfaction guaranteed. M. Bates, Greenville, Ala.

PURE 3-banded Italian queens, untested but warranted, \$1; 6, \$5; tested, \$1.50; 6, \$8. Last year's tested queens, clipped, \$1. Good fat nuclei and full colonies in abundance. Write for price list. J. F. Diemer, Liberty, Mo.

THREE-BANDED Italian queens from our hardy, vigorous strain of honey producers; untested, one, \$1; doz., \$9; nuclei and pound packages June 1. Satisfaction guaranteed. A. E. Crandall & Son, Berlin, Conn.

NOW is the proper time (not tomorrow) to place your order for bees and queens. A postal brings you the story of a pound package of bees. Rosedale Apiaries, J. B. Marshall & Son, Big Bend, La.

BEEES WANTED—From one to 100 colonies within 200 miles; also used equipment. John E. Geiger, Syracuse, Kans.

BEEES AND QUEENS—What a pleasure when you know and I know and the bees know that you have placed your order to be shipped to you in April and May; no war prices. Write S. Mason, Hatch, N. M.

THREE-BANDED Italians; untested queens in April and May, one, \$1; 6, \$5; 12, \$9. Tested, \$1.50 each. One-pound packages of bees, \$1.50 each; two-pound packages, \$2.50 each. Add price of queens if wanted. If you want as many as 50 packages write for prices and discounts on early orders. Safe arrival and satisfaction guaranteed. No disease, and all queens purely mated. Cotton Belt Apiaries, Box 83, Roxton, Texas.

GOLDEN and 3-banded Italian queens will be our speciality. We can also furnish Carolinas. Tested \$1, untested 75c each. Bees, per pound, \$1.50; nuclei, per frame, \$1.50. Send your order for bees early. C. B. Bankston & Co., Buffalo, Leon So., Tex.

HONEY AND BEESWAX

WANTED—Comb, extracted honey, and beeswax. R. A. Burnett & Co., 6A12t 173 S. Water St., Chicago, Ill.

WANTED—Beeswax at all times in any quantity, for cash or in exchange for supplies. Dadant & Sons, Hamilton, Ill.

CHAS. ISRAEL BROS. CO., 486 Canal St., New York. Established 1878. We are in the market for both comb and extracted honey. Send prices delivered New York; state the quantities you have and how packed, and send samples.

WANTED—Shipments of old comb and packages for rendering. We pay the highest cash and trade prices, charging but 6c a pound for wax rendered. The Fred W. Muth Co., 204 Walnut St., Cincinnati, Ohio.

WANTED—Beeswax; we pay higher than market price for good grades light and light yellow wax; get our prices before disposing of your wax. Queea Mfg. Company, Falconer, N. Y.

WANTED—White or light amber extracted honey in any quantity. Kindly send sample, tell how your honey is packed and your lowest cash price; also buy beeswax. E. B. Rosa, Monroe, Wis.

BE sure and include the Domestic Beekeeper with your list of bee journals for 1918. The Domestic Beekeeper will help you to dispose of your crop of honey without expense to you; also, buy your beekeeper supplies for you at cost. If you knew all we were doing for our subscribers, you would certainly be with us during 1918 as a subscriber. Can we have the pleasure of entering your name on our subscription list? Address The Domestic Beekeeper, Northstar, Michigan.

FOR SALE—White clover and heartsease blended extracted honey. Send for prices. W. H. Hyde, New Canton, Ill.

SUPPLIES

SIBERIAN FUR FARM, Hamilton, Canada, breeds foxes, martens, mink, ermine, skunks and black Siberian hares. Information and price list free. Write address plainly.

FOR SALE—Cedar or pine dovetailed hives, also full line of supplies, including Dadant's foundation. Write or catalog. A. E. Burdick, Sunnyside, Wash.

You have likely been thinking for some time that you would like to have The Domestic Beekeeper come to you regularly each month, but have been putting it off for some reason or other. We would like very much to have you all start in with us this next year. We are very sure you will not regret it if you make this start. To some of the early December subscribers for 1918, we will send, free, the last three numbers of 1917. If you expect to get in on this back number proposition you will need to be prompt in ordering, as those back numbers are going fast and there will be none when the present supply is exhausted. Address, with remittance, The Domestic Beekeeper, Northstar, Michigan.

FOR SALE—600 Extracting Supers, nailed a 1 painted, with frames; will sell cheap. A. F. Stauffer, Delta, Colo.

BERMUDA GRASS SEED direct from grower 30c lb. Peruvian alfalfa, the variety that grows during the winter, 20c. B. O. Hadley, P. O. Box 471, Yuma, Ariz.

GOOD second-hand shipping cases for 4x4 1/2 sections, while stock lasts at 15 cents apiece each. In lots of 10 cases or more. C. H. W. Weber & Co., Cincinnati, O.

FOR SALE—A lot of comb-honey supers, 25 and 35 cents each; mostly with sections and foundation; no disease. Also a large showcase 40 in. long, 36 in. high and 24 in. wide; glass on all four sides. Price \$5. A light scale and other supplies. Chester E. Keister, Clarno, Wis.

SOUTHERN BEEKEEPERS, save money on comb foundation. Send me your beeswax to be worked, for cash or on shares. Terms the lowest, and satisfaction guaranteed. Send for terms. E. S. Robinson, Ft. Myers, Fla.

HONEY LABELS

HONEY LABELS—We have just issued a new and up-to-date catalog of honey labels and stationery. Write for your copy. Neat labels and quick delivery guaranteed. American Bee Journal, Hamilton, Ill.

WANTED

WANTED—Bees on shares; extracting outfit. M. Knudsen, Albert Lea, Minn.

WANTED—Your old combs, cappings or slungum to render into beeswax by our high steam pressure wax presses. Dadant & Sons, Hamilton, Ill.

\$1.50 pays for a year's subscription each to The Domestic Beekeeper and the American Bee Journal. You can order them from either office, as you prefer.

IT will be the same to us whether you remit for The Domestic Beekeeper direct to Northstar, Michigan, or whether you send it in with your subscription to the American Bee Journal; only, be sure and include it, as we want every American Bee Journal subscriber to become a Domestic Beekeeper subscriber.

WANTED—One to 100 strong colonies of Italian bees in 10-frame, dovetailed hives. Bernard Benziger, Beekman Terrace, Summit, N. J.

WANTED—Extra combs shallow and deep Hoffman frames. Want extracted honey. Send price first letter. V. O. Blaylock, Roxboro, N. C.

WANTED—25 to 150 colonies of bees. Gen. Deliv., Los Angeles, Calif.

WANTED—We are looking for old bee-books, back numbers of the Bee Journals, issued prior to 1907, etc., for some of our subscribers who wish to complete libraries of beekeeping literature. Just now we want especially copies of Alley's Beekeepers' Handy Book, the second volume of Cheshire on Beekeeping, and copies of Harbison's and Wildman's books. Readers having old beebooks or bee journals which they no longer care for will please write us fully what they have to offer, with prices asked. American Bee Journal, Hamilton, Ill.

SITUATIONS

WANTED—A queen breeder for season of 1918; one who understands the business thoroughly and is willing to help in large extracting apiaries. Only a live wire need apply; also a helper in yards. Answer, stating wages required and references. W. J. Oates, Lompoc, Calif.

WANTED—Industrious young man, fast worker, as a student helper in our large bee business for 1918 season. Truck used for out-wards and hauling. Apiaries located near summer resorts. Will give results of long experience and board and small wages. Give age, weight, experience and wages in first letter. W. A. Latschaw Co., Clarion, Mich.

WANTED—Situation for season of 1918 by an A1 all-round beeman, including queen-raising and the combless package business. Fast worker; no bad habits. M. C. Ward, Duncan, Ariz.

WANTED—A young man to work on fruit farm in an apiaries all of 1918. Must have a clean moral character, use no liquor or tobacco, and be an industrious, intelligent worker, able to do well what he undertakes. Board and washing and good wages will be paid to man who can fill the bill, and a chance to learn the business from one who has had 40 years' experience and has made good. Emil J. Baxter, Care of American Bee Journal, Hamilton, Ill.

WANTED—Practical beekeeper with small capital, to take interest in 500 colonies of bees, and work them. Give references. D. M. Hays, Ill.

1421 Josephine St., Berkeley, Calif.

WANTED—Expert comb-honey man, with references, to handle 700 stands of bees. Good proposition to right man. Hagerman Valley Bee and Honey Co., Hagerman, Idaho.

Crop Report and Market Conditions

PASTURAGE

At this time of the year there is relatively little that can be said regarding pasturage for next year. In the west, especially, where the main crop is from alfalfa, the conditions in the spring have mostly to do with prospects.

Throughout the north, central west and east, there have been snows which are now melting and will generally insure against drouth of the clover which was beginning to be feared in many localities.

BEE CONDITIONS

From the questions being received at this office asking how to best feed bees which are short of stores there is an extra large number of colonies that went into winter quarters without enough food to carry them over until the spring. Ordinarily this does not apply to the larger beekeeper who has seen in advance that his bees were supplied. Yet there are a considerable number who, either through neglect or through failure to get sugar, are awaiting the spring with foreboding. An acute shortage of sugar in spring is not expected (see editorial), but should it occur and beekeepers fail to get food for the bees in spring, many bees would die outright.

In Texas the conditions are unchanged. One of the most prominent beekeepers, writing from there, says: "Most of my bees will do well to drag a miserable existence into spring. I have talked with beekeepers from adjoining counties and they tell the same story."

Unless Texas has rain within the next month prospects will be as bad as can ever be expected.

HONEY CROP

Practically all honey is out of the hands of producers. What little is left is being held to supply local demands or, likely, as a speculation to see how high the prices will go. The demand on the part of foreign governments has made our domestic supply the lowest in years. Then, too, where the sugar shortage has been most acute, honey has had to replace it. One party in the East who

had bought considerable honey west to resell, wired to the shippers to hurry shipments through, as the sugar shortage was acute and honey was a necessity.

Two large bottling firms state that they will not have enough honey to supply their trade through the spring and that when their available supply is exhausted they will be unable to buy in sufficient quantities to do any good at any price.

Foreign buyers are still active, although the amounts they are now able to buy are not large. Prices paid for foreign shipment now exceed 15 cents f. o. b. shipping point for white extracted.

HONEY PRICES

As stated above, foreign buyers are willing to pay at least 15 cents for white extracted f. o. b. shipping point, in car lots. The domestic market exceeded this considerably. One large commission firm on the Pacific Coast has been offering white honey in limited quantities at 17 to 18 cents f. o. b. coast, with amber only a cent or two lower. Prices have been going up regularly.

Naturally retail prices have had to follow. One of our staff bought a 5-ounce tumbler of honey in the South at a retail store for 15 cents.

The comb-honey market is practically bare, though small lots are being offered at about \$5 per case.

INCREASE FOR 1918

The response to the government demand for more honey has been remarkable. All supply dealers report the best demand in years, with many large beekeepers expecting to double their holdings if possible. If bees come out in the spring in anything like normal condition, and if the Southern breeders are not hampered by an unfavorable spring as in 1917, there is no doubt but that the increase in bees will be enormous, and the increase in honey crop over 1917 is likely to be large, especially since this has not been even a normal year.

Uncle Sam Says Eat Honey

Save on Sugar and Help Win the War

This will increase the now heavy demand for honey.

It will mean money in your pocket to get a good stock of KRETCHMER supplies now, before prices advance further, and work your bees to the limit next season. Freight conditions may be bad in the near future and cause delays. Fix up your order tonight; you may forget it if you wait.

Kretchmer Mfg. Co.

301 Eleventh Ave.

Council Bluffs, Iowa.

A BOOK FOR BEGINNERS

"First Lessons in Beekeeping," written by the editor of this magazine, is intended primarily for the use of beginners in beekeeping. You should have it. Price, postpaid, \$1, or clubbed with the American Bee Journal, one year for \$1.75.

American Bee Journal, Hamilton, Ill.

YOUR PERPLEXING QUESTION

will undoubtedly be answered in the new bee book, "Dr. Miller's Thousand Answers." For beginner and veteran alike. Not intended to replace other bee books, but to supplement them. Price, postpaid, \$1.25, or with the American Bee Journal one year, both \$1.75.

American Bee Journal, Hamilton, Ill.

A Business Weekly

The beekeepers need a weekly paper, giving a weekly review of the markets, crop conditions, shipments, imports, exports and other vital matters influencing the business end of beekeeping.

We have been urged to print one not a bee journal, but a news bulletin. We put it up to you. If you want it had enough to pay \$2 for it, we will attempt it. It will cost that to keep it independent of and side business or advertising influence.

There will probably be the largest production next season the world has ever seen. Better keep in touch with conditions.

Do not send any money, but if you are interested, give us your pledge of support and we will inform you if we conclude to print it.

DR. MILLER'S BOOKS IN COMBINATION

WE ARE GLAD TO BE ABLE TO OFFER OUR READERS A SPECIAL COMBINATION PRICE ON THE TWO DR. MILLER BOOKS

"Fifty Years Among the Bees" AND "A Thousand Answers to Beekeeping Questions"

We also believe that it is to the best interests of every beekeeper to have these two books. Dr. Miller has always been a popular writer. His books are entertaining. But more than this, they come from mature experience and can be depended upon as a guide to both the beginning beekeeper and to the more experienced honey producer.

"FIFTY YEARS" gives the actual experiences in beekeeping of the author who has been engaged in this pursuit for over fifty years. It gives not only his successes, but also his failures, explanations, etc., and special beekeeping fixtures which he has adopted after extended trial.

"THOUSAND ANSWERS" is alphabetically arranged and answers questions of nearly every conceivable angle of beekeeping. It is a compilation of different questions as answered by Dr. Miller in the American Bee Journal in the last twenty-two years.

"FIFTY YEARS," postpaid, \$1.00 . . .	} Our price for both, postpaid,	\$1.75
"THOUSAND ANSWERS," postpaid, \$1.25		

**Both Books and the AMERICAN BEE JOURNAL
one year, new or renewal, for only \$2.50**

AVOCA, NEW YORK

A NEW BOOK

Our Backdoor Neighbors

By

FRANK C. PELLETT

"I have read 'Our Backdoor Neighbors' with great pleasure, and my small boys also liked it very much. The chapters on hawks are certainly a most valuable and unique contribution to ornithology, and one, I should say, which will not be duplicated for many a long day. No one could help reading the chapter on squirrels, the skunk and the rabbit, once they had begun them.

"How many hours and how much careful observation this book represents no one but a naturalist can guess. Such books do an untold amount of good in awakening a new interest in nature and in leading others to study and observe. It is upon the study of nature that the progress of the human race depends.

"JOHN H. LOVELL, Waldoboro, Maine."

Cloth, 210 pages, profusely illustrated with photos from life.

Price, postage paid, \$1.50

Beekeepers, We are Ready!

We are ready for the biggest year in the history of beekeeping—ready to serve the beekeepers of America more promptly than ever, and with equally as good goods as ever. We have anticipated the beekeepers' wants for the big coming year of 1918. The high price for honey, and the prosperity of most beekeepers in 1917, led us to begin filling our big warehouses with beekeepers' necessities last fall. That's why we are ready now.

Don't Delay

You beekeepers have never before had the promise of so prosperous a year as the one that lies before you. Not only the high price of honey, but a patriotic duty urges you to produce every pound of honey possible in 1918. To this end you should make sure of your supplies NOW. Freights are slow, and may be slower by next spring. The freight congestion of the past season may be repeated in even worse degree. DON'T be one of those beekeepers whose bees will have to wait on delayed shipments.

Do This Today

Send us today a list of your needs, and ask for our new beekeepers' supply catalog. We are ready to make a close estimate, especially on the earliest orders. Don't wait—don't delay. Do it today.

Remember that we absolutely guarantee our goods to be manufactured perfectly of best material. As always, if in any instance our goods are not found to be exactly as represented by us, money will be refunded and all transportation cost paid by us.

Order standard goods, if possible, and serve your own convenience by ordering either from us direct or from the nearest Root service branch or agency.

The Old Bee and Honey Man,
W. D. SOPER,
425 Liberty St., Jackson, Mich.

New Bingham Bee Smoker

In 1878 the original direct draft bee smoker was invented and patented by Mr. T. F. Bingham, of Michigan. Mr. Bingham manufactured the Bingham Smoker and Bingham Honey Knife for nearly thirty-five years, and in 1912, becoming a very old man, we purchased this business and joined it to our established business of beekeepers' supplies and general bee-ware. Those who knew Mr. Bingham will join us in saying that he was one of the finest of men, and it gives us much pleasure to help perpetuate his name in the bee-keeping industry.

Bingham Smokers have been improved from time to time, are now the finest on the market, and for nearly forty years have been the standard in this and many foreign countries. For sale by all dealers in bee supplies, or direct from the manufacturers.

Smoke Engine, 4-inch stove.....28 oz. \$1.25
Doctor, 3½-inch stove26 oz. 1.00
Two larger sizes in copper extra.

Hinged cover on the two larger sizes, postage extra.

NEW BINGHAM BEE SMOKER

A. G. WOODMAN CO.
Grand Rapids, Mich.

WOODMAN'S SECTION FIXER

A combined section press and foundation fastener of pressed steel construction. ONE OF THE GREAT ADVANTAGES this machine has over all others on the market in the putting in of top and bottom starters is, **YOU ALWAYS HANDLE LARGE PIECES OF FOUNDATION**. You know how hard it is to set small, narrow pieces for bottom starters. With this machine a large piece of foundation is set and the hot plate is again used to cut it off, leaving the narrow bottom starter. What is left of the large piece is then set for the top starter.

Price of machine, \$3; with lamp, \$3.40. Weight, 5 lbs.; postage extra.

THIS IS THE ONLY MACHINE ON THE MARKET from which the section always comes away right-side up, with the large piece or top starter hanging down. It does not become loosened in reversing, as with other machines.

A. G. WOODMAN CO., Grand Rapids, Mich.

Tin Honey Packages

YOU WILL MAKE A MISTAKE if you do not ask for our **Low Prices on Friction Top Pails and Cans**. We are **Saving money** for car load buyers and others of smaller lots. Why not you?

Our three-year contract is enabling us to make prices considerably under general market quotations. Let us hear from you, specifying your wants.

Friction Top Tins

	2-lb. Cans	2½-lb. Cans	3-lb. Cans	5-lb. Pails	10-lb. Pails
Cases holding	24	24	---	12	6
Crates holding	---	---	---	50	50
Crates holding	100	---	100	100	100
Crates holding	603	450	---	203	113

Sixty Pound Square Cans

We are now booking orders and making shipments of 60-lb. cans from several different factories about the country. We believe it would be a wise idea to secure your supply early, as we have been told that the supply of tin plate will not take care of the demands. Ask for prices, stating quantity wanted.

A. G. WOODMAN CO., Grand Rapids, Mich.

The Guarantee that Made "falcon" Bee Supplies Possible

The "falcon" GUARANTEE. Every hive, every super, every crate of sections, every pound foundation, every article, and every queen leaving the "falcon" plant goes out with our "absolute satisfaction or money back" guarantee. For more than a third of a century we have stood behind everything we sell. If anything is wrong or not just what you thought it would be, we'll appreciate it if you will write us, and we'll make it absolutely right at our expense. Our satisfied customers are to be found everywhere, and our best advertisement. "Once a customer always a customer," is synonymous with the name "falcon"

The beekeepers' past experience when "short" should have taught him that it's a "wise move" to get hives, sections and supplies ready in the next two months. We will be glad to quote on "falcon" supplies if you will send us an approximate list of what you will require for the coming season.

ON THE SUPPLY MAKER'S TRAIL

No. 1.—Making Hives and Sections

BY FRANK C. PELLETT

THE boss down at the office is always thinking up something new to keep the staff correspondent busy. When the mail man comes I find it is always well to have my hat handy, for there is no telling where he will be sending me next. Not long ago he got the idea that maybe the readers of the American Bee Journal might be interested in knowing how bee supplies are made. He accordingly wrote to me to see what I could find out about the making of beehives, smokers, extractors, honey containers and a few other things of use to the beekeeper. The idea was all right, and I started in very dutifully to see what there was to be seen around the different factories. But neither the boss, nor I either, for that matter, counted on some of the plans of the women folks at our house. Oh, yes, I heard the wife and her unmarried sister whispering mysteriously about gowns and preachers and other things that have to do with weddings, but I was entirely too much interested in finding out how bee supplies are made to pay much attention to what they were doing. Now, when a fellow starts out to in-

vestigate anything having to do with bees, he can never tell how long he will be gone. These good women folks felt very sure that I would get around in plenty of time, since I was not going so very far anyway. Well, after two or three weeks they got uneasy for fear that I would stray off

time to spare, but I did not get much more than half way around the circle of finding out how bee supplies are made. After the girl was safely married and started off in the automobile with old shoes and other useful decorations tied on behind (yes, it is the same girl that we had on the

front cover among the flowers in November, 1915), I began to wonder how much I had really learned about how bee supplies are made.

Some of the big machines used at some of the factories do so many things that I never could quite understand it all, even when I was looking at them with a guide at my elbow to explain the whole thing. Not being much on mechanics anyway, I fear that what I did not learn on the subjects assigned me would make longer stories than the things I did.

When one watches the bees busily working at the entrance of a hive under an apple tree in somebody's back yard, he is inclined to think of honey production as a small business. But when he gets into the big factories, where hundreds of men are hustling to turn carloads of lumber into hives, sec-

HUNDREDS OF CARS OF LUMBER ARE MADE INTO HIVES

and not get home in time for the party which they had in mind, so they began to follow me up with urgent messages, to the effect that my presence was very much desired at home. Anyway, I got home in time for the wedding, with not much

PART OF BIG BEE SUPPLY FACTORY.

tions and other equipment; where big saws are buzzing and boards zipping through the planers, and dozens of freight cars on the siding are being loaded with supplies for all parts of the country, one gets a new view of the business. There are many factories, large and small, devoted to the manufacture of bee supplies. These are distributed from New York to California, so that even in the largest factory, one sees but a small part of the business.

The G. B. Lewis Company's plant at Watertown, Wisconsin, is one of the largest in the world devoted to the manufacture of hives and other beekeeping equipment. It is a very interesting little journey to follow a load of boards from the time they enter the factory until they are made into hives and packed into crates, ready for shipment to the apiary. Machinery has added much to the comfort and convenience of the everyday life of modern times. When our grandparents were forced to make everything by hand, even the

clothing from the time it was sheared from the sheep's back, they had little time for recreation, and few were the comforts which they were able to afford. Under modern conditions, one man with a big ma-

THE OUTGROWTH OF A LITTLE MILL ESTABLISHED IN 1864.

chine can do the work of twenty-five by hand, and thus the conveniences and comforts of life are multiplied in like proportion.

and the most up-to-date machinery for saving labor. Only a small part of the plant could be shown in one picture.

So great has been the demand for supplies that much difficulty has been experienced in getting suitable raw material. Lumber has advanced in price 50 per cent the past season, all wages are higher, and metals have increased 300 per cent. The advance of metal prices has been so great as to become prohibitive for some purposes, and metal covers will probably be less used until the close of the war. As a matter of necessity, these increased costs of material and labor must be added to the cost of the finished product, so that the beekeeper must pay higher prices for his hives. Fortunately, however, honey has also advanced, so that the beekeeper is as well off as before. In spite of the greatly increased prices of bee supplies, the manufacturers claim to be turning them out at a much smaller profit than ever before. They are able to do this by adding high-speed machinery, which greatly increases the output of the factory without additional labor. The machinery used in this factory for making beehives costs in the neighborhood of \$30,000, yet one hundred

THE OFFICE IS SEPARATE FROM THE FACTORY.

men, by its aid, can do as much as two thousand men working with hand tools. The saving in wages of this large number of men will very soon pay the cost of the big machines. To get it down to a fine point, the machine can do, for three cents, what it costs seventy-five cents to have done by hand. This is the reason that few beekeepers can afford to make their own supplies. They are not only better made by machinery, but a man, working by hand, can never compete with a machine which does the work of twenty-five men.

Let us follow a load of basswood lumber through the mill and see what happens. The boards are wheeled into the factory on three-wheeled carts that carry a wagon load of lumber at one time. For making sections, absolutely clear lumber is used. First every board is planed to fit a gauge, so that all are exactly alike. The basswood boards are twenty-nine thirty-seconds of an inch in thickness after coming from the planer. All knots are cut out, and waste wood is used for other purposes requiring small pieces of indifferent quality. Motor-driven mandrills now plane each edge, above and below, and cut each strip into five parts. There are seventy-five saws on each machine. The strips are then run through a sander to polish both sides and cut into 17-inch lengths for sections. At this stage the pieces are sorted by hand into grades, for no machine has yet been perfected which will sort out the off-colored pieces. After the pieces are graded they are clamped into bundles of 100 and the various cuts necessary to make them into finished sections made quicker than it can be told. The dovetails are cut at the ends by rapid saws, the V grooves by a scoring machine, and the beeways by rabbets. These machines have an automatic feed, and the machine counts them, also, ringing a bell for every crate of 500 finished sections. It only requires three men to attend this machine. One supplies it with lumber, one fills the crates and the third nails the crates up ready for shipment. The machinery necessary to manufacture sections in this rapid manner cost in the neighborhood of \$10,000, but with it three men are able to do the work of 100 men by hand labor. The fact is, that it would be almost impossible to make good sections by hand. The one machine turns out 64,000 every ten hours.

Hives may be followed through the big factory in similar manner, although the process is much the same. The lumber is first planed, and cut clear, edges are planed and the boards are cut into short lengths, to fit the hives. We have some way come to demand dovetailed corners in all our beehives, although it is quite possible that well boxed corners would do quite as well. In order to satisfy this whim on the part of the beekeepers, it is necessary to install a Morgan lock-corner machine at a cost of \$1,300, which cuts

THE LUMBER IS WHEELED TO THE FACTORY ON THREE-WHEELED CARTS

the dovetail so evenly that there is not a miss in a hundred hives.

Small pieces of boards are worked into end bars and frame parts. The top bar is cut out entirely complete at one operation. Take a look at a thick top bar from a Hoffman frame and try to imagine what an ingenious machine is necessary to turn the trick. To describe it so it could be understood would require a better reporter than I. I could not even figure the thing out when I saw it working.

Every machine in the big factory has its own individual motor, thus doing away with hundreds of belts and tons of shafting and overhead pulleys. In one corner is a repair shop in charge of an expert mechanic. Here necessary repairs are made for the machines without leaving the building, and with the least possible delay.

After all, beekeeping is not a business to be sneezed at, when it takes several hundred carloads of lumber yearly to keep one factory busy turning out supplies. After we have pasted a few million more of the "Eat Honey" stickers on our outgoing mail, we will have to enlarge all the factories and start more to sup-

ply enough hives to hold the bees necessary to meet the demand for our product.

Northern Wisconsin Meeting.—The annual meeting of the Northern Wisconsin Beekeepers' Association was held at the court house here Saturday, Dec. 29, 1917. Dinner was served by the ladies of the association and was very much appreciated. An address was given by Professor Mathews, of the U. S. Agricultural Department, on Wintering Bees and Increase of Honey production. Some important bee problems by Jas. Chief, a local and up-to-date bee-man, were discussed. Co-operation for better results in beekeeping, diseases in bees, frames, combs and using foundation, also were touched upon by Professor Mathews. The following officers were elected for the ensuing year:

President—H. H. Schroeder.
Vice President—James Chief.
Secretary-Treasurer—E. H. Marsh.
Directors—Otto Klessig, Joe Croterfil and C. S. Leykom.

Honey is very scarce here now, extracted bringing from 20 to 30c a pound.

E. H. MARSH,
Sec'y.

THE EDITOR'S VIEWPOINT

Federal Supervision of Queen Breeders

There has been much complaint of the spread of foulbrood and other diseases through the purchase of queens. A few years ago a new postal regulation required that all queen breeders secure a certificate of health from some authorized inspector. This provision was waived when it was shown that many States had no inspector. However, the provision requiring the boiling of honey for thirty minutes, from which candy is made to stock the cages is not sufficient protection. Apparently it insures safety from the spread of American foulbrood, but there is much evidence to show that European foulbrood or paralysis may be spread by queens and their attendant bees shipped through the mails. The late O. O. Poppleton attributed his difficulties with paralysis to the purchase of queens and found it necessary to re-queen with different stock to eliminate the disease. He felt doubly sure of the source of infection when he brought the disease to his yards the second time with queens of the same stock bought from another breeder.

Most of the queen breeders do the bulk of their business outside the State in which they are situated. Being an interstate business, queen breeding should have federal supervision. Now that the department is adding a number of expert beekeepers for the extension service, some plan might be worked out whereby federal inspection could be secured. The total number of queen breeders engaged in commercial sale is not large, and greatly increased confidence on the part of the purchasers would result from such a plan.

While several of the States maintain rigid inspection of queen yards,

several States have no such inspection, and those which have do not have uniform regulations. The safety of the future of the industry depends much upon placing proper safeguards about the shipping of bees and queens.

Comb Honey Losing In Popularity

The high price of extracted honey is having the effect of leading many beekeepers to give up the production of comb honey. Of late we have heard of several well-known comb-honey specialists who have already made the change, or who are preparing to do so with the next crop. At present, the difference in price between comb and extracted honey is slight, as compared to the increased cost of producing a fancy article of comb. The confidence of the public in extracted honey is largely the result of the pure food laws. Since adulteration is no longer possible to any large extent, we look for extracted honey to displace comb honey in many markets. So many beekeepers are making the change that the shortage of comb honey may be so pronounced that the price will advance sharply, for there are many consumers who will take it in no other form.

Under present conditions there is more profit to be made in the production of extracted honey.

Advance of Beekeeping

Everyone sees evidence of the dawning of a new day for beekeeping. Honey production is developing from a fad into a commercial enterprise, which is rapidly growing in importance.

Whereas, ten years ago two or three agricultural colleges gave courses in beekeeping, now more than twenty are giving attention to

the subject and some of them give it the prominence of a separate department. This indicates a greatly increased interest and demand for information on the part of the public. The U. S. Department of Agriculture has greatly increased the staff of men engaged in the beekeeping work, with a prospect that still more men will be added to meet the increased demand for help from every section of the country.

The agricultural press is devoting far more space than formerly to beekeeping subjects, and the newspapers give more prominence to the doings of the beekeepers. Everywhere new organizations of beekeepers are springing up, until it is difficult to keep in touch with them all. Beekeepers' conventions and field meetings are now held in so many localities that there are few beekeepers no longer within reach of the bee meetings.

Honey is higher in price than for many years past. This is due to the war, in large measure, but thousands of people are learning to use honey who have not been in the habit of using it in the past. This insures a greatly increased demand for years to come. The prospects for beekeeping were never so bright.

Isle of Wight Disease Another Remedy

S. H. Smith, in the British Bee Journal for November 29, mentions another remedy for Isle of Wight disease that we had not yet read about. It is "acriflavine" (diaminomethyl-acridinium chloride). A quarter grain of the drug dissolved in a quart of water was sufficient for a dozen colonies, sprayed over the bees, combs, floor and brood-chamber walls, as well as over the crawlers around the bives. A week later the treatment was repeated. "Those bees were not treated again. All survived and gave surplus."

The Master of Beekeeping

The first issue of the American Bee Journal, which appeared in January, 1861, contained the following:

"He may be regarded as a master in bee culture, who knows how to winter his stocks in a healthy condition, with the least loss of bees, the smallest consumption of stores, and with the combs unsoiled."

The same is still true, for in the Northern States wintering is the most serious problem which the beekeeper has to meet.

Beemen of the Present---M. H. Mendelson

By W. A. Pryal

AMONG the many beekeepers in California who have produced honey on a large scale few have exceeded the operations of Mr. M. H. Mendelson, whose apiaries have done much to make Ventura county famous as a honey-yielding section of the Golden State.

It was in the early winter of 1892, I believe, that I first met Mr. Mendelson at a meeting of beekeepers in Los Angeles. At that time he began to agitate for beekeepers of the State making a presentable exhibit of their apiarian resources at the Columbian Exposition to be held the following year in Chicago. And a year or two following he did his utmost to make the beekeepers show at the Midwinter Exposition to be held in San Francisco during 1894 a success.

A VENTURA COUNTY BEAN FIELD—And there are miles and miles of them. How doth the busy bee and the buttery Lima Bean that helps make everything so sweet and hopeful.

had left that location a day or two previously for his Ventura place.

At Fillmore I thought I would take a run out to see the McIntyre apiaries. I was told that it was not likely I should find Mr. McIntyre there; that the bees were being attended to by his wife and daughters. I did not try to find the location. Later I learned why Mr. McIntyre suspended apicultural operations. I was sorry to hear of this and I trust he has been able to take up the pursuit in the large way that he had conducted it so successfully for over a quarter of a century. As it was, I learned that the women folks of the household managed the bees as competently as of yore, and why not? Who in the country could be more competent than the daughter and granddaughters of the late R. Wilkin?

Our trip from Fillmore to Ventura, or rather for many miles west of the former town, was over one of the vilest roads we ever traveled. The main highway was under reconstruct-

tion, and a Mexican we met at the crossroads gave us wrong directions as to the best temporary route.

On the State highway something less than three miles east of Ventura, we found what Mr. Mendelson calls his camp. While I had written to Mr. Mendelson that I hoped to call upon him on my way home, he did not recognize me, neither would I have known him should I have chanced to meet him in town or on the highway. Nigh a quarter of a century had made changes in us both.

Some 200 colonies of bees had been moved into the place a few days previous to our visit, and the hives were arranged all around the house and outbuildings. Some of them had swarmed, even as late as the latter part of August, when we were there. One of the little girls of our party discovered a swarm hidden away among the leaves of a large palm tree.

Many of the colonies were used for queen-rearing purposes. The ten-

M. H. MENDELSON IN WORKING GARB. One of his hired men is gathering the "Queen Crop."

He also worked strenuously to have a creditable exhibit of California's bee products at the great exposition of 1915. He had outlined a plan that would have done credit not only to our apiarists, but those of all the world. But through the meddling of others, the plans had to be abandoned, and there was no exhibit of the apiarian industry worthy of the name, though a few individuals and firms made good scattering exhibits of bee supplies.

While on my trip through California south of here, in 1916, I made it a point to visit Mr. Mendelson. I hoped to find him at his big apiary some two and one-half miles south of Piru, but on enquiring at the largest store in that town as to the best auto road to take, I was informed that he

FLOWERING PLANTS AND FRUIT TREES GROW ALL ABOUT MENDELSON'S COTTAGE BEE-CAMP

ONE OF MENDELSON'S APIARIES IS IN A BLUE GUM GROVE IN THE CENTER OF EXTENSIVE BEAN FIELDS.

frame Langstroths were so divided that they made three or four compartments, in each of which a queen was raised to egg-laying maturity. Mr. M. had two men assisting him and when we called he was filling an order for a hundred or more Italian queens. The main object in moving the bees to this location is to take advantage of the bean fields, Lima beans being grown extensively in the coast portion of Ventura county.

Mr. Mendelson reports that the season of 1916 had been a poor one at the Piru apiary; that that good sage range did not give him a half carload of sage honey. A part of this apiary was moved to the bean fields. From this source he secures a fair crop, unless the fall is continuously foggy.

Some of the canyons in this portion of Ventura county are among the very best sage-honey yielding locations in California. The pity is that so many years prove failures. Too often a full crop is secured only once in five years, though at times every third year is a satisfactory

one. Mr. Mendelson's honey crops have averaged better, I believe, than have the crops of many other beekeepers in the county. This is because after the sage honey is in, he moves a portion of his big apiary to the low lands where the bees can collect the nectar from the bean flowers. I did not secure data as to Mr. Mendelson's harvests for the years he has been engaged in apiarian work in California, but I believe his best yield was from thirty-five to forty tons. He has been in the State thirty-seven years, coming here from New York State, where he was born about 64 years ago. He had quite an extended knowledge of bees before coming to the Land of Sunshine, Flowers, Fruit and Honey; his father had kept some colonies and young Mendelson as a child acquired an enthusiastic love of bees and nature.

The equipment of the bee ranches run by this man is probably the most extensive of its kind in California. Some twelve thousand dollars would hardly cover the cost of bees, fix-

THE IRON FIRE PROOF EXTRACTING ROOM AND STOREHOUSE COMBINED AT THE FAR END OF THE GARDEN

tures, etc. At the Ventura plant, the big honey-extractor is driven by electric power, current being obtained from the local power company. Here we saw the great big "road-schooner" he uses to transport his bees from one apiary to another, as the honey flow warrants. And in his stables we saw several powerful specimens of horse flesh that were beauties. They are the motive power for propelling the aforesaid "road-schooner."

Mr. Mendelson complains that one of the great obstacles he has to contend with is getting suitable help in the apiary. I presume, since this country has entered the world war, it will be harder the coming season to secure assistance in the larger apiaries.

While I found our host such an enthusiastic apiarist, I found him also interested in plant life. The soil about his Ventura place is of a rich, sandy loam and well watered. It is ideal garden soil. Here he was growing a large number of plants that I have been interested in for years, especially gladiolus. Many of his trees and plants are rare, some almost tropical. To name them would be like setting out to make a plant catalog.

Herewith I present some views I obtained at the home camp; also some I obtained of his Piru apiary and one of his apiaries when the bees were picnicking among the beans. Some beeman truly is M. H. Mendelson and may the flowers for years to come be nectar-laden, that the myriads of bees from his hundreds of hives may sweeten his way through the rest of his life's journey.

Oakland, Calif.

Boys' and Girls' Bee Club

By J. H. Merrill, in Charge of Apiary Work, Kansas State Agricultural College

DURING the winter of 1916-17, the Lyon County Boys' and Girls' Bee Club was organized by Charles A. Boyle, district club leader, and Herbert Popence, county agent for this Kansas county.

Mr. Boyle's purpose in organizing the club was not to increase the number of beekeepers but to make better beekeepers out of those already possessing bees. Instead of having one or two neglected and almost forgotten boxes of bees hidden away somewhere under a tree, it was planned to give these bees a new home, decent treatment, and make them pay their own way, thus justifying their existence.

When it came to purchasing equipment it was found that this would be divided into two classes—one to include large articles to be used in common, and the other individual equipment which each club member should use.

In the first class were included text and reference books on beekeeping, as well as the leading magazines. The tools which were necessary for assembling hive parts were also in-

MENDELSON'S PIRU APIARY

cluded in this class. Some of the members were to raise extracted honey, and since an extractor was rather expensive for an individual club member to own, the club purchased the extractor and all equipment necessary for extracting.

Each club member was urged to subscribe to one bee journal and, if possible, secure a text book. Gloves, veils, smokers, hive tools, hives and hive parts, including supers, frames, sections, foundation, bee escape boards and queen excluders, were secured by each member for his individual needs.

Since the object was to make better beekeepers rather than more beekeepers, it was planned to have each member make his start with a colony of bees, secured, if possible, from his parents. By so doing it was intended to make a practical demonstration, not only to his parents but to others, of just what could be accomplished by using modern methods and intelligent care in handling the bees.

The club opened in the spring of 1917 with twelve members. Four of these were obliged to discontinue, but the other eight remained enthusiastic members throughout the season.

In order that an exact rating should be given to each member, the hive with which he had started was examined and a value placed upon it. In making this examination the condition and strength of each colony, the race, age and prolificness of the queen, and the condition of the hive and hive parts were all taken into consideration. If a colony was in an old box hive, which would later have to be changed to a better hive, it received a lower valuation than it would have had it been already in a modern hive.

After each colony had been appraised and its value recorded the club was ready to begin work. Mr. Boyle and Mr. Poptence demonstrated how the hive parts should be put together, how many nails to use and where they should be used, and how to paint them so as to have all of a uniform color.

Those who were going to raise extracted honey learned how to make extracting frames and how to fasten in the foundation which was used to secure straight comb. Those who were interested in producing comb honey learned how to make the sections and how to fasten in the little sheets of wax or "starters."

Those who had colonies in old boxes were shown how to transfer them to modern hives with movable frames. After the bees were housed in their new homes they could be examined at any time, because the frames in these hives could be removed at will.

As the work progressed new problems constantly presented themselves and Mr. Boyle and Mr. Poptence were kept busy throughout the summer answering questions and solving problems.

After the honey season is over, there is a valuation to determine the standing of each club member. Each contestant must submit an itemized account of all his expenses and receipts. Then his colonies are examined along the following line: (1)

the number of colonies; (2) the strength of each colony; (3) the number of bees in each colony; (4) amount of stores; (5) improvement in the race of bees, and (6) possibilities of wintering.

The standing of each contestant is determined by adding the total receipts to the value of the colonies, minus the total expenses.

Although the summer of 1917 was, in general, a poor season for honey, yet several members of the Boys' and Girls' Club did very well. They not only secured very creditable crops of honey, but also learned a great many facts about beekeeping. At the close of the season each contestant wrote the story of his summer's work. These stories made more than ordinarily interesting reading.

Ezra Palmer's father gave him a colony of bees in an old box hive with which to make a start. Ezra bought a standard hive, supers and other necessary equipment.

In the fall he sent a frame of honey from his colony to the State Fair at Topeka, for which he was awarded a \$3 premium. In addition to this he sold 100 pounds of honey for \$20, making a total income of \$23. As his total expense was \$4.73, his total profit from his one colony of bees was \$18.27. Joseph W. Stout secured a yield of 115 pounds of honey and was given an award of merit for his honey exhibit at the State Fair at Hutchinson. Clarence Gladfelter also did well, as he took 81 pounds from his colony of bees.

The work of the club was so successful and attracted so wide attention that the members have decided to take advantage of this publicity and market their product under a club name.

Already fourteen new members have been enrolled for next year and there are at least fifty who wish to join the club. The older members will take up some of the more advanced problems of beekeeping. Such

MEMBERS OF THE LYON COUNTY BEE CLUB HAVE A GREAT INTEREST IN BEEKEEPING

problems are the best methods of making increase artificially, naturally, or by using pound packages, whether comb or extracted honey should be produced in their region, etc. There are 2,000 colonies of bees in Lyon county and it is planned by the club to secure and handle some of the colonies which would otherwise be neglected. Such a move will not only show the owners of these colonies some of the modern methods of handling bees, but should prove very remunerative to the club members.

Manhattan, Kans.

Another Advertising Objection Answered

By Chilton Gano

A NATURAL doubt raised in the mind of a beekeeper, when it is proposed that an association of beekeepers enter upon national advertising of a branded honey, is whether such a brand would fare well in competition with local honey in various sections. In other words, is sectional feeling so strong in various localities that people will prefer to patronize independent producers of honey in their own locality? This is a point that should not be ignored, by any means.

The experiences of a number of concerns shed light on it, that of the Northwestern Fruit Exchange, now advertising "Skookum Apples," probably giving the most conclusive answer. If local, unbranded products offer dangerous competition to a nationally advertised product, then surely "Skookum Apples" would have suffered from such competition, because apples are known in nearly every State in the Union.

Yet Skookum went clear across the continent from its home in the northwest, and did its first experimental advertising in New York City, right under the noses of New York apple growers, and the advertising was highly successful. Altogether, about \$15,000 was spent in advertising this brand of finest boxed apples in New York City. The advertising was unique in that it educated the public as to what are the most nutritious and highest quality varieties of apple, their proper seasons for use, and how to secure appetizing variety in their use. Twelve varieties of apples, claimed to be the best varieties in every way, are packed under the Skookum label. The strictest grading rules possible insure that only extra fancy apples go into the packs. Such facts as these, together with appetizing illustrations and the offer of the recipe booklet, soon won their way with the New York public, and today Skookum apples sell at a premium in New York and are even named on the menus of many leading hotels and restaurants. Today practically no New York apple can command the same price as Skookum apples, in New York City.

A little over a year ago, in the fall of 1916, the Exchange, convinced that national advertising would succeed as

well as local advertising had in New York, appropriated \$60,000 and began advertising in national magazines, mainly with color advertisements on cover pages. Before the advertising was begun big fruit jobbers throughout the country were canvassed for advance orders, proofs of the proposed national advertisements being carried in portfolios by the canvassers as a selling argument. These advance sheets of the campaign made so profound an impression on the trade that the company's representatives were in some cases invited to address meetings of retailers, while actual advance orders for Skookum apples totaled several hundred cars. Prices were to be agreed upon before the fruit was ready for harvest. In addition to the magazine advertising, newspaper and street car advertising were used in selected cities, while trade papers copy supplemented the personal salesmanship to the trade.

At the close of the first year of national advertising General Manager Gwin, of the Exchange, said: "For a national campaign our fund would ordinarily be called small. Yet Skookum apples are today talked of in America on a par with Gold Dust, Shredded Wheat, Crisco, or any other advertised commodity. Conservatively estimated by advertising people, the growers' investment in Skookum good-will represents a value tremendously in excess of the cash spent. This fund made for Skookum a dominant position in the apple world that will not be wrested from it."

The most convincing evidence of success is that the apples are actually featured by fruit dealers in every large city and that the Exchange has increased its advertising appropriation.

This experience would seem to indicate that Americans are not too sectionally clannish, but that anything American, whether from Maine or Texas, will sell readily to all Americans if attractively presented to them. Branded foods usually find their first and most economical markets in the larger cities of the country, and in larger cities the insistence on locally produced

products is not found, which sometimes obtains in rural communities.

Another experience comes to mind which illustrates the truth of this—that of the Blue Valley Butter people. Blue Valley sells readily in the larger cities throughout the country, but it makes little effort to enter the small country towns, because of the competition of local country butter. Even in this case it is the attitude of the country grocer, not the consumer, which is most discouraging. These grocers buy their butter from farmers whom they know and who are their customers, and they are afraid to offend these farmers by carrying city-manufactured butter. Yet this small town obstacle has not prevented Blue Valley from building up a most enviable reputation and a most lucrative and tremendous business.

It may be said, in fine, that Americans don't ordinarily ask what state a product comes from, provided they have been appealed to by the product itself, its name, personality, and the conditions under which it is packed.

In closing a word about the organization of the Northwestern Fruit Exchange may be of interest. It was incorporated in 1890, to perform for local apple growers' associations of the Northwest what the C. F. G. E. performs for the California orange growers. About twenty-five local associations are now within the Exchange, which has come to control probably the largest apple tonnage of any organization in the world, i. e., between 30 and 35 per cent of the entire tonnage of the four great apple States of the Northwest. Only about one-fourth of the Exchange's apples are high grade enough to make the Skookum brand, and it is doubtful if more than 1,500 cars of Skookum will be shipped in 1917-18, though the Exchange markets, all told, over 4,000 cars of apples annually.

The Exchange has not its own sales organization, but markets through the North American Fruit Exchange and Sales Agency of America, an agency which has a national organization and markets fruit for other associations, also.

ATTRACTIVE SAMPLES OF ADVERTISEMENTS OF SKOOKUM APPLES.

Porto Rico Beekeeping

By Henry Brenner

MY brother beekeepers who think me in Porto Rico will be surprised to see these lines dated from Santo Domingo. I certainly had a fine time in Porto Rico and enjoyed very much my experiences, the land, people, scenery, and especially my observations on Porto Rican beekeeping. I do not think that from November, 1916, till September, 1917, I ever spent more than two days at one time in towns, always in camp and apiaries in different places. The best kept apiaries I visited were those of Dr. Henry Smoyer in Naranjito and Corozal; the Warner apiaries in Comerio, Sabana, Naranjito and Aguas Cuenas; Rudolfo del Valle's two up-to-date apiaries in Ponce, and Wm. De Chaberts' in Rio Piedras.

These gentlemen are experienced beekeepers and some belong to the pioneers. Every one of their api-

boards in use. I discarded both. When the hands were done extracting I let them rest a day or two and started anew. With my powerfully strong colonies and a young, vigorous queen and only one or at most two supers, we kept continually at it. We picked out the ripe honey, shook the bees off and replaced right away with empty comb. In some of the apiaries where the hands followed my instructions, rearing cells, making the virgins in the supers and extracting we more than doubled the honey yield. I also made the acquaintance of smaller beekeepers and beginners.

In the parts of Porto Rico which I visited the main honey-flow starts in June and ends in September, and it is possible to keep the bees continually at work if proper attention is paid to the brood-nest and the queen.

The main sources of nectar are the shade trees in the coffee plantations. Coffee blossoms several times and

DON RODULFO DEL VALLE.

business in Santo Domingo and have already ordered more breeding queens from Texas.

One of my proudest days in Porto Rico has been when Mr. Henry Smoyers visited me and told me that he succeeded in getting more queen cells, and good ones, introduced in the supers and had a larger percentage of matings than myself.

I have now been five weeks in Santo Domingo and had the good fortune to meet with Dr. Maldonado in Sanches, in whose apiaries I am trying my hand at present. Have queens laying in the supers already, from hybrid queens I brought along from Porto Rico, and am waiting for my Texas queens to improve the bees faster.

DON RODULFO DEL VALLE'S APIARY AT PONCE, PORTO RICO

aries has an extracting house, dwelling house for the manager and his family and a reservoir to catch the rain water. Two and four-frame extractors, capping melters, honey tanks I have also noticed.

In the Smoyer apiaries they use steam heated uncapping knives. The apiaries are without exception well kept and clear of grass and weeds and the hives well painted.

In the Warner apiaries I started extensive queen rearing from Texas queens I brought along from home. In March or April Mr. Warner sent the first small shipment of 25 queens to New York and received orders for all the queens he could send at once. Of course, we needed the young queens ourselves to build up the colonies and to re-queen and for increase.

For every apiary I found queen—or better-honey excluders and escape-

yields nectar also. Wild flowers and numerous shrubs and bushes produce nectar and pollen also. In the citrus plantations the flow is during the bloom and is very heavy, but of short duration.

I opened thousands of hives in Porto Rico and a good many here in Santo Domingo, but have not found a single diseased colony. In one of the apiaries I saw in January bees crawling along the ground showing decided symptoms of paralysis. I examined the colonies and found, in two, fermented honey of sour taste. I marked these colonies and found at my next visit the honey good and sweet and not a sign of paralysis.

A large business can be built here in the Tropics in shipping combless bees in pound packages. The only precaution to be taken is to ship gentle bees, not the vicious brutes or hybrids. I intend to go into this

DON RAFAEL SERRA AND HENRY BRENNER IN DON RODULFO DEL VALLE'S APIARY.

WARNER APIARY AT THE FOOT OF A STEEP MOUNTAIN, SABANA, PORTO RICO.

Honey conditions here, land property, etc., I will mention in my next.

I wish I could get Dr. Maldonado and Don Rafael Serra in Ponce, personally acquainted with one another. I never met two gentlemen so alike in education, taste and culture. I hope when Don Rafael sees these lines he will write the doctor a letter, as only he can do it. He will get an answer that will please him.

Sanchez, Santo Domingo.

The Future of Beekeeping in Florida

By J. J. Wilder

FLORIDA, as a whole, has no great future for beekeeping.

No one can drop down in the State at any old place with a solid car of bees and expect to succeed, much less to locate and start in and build up. This has been tried, to the sorrow of many. By far the larger part of Florida will not support bees. Of course, there are bees kept most all over the State, but not at a real profit, all told. As many colonies die as are made, and as much money lost in bees as is made, if not more. This not only applies to farmers who keep bees, but apiarist as well. The number of new ones to give it a trial is increased a little each year as population increases, which keeps some life in the industry and thus it moves on. There are many reasons for this great blank spot of Florida for beekeeping, but I will name only a few.

First, the scarcity of honey plants. We might say that at least this condition covers half of the State. For the most part this is an open pine country and prairie. Next we come nearer the streams and where the country has been thinly settled and they have planted small groves of citrus. Here the bees will store some surplus, some years, but most of the seasons end in a failure for surplus; but bees with proper care will tide over. Then there come seasons of no honey as often as seasons with yield, and the bees have to be fed

back nearly all the surplus or they will die out wholesale. So there is but little gain for the honey producer. This partial or total failure is due to excessive drought or rainfall, and freezes.

Next we come to the streams of salt water and the sea. Here we find the most honey plants, and chances are better for a surplus for the hard-working apiarist. Yet failure in obtaining surplus stares him in the face and is his greatest dread. He plays even about as many seasons as he gains, but if he lives economically he has a support almost continually except years of total failure, when he may have to do some other work to help pay his bills for feed for his bees. Failure here is due to weather conditions, same as in any other section.

In a very few counties in the high sand ridge section of cut-over pine land along northern central portions

of the State the partridge pea grows extensively enough to give a yield, with conditions entirely different from those of other parts of the State. The flow comes in mid-summer and only a drought will check it. But when drought prevails there is another honey plant growing along with it known as "summer farewell," which only yields under very dry weather conditions. Here we have a surplus every year, but never great, the average being around 30 pounds per colony, and here bees are always in safe condition, in the hands of farmers or apiarists, but the average yield is so low that one has to keep lots of bees in order to make a living, and, of course, a large amount of capital is tied up. Yet bees never breed up very high in this section, and an apiarist can care for many colonies.

We now come to the best section in the State for beekeeping, which is the tupelo gum region, and is only a very small speck on the map; extending up and down the Apalachicola river and also a small strip on the Ocklocknee river, both of which head up in Georgia and flow down through the western portion of the State, emptying into the Gulf of Mexico, but some forty or fifty miles before they reach it they greatly widen out over the low, flat country with almost no banks, the main channel breaking up and winding about in small streams and in some places this bed of streams is ten miles across. Here in this overflowed section both the white and black tupelo gum grow in all their glory and make the beekeeper's paradise in Florida. The most unfortunate thing about it is its being a desolate, lonesome swamp, and the only means of transportation is by boats, but they have a regular sched-

DWELLING HOUSE AT CUENAS, PORTO RICO. At the top of the hill are dwellings for the peons.

ule boat line operating up and down the rivers. Then the beekeepers have their own private small gasoline boats, used mostly for passenger service, as the larger boats laud for honey at the apiary docks, which are built along large getatable streams. These boats are very accommodating to the beekeepers, as their revenue comes mostly from them. These beekeepers have homes up the river where the boats have a landing at the main land, and there their families reside all the time, while the beekeepers themselves play up and down the river in their small boats, looking after their bee interests during the busy season. Their apiaries, together with honey houses and small living quarters, are the most noticeable objects up and down the rivers, setting high up on scaffolds above high water mark. These beekeepers are the most prosperous

DR. SMOYER'S APIARY AT NARANJITO, PORTO RICO.

citizens of that country and beekeeping is looked upon by all as a great business. They are very congenial towards each other and one never places bees on another's territory, and when a stranger comes in with his bees and puts them down near some one of them, there is great commotion among them all, and they see to it that he moves them off. In this section there are many good unoccupied locations for apiarists, but they are not so convenient to reach, owing to the lay of the streams and main land out from them. Nearly all good locations in easy reach are stocked. However, all locations could be reached with little difficulty by land or water.

It is here Florida has the greatest future in beekeeping, and if it was well stocked the output would be enormous. Great progress in beekeeping of late is fully under way there and the early honey market nearly all over the United States feels the effect of their output.

Bradentown, Fla.

Beekeeping for Women

Our esteemed friend and correspondent, Ph. J. Baldensperger, of Nice, France, writes an interesting appeal, entitled "Revictualling," which we translate in part from "L'Apiculteur" of September-October, 1917:

During these times of penury in sweets, it is pleasant for us beekeepers to see the bees praised as auxiliaries in the service of mankind, in the present world catastrophe. As long as it is only our bee magazines who try to place the bee and its products in the front ranks, we see nothing extraordinary about it, for it is, as usual, the corporation of producers who defends its products. But when the daily press gets interested in the matter, we have good cause to be pleased with this forward movement. This world commotion was required to take beekeeping out of

consumer that he must eat honey, because of its healthfulness?

The prophet Mohammed gave the name of the honeybee to one of his 114 Suras, although this chapter contains only two or three stanzas relative to bees. He recommends honey, of which he was very fond. He says: "The Lord prompts the bees to make their homes in the mountains, in the trees or in the bushes, to feed upon the products of the trees and to follow the way that the Lord teaches. A product comes out of their body, a liquid of varied colors, which contains a human remedy."

The mystic appeal of the prophet should be modernized for our cities and our country. With a little thought and some reasoning, we will finally give beekeeping the place which it occupied formerly.

I was called lately to a country place to dislodge several swarms which had taken possession of a villa. I hastened to answer the call, in spite of my crop work, in order to be of service to some of the "women of France" who are now struggling magically to help French agriculture.

However, I have not quite as much "enterprise" as a veteran beekeeper mentioned to me by a Piedmontese, who is hardly as famous, as a liar, as the inhabitants of Tarascon. This veteran, he says, having discovered bees in a hollow rock in the bluffs of the Alps, hired, one day, seven mules to transport the necessary ropes for the assault. The king, Victor Emmanuel II, having heard of the caravan, joined the expedition. The big cavern, according to my Tartarin story-teller, contained thousands of swarms. Several men were required to gather the honey in large tubs and let it down with ropes. After a few hours of watch of this wonderful work, the king became tired of it and asked to be let down. But the veteran was unwilling to dispense with the flattering presence of the king, and continued to gather the Pactolian flow. But let us leave them with their seven mules, to come back to our villa.

Some swarms were situated against the sash of a window and obscured the room. Others had located between the floor and the lower ceiling. These charming bees belonged to a swarm of as charming young ladies. Blondes and brunettes had protected their heads with scarfs which made a great diversity of colors. They were greatly interested in the work. After having carefully smoked the bees at the entrances, I tore out some boards and went to work. For four hours, kneeling down before this treasure, once in a while I pulled out a great comb of honey and handed it to my enthusiastic lady beekeepers. Any one witnessing the work from the forest across the hill might have supposed that I was a faithful Hadji, starting for Mecca and kneeling to Allah to ask for a successful voyage. The pilgrimage was certainly crowned with success, and at sight of combs of honey four feet in length by one foot in depth, I felt

the shadow in which it stood behind its sisters in "ing."

A large American daily which I read a few days ago calls the bee "our recent recruit," and a Boston professor makes a warm appeal to the public in favor of beekeeping. He quotes the statistics of the Washington Government to show that the United States produce only 300 million pounds of honey for a population of 100 million, 3 pounds per head.

What then will we say of the crop of our "belle France," as our friend Dadant calls her? We reach a production of 22 million pounds for a population of 40 million, or about half a pound per head. There must be inequality of distribution, for what would a beekeeper do with only half a pound of honey to eat annually? Is it not high time for us to go about praising the value of the honeybee, since with the present shortage of sugar there is no need of great eloquence to persuade the

like using the Moslem expression: "Tabarak, Allah," (What a blessing, Allah). Had it not been for the occasional stings and the unpleasant posture, I might have believed myself in the Paradise of Mahomet. Think of those pretty girls and their artistic conversation and that stream of white honey! If we did not have seven mules, we had at least seven tubs of fine honey, all evidently gathered from the numerous basswood trees of the public drives. An old Italian woman, who transported the honey in a little hand-cart, had some difficulty in keeping all the recipients aboard, and as she tried to straighten up one of them, at the foot of the hill, she touched with her finger a bee which she thought dead. "Ah, la Carogna e ancora viva!" "Ah, the carrion is still alive!" cried she, as she was stung on the finger.

We finally dipped out some of the combs with a skimmer, but a shovel would have been better, and we at last left the balance because they were too far. The swarms had been there since the beginning of the war, and one could see the 1914 combs of dark color, those of 1915 and 1916 of light brown, and the 1917 combs of immaculate white. I secured about 12 combs of brood from each swarm, and the ladies had a long job straining the honey.

As the Vestals were too numerous to keep up the sacred fire properly, the smoker was run very intermittently and there were more stings than there should have been had the smoke been produced judiciously. Then the bees were too numerous and scattered over too large a space, for they occupied over 9 feet each way.

The ladies promised to continue the study of beekeeping, reading good practical works and periodicals. Although the evenings are short in summer, each is anxious to discuss bees and to put her acquired knowledge to the service of "revictualling." If they only scatter a few hints among their friends and neighbors, it will be just so much gain for all.

Beekeeping by the women, who do so much work already, will help bring the world back to its own. How many brave women are seen to sow, plow, harvest, haul the crops, while the men have harder tasks! No; beekeeping is not too difficult, nor too tiresome for women. With a good smoker, half of the work is mastered. The other half will soon be done through good teachings. Before proceeding to keep bees, they must use good judgment, learn the value of a colony, how to hive or transfer it with progressive and judicious development.

Theory and practice in right proportions are absolutely necessary to succeed. The heavy tasks, such as hauling honey, may be done by others. But we must not figure that all there is to it is to allow the bees to harvest the honey and then for us to take it away from them with a good smoker. We must know the

conditions and time of development, the obstacles, the inclemencies of the weather which retard or arrest the cultivation, and all essential requirements for success.

Study the flora, to have an exact idea of its yield. Many blossoms yield little or no honey.

Ladies, and you also, gentlemen, go into the keeping of bees. You will find a few spare hours which will give you satisfactory results, if you do not neglect them. If it is too late for this year, try and have bees for a crop next year.

Notes On Honey Plants

By L. H. Pammel

Buckbrush or Indian Currant and Snowberry

Most beekeepers living in the region where grows the Indian currant, coral-berry or buckbrush (*Symphoricarpos orbiculatus* Moench), appreciate the importance of this plant as a honey-producing species. Two other species of the genus *Symphoricarpos* are well known as buckbrush. The

THE SNOWBERRY IN BLOOM.
(Photographed in the field.)

BERRY AND LEAF OF THE CORAL-BERRY.

common wolfberry (*Symphoricarpos occidentalis*) is the species so common in western Iowa, north to Minnesota and North Dakota, south to Kansas and east to Michigan. It is the most common species in the Missouri river basin and is very common on the loess bluffs of the Missouri, where it answers the same purpose that the hazel does in the north. The snowberry (*S. racemosus*), which somewhat resembles the preceding, has large white berries and is a striking object in late summer and fall. There are two varieties of this species. The variety *laevigatus* has long been cultivated. The variety is, however, less widely distributed in nature than the species. The snowberry of the north *S. racemosus*, has a wide distribution, from Quebec to Alaska, Massachu-

setts, northern Minnesota, the Rocky Mountains and California. The snowberry of Iowa furnishes a large amount of excellent honey during the summer. It remains in blossom for a long time. The flowers of this species are more conspicuous than those of the coral-berry. The coral-berry is native to Iowa, as far north as Story county; along the Missouri river it reaches farther north. South Dakota is given in the manuals, but I have my doubts about the species extending very far into South Dakota. It is fairly common in the vicinity of Council Bluffs and also in Polk county. It blooms later than the snowberry and where the two species occur together there should be continuous honey flow. The flowers of the coral-berry are much smaller than those of snowberry, whitish and red with a slight rose color. The cell-shaped corolla is five-lobed with five stamens inserted on the corolla between the lobes. The nectar occurs in abundance on the lower part of the corolla tube, below the hairy style. The flowers occur rather abundantly on the axils of the leaves, pointing away from the lower surface of the leaves. The bee must enter the flower from below. The honey is, therefore, not as easily accessible as in some other flowers. I have watched bees for several weeks gather the nectar from these flowers. Although white clover was in bloom, the bees seemed to prefer the buckbrush or coral-berry in the autumn. The coral-berry should be valuable as a honey plant southward to Texas. It is regarded as a weed by many farmers in southern Iowa. The strong, vigorous shoots of the plant are used for making baskets, in Arkansas, where the country folk make a unique basket of good quality. Mr. Simmonds, the landscape artist, is using this species to a considerable extent as an ornamental

plant. For this purpose it is a highly desirable species.

Horsemint

Many years ago, when I became interested in bees on a Wisconsin farm, we used to look forward to the blooming of the horsemint (*Monarda punctata*). This plant could always be counted on to yield an abundance of nectar every season. Much of the sandy prairie about one and one-half to two miles from our apiary was still unbroken and this plant grew in

is correctly called *Monarda fistulosa*, but the plant which produces the honey for bees is the *Monarda punctata*, which is a much better honey plant so far as bees are concerned. The statement made by Mr. Pellett on page 132 of the American Bee Journal for 1915, is a very general statement. I am inclined to think that bees do not get very much honey from *Monarda fistulosa*, notwithstanding the opinion expressed by some that they do. It is a regular bumble-

Watch for Starvation in Spring

By G. C. Greiner

WHAT I expected and feared on account of the unusual warm spell last winter came to pass in a limited way, and it was only my timely attention that averted a dire calamity.

It is very seldom that I disturb my bees before they are unpacked and placed on their summer stands about May 1. Unless something unforeseen takes place, something like the aforementioned emergency, I cannot do them any good until the season is far enough advanced to begin spring management. Besides, packing them in chaff, as I practice it, does not admit easy access to the hives; it requires some preparations to reach them, which are not desirable at this time unless strictly necessary.

Judging from the unusual display of young bees whenever a fair day induced them for their customary play spell, I concluded that heavy breeding must have reduced their stores to the danger point of starvation. As my anxiety to ascertain the condition of my bees grew stronger from day to day, on April 7, the first suitable day for the operation, I examined every colony in the yard. Previously, on another suitable day for that work, I had taken the precaution to prepare the bees for this examination. All the chaff packing above the honey-board (inside cover) I had gathered up and placed in sacks, which I keep for this purpose, and after being filled, I had again put them in the place of the removed chaff. While this does not conform exactly to the theory of perfect airtight winter protection it retains the heat of the hive during cool spring days and nights quite well. By simply taking the sacks from the hives I had ample opportunity to open the hives for the intended purpose.

Of course, I did not disturb them more than was necessary to make a superficial estimate of their supplies. The result of my investigation proved my correct conception of the situation. Over one-half of the yard was either starving or starvation was knocking at their doors.

Fortunately, when doing my last extracting the fall previous, I had reserved a goodly supply of heavy combs for this very emergency, the first time in many years, if it ever happened, that this precaution amounted to such an inestimable benefit to my occupation. Every side-comb of every hive was taken out and glanced over, and when found empty or insufficiently supplied was replaced by one or two combs of honey. In connection with this observation, I wish to emphasize the great convenience of the loose, hanging frame and its superiority in all its manipulations over any self-spacing device. A self-spaced frame would have greatly hampered this work and required much more time.

HORSEMINT—(*Monarda fistulosa*.)

abundance. I sent a note on the value of this plant as a honey plant to the American Bee Journal. The plant was identified, Vol. 15, page 540, by Dr. J. W. Beal, of the Michigan Agricultural College, as *Monarda fistulosa*. The identification by Dr. Beal is an error. The plant in question is *M. punctata*. The perennial horsemint is minutely downy, with lanceolate petioled leaves. The lanceolate bracts are yellowish or greenish yellow and purple. The flower is yellowish, the upper lip spotted with purple. The plant is found on sandy soil from New York to Wisconsin and Minnesota, to Texas and Florida. In the more southern region the annual lemon mint (*M. citriodora*), occurs, which is perhaps also valuable as a honey plant.

In a recent visit to La Crosse and Onalaska, Wis., I noted that bees abundantly visited the horsemint. The bees were so abundant that it sounded like a swarm. This horsemint is not common in Iowa, only occurring in the sandy region along the Mississippi, the Wapsipinnicon, Cedar and Iowa rivers. I know of no plants in central Iowa. In western Wisconsin and eastern Minnesota it is common on the sandy jack pine and oak barrens.

The wild bergamot or horsemint figured by Mr. Pellett on page 132 of the American Bee Journal for 1915,

bee flower. At one of the meetings of the Iowa State Beekeepers' Association a Mr. Brown from Sioux City, I think, made the statement that this plant yields honey for bees. I am inclined to think the plant referred to by Mr. Brown is not the wild bergamot or horse mint (*Monarda fistulosa*). It may have been the *Monarda punctata*, which is a regular honeybee flower.

Common names are often misleading and lead to erroneous conclusions. The manuals give wild bergamot as *Monarda fistulosa*. In Iowa and Wisconsin, however, the *M. punctata* is known as wild bergamot, and the manuals give this as horse mint. Our Iowa horse mint (*Monarda fistulosa*), and this applies to some other northern regions, is not adapted to honeybees. It is adapted to bumblebees. The nectar is out of reach for honeybees. The flowers are lilac or pink and in the northern Rockies, in northern Wyoming are a very deep pink. The *Monarda punctata* has become a plant of considerable economic importance because it contains considerable quantities of thymol, which before the war was largely imported from the continent of Europe. It would seem that large sandy areas might very profitably be cultivated with this plant, yielding not only thymol, but an excellent honey.

It is somewhat of a strange happening that I lost two colonies under exactly the same conditions. They had started quite a large brood-nest on one side of the hive, occupying five combs with patches of brood about the size of two hands in the center combs. The spaces between the combs were filled with dead bees, but not a drop of honey in the five combs. The three combs on the other side were practically free from dead bees and contained about ten pounds of honey scattered over the combs. When the March weather changed to zero temperature the poor bees tried to protect their offspring; they remained with their brood until all supplies within reach were exhausted and not being able to reach the stores on the other side of the hive they became a victim to that grim messenger, starvation. Thus bees starved with plenty of honey in the hive.

It may be too late to call the attention of beekeepers to the danger of starvation in spring, when these lines reach their eyes. Nevertheless, to caution those who have not yet ascertained the status of their bees may be the means of preventing sad disappointments.

La Salle, N. Y.

Crane's Honey-Board

By J. E. Crane

SOMETIME about a year ago the editor of American Bee Journal gave a description of a honey-board I have been using for a number of years with a good deal of satisfaction. Since then I have received a number of questions as to how it works, with request that I answer in some one of our standard journals. Before doing so, however, it may be well to state the object of making it and using it, which was to get rid, so far as I could, of the travel-stain, so-called, on the sections. Now the word "travel-stain" is a misnomer. We get the impression at once from the word that the stain is caused by the bees traveling over the combs with dirty feet, which is not the case at all. There are two entirely distinct causes of stained combs. One is by bees entering their hives with their bodies covered more or less with pollen and passing up and down between the combs, rubbing it off. As it is somewhat glutinous, it sticks to the surface of the combs and discolors them. I have known the whole inside of a hive to change its color in a few days. It is apt to occur when bees are at work on dandelions or goldenrod or other flowers on which pollen is very abundant. This stain is usually easily removed by exposure to the sun light for a few days. Another and worse stain is caused by the bees carrying up from the brood-chamber soiled wax, propolis or cappings from the cells of hatching brood and mixing them with the new snow-white wax for capping the section honey. Sometimes they will gnaw cloths that have been laid over the sections over sur-

plus combs, and thus produce a discoloration of cappings that cannot readily be gotten rid of, for the dirty wax cappings of brood, etc., form a part of the cappings and extend clear through them. In studying the subject many years ago I came to the conclusion that the moving of dark bits of wax, cappings, propolis etc., from the brood-chamber was the cause, for I observed that the combs in the center of the brood-chamber were much the darkest, while the outside combs were often quite white. The same was true of the sections in the super. Those on the outside were nearly or quite white, while those in the center of the super were, many of them, badly discolored. I also found by a glass of moderate power that bits of colored wax extended completely through the cappings. How could this be prevented? I tried Heddon's break-joint slatted honey-board, without much improvement. Then it occurred to me that if all communication between the center of the brood-chamber and the super was cut off the appearance of the sections would be greatly improved. I then constructed a honey-board of the same size as my brood-chamber, with a rim one-half-inch thick and one inch wide, with the center filled in of one-quarter-inch stuff so that when a clamp set on it there would be a quarter inch space between the bottom of my super and the upper side of the honey-board. I left a slot one-half inch wide on each side of the honey-board just inside the rim, so that when on the hive these would be at the sides of the top of the brood-chamber and over or outside of the outside brood-combs which were the whitest and had the least brood or soiled wax. I feared having so small a passageway from the brood-chamber to the super and so far from the brood would keep the bees from storing as freely with-

out it. But I was happily disappointed in finding that it made little difference. Of course, I do not put these boards on until the bees have made a good beginning in the sections, nor is it necessary, for there is no danger of soiled cappings till they begin to cap them. Used in this way this honey-board does not appear to delay or interfere with the storing of honey in supers as a rule, but I have now and then found a hive that I thought would have finished its combs or sections more completely without the board under the super. Are the sections entirely free of stain? I am sorry to say that they are not, but are very much whiter than when the board is not used. The sections over the center of the brood-chamber instead of being the most stained are the least so. And the sections on the outside of the super do not appear to be much if any more stained than without the board. As a rule I think they finish the sections more evenly than without it, that is, they finish the combs on the outside of the super at the same time as the center sections, more nearly than without the board. We do not put the board on till some of the sections are about ready to seal, or the bees have already begun to seal them. When we tier up, by raising the first super and placing another under it, we delay putting on the board, as the first super is so far removed from the brood that there is little danger of the sections becoming stained. There is a great difference in different seasons and different localities in getting stained combs. As a rule the sections will be whitest where and when honey comes in fastest. We find little objection to the use of these honey-boards aside from the work of putting them on and taking them off. I have used them with eight-frame hives, and they might not work as well with a ten or twelve-frame hive.

CRANE'S HONEY BOARD FOR FINISHING OUTSIDE SECTIONS.

as the distance from the outside slots to the sections in the middle of the super might be so great that the bees might not finish perfectly and I would advise testing them on a few hives before trying to use them extensively. A honey-board thicker than the one I have described would doubtless work just as well, perhaps better, only it should be made so that part of it between the two slots should be one-fourth inch below the super, for a beespace, so the bees can readily enter the super.

Middlebury, Vt.

My Neighbor's Garden

By Charles Duff Stuart

IT was but scant sympathy I received on the occasion of my first bee sting.

"Your thoughts were not right," my neighbor assured me. And as I bathed my swollen forehead and half-closed eyes, I was obliged to admit that they were not. Even then I had in mind the fly-swatter as a means of exterminating the entire Bee family.

"If you don't feel right toward them they know it," he continued; "You can't fool them. Fear is a poison that communicates itself through the atmosphere. That's what makes them sting."

The diagnosis seemed plausible, but it failed to abate the swelling, which steadily increased, much to the amusement of my neighbor, who attributed his own personal immunity to life's little discomforts to deep breathing and a proper mental attitude. But I would have traced the cause of his longevity still further, to the very source—long hours spent in the intensive cultivation of his garden.

It is truly a wonderful garden. My neighbor himself did not fully appreciate it until the visits of our bees revealed to him its beauty and variety. Each plant and blossom then took on a special meaning, and this awakened interest expanded to include the honey bees themselves.

"See? They don't bother me!" With bared head my neighbor stood beneath a Loquat tree, laden with blossoms on which our bees were working busily. It was an old tree of the Japan plum or Japonica variety, and pruned so that its branches were nearly on a level with his face. He stood with head thrown back, listening to the hum of the honey-gatherers and inhaling deep draughts of the clear morning air, while I found refuge behind the screen door of the kitchen and besought him not to tempt Providence too far.

"Get your thoughts right and they won't sting!"

"It's true!" corroborated his wife; "they know their friends instinctively, the darlings! How I'd love to squeeze them!"

It was not in me to destroy such perfect faith. I could only stammer, "Oh, d-don't squeeze them! You—you might hurt them, you know."

"She never hurt a living thing yet," declared my neighbor. And one might well believe it, judging from the care with which a few weeks later she carried cross lots a covered teacup. In it was a magnificent drone, captured and preserved by her, under the impression, no doubt gained from its size, that she was restoring to us a valuable queen bee.

After the Loquat, in December, came the Acacia bloom, in January and February, yielding white and yellow pollen, respectively, and much nectar. The bees thrived. The hives waxed strong and full of stores. Already young bees were flying and eager to gather the nectar from my neighbor's strawberries. Simultaneously my neighbor's thoughts also turned to the strawberry patch which was situated just beyond and adjoining our apiary. My neighbor's garden at that point not only joins our bee-yard, but overlaps at the joint. And, notwithstanding the surveyor's stake and my tax receipts, it is that choice strip which for years had produced the berries for which he is famed.

My neighbor's thoughts were not in "error"—it was March and high time to put the bed in order—but his demonstrations were not in accord with the mental science of the bee. At the first stroke of the hoe they flew around him in mild wonder, tinged with an air of reproach. At the second, there was an alarmed, angry buzzing that should have forewarned him; but he only stopped and inhaled a deep breath. The following strokes brought the situation to a swift climax. The bees attacked en masse. There was no time in which to quell them with loving thoughts. He no longer yearned to pet the "intelligent little creatures." Safety first was the most urgent consideration. It was clear that he did not share the philosophy of the old Irishman who raked our yard, who, when a bee attempted to oust him from the premises, fought with one hand and worked with the other, even apologizing for the bee. "Och, he didn't mane innything at all. He was just busy, an' I was disturbin' av 'im."

Quite the contrary! My neighbor fled to the shelter of our porch. Gore was in his eye, and just above it waved the poisonous souvenir of his assailant. I gently removed the stinger, but could not assuage the sting. Indeed, no reparation short of the immediate extermination of the entire apiary by sulphuric fumes, to be administered by himself, personally, would satisfy.

"The book says," I ventured, when at last he paused for breath, "that a high board fence prevents bee

PLUCKED FROM MY NEIGHBOR'S STRAWBERRY BED ON FEBRUARY 28.
(Photograph by John R. Douglass.)

stings." I then proceeded to expound at length the theory of a bee's flight—how it rises straight in the air above all impediments, before it strikes out to pasture, and how absolute safety depended only

A BRANCH OF ACACIA BLOOM
(Photograph by John R. Douglass).

on the height of the fence. I watched the effect from the tail of my eye. He was growing visibly calmer. The prospect of a half-payment on a fence that would leave the strawberry patch on my side of it, had worked the magic. His wife, too, was deeply impressed. She presented me with a jar of strawberry preserves, casually remarking that fences, particularly high board fences, were out of date and no longer used in connection with modern homes.

Early next morning I was awakened by a sharp metallic sound.

"The milkman," I murmured, and turned over for another snooze.

Again the sound came—a stealthy, scraping sound. I stole to the window. In the half-light I perceived a dim form that now and then cast furtive glances in the direction of our lives. It was my neighbor. He was hoeing the unfinished rows of strawberries.

Bees in Combless Packages

By the Editor

THE irregular results in crops harvested from packages of bees by the pound, received from the South, when they have arrived in good order and have been properly lived on empty combs, are mainly dependent upon the time at which they are received, when compared to the honey flow.

The results obtained in honey by the purchase of such small swarms as one pound or two pounds of bees, often do not come from these bees directly, but from the great increase in hive force secured from the queens themselves, by active egg laying.

Whether we rear bees at home for

the honey crop, or whether we order them from far away, we must bear in mind that it takes 21 days to hatch a worker from the egg, and that it usually takes about 14 days more before that worker becomes an active field bee. So the actual amount of time necessary between the laying of the egg by the queen and the harvesting of honey by the bee produced from that egg, is 35 days. Let us suppose that our honey crop is usually due to begin on June 10. Then the first of our field force must be bred, the eggs must be laid, at least 35 days previously, or about May 6. If the egg-laying does not begin until May 20, the field force will begin its labors only about the end of June. If our crop lasts 6 weeks, nearly half of it will be gone before our bees can throw a sufficient force into the field.

This explains why countries in the far north usually succeed best with bees by the pound. Often their crop does not begin till the end of June. If they receive their combless packages by the middle of May and put them at once on drawn combs, the queens have at least 10 days in which to lay eggs that will make a working force for the first of the harvest. Queens that lay 3,000 eggs per day will thus furnish some 30,000 workers, more or less, at the opening of the crop, with additional thousands coming every day following.

In some parts of the country there

are two distinct honey crops, the June crop and the August-September crop, or, as some call it, fall crop. If we secure our bees by the pound early in July, they will be ready for the harvest of the second crop after August 15. A package of bees by the pound secured in the middle of June would begin to hatch its first bees about the 6th of July, during the dearth between the two crops and would breed a large, useless force that would consume honey during the month of July without being of any use as field workers till six weeks later.

As bees live only about 45 days on the average, it is as necessary that we should not breed them too early as to rear them too late. As a matter of course, we need bees during the entire summer and a colony that would entirely stop breeding at any time would soon dwindle in numbers. But the beginning of the active egg-laying should come from 45 to 50 days before the opening of the prospective crop, so as to have the bees of 10 to 15 days of laying when the crop opens, with an increasing force after that, until the combs begin to be well filled with honey, when the laying perforce decreases for want of room for the queen to lay.

So it is of importance for the apiarist to be well acquainted with his locality and its bloom and also to keep informed on the earliness or lateness of the season, since seasons vary considerably.

LOQUAT BLOSSOM IN JANUARY
(Photograph by Alice Caldwell)

The queen breeder and bee shipper of the South must also have these matters in consideration, as he may help his customer by shipping at the right moment. But in order that both may have the greatest amount of satisfaction it is necessary that the purchaser should inform the shipper of his wants long enough ahead to enable him to prepare the supply. Nothing is more unreasonable than for a purchaser to make up his mind, at the last minute, to order 10 or 20 packages of bees and demand immediate shipment or money refunded. Although a breeder might happen to be in position to fill such an order, there is more probability of his having to return the money, as it is not always possible to keep bees and queens on hand subject to unexpected and immediate demands of far away customers. February is none too soon for the buyer of bees in pound packages to make his wants known and he should also remember that the breeder is just as dependent upon the weather as he is himself.

Experience has shown that queenless packages arrive in poorer condition than queenright ones. They could only be used to reinforce other colonies. The above explanation also shows why already built combs are of great importance in the success of bees in pound packages. It goes without saying that if there is no honey to be had in the field the bees must be fed to secure constant and copious laying.

Mating of Queens

By Geo. F. Hayes

IN his first "Answer" of the November (1917) issue of the American Bee Journal, Dr. Miller states that he "thinks, in some cases, queens mate at swarming time." I had an opportunity last summer to observe that such is the case.

I shook from a low-hanging branch, a large swarm in front of a hive. After a few moments I noticed the queen crawling in the grass. I caught her and after concluding that she was a virgin, attempted to drop her directly in front of the entrance. She refused to drop, however, and flew into the air. After some confusion the bees settled again on the branch, from which I shook them a second time, and again succeeded in finding the queen. This time she bore the usual signs of being newly mated. I caught her to explain her appearance to a couple of neighbors who were watching. When I released her she took wing as before, but soon came back and alighted on the front of the hive.

The thought came to me that perhaps here might be a way to get queens mated in the home yard. This queen must have met the drone within a few feet of the hive, while she was circling preparatory to alighting again. The yard was close by, and there were many drones flying from Italian colonies. The queen was purely mated and was

laying in a couple of days. The difficulty is, of course, that virgin queens are not always in the mating humor when they swarm. May this not be because they are too young, and if they were manipulated so as to cause swarming when four or five days old would they always be in swarming humor? If so, it would be an easy matter to capture her while hiving the swarm and toss her into the air. She would circle around a few times before alighting, thus giving the drones an opportunity to seize her.

Prices of Bees

ON page 262, August, 1917, an article appeared in the American Bee Journal concerning the pound package business. The article in question advised the dealer or breeder of bees and queens not to make any advance in prices for 1918. If buyers will but consider the matter fairly they will conclude that it is impossible for dealers to maintain last season's prices, especially those who sold bees at one dollar a pound and seventy cents for a queen. The material used in making one of these pound package cages costs about 31 cents, unprovided. We use the best XXXX pulverized sugar for feed; as a precaution we use an abundance of feed, never less than one-half pound when the shipment is to be made within our State, and when we ship out of Louisiana we always use one-pound of feed to each pound of bees. This item is 10 to 12 cents per pound. Now consider the work, which must be done by an expert. Then estimate the value of what honey one of these pound packages would bring to you if you should keep it at home. Shipping bees to northern and western buyers begins right at the time our best honey flow begins. The above will give the buyer an idea of whether a dealer would be justified in offering bees at even \$2 for a one-pound package with queen.

A BREEDER.

Glimpses of Southern Bee-keeping

By Joseph S. Scott

LAST year the whole Gulf Coast was visited by a terrible wind and rain storm in July, and the amount of damage was great. The government had to open supply stations on the Alabama river to feed the laborers; most of them were tenants, and the overflow from the river wiped away their crops and there was no other work that they could do. Several beekeepers lost a lot of bees.

These were not lost by overflow, either; they were blown away. I did not lose any, but, as usual, I anticipated a flow from summer titi in July and bonaset and goldenrod in September, so I had extracted all the honey that was on the hives and

even some that was in the brood-nest and sold it ail. Several days after the storm came I had to begin to feed. I think that I fed everything that I could get that was sweet, but out of 225 hives I only pulled through the winter with 90, and they were living from hand to mouth (my hand to their mouth). However, there was a good early flow and they began to pick up, and they never stopped picking up, either. I have kept bees here for seven years and this is the first year that I ever saw them gather honey practically every day in the month from February up to the last of September. Titi was followed by blackberry, then tupelo, then black gum, then poplar, then cow peas, then summer titi, then velvet beans, then bonaset.

The peas were from the heavy plantings for food, as they make a good dish for the table, come early, and need very little work. Velvet beans were more extensively planted this year than ever before. While I have gotten honey from both before, it was only just enough to know that we could get honey from these plants. Mr. Simmons, from Greenville, Ala., had a fine sample of velvet bean honey at the county fair at Mobile last year. The velvet beans were planted and introduced there several years before they were here. I examined a bloom this summer and found in one blossom enough nectar for three bees. I mean by that that it would take at least three bees to clean up that one bloom.

As for the cow pea, the bee does not get the nectar from the blossom at all, neither does it get it from where the leaves come out. A stem about the size and length of a lead pencil will grow from the vine and this stem will have several blossoms on it and when the blossoms drop off they will leave the little pea and after the pea gets about half grown then the bees will get the nectar. There will be at the end of the stem near the peas a very few little "eyes." They look like potato eyes, and the bees will suck the nectar from these eyes. They will visit a great many stems before they get a load, and I rather think that the fluid that they get is really not honey, but a sweet substance. I have never had enough peas to get this honey in its purity, but hope to have them next year.

Velvet bean honey is of a light amber color with a mild flavor, but not the body of basswood or clover or tupelo.

This is also the first year that I ever got a large surplus from bonaset. We had a terrible rain and wind storm here the last of September and the bees were working furiously on bonaset when it came. As the weather turned cold for a few days after, that cut off the rest of the surplus from that source. This bonaset has sprung up on low places where the pine timber has been cut, and I think that in a few more years I will have a fine place for a surplus from that source alone. I got as it was an average of twenty pounds

and think that if the storm had held off for a week longer I would have gotten a least fifty pounds average surplus.

My average this year from all sources has been 88½ pounds, spring count, and an increase from 90 to 220, against an average for the last seven years of 70 pounds. So there is one

lining to that cloud, and when I tell you that I used to get 6 cents for extracted honey and 10 cents and pay freight for comb, and that this year I got 10 cents for extracted and 15 cents for comb, and the purchaser pay freight, there is another lining to the cloud.

Mt. Pleasant, Ala.

well says: "I am afraid the working man does not get much honey."

What Our Farm Women Ask and Answer

In a department of a farm paper, under the above heading, occurs the following item:

"Miss I. E. B., New York, suggests that someone give cake and cookie receipts making use of honey."

It is encouraging to know that farm women are asking questions of that kind. It would be a good thing for beekeepers, and a still better thing for the general public, if farm women could know the whole truth about honey and sugar. If they did they would not only want to use honey for "cake and cookie receipts," but in staple articles of food and in drinks as well. It will bear repeating again and again that the more than 80 pounds of sugar used annually for every man, woman and child of the nation is a menace to health, because the sugar must be changed from cane to grape sugar by the digestive organs before it can be assimilated, and that throws too heavy a burden upon said organs, while on the other hand the bees are the little chemists that prepare honey for direct assimilation. It is to be feared that even the women in the homes of beekeepers do not sense this as fully as they should, and act upon it.

Few as the number of women may be who are fully aware of the real advantage honey has over sugar in the way of ready digestion—rather in the way of predigestion—still fewer are aware of the fact that honey contains elements that are absolutely lacking in sugar, mineral elements, to be sure in small quantity, yet of great importance in supplying what is needed for the full support of physical well being.

It might not be a bad thing if this sentence should be placarded on the walls of homes, indeed everywhere: "Honey is much easier of digestion than sugar, and contains important mineral elements that are entirely lacking in sugar."

Making Bees Carry Up Honey

Your reply, advising to pound on the hives to make the bees carry up stores from below, seemed very practical to me, but in one little place, suppose we had pounded on or disturbed a colony, as you suggested, that had had a flight later than any of the rest and did not need it, would not the disturbance then do more harm than good? Our bees generally come out from 12 until 2 o'clock in the afternoon. If we waited until the rest had flown before pounding on the hive, when they would warm up it would be too late for them to fly, and the large amount of honey they had taken up would do more harm than good, for it might cause dysentery. So the only remedy I would see would be to first listen at the entrance and see if we could

Net Weight of Sections

"Must each section of honey be stamped with the net weight, in Iowa, to comply with the law, or can it be sold by the section or case?"

Answer. There has been much confusion regarding this matter in Iowa, owing to the fact that the Iowa State law is patterned after the federal law. While the federal law is so interpreted that all section honey which is produced in one State and sold in another must be stamped with the net weight, in Iowa the commissioner has not seen fit to enforce that regulation. The section of the pure food law which applies reads as follows:

"If any person shall sell, offer or expose for sale any food in package form, if the quantity of the contents be not plainly and conspicuously marked on the outside of the package in terms of weight, measure or numerical count; provided, however, that reasonable variations shall be permitted, and tolerances and also exemptions as to small packages shall be established by rules and regulations made by the State Food and Dairy Commissioner."

This State law reads almost word for word like the National law. The federal commissioners insist on the marking of all sections of comb honey, but the Iowa official, acting upon the authority vested in him to

grant exemptions, has so far made an exception of comb honey. In a private letter he writes as follows:

"There is no exemption in the law to any product, yet this department has not been enforcing this law so far as it applies to section comb honey, because we understand that it is a little hard to weigh each section and put on the net weight. Unless we change our attitude, or the law is changed, we will probably not require that section comb honey be marked as to its net weight."

W. B. BARNEY, Commissioner.

To add to the confusion, Iowa has a net weight law, which exempts comb honey from its provisions.

The best policy for the beekeeper to pursue is to weigh all sections and stamp them with the net weight in order that he may be in position to fill orders from outside of the State without violating the provisions of the National law, or to avoid possible conflict by a change in the regulations of the food and dairy department of which he might not have due notice. It is highly desirable that a uniform policy be generally followed, and since the National law requires that all comb honey going from one State to another be stamped as to the net weight of the sections, it is only a question of time until a similar requirement will be made in all the States.

BEE-KEEPING FOR WOMEN

Conducted by MISS EMMA M. WILSON, Marengo, Ill.

Honey Custard

A senior in "Home Economics" at the Oregon Agricultural College, is conducting some interesting experiments with honey, provided by the college apiary, according to an extension bulletin just received.

The following recipe, "Boiled Honey Custard," is recommended by her:

Two cups milk.
Three egg yolks.
One-third cup honey.
One-eighth teaspoon salt.

Mix the honey, eggs and salt; scald the milk and pour it over the eggs. Then cook in a double boiler until

the mixture thickens. This custard is suitable for use in place of cream or gelatine desserts, or to be poured over sliced oranges or stewed fruit.

A Neglected Industry

A Manitoba correspondent sends a newspaper clipping in which Lady McDougall directs attention to beekeeping as "a very ancient, but now neglected, British industry." If price is any inducement, surely there should be an inducement toward beekeeping, since "at present heather honey is selling at from 2s to 2s 9d per pound section." That's 20 to 68 cents per section! Our correspondent

hear them roaring and then pound on the hive while the others were flying.

BIRDIE M. HARTLE,

Reynoldsville, Pa.

Your anxiety for the welfare of the bees is commendable, but in this case hardly well founded. Please note that you are advised to pound on the hives of those that are quiet while others are flying, and not after they have ceased flying. If it is warm enough for them to fly they will likely be flying within five minutes after you begin pounding, and as it is not at all likely to cool down instantaneously, they are practically sure of having abundance of time to fly if they should. Indeed, if you should delay pounding until flying had about ceased, any colony that had not flown would still find it

warm enough to fly if any flight should be heeded.

You say "the large amount of honey they had taken up * * * might cause dysentery." So it might if they consumed the honey, but carrying honey up and emptying it in the cells is entirely different from consuming it, for in the former case there is no loading of the intestines, and in the latter there is. Loading the honey-sac with honey does not produce dysentery, but loading the intestines with what remains after digestion does.

It would do no harm to listen at the entrance, but it would hardly do any good, for if the bees should be stirred up to the point of roaring, they would quite surely be flying.

I expect to increase to 25 colonies this year. Hereafter my little truck and bee farm will go by the name of "Honey Hill," and I hope the bees will keep it true to name.

ELMER KOMMER,
Cambridge, Ill.

A Price Booster

I am selling my honey to consumers for 25 cents a pound for extracted and 30 cents for fancy sections. When I find a fellow who cuts the price of honey I try to buy him out.

S. M. VARNIE,
Thompsonville, Ill.

Gets Some Honey Anyway

The past season was a bad one for most beekeepers in this section, but I averaged 100 pounds surplus per hive; not so bad for my second year with bees.

HUGO E. BARTZ,
Keytesville, Mo.

From Across the Sea

I am from the old country, raised in Alsace, about eight miles from the French border. I learned the German methods of beekeeping. My father was an old-time beekeeper who kept bees in straw hives (Strahkoerbe). For the last few years before I came over here I had a house apiary, but on account of poor season I came here in 1912 to study American bee culture. I have done well so far.

JOSEPH GARRE,
Janesville, Minn.

Ridding the Apiary of Ants

Here, if unhindered, the ants multiply until unendurable. When they become so numerous as to be found all over the hives and combs they annoy the operator as well as the bees. If the pest is in the open, boiling water or disulphide of carbon may be used to destroy them by wholesale. Soapy water will discourage them somewhat. A thick syrup of sugar and water, containing to each pound of sugar one-twentieth ounce of sodium arsenite will get them in the apiary or honey room. If they do not take the uncooked syrup readily, beat it thoroughly, using care not to scorch it. Soak bits of cloth in the syrup and put it back out of the way in a tin can opened just far enough to permit the ants to enter.

LEE ELLIS KERR,
Fort Smith, Ark.

Concrete Without Stones

Finding it desirable to convert a disused hen house into a honey house, a four-inch wall was needed to raise the house twelve inches to give head room. Cement and sand in plenty were available, but no stone or cinders. Tin cans, glassware and crockery of all sorts were substituted to good advantage. The contents of that wall will delight antiquarians in time to come.

D. QUEEN, New Jersey.

Italians Resist I. O. W. Disease

I have had a good year, as trade has been good for both bees and honey. Isle of Wight disease is still with us, but the nearer pure Italians I keep, the less I lose with it. I have never lost a pure Italian stock.

HERBERT WATTS,
Holmleigh, England.

No Failure in Ontario

I extracted over two tons of clover and basswood honey from thirty colonies of bees and sold it all at 15 cents per pound. I am a beginner with bees, but like them very much. Being a machinist, I have made my own extractor, five frames working direct, with no gears.

F. E. MOTT.

Honey Springs Apiary, Ontario.

Feeding Sugar Affects Laying of Queens

I have made a comparative test of feeding sixteen colonies of bees. Eight colonies were fed sugar syrup and eight were fed honey. All queens were from the same hatch, so there should be no difference in that respect. I started feeding February 15 and continued until titi began to yield nectar on March 7. Eight colonies were stimulated by feeding a half pint of sugar syrup daily, the other eight colonies received an equal amount of honey daily.

The eight colonies fed on sugar syrup stored surplus as follows: No. 1, 82 pounds; No. 2, 73 pounds; No. 3, 91 pounds; No. 4, 79 pounds; No. 5, 87 pounds; No. 6, 108 pounds; No. 7, 86 pounds; No. 8, 71 pounds, in all 677 pounds.

The eight colonies fed on honey stored as follows: No. 1, 123 pounds; No. 2, 116 pounds; No. 3, 142 pounds;

No. 4, 112 pounds; No. 5, 149 pounds; No. 6, 117 pounds; No. 7, 127 pounds; No. 8, 198 pounds, in all 1,084 pounds.

Of the eight colonies fed on sugar syrup, five swarmed, while there were only two swarms from the colonies fed on honey. There is soon a difference in the appearance of queens in colonies fed on sugar syrup; they become dark and slick, while those in colonies fed on honey remain bright yellow. I lay the difference in behavior of the colonies above mentioned to the difference in the feed.

LOUIA SHERMAN,
Little River, Ala.

A Season of Failure

Last season was the nearest a failure with me that I have had in more than thirty years of beekeeping. When basswood began to yield the bees were on the point of starvation. The flow only lasted four or five days, but served to rally the bees and keep them in shape until heart-ease. I only had two swarms and they had a hard pull to build up. The prospect for next season is good, as white clover came from seed and made a fine growth.

B. A. MANLY,
Milo, Iowa.

A Poor Season

We had a poor season here and there will be a big loss of bees this winter for lack of proper care.

JOSIAH SWINEHART,
Wooster, Ohio.

Starts With Stray Swarm

I am just starting in the bee business from a stray swarm which came to me in 1915. I now have eleven colonies, all packed with forest

MISCELLANEOUS NEWS ITEMS

The National Meeting.—As stated in our January issue, the National meeting is to be held at Burlington, Iowa, February 20, 21 and 22.

Owing to the mails being snow-bound, I have not been able to complete the program for the National meeting. The following expect to be present or will send papers:

E. R. Root, "Present and Future of Beekeeping."

F. Eric Millen, "The State Agricultural College and Beekeeping, 1918."

Dr. E. F. Phillips, "Extension Work."

E. D. Townsend, "Some Proposed National Work for 1918."

C. P. Dadant, "Making Honey a Staple."

J. W. Stine, "Legislation; What Can Our Government Do to Help the Industry?"

Geo. W. Williams, "A Merger of All Beekeepers' Societies."

E. S. Miller, "The Future of the National."

John C. Bull, "Government Aid for Beekeeping."

There will be an evening session the 19th, three sessions the 20th and two sessions the 21st. (It was announced in the January journals that the convention would be held in Remy hall. Since that announcement it has been arranged to make the Burlington Hotel our headquarters and hold the convention in the banquet room of the hotel. All who expect to attend will please make reservation for rooms at the hotel ahead so that the hotel management will be able to take care of us. Any-one wishing programs may have them for the asking.)

JOHN C. BULL,
Secretary-Treasurer.

Obtaining Sugar

Today I had a conference with the Federal Food Administrator for Michigan, Mr. Prescott. After outlining the critical situation in which the beekeepers of this State find themselves as a result of the shortage of sugar, the food administrator assured me that he would make every effort possible, consistent with the duties of his position, to supply the beekeepers of Michigan with the sugar which they so badly need. In so far as possible, permits will be issued to wholesalers to supply beekeepers with sugar, upon my recommendation. I am, therefore, asking you to give this bit of information as wide publicity as possible, so that we may be able to serve the bee-

keepers of the State. Beekeepers should write me direct, and I will furnish them a regular form, which they must use in mailing application for sugar.

B. F. KINDIG,
State Inspector of Apiaries,
East Lansing, Mich.

Extending Beekeeping Activities

In connection with the effort to increase food production, the Bureau of Entomology is enlarging its extension work in beekeeping by the appointment of several new men. Some of these men have been in the field for several weeks and others are just leaving Washington. During the winter months an effort will be made to reach beekeepers with the message that an immediate increase in honey production is needed, and during the active season field meetings will be held to assist beekeepers with practical production problems.

The following men have been appointed:

E. F. Atwater, of Meridian, Idaho, assigned to California, Arizona and New Mexico.

J. H. Wagner, of Wetmore, Colo., assigned to Washington, Oregon, Northern Idaho and Montana.

C. E. Bartholomew, transferred from Tennessee and assigned to Colorado, Utah, Southern Idaho and Wyoming.

E. W. Atkins, of Ames, Iowa, assigned to Iowa, Missouri, Kansas and Nebraska.

G. C. Matthews, of Hanson, Idaho, assigned to Illinois, Wisconsin and Minnesota.

P. W. Erbaugh, of East Lansing, Mich., assigned to Michigan and Indiana.

David Running, of Fulton, Mich., unassigned.

Mr. Kenneth Hawkins will continue work in the Southern States and Mr. C. L. Sams will remain in North Carolina. The work in Tennessee has been discontinued.

The increased activity in extension work in beekeeping is made possible by the assignment of funds from the emergency appropriation to the Department of Agriculture for stimu-

lating agriculture and the distribution of products.

The "Little Bees" in Belgium.—One of our staff having recently made a direct contribution for the relief of suffering Belgium, received, Jan. 4, the following letter from the assistant director of the Commission for Relief in Belgium:

Formal acknowledgment has already been mailed you for your generous contribution sent us under date of December 27, but we are sure you will be interested in knowing that same has been remitted to Brussels to the organization known as "The Little Bees" (Les Petites Abeilles). This society, which is taking care of practically all of the children—babies and older ones—in that city, who are in one way or another victims of the war, was organized some five years before the outbreak of the conflict. A group of young women banded together to help the children, and organized centers in Brussels for the distribution of needed clothing to children whose parents were unable to properly provide for them. Their efforts at once won the enthusiasm of the people. The Queen and the adored Princess Marie-Jose were their patronesses, and they became the most popular organization of their kind in Belgium.

When the war came the mothers quickly took charge. They established a vast home for refugees, where they housed over 5,000. Later they appealed to the relief committee to be allowed to develop their work to meet the terrible emergency, and their offer only too gladly accepted, one after another canteen for feeding, as well as clothing, was opened in the various sections of the city. At the present time there are more than 125 Brussels sections of the organization, caring for more than 50,000 children, and about 3,000 women are giving a great part of their time to the work.

The canteens served by these devoted women, with bees embroidered in the Belgian colors, on their white caps, are in every section of the city; in a vacant shop, a garage, a private home, a cellar, a convent—in any available, usable place—but every one immaculately clean.

The children of Belgium were, of course, the first to feel the effects of the stern repression of the food supply. Such diseases as tuberculosis and rickets spread rapidly among them, and the work of "The Little Bees" in supplementing the ordinary ration allowed by the Commission became of vital importance to the future of the race. They have labored unceasingly for three and a half long years, and are today beset with more obstacles than at any time since the war began. For over a year now, the lack of ocean tonnage has prevented the Commission from shipping hardly more than 60 per cent of the foodstuffs required to keep the population of Belgium in ordinary health, and the prices of what small

supplies of native foodstuffs are available have soared beyond the reach of the common people. None of the funds advanced by the United States Government for the relief are available for the work of "The Little Bees," as the law requires that they be all expended in this country; and they and similar organizations have had to rely almost entirely on the charity of the outside world. The Commission is remitting what it can to "The Little Bees" and the other worthy charities weekly, and we believe sending your contribution to the first-named will accomplish the result for which it was intended.

A more detailed description of the work of "Les Petites Abeilles" and the various other works above referred to, will be found in the book, "Women of Belgium," by Mrs. Vernon Kellogg, of Stanford University, California, a copy of which we are sending you under separate cover with our compliments, and if you can do anything to give this book publicity in your Journal, we shall more than appreciate it, as we feel that its wide circulation will do much to further a spirit of practical sympathy for Belgium among the larger American public.

Very truly yours,
THE COMMISSION FOR RELIEF
IN BELGIUM,
PRENTISS N. GRAY,
Assistant Director.

To Iowa Beekeepers.—The Iowa State College is making special efforts to induce Iowa beekeepers to produce the maximum crop of honey the coming season. In order that a large number of beekeepers may be aided, a correspondence course in beekeeping has been prepared. The course includes ten lesson outlines, which will be sent out one by one, as needed, throughout the season. Besides the ten lessons, each student enrolling will be supplied with two reliable books on beekeeping management. Anyone having one or more colonies and wishing to keep bees with more pleasure and profit, is urged to enroll for this course.

A fee of three dollars will be charged to cover the cost of the books, and this will be the only expense, all correspondence being included.

The world has realized as never before that the final success of a nation depends upon its food supply. To increase the supply of most foods, extra labor, machinery, ground and seed are required. Beekeepers are very favorably situated, for in the majority of cases, a much greater crop of honey can be obtained with the supplies on hand. Preparedness and a little attention at the right time will turn the trick.

Give the bees a chance to do their bit the coming season, enroll for the correspondence course and harvest the nectar which nature provides.

Besides the correspondence course in beekeeping, there will be a one-week's beekeeping short course in May, notice of which will appear later. A large number of field meets

will also be arranged for the working season and we hope to come in contact with a large number of Iowa beekeepers.

F. ERIC MILLEN,
State Apiarist.

Idaho-Oregon Honey Producers' Association Meeting.—At the annual stockholders' meeting of this Association, held recently at Ontario, Ore., the following members were elected directors:

C. E. Dibble, Payette District.
J. M. Stark, Middleton District.
J. F. Weaver, Ontario, District.
L. P. Peterson, Vale District.
H. E. Crowther, Parma District.
P. R. Randall, Nampa District.
Homer Cheney, New Plymouth District.

At a later meeting of the above Directors, the following officers were chosen:

President—C. E. Dibble.
Vice President—J. M. Stark.
Secretary—P. S. Farrell.
No attempt was made to present a program at our annual meeting, the entire session being given up to a resume of business of the past season and a discussion as to methods to make our organization of greater service to members.

P. S. FARRELL, Sec'y.

Pennsylvania Meeting.—The annual meeting of the Pennsylvania Beekeepers' Association will be held in Lancaster on Friday and Saturday, March 15 and 16. A good program is being prepared.

H. A. SURFACE,
President.

The beekeepers of Illinois may find difficulty in securing sugar for spring feeding. The State Inspector, A. L. Kildow, is taking steps through the State Board of Agriculture to supply this want. Definite instructions will be supplied in the March number.

UNITED STATES DEPARTMENT OF AGRICULTURE

Bureau of Markets

Semi-Monthly Market News Bulletin

Honey arrivals since last report:

Medina, Ohio.—150 pounds Tennessee 17,045 pounds New York, 33,900 pounds Ohio, 72,636 pounds Wisconsin.

Hamilton, Ill.—1,230 pounds Iowa.

Markets—Jobbing Prices

(In many markets in the honey trade the term "jobber" is commonly applied to the original receiver who buys direct from the grower in carlot quantities. However, in these reports we use the term "wholesale carlot receiver" to designate the carlot purchaser, while the term "jobber" refers to the dealer who buys in less than carlot quantities from the carlot receiver and who sells direct to retailers. The prices quoted in this report represent the prices at which the "wholesale carlot receivers" sell to the "jobbers.")

Note: Arrivals include receipts during preceding two weeks. Prices represent current quotations.

Kansas City.—No fresh arrivals. Demand limited, movement slow, market firm; few sales, all sales in small lots. Comb honey: 24-section case, No. 1 Kansas, \$4.50; Missouri, \$5.00-5.50. Extracted honey: California, Iowa and Colorado, light amber, 16½-18½¢ per pound. Beeswax: receipts light, buyers paying 38¢ per pound.

Minneapolis.—No rail arrivals; local receipts very light, supplies light. Demand moderate, market very firm. Comb honey: 24-section cases, Minnesota white clover, mostly 19-20¢ per pound; Colorado white, mostly \$5 per case. Extracted honey: Minnesota, white, 10-lb. pails and cans, mostly around 20¢ per pound. Beeswax, no sales.

St. Paul.—No rail arrivals; local receipts very light, supplies light. Demand slow, market firm. Comb honey, 24-section cases, Minnesota, fancy white, mostly \$5 per case; No. 1, mostly \$4.50; few Colorado, white, mostly \$5. Extracted honey: Minnesota, 5 and 10-lb. pails, white, mostly 19-20¢ per pound.

New York.—Arrivals by boat: 13 barrels Texas, 2 barrels Haiti, 257 barrels South America, 30 barrels San Domingo, 161 barrels Porto Rico, 1 barrel Florida, 403 barrels Cuba; freight, 1 car Ohio. Domestic: no sales reported. West Indian supplies moderate, market strong, 15-17½¢ per pound. Beeswax: Boat arrivals: 33 cases South America, 2 bags, 2 packages San Domingo, 390 bags Cuba. Demand moderate, market steady. Yellow, 38-40¢; dark, 35-37¢ per pound.

St. Louis.—Supplies very light, insufficient to meet demand. All sales in small lots. Extracted honey: light amber, in cans, 15-15½¢; in barrels, 15-16¢ per pound.

Denver.—Less than 100 cases comb and approximately 15,000 pounds extracted arrived. Supplies cleaning up. Demand and movement good, market strong. Quality and condition good. Comb honey: 24-section cases, fancy white, \$5; No. 1, \$4.50; No. 2, \$4.05. Extracted honey: white to light amber, 15-17¢ per pound. Beeswax: receipts light. Cash to producer, 38¢ per pound.

Cincinnati.—No fresh carlot arrivals; local receipts light. Demand moderate, movement slow, account of high prices; market firm. Extracted honey: domestic, light amber, 17-18¢ per pound; orange and white sage, 21¢ per pound. Comb honey: demand and movement good, market strong; 24-section cases, fancy white heavy, \$5.25 per case; No. 1 white, heavy, \$5 per case. Beeswax: demand good, market strong; average yellow, 40-42¢ per pound.

Philadelphia.—Arrivals, extracted honey: 7 barrels Porto Rico, 10 barrels Haiti, 4 barrels Florida, 13 cases New York, 468 cases Idaho. Comb: 185 cases New York. Demand good, market strong; very few sales. Extracted honey: Porto Rico and Haiti, 17¢ per pound. Comb honey: dark

amber, 20-24c per pound. Beeswax: 1 bag, 27 pounds, net, arrived. Very few sales, 35-37c per pound
Chicago.—Unreported.

The Season in California.—California cannot have a honey crop without rain. This year appears to be an unusual one for drought. Mr. Harry S. Merriam sends us the following clipping from the San Diego Sun, dated January 3. Mr. Merriam is the son of our old esteemed friend, the late Col. Merriam. His location is San Marcos, San Diego County, where he has kept bees for years: "On this third day of January, 1918, we have to record the shattering of all precipitation records since the first record was made in 1851, 67 years ago.

That is to say, the lightest rainfall ever known from July 1 to December 31, hitherto, was in 1876, when a total of .39 of an inch was recorded. This year, during the same period, we had just .25!

There has not been a December without a trace of rain in 67 years, and but two Decembers with only a trace. These were in '76 and '17. So we have shattered one record and tied another.

Now listen. The warmest fall, beginning with September, ever recorded by the local weather bureau, was the season just passed, ending with December 31, 1917, December having an excess of 88 degrees above normal. The next warmest fall season was that same fall of '76—that famous season when no rain fell, or practically none, from July to January.

Thus we have two points of similarity between these seasons 41 years apart.

The spring of '78 was the driest ever known in the history of San Diego. The total rainfall for the season '77-'78 was 3.75 inches. The next driest was the far-away season of '62-'63, when the record showed 3.87 for the entire 12 months. The normal rainfall for 67 years is 9.68 inches.

So, you see, the outlook for a dry season, based on past performances, is exceedingly good.

In that terrible year, '77-'78, there were no irrigation systems in the country, excepting the Mission dam at the old mission, and the cattle died like flies in the mountains, while the settlers had to dig wells in the bed of the San Diego river to get water for domestic purposes.

This season no such disaster will eventuate, for with Morena and smaller dams full of water throughout the county, there will be plenty of water for domestic purposes, even if no rain should fall at all, and by reasonable care the orchards can be kept in good shape, but the dry farmer will suffer the loss of his crop if rain does not come in reasonable quantity during January.

However, we can take some hope here, for in 67 years there has never been a dry January. December, 1900, when only a shade more than a trace fell, was followed by a wet January and February, with a total seasonal

rainfall of 10.45, and big crops and plenty of prosperity for everybody.

In his "sixty-five years of rainfall records," Mr. Aleiature has compiled some very interesting figures. The heaviest rainfall ever recorded was the season of '84-'85, when 25.97 inches fell. With the exception of that abnormal season there has never been a season recording above 17 inches. There has never been a sea-

son with less than 3, and only two (those mentioned) with less than 4 inches, but five seasons in 65 have had less than 5 inches.

The drought this year has been unusual, in that it has extended to all parts of California, even to the mountains, where the snowfall has been phenomenally light, and all the way down the coast to the edge of the tropics."

DR. MILLER'S ANSWERS

Send Questions either to the office of the American Bee Journal or direct to
DR. C. C. MILLER, MARENGO, ILL.
He does not answer bee-keeping questions by mail.

It is inferred that all readers have access to the book "A Thousand Answers to Beekeeping Questions." This will avoid duplication in answering, as the book contains answers to practically all questions ordinarily asked on beekeeping. Subjects not specifically treated, or which are not clear to the reader will be further explained in this department at the request of any subscriber.

What Hive Preferred—Shallow Super for Extracted Honey Production

1. For the production of extracted honey do you not think the Dadant or Jumbo hive would be preferable to the 10-frame dovetailed hive?
2. Which do you prefer, a shallow, or deep super for the production of extracted honey?
MICHIGAN.

ANSWERS.—1. Very likely, in most places.
2. The shallow; although there are advantages in combs that may be used interchangeably in either brood-chamber or extracting-super.

Bee Paralysis

Would you kindly let me know Mr. LeSturgeon's cure for the same disease described in your Journal of September, page 313 of bees dying, as I have three hives with the same complaint. Perhaps you have a better cure.
IRELAND.

ANSWER.—The LeSturgeon cure for paralysis is just what is given at the place you quote: "Feed them some fresh, pure food." That's all there is of the cure, and Mr. LeSturgeon claims that the disease is caused by soured stores, and all that is needed to cure it is to give pure food. There is, however, the possibility that you have something different from paralysis.

Bottom Racks—Nucleus Division

1. In describing that bottom-rack as being in the form of a ladder, what is the width and thickness of the rungs and how much space between them and the bottoms of the frames, and do the parallel pieces run lengthwise of the hive?
2. I want to double my number of colonies next season by the nucleus plan, page 137 of "Thousand Answers." I produce extracted honey. When would be the best time to make increase, at swarming time or extracting time? I have a fair fall flow.
MISSOURI.

ANSWERS.—1. In most of them the rungs are three-eighths by three-sixteenths. It might be even better if they were thicker, say three-eighths square. Space between bottom-bars and back about three-fourths inch. The parallel pieces run lengthwise of the hive.
2. It may be as well to wait till extracting time, seeing there is a good fall flow; yet you would be saved swarming trouble by dividing at swarming time.

Queen Excluders

What kind of a queen-excluder is the best to use, and how used?
Do you put them between hive body and bottom board to prevent swarming?
INDIANA.

ANSWER.—I think from the little experience

I have had with them wire excluders are best. One of the commonest ways in which they are used is to put them between the brood-chamber and extracting-super to keep the queen from laying in the extracting-combs.

From the last part of your question I suspect you have some idea that by putting an excluder between the hive-body and the bottom-board, so that the queen cannot get out, you will prevent swarming. Don't be fooled into trying anything of the kind. While this might prevent the queen from leaving with a swarm, it would rat prevent the bees from swarming and returning day after day, and would finally result in having a drone-laying young queen.

Shaking Bees From Combs

To be sure and not take the queen, does it hurt the brood to shake the bees, or is it better to brush them off the combs?
MISSOURI.

ANSWER.—Shaking does no harm to the brood unless queen-cells are present, and then only queen-cells are hurt.

Combs in the Cold—Increasing

1. In looking over my combs in the extracting house I notice they are badly cracked. Is it the cold weather that causes this, there being no heat in the building?
2. I have some forty combs of sealed honey for spring feeding in Langstroth frames, with four wires in each frame, in the same building; will they be hurt?
3. I want to increase, which will be the better way, buy bees in pound packages, or buy sugar and feed my present stock in spring and divide, as we have no flow until the last of June?

ANSWERS.—1. I know a beekeeper who is trying a 15-frame Langstroth. What do you think of such a large hive in this locality?
ONTARIO.

ANSWERS.—1. Yes, it is the freezing. The bees will mend them all right.

2. There will be some cracking of the combs, and a worse thing is that the honey in them will granulate and some of it will be wasted when given to the bees. Can't you keep them in a warm room or in a cellar?

3. You can at least get on faster by buying package bees.

1. It may be a good thing.

Demaree Plan

1. From what I can glean from "Thousand Answers" and "Fifty Years Among Bees" I infer that when using the Demaree plan, one should not allow a large amount of brood to accumulate below the excluder. What would be a good rule to go by to know when this brood should be moved into the second story

and foundation or empty combs given instead?

2. When using the Demaree plan, if a swarm issues I have thought of managing about like this: Cage the clipped queen and destroy all queen-cells and when the swarm returns to the parent hive give the queen and all eggs and young brood into the care of another colony for about five days, or until the swarming colony realizes that they are absolutely queenless. Then return the queen and one frame of brood below the excluder and balance of brood above. Is there a better way?

ANSWERS.—1. Your idea is a mistaken one. At the time the Demaree plan is used the brood-chamber is crammed with brood, and it would hardly be wise to operate until the brood-chamber is in that condition. The time to move this brood into the second story, over the excluder, is any time when swarming in general is likely to occur; or, to be more specific, when the colony is very strong and has started queen-cells. However, if the matter should be neglected until the colony has swarmed, the swarm may be returned and the colony treated on the Demaree plan, just as if no swarming had taken place.

2. Yes; I think it is easier, and on the whole a better way, to leave the queen and use the regular plan.

Feeding Sections

I have five hives that are reasonably strong and have a fairly good amount of honey in the frames, but I am not sure whether they have enough. I have about 75 sections that are drawn out very well and have all the way from one ounce to half a pound of honey in them. I have no extractor. My question is, would it be all right to feed it to the bees this winter? If not, when would be the best time to feed it? Just how would you feed it? KANSAS.

ANSWER.—You can use such sections as feed. If you think a colony is in danger of starving before spring, put over it an empty super, lay sections flatwise upon the top-bars, and then pack over them cloths to keep them warm. If you think there is no danger of the bees starving before spring, wait until the bees are flying every day or so, then put sections in supers the regular way and set the supers on the hives, of course giving them to colonies most in need.

Bigger Fruit Profits

The fruit grower of today is reaping his greatest profits by keeping in close touch with the progress of the industry and developments.

Green's American Fruit Grower
"The National Fruit Journal of America"

through its many articles on growing, marketing and related subjects, points the way to bigger fruit profits. A sample copy will be sent you on request; better still, take advantage of our rate of

3 Years for \$1.00

which brings you 36 copies of Green's American Fruit Grower—filled from cover to cover with money-making suggestions.

Queens That Will Please

Over 20 Years of Careful Selecting and Breeding

They are bred from Imported stock, the very best for honey gathering and gentleness. They are not given to swarming and are highly resistant to diseases. Give me your order, and after you have given my queens a fair trial, if you are not satisfied in every way that they are as good as any you have ever used, just return them and I will send you queens to take their place or return your money with any postage you have paid out on returning the queens.

Prices April 1 to June 15

Paint Without Oil

Remarkable Discovery That Cuts
Down the Cost of Paint Seventy-
Five Per Cent.

**A Free Trial Package is Mailed to
Everyone Who Writes**

A. L. Rice, a prominent manufacturer of Adams, N. Y., has discovered a process of making a new kind of paint without the use of oil. He calls it Powderpaint. It comes in the form of a dry powder and all that is required is cold water to make a paint weather proof, fire proof, sanitary and durable for outside or inside painting. It is the cement principle applied to paint. It adheres to any surface, wood, stone or brick, spreads and looks like oil paint and costs about one-fourth as much.

Write to Mr. A. L. Rice, Manufacturer, 23 North Street, Adams, N. Y., and he will send you a free trial package, also color card and full information showing you how you can save a good many dollars. Write today.

BEEES AND QUEENS

FOR SALE—First-class Italian queens and bees in season. Send for price list. Free from disease; safe arrival and satisfaction guaranteed. M. Bates, Greenville, Ala., R. 4.

BREEDING QUEENS—I have a few extra choice Italian breeders for spring delivery. Price \$5 each. J. E. Wing, 165 Schiele Ave., San Jose, Calif.

FOR SALE—75 colonies bees in a fine location. J. L. Leath, Corinth, Miss.

FOR SALE—Bees. Pound pkgs. and nuclei, with queens. Mrs. T. H. Carruth, Big Bend, La.

FOR SALE—Nuclei, with or without queens; pound and two-pound package bees with queens; best Italian stock. Lewis J. Bond, Big Bend, La.

OUR BRIGHT ITALIAN QUEENS will be ready to ship after April 15. Untested, 75c each, \$8 per doz., or \$65 per 100. Safe arrival guaranteed. Tillery Bros., Georgiana, Ala., Route 5.

FOR SALE—Fine Italian queens at 90c each, \$9 per doz. Ready April 15. Safe arrival guaranteed. T. J. Talley, Route 3, Greenville, Ala.

THREE-BAND ITALIANS ONLY—Queens, packages and nuclei. Untested queens, each \$1, 6 \$4.25, 12 \$8.25. Write for prices in larger lots, also nucleus and packages; booking orders now. If you consider quality, pure mating and low prices, I am your queen breeder. I have adopted Gleanings Code for the sale of bees and queens. H. G. Dunn, The Willow, San Jose, Calif.

GOLDENS THAT ARE TRUE TO NAME—Queens, nuclei and bees by the pound; we receive hundreds of testimonials annually. Write for list. Untested queens, each \$1, 6 \$4.25, 12 \$8.25. Write for prices in lots. We are now booking orders for early delivery. We have adopted Gleanings code for the sale of bees and queens. Garden City Apiaries, San Jose, Calif.

FOR SALE—Bees. April 15 is the date on which we can ship you the best three-banded bees and queens on the market; we have been in the bee business continually for twenty-four years and have been striving to secure the best three-banded bees which money could buy and skill produce, all these years. Judging from the many letters we have received from satisfied customers, we have succeeded in our efforts. We believe we can furnish you with the best honey-gatherers to be found anywhere. You will find our nuclei better filled with bees and brood than any other nuclei you can buy. All our bees are on standard, wired, Hoffman frames; full sheets of foundation. File your orders now, sending money when you want the bees shipped. Satisfaction and safe arrival guaranteed. We quote you, without queen, as follows: Three-frame nuclei, \$2.50; one-frame nuclei \$2.00; one-frame nuclei, \$1.50; three pounds bees, \$3.50; two pounds bees, \$2.50; one pound bees, \$1.75. If queen is wanted with bees, add price of queen wanted. Young untested queens, 75c; young tested queens, \$1. The Hyde Bee Company, Floresville, Texas.

BEEES AND QUEENS from my New Jersey apiary. J. H. M. Cook, 84 Cortland St., New York City.

TESTED leather-colored queens, \$2.00; after June 1, \$1.60; untested, \$1.00; \$10 per doz. A. W. Yates, 8 Chapman St., Hartford, Conn.

VIGOROUS, prolific Italian Queens, \$1.00; 6, \$5.00, June 1st. My circular gives best methods of introduction. A. V. Small, 2308 Agency Road, St. Joseph, Mo.

GOLDEN QUEENS that produce Golden workers of the brightest kind. I will challenge the world on my Golden and their honey-getting qualities. Price, \$1 each; tested, \$2; breeders, \$5 and \$10. I. B. Brockwell, Barnetts, Va.

THREE-Banded and Golden Italian Queens and pound packages in spring, from the Sunny Southland. Grant Anderson, Rio Honda, Texas.

FOR SALE—1 to 100 strong 8-frame colonies extra fine strain Italian bees, \$5 each; all free from disease. Write for writer; Standard full-depth, self-spacing Hoffman frames; all straight combs in new one-story single-wall hives, f. o. b. here. Wilmer Clarke, Earlville, Madison Co. N. Y.

PURE 3-banded Italian queens, untested but warranted, \$1; \$5; tested, \$1.50; 6, \$8. Last year's tested queens, clipped, \$1. Good fat nuclei and full colonies in abundance. Write for price list. J. P. Diemer, Liberty, Mo.

THREE-BANDED Italian queens from our hardy, vigorous strain of honey producers; untested, one, \$1; doz., \$9; nuclei and pound packages June 1. Satisfaction guaranteed. A. E. Crandall & Son, Berlin, Conn.

NOW is the proper time (not tomorrow) to place your order for bees and queens. A postal brings you the story of a pound package of bees. Rosedale Apiaries, J. B. Marshall & Son, Big Bend, La.

BEEES WANTED—From one to 100 colonies within 200 miles; also used equipment. John E. Geiger, Syracuse, Kans.

BEEES AND QUEENS—What a pleasure when you know and I know and the bees know that you have placed your order to be shipped to you in April and May; no war prices. Write S. Mason, Hatch, N. M.

THREE-BANDED Italians; untested queens in April and May, one, \$1; 6, \$5; 12, \$9. Tested, \$1.50 each. One-pound packages of bees, \$1.50 each; two-pound packages, \$2.50 each. Add price of queens if wanted. If you want as many as 50 packages write for prices and discounts on early orders. Safe arrival and satisfaction guaranteed. No disease, and all queens purely mated. Cotton Belt Apiaries, Box 83, Roxton, Texas.

GOLDEN and 3-banded Italian queens will be our specialty. We can also furnish Carniolians. Tested \$1, untested 75c each. Bees, per pound, \$1.60; nuclei, per frame, \$1.50. Send your order for bees early. C. B. Bankston & Co., Buffalo, Leon So, Tex.

HONEY AND BEESWAX

FOR SALE—White clover extracted honey, 60-pound cans and 10-pound pails. Write, Wes. L. Roberts, La Valle, Wis.

WANTED—Beeswax; we pay higher than market price for good grades light and light yellow wax; get our prices before disposing of your wax. Queca Mfg. Company, Falconer, N. Y.

WANTED—White or light amber extracted honey in any quantity. Kindly send sample, tell how your honey is packed and your lowest cash price; also buy beeswax. E. B. Rosa, Monroe, Wis.

WANTED—Shipments of old comb and cap for re-ordering. We pay the highest cash and trade prices, charging but 6c a pound for wax rendered. The Fred W. Muth Co., 204 Walnut St., Cincinnati, Ohio.

BE sure and include the Domestic Beekeeper with your list of bee journals for 1918. The Domestic Beekeeper will help you to dispose of your crop of honey without expense to you; also buy your beekeepers' supplies for you at cost. If you knew all we were doing for our subscribers, you would certainly be with us during 1918 as a subscriber. Can we have the pleasure of entering your name on our subscription list? Address The Domestic Beekeeper, Northstar, Michigan.

FOR SALE—Number 1 comb honey at \$4.80 per case of 24 sections. Ray Dunham, Westboro. Mo.

WANTED—Comb, extracted honey, and beeswax. R. A. Burnett & Co., 6A12t 173 S. Water St., Chicago, Ill.

WANTED—Beeswax at all times in any quantity, for cash or in exchange for supplies. Dadant & Sons, Hamilton, Ill.

SUPPLIES

FOR SALE—One thousand beehives with supers; three-fourth dovetailed, balance halved together at corners and nailed both ways. Hoffman frames throughout. We will guarantee them to be sound and free from disease. Will sell all or any part at about half what new hives will cost. Apply to The Hyde Bee Co., Floresville, Texas.

200 VEGETABLE PLANTS, \$1, including tomatos, peppers, egg plants, lettuce, celery, cabbage; 100 flowering plants \$1; choice assortment R. I. Red eggs; day-old chicks, bees, queens, honey. Grubb, Box B 14, Woodmont, Montg. Co., Pa.

SIBERIAN FOX FARM, Hamilton, Canada, breeds foxes, marten, mink, ermine, skunks and black Siberian hares. Information and price list free. Write address plainly.

FOR SALE—Cedar or pine dovetailed hives, also full line of supplies, including Dadant's foundation. Write for catalog. A. E. Burdick, Sunnyside, Wash.

YOU have likely been thinking for some time that you would like to have The Domestic Beekeeper come to you regularly each month but have been putting it off for some reason or other. We would like very much to have you all start in with us this next year. We are very sure you will not regret it if you make this start. To some of the early December subscribers for 1918, we will send, free, the last three numbers of 1917. If you expect to get in on this back number proposition you will need to be prompt in ordering, as those back numbers are going fast and there will be none when the present supply is exhausted. Address, with remittance, The Domestic Beekeeper, Northstar, Michigan.

FOR SALE—500 Extracting Supers, nailed a 1 painted, with frames; will sell cheap. A. F. Stauffer, Delta, Colo.

HONEY LABELS

HONEY LABELS—We have just issued a new and up-to-date catalog of honey labels and stationery. Write for your copy. Neat labels and quick delivery guaranteed. American Bee Journal, Hamilton, Ill.

PRINTING at lowest prices; 100 envelopes, 6 1/2c; for 40c; also cards, tags, letterheads, notebands, etc. Alfred Bentz, Granton, Wis.

SOUVENIR Bee Postal Cards, 5 for 10c; "Songs of Beedom" (10 songs), 20c, all postpaid. George York, Sandpoint, Idaho.

WANTED

WANTED—50 to 200 colonies of bees, preferably near home. H. G. Quirin, Bellevue, Ohio.

WANTED—25 to 100 Italian colonies of bees in movable-frame hives; must be strong, healthy and free from disease. Send full description and price. Louis Waeltz, Marissa, Ill.

WANTED—To buy bees in the southwest or work apiary on share. Give particulars. Box 1291, Tucson, Ariz.

WANTED—White sweet clover seed; send sample; state quantity and your lowest price in first letter. Dadant & Sons, Hamilton, Ill.

WANTED—One copy January 31, 1895, American Bee Journal; one copy January, 1912, Beekeepers' Review. C. D. Stuart, 410 Phelan Bldg., San Francisco, Calif.

WANTED—One extractor; must be in good condition. State kind and price; also 5 or 6 beehives, 10-frame, with frames. Geo. Varnum, Miller, Ohio.

WANTED—Barnes foot-power circular saw, second-hand. Give description and price in first letter.
D. C. Noble, Columbia City, Ind.

WANTED—Your old combs, cappings or slurr-gum to render into beeswax by our high steam pressure wax presses.
Dudant & Sons, Hamilton, I.

\$1.50 pays for a year's subscription each to The Domestic Beekeeper and the American Bee Journal. You can order them from either office, as you prefer.

IT will be the same to us whether you remit for The Domestic Beekeeper direct to Northstar, Michigan, or whether you send it in with your subscription to the American Bee Journal; only, be sure and include it, as we want every American Bee Journal subscriber to become a Domestic Beekeeper subscriber.

WANTED—One to 100 strong colonies of Italian bees in 10-frame, dovetailed hives.
Bernard Benziger,
Beekman Terrace, Summit, N. J.

WANTED—We are looking for old bee-books, back numbers of the Bee Journals, issued prior to 1907, etc., for some of our subscribers who wish to complete libraries of beekeeping literature. Just now we want especially copies of Alley's Beekeepers' Handy Book, the second volume of Cheshire on Beekeeping, and copies of Harbison's and Wildman's books. Readers having old beebooks or bee journals which they no longer care for will please write us fully what they have to offer, with prices asked.
America, Bee Journal, Hamilton, Ill.

P. gasoline engine; saw with dado, planer heads and attachments for making supplies; a complete apiary in No. 1 condition; good location. 1917 crop was 14 tons honey. Will also sell my home place of ten acres, 6-room house and No. 1 improvements, near to a \$5,000 schoolhouse. Will sell home separately and give terms. J. R. Marlow,
R. D. No. 1, Weiser, Idaho.

Crop Report and Market Conditions

At this season of the year there is so little that can be reported upon that we have not sent out inquiries to reporters as usual. With the opening of spring the market page will again be taken up in earnest, as it will then be possible to give our readers an idea of how the bees have gone through the winter and of what the flora prospects are for the coming year.

HONEY

Honey is so nearly cleaned up that what little is left in the hands of the producers may be considered as a negative quantity. Such as is held in the hands of dealers is mostly for the supply of the bottle trade, and most bottlers find that they will not have sufficient to carry them till the new crop. Some are buying Cuban honey already, to mix with what they have left.

White extracted honey should command not far from 20 cents per pound put up in five-gallon cans. Comb honey is even more scarce than extracted.

CHANGING TO EXTRACTED

All supply houses note a remarkable change in sales over previous years. The demand for deep and shallow supers and for shallow frames to be used to change comb-honey supers into extracting is large.

Many beekeepers also are increasing their holdings, or expect to, some even doubling the number of colonies which they had in 1917.

THE WINTER, SO FAR

The winter's cold has been unusually prolonged over the north and outdoor wintered bees that were not carefully packed against the cold winds are apt to suffer great losses. A warm spell now would be a boon to the outside wintered bees. Those in the cellar seem to be wintering about on an average.

WATCH FOR STARVATION

Beekeepers will do well to watch for colonies short of stores just as soon as the first warm days of spring. Many colonies went into winter without an abundance of stores and are likely to run short early.

THE CANADIAN HORTICULTURIST AND BEEKEEPER

THE ONLY BEE PUBLICATION IN CANADA

It is the official organ of the Ontario Beekeepers' Association, and has incorporated with it the former Canadian Bee Journal.

Beekeeping and Horticulture in its various branches are effectively combined to form a live, attractive and practical monthly magazine.

Well illustrated and up-to-date. Subscription price postpaid.

Canada, \$1.00 a year. United States, \$1.25 a year. Foreign, \$1.50 a year.

Sample copy sent free on request.

Suggestions for the Wide-Awake Beekeeper of Today

If you hired a carpenter to repair your barn and he arrived without his tools, he could not give results, even if he were the best carpenter in the country.

It goes without saying that you, a beekeeper, must look to the future or the honey season will be on and your needed supplies will be tied up in some freight car—EMBARGOED.

Order from us *now*, allowing for slow freight delivery, and your supply will reach you in plenty of time.

OLD COMB

Ship your old comb and cappings to us for rendering. We charge you 5c per lb. for the wax rendered and pay you the highest market price.

WAX AND HONEY

We always buy Comb and Extracted Honey, as well as Beeswax, so when you have the above to offer, write us and you will be well pleased.

A NEW BOOK

Our Backdoor Neighbors

By
FRANK C. PELLETT

"I have read 'Our Backdoor Neighbors' with great pleasure, and my small boys also liked it very much. The chapters on hawks are certainly a most valuable and unique contribution to ornithology, and one, I should say, which will not be duplicated for many a long day. No one could help reading the chapter on squirrels, the skunk and the rabbit, once they had begun them.

"How many hours and how much careful observation this book represents no one but a naturalist can guess. Such books do an untold amount of good in awakening a new interest in nature and in leading others to study and observe. It is upon the study of nature that the progress of the human race depends.

"JOHN H. LOVELL, Waldoboro, Maine."

Cloth, 210 pages, profusely illustrated with photos from life.

Price, postage paid, \$1.50

W. D. SOPER,
425 Liberty St., Jackson, Mich.

New Bingham Bee Smoker

In 1878 the original direct draft bee smoker was invented and patented by Mr. T. F. Bingham, of Michigan. Mr. Bingham manufactured the Bingham Smoker and Bingham Honey Knife for nearly thirty-five years, and in 1912, becoming a very old man, we purchased this business and joined it to our established business of beekeepers' supplies and general beeware. Those who knew Mr. Bingham will join us in saying that he was one of the finest of men, and it gives us much pleasure to help perpetuate his name in the beekeeping industry.

Bingham Smokers have been improved from time to time, are now the finest on the market, and for nearly forty years have been the standard in this and many foreign countries. For sale by all dealers in bee supplies, or direct from the manufacturers.

Smoke Engine, 4-inch stove.....28 oz. \$1.25
Doctor, 3½-inch stove26 oz. 1 00
Two larger sizes in copper extra.
Conqueror, 3-inch stove.....22 oz. .85
Little Wonder, 2½-inch stove.....16 oz. .65
Hinged cover on the two larger sizes, postage extra.

NEW BINGHAM
BEE SMOKER

A. G. WOODMAN CO.
Grand Rapids, Mich.

WOODMAN'S SECTION FIXER

A combined section press and foundation fastener of pressed steel construction. ONE OF THE GREAT ADVANTAGES this machine has over all others on the market in the putting in of top and bottom starters is, **YOU ALWAYS HANDLE LARGE PIECES OF FOUNDATION.** You know how hard it is to set small, narrow pieces for bottom starters. With this machine a large piece of foundation is set and the hot plate is again used to cut it off, leaving the narrow bottom starter. What is left of the large piece is then set for the top starter.

Price of machine, \$3; with lamp, \$3.40. Weight, 5 lbs.; postage extra.

THIS IS THE ONLY MACHINE ON THE MARKET from which the section always comes away right-side up, with the large piece or top starter hanging down. It does not become loosened in reversing, as with other machines.

A. G. WOODMAN CO., Grand Rapids, Mich.

Tin Honey Packages

YOU WILL MAKE A MISTAKE if you do not ask for our **Low Prices** on Friction Top Pails and Cans. We are **Saving money** for car load buyers and others of smaller lots. Why not you?

Our three-year contract is enabling us to make prices considerably under general market quotations. Let us hear from you, specifying your wants.

Friction Top Tins

	2-lb. Cans	2½-lb. Cans	3-lb. Cans	5-lb. Pails	10-lb. Pails

The Guarantee that Made "falcon" Bee Supplies Possible

The "falcon" GUARANTEE. Every hive, every super, every crate of sections, every pound foundation, every article, and every queen leaving the "falcon" plant goes out with our "absolute satisfaction or money back" guarantee. For more than a third of a century we have stood behind everything we sell. If anything is wrong or not just what you thought it would be, we'll appreciate it if you will write us, and we'll make it absolutely right at our expense. Our satisfied customers are to be found everywhere, and our best advertisement. "Once a customer always a customer," is synonymous with the name "falcon"

The beekeepers' past experience when "short" should have taught him that it's a "wise move" to get hives, sections and supplies ready in the next two months. We will be glad to quote on "falcon" supplies if you will send us an approximate list of what you will require for the coming season.

Paint Without Oil

Remarkable Discovery That Cuts Down the Cost of Paint Seventy-Five Per Cent.

A Free Trial Package is Mailed to Everyone Who Writes

A. L. Rice, a prominent manufacturer of Adams, N. Y., has discovered a process of making a new kind of paint without the use of oil. He calls it Powderpaint. It comes in the form of a dry powder and all that is required is cold water to make a paint weather proof, fire proof, sanitary and durable for outside or inside painting. It is the cement principle applied to paint. It adheres to any surface, wood, stone or brick, spreads and looks like oil paint and costs about one-fourth as much.

Write to Mr. A. L. Rice, Manufacturer, 23 North Street, Adams, N. Y., and he will send you a free trial package, also color card and full information showing you how you can save a good many dollars. Write today.

1424 Market Street, Denver, Colo.

SAVE TIME ≡ SAVE HONEY

An article in a recent business magazine gave the details of a saving plan instituted by a factory employing 2,000 men. By installing time-saving machinery the firm figured that it saved one hour's time of all its employees each week, or 2,000 hours per week for the factory.

This, when totaled for the year, amounted to over \$30,000 saving, a sum which more than paid for the small amount of machinery required to start the time-saving plan.

YOU ARE THE HONEY FACTORY MANAGER YOUR BEES ARE THE EMPLOYEES

They have a very short working season. All the more reason that you should save every minute for them when there is honey in the field to gather.

If you can cut down the time required for them in the hive to build combs by a few hours, you can increase their output just that much. And you can do that very thing—*Anyhow, others do it. Read—*

As far as I am concerned, your Foundation is in a class by itself, and the bees are of the same mind, as I have tried putting one of your sheets on one side and other makes on the other side of the cluster, and they took to yours like ducks to water.

POLLEN AND POLLEN PLANTS

BY JOHN H. LOVELL

It is seldom in the Northern States that bees run short of pollen, although this occasionally happens in early spring. Usually a supply sufficient to last until the willows and elms bloom is carried through the winter. The only locality in this country known to the writer, in which serious pollen famines occur is in the tupelo section along the Appalachian river. Most of the pollen here in April and May is obtained from willows, maples, elms and oaks. The tupelo yields very little, and there is not much general farming. The tupelo flow, writes W. D. Achord, averages from April 20 to May 5, during which from 50 to 125 pounds of honey are stored. There is plenty of pollen up to about June 15; but after that there is little or none for from 60 to 90 days, or until September. One hundred miles northward there is an abundance of pollen throughout the season. The colonies become very weak and the queens cease laying; but neither Achord nor Marchant, two prominent beekeepers in this section, feeds substitutes.

But in Australia pollen famines are as regular as the seasons themselves. There is a "critical period" in mid-summer, when the pollen fails, the queen ceases to lay eggs and the brood dies of starvation. This shortage is attributed by Rayment to the failure of the gum-trees, or eucalypti, to produce much pollen. There are some 200 species of gum-trees in Australia, which cover great areas of arid land. So lavish is the flow of nectar that three or four nests of wild bees have been found in a single tree, and when a flowering branch is shaken the nectar falls like rain. But so small is the supply of pollen that colonies of bees working on yellow gum dwindle down to mere handfuls, although there is a fine crop of honey. Beuhne says that he has used all kinds of substitutes in large

quantities, but, although the hives were well filled with brood, the bees thus raised were lacking in vitality and were short-lived. He has never been able to obtain a strong force of field bees.

Cannot, then, substitutes for pollen be used to advantage? When there is a scarcity of pollen the bees bring in bits of fresh sawdust, spores of fungi, and occasionally, in the vicinity of cheese factories, cheese mites. The beekeeper usually resorts to rye meal, cottonseed meal, wheat flour, oatmeal or pea meal, and sometimes to strange mixtures of eggs, milk and sugar. Rye meal is a favorite spring feed, and cottonseed meal has been strongly advocated. If it is desired to feed the meal inside the hive flour candy is used. This is made by mixing one part of rye meal with three parts sugar and a little water, and cooking it until

it will sugar. It is then vigorously stirred and poured into greased pans. It is difficult to make, may cause brood rearing at the wrong time, and is probably of no benefit.

The bees gather rye meal eagerly, indeed they may gather too much of it; and Root says that he has known the combs to be packed with it to the exclusion of pollen. Neither can there be any doubt that these substitutes stimulate brood rearing, for in colonies in which were healthy queens but no pollen, eggs or brood, three days after rye meal had been fed, there were a large number of eggs in the cells. The fact that brood rearing can thus be stimulated has led many beekeepers to jump to the conclusion that the use of pollen substitutes must be desirable; but Allen Latham has recently asserted that they are not only not beneficial but are positively injurious. He found that later in the season the colonies not fed were in better condition than those that were. We think these conclusions sound: Feeding meal in early spring causes the bees to waste away by flying out in cold weather when they had better remain quiet; injures their digestive powers, and the weak brood and bees thus obtained lessens rather than adds to the strength of the colony.

There are no plants more valuable for pollen in early spring than the willows, especially the pussy willow (*Salix discolor*), the earliest of the willows to bloom. Provide an ample pollen supply by planting along the brook or in low waste land as many of the staminate bushes as you can. Do not plant the pistillate bushes, for they yield no pollen. The staminate bushes bloom regularly and produce enormous quantities of pollen. They also secrete nectar freely. They have this advantage over the elms, alders, birches, oaks and other wind-pollinated plants that none of the pollen is lost. They are insect-

Fig. 1. WHITE WILLOW (*Salix alba*). Staminate or pollen-producing catkins. A large, freely blooming tree.

Fig. 2. YELLOW BIRCH (*Betula lutea*.) St., staminate flowers; p., pistulate flowers. A wind-pollinated tree producing large quantities of pollen.

pollinated and the pollen is so adhesive that none of it is carried away by the wind. Shake an alder branch in full bloom over a sheet of white paper and it will be covered with pollen; do the same with a branch of "pussies" and only a few grains will fall. Many wild bees, ants and flies, however, visit them. A little later in the season the staminate trees of the white willow will be a great help. (Fig. 1).

Bees not infrequently gather pollen from the alders, elms and other wind-pollinated trees (Fig. 2), and if you have an avenue of elms you have little to fear from a dearth of pollen early in the season. The maples are far from being as good pollen plants as the willows. If only bees would gather pollen from the fir, spruce, pine and running juniper they would, for a while, be provided with an inexhaustible store. Beat a running juniper bush with a stick and the air will be so filled with pollen that you will be glad to retreat. The clouds of pollen from the pines are easily mistaken for smoke. (Fig. 3.) The pollen seems to be too resinous to suit the taste of bees. During bloom there is, of course, no lack of pollen in the northern and western States.

Of herbaceous plants blooming in May I know of none more valuable for pollen than the dandelion. My apiary is surrounded for about two weeks with an almost unbroken sheet of yellow flowers. This result was obtained by permitting cultivated plants to produce seed. The pollen is very abundant and easily gathered, and the bees are constantly bringing it into the hives. A more pleasant, cheerful display can hardly be imagined, and many persons ask the privilege of digging "greens."

The planting of corn by the million acres renders it more important as a source of pollen than any other cultivated plant, and it blooms, moreover, at a time when pollen flowers are apt to be scarce. It is wind-pollinated and wholly devoid of nectar.

Yet of the mythical honeys "corn honey" is the most famous. Only a few months ago a report of a phenomenal yield of corn honey came from Louisiana. The flow continued for more than a month; the cornfields swarmed with bees to an extent never before witnessed, and good colonies averaged 100 pounds or more from this source alone. Corn honey is described as light amber in color and pleasantly flavored; it had previously been supposed to be dark and strong flavored.

Think of it, 100 pounds of corn honey per colony. Who will now be surprised to hear of the sale of ambrosia by the bottle? At a gathering of beekeepers an apiarist still insisted, after the structure of the bloom had been described, that his bees brought in a little honey from corn. It is claimed that the nectar is secreted by the silk and in the axils of the leaves. Now the silk is com-

Fig. 3. BALSAM FIR (*Abies balsamea*.) Staminate cones producing quantities of pollen, but the bees do not gather it.

posed of the thread-like glutinous stigmas, and it would not only be useless but would be positively harmful to the welfare of the plant for them to secrete nectar, and as a matter of fact they never do. Whence come, then, the stories of corn honey? We have all seen bees gathering pollen from the spindles of corn, and Frank C. Pellett says that he has seen multitudes of them so engaged. As plant-lice are sometimes found on the foliage or stalks of corn he suggests in "Productive Beekeeping" that the gathering of honey-dew may have given rise to these reports. This seems not improbable, especially in a warm climate, and would offer an explanation of the different qualities of corn honey in different years.

In many instances, however, "corn honey" is purely a product of the imagination, like the "tule honey" of California. The tule is a wind-pollinated sedge growing five to ten feet tall, and covering some 500,000 acres of wet land; in the delta region of the San Joaquin and Sacramento rivers there are estimated to

be 50,000 acres of tule. As there are many beekeepers who suppose that all flowers are nectariferous, it is not surprising that they believe that this great expanse of vegetation must be the source of much honey; but Richter very properly denies the existence of "tule honey."

Since both the wild and domestic bees would speedily perish if deprived of pollen, it is astonishing to note how little attention this subject has received from the bee journals. In looking over the indices I have been surprised to find that in some years there is not a single entry under pollen, while in others there are only two or three, mostly notes relating to pollen substitutes, or the exclusion of pollen from the honey. Pollen plants certainly grow in a terra incognita of the beekeeper's world, and pollen problems are left largely to the bees. Yet they are very vital questions, and nature has spared no pains in equipping the bees with apparatus and mental qualities to deal with them. And in the end what is vital to the bee is vital to the beekeeper.

The clovers, contrary to the general impression, are not good sources of pollen. In the white clover the anthers, the organs containing the pollen, are enclosed in a keel formed by two petals and emerge only when the bee's head rests upon it; thus bees never gather pollen directly from the clover blossoms. More or less of it is deposited on the under side of the head or body by the floral piston mechanism, which the bee brushes up with its legs and deposits in the pollen baskets. I have watched bees at work on white clover day after day, but have never yet seen one attempt to obtain the pollen; and many of them had no pollen on their hind legs, and, as a rule, the masses of pollen in the baskets were small. The pollen is almost invariably described as brown or greenish brown, and on the bee's

Fig. 4. BEAN (*Vicia faba*.) The stamens are enclosed in the black-spotted keel, and consequently bees cannot gather the pollen. It belongs to the same family as the clovers, but by reason of its larger size shows more clearly why bees can bring away only the pollen the flower places on them.

legs or in the hive after it has been moistened with nectar it is brown; but in the flower it is bright yellow. Not all brown pollen in the hive comes from clover, and I have examined specimen after specimen under the microscope without finding any

Fig. 5. Wild rose (*Rosa humilis*). A pollen flower with many stamens.

clover pollen. Irregular flowers, like peas and beans, do not furnish much pollen. (Fig. 4.)

Groves of nut trees, such as the pecan, hickory and chestnut, the only nut trees which have been domesticated in this country, furnish an abundance of pollen. Rayment says that in Australia the date palm is a "splendid honey plant"; but he adds in the next sentence that large crops from it have never been reported. A part of the trees are staminate and a part pistillate and the pollen is carried by the wind, not by insects. In other words, it is not a honey plant at all, although bees very often visit the staminate trees for pollen. But wild roses are splendid pollen flowers, and the bees, both wild and domestic, visit the flowers so eagerly, as soon as they open, that the entire supply is carried off in a few hours. (Fig. 5.) The California poppy is also a good pollen flower, and in the valleys of that State covers the ground with a golden carpet much visited by bees for pollen. As for the banana, you can gather pollen by the spoonful, and bees work on it much as they do on a pile of meal. In warm regions where there are acres of this fruit there must be enough pollen to meet all requirements.

In autumn a large amount of pollen is gathered from the goldenrods and sunflowers. (Fig. 6.) They belong to the largest plant family, the compositae, which also includes the asters, Spanish needles, gum-plant, broomweed, thistles, boneseed, crown-beard and marigold. In moving over the flower clusters bees controvert the familiar proverb that it is possible to do well only one thing at a time, for they suck nectar and sweep up the pollen simultaneously.

In New England large quantities of

goldenrod pollen are stored away for another season. To the same family belongs that pernicious weed, the Roman wormwood, so common in worn-out fields, a wind-pollinated plant, which produces so much pollen in late fall that it is said to be one of the causes of hay fever.

We have shown that the pollen supply in a locality may be increased by planting the staminate bushes of the willows, by setting out avenue and nut trees, by seeding the land with dandelions, by raising corn, and also sunflowers, where the latter do not grow wild. The sunflower produces a great amount of pollen and yields it for a long time. In this connection it may be inquired whether there are any foreign plants the introduction of which would increase the pollen supply. One of the most promising is cape weed (*Cryptostemma caudulaceum*), the most important pollen plant of Australia, which was introduced from South Africa in 1836 and has since spread over the entire Australian continent. Its leaves and flowers resemble those of the dandelion, and it not only yields large quantities of bright orange pollen but it is a good honey plant as well, and excellent feed for milch cows. A full description of this plant appeared in the American Bee Journal for December, 1915.

Rejecting the feeding of pollen substitutes as of no benefit, or injurious, there are only three ways in which a beekeeper can meet a pollen famine. He may increase the number of plants producing pollen in large quantities, as has just been described, or, secondly, he may move his hives to another locality temporarily; or, thirdly, he may give combs of pollen. A. B. Marchant described some time ago in Gleanings in Bee Culture how he would make use of the second method. From April to June his bees were to remain in the tupelo section, storing an ample crop of honey. After the flow was over they were to be removed to an island some 15 miles southward, where pollen was more abundant, and where they were to remain for the balance of the year.

A writer in the American Bee Journal has pointed out that it is as necessary for beekeepers to reserve surplus combs of pollen as it is combs of honey. It may in some cases be even more important, since we can feed sugar syrup, but have no substitute for pollen. It not infrequently happens, especially in localities where pollen is very abundant, that combs largely filled with pollen can be removed from a hive with apparent advantage. Bees without queens are said also to store large quantities of pollen. If put in a very dry room combs of pollen will keep for a long time, indeed, so far as I know, indefinitely, for the lycoperidium powder sold by druggists is nothing more than the spores of club mosses. Why should not these combs of pollen be offered for sale like other bee supplies? The introduction of a few of them into a hive would often make a great difference in the season's results. We need to

know more about the quantity of pollen a colony requires, and its relation to the economy of the bees and the gathering of the nectar.

Fig. 6. SUNFLOWER (*Helianthus annuus*). Each morning two circles of florets bloom, so that it remains in blossom a long time. Notice the little masses of pollen on top of the flowers.

There are many problems relating to pollen and pollen plants that will well repay investigation.

Waldboro, Maine.

The Missouri Meeting.—The meeting of the Missouri Apicultural Society was held at Columbia during Farmers' Week. The weather was most unfavorable with extremely cold weather following a heavy snowfall. Trains were late, and some were annulled entirely. As a result, many were discouraged from attending. However, the program was carried out substantially as planned as most of those who could not attend sent their papers. Since a number of the men who have been most active in the affairs of the association were unable to be present, it was decided to retain the present officers until a time when they could attend. Prof. L. Haseman resigned as secretary and the place was filled by selecting Mr. A. V. Small, of St. Joseph.

Mr. E. M. Atkins, one of the men engaged in emergency work in the Bureau of Entomology, was present. He has been assigned to Missouri, Kansas, Nebraska and Iowa and will divide his time between the four States. Plans are under way for some field meetings to be held next summer. A special feature of the meeting which attracted much attention from short course visitors, was a bee demonstration in a cage by Mr. E. E. Tyler. A talk on "Using Honey to Save Sugar," by Miss Louise Stanley, of the college staff, attracted a number of ladies who were in attendance on other meetings held at the college at the same time.

Mr. George O. Shinji gave an interesting account of beekeeping in Japan to an appreciative audience. Taken altogether, the meeting was well worth while, in spite of the extreme weather.

THE EDITOR'S VIEWPOINT

How Old is the Smoke Method?

There is an old saying that there is nothing new under the sun, and this seems to apply particularly to bee culture. Most of us have had the experience of making some (to us) new discovery, only to learn later that somebody else had given it to the world, in some form, before we were born.

A few months ago there was much discussion of the smoke method of introducing queens and some seemed to think that it was entirely new. Henry Alley wrote in his book, "Bee-keeper's Handy Book," more than thirty years ago, as follows:

"When tobacco smoke is used to introduce queens, throw some grass against the entrance to keep the smoke in and the bees from coming out. Blow in a liberal amount of smoke and then let the queen run in at the top through the hole used for the cone-feeder."

There is nothing to indicate that the plan originated with Alley. In fact, from reading the above extract one would get the idea that it was a common method of introduction at that time.

The Mason Bees

To the nature lover, no more fascinating stories have ever been written than the books by Henry Fabre, the French Naturalist. These are now being translated into English and published by Dodd Mead & Co., of New York. In the "Mason Bees" we find some very interesting accounts of experiments that throw some light on insect intelligence. All beekeepers have noted the care with which the

hive-bee marks the location of her hive and the precision with which she returns to the exact spot of its location. If moved even a few feet she finds much difficulty in locating it again. The Mason bee was unable to find her nest when moved but two or three feet distant. Even if she found it she was unable to recognize it as her own in its new position and started a new nest rather than accept the old one in a new place. On the other hand, when the nest of another bee was placed in the exact place where her own had been it was accepted without question, even though it did not resemble her own.

Mature bees carried to a distance of two miles from their nests returned directly, usually stopping to gather a load of honey or pollen on the way. Experiments indicated a strong homing instinct in these wild bees. This is the same instinct that guides the carrier pigeon to its home, even though it is carried in a dark basket many miles from any place it ever knew.

In marked contrast, he found the Amazon ant unable to find its way home from any distance except by the exact route it had followed on the going trip. If placed even two or three feet aside from its path it was unable to find its way back again, and wandered around in hopeless confusion. The book is well worthy of a place in every nature lover's library.

California Beekeepers

The California Beekeepers Association seems likely to organize itself

into a Co-operative Association and the Western Honey Bee is doing all it can to promote this. It would be a step in the right direction. The time is coming when such organizations will be found everywhere, we believe.

Are the Cells of the Bees Hexagons?

Mr. E. F. Bigelow, editor of the "Guide to Nature," in an article published in his February number and illustrated with numerous beautiful studies, criticises the making of comb foundation in hexagon cells, because he holds that the bee does not build hexagons. He brings, in proof of this, cuts of foundation partly finished by the bees in which the tops of the cells are round. He also mentions the fact that queen-cells are always round.

The bees build their cells with the least expenditure of costly material, beeswax. Economy requires that the cells be built so as to fit closely to each other and the six-sided shape is the most economical. On the other hand, the surface of the cells must be strong enough to carry the bees in their travels, so the bees make a heavier rim at the surface. When we uncap the sealed honeycombs we destroy the strength of the upper edge and uncover the hexagonal shape. But the bees, as soon as the comb is returned to them, hasten to give it the stronger surface, by rounding the tops of the cells.

Foundation mills used to be manufactured with a rounded cell. The Dunham mill, which was so popular 35 years ago, made foundation with round cells. But the bees always excavated the surplus wax from the three-cornered angles and used it in other parts of the comb. So, after all, comb foundation with hexagonal cell walls is **not** an error.

But that the hexagons of the cells are not always perfect does not admit of a doubt. Neither need we doubt that, if the bees had plenty of material, they would probably build all their cells round, for their bodies are round.

The Mating of Queens

"A study of the factors which govern mating in the honeybee," Bulletin No. 34, of the Michigan Agricultural College Experiment Station, by Dr. George D. Shafer, is before us.

This is a scientific description of

the mating organs of both the queen and the drone, and a study of the position assumed by the insects in the act of copulation. It should be of interest to all scientific students of bee anatomy, though containing too many scientific terms to be read with profit by the average scholar.

The text is accompanied by two plates of drawings and photographs. Mr. Shafer shows that he has carefully studied his subject.

Slowly but steadily these cloudy questions are getting more distinctly understood. The amount of research which has been expended, for so little positive knowledge, shows how much remains to be done. Praise is due to the men who spend years of their life in these arduous studies.

American Honey in Italy

According to L'Apicoltore, of December, 1917, they have received in Genoa about 11,000 quintals of American honey, which was selling at 500 lire per quintal. We first figured this at the regular exchange price of lire for dollars. But the Italian lire is now very much depreciated in its exchange for our money. The usual exchange value is 5.20 per dollar; the present is (January 22), 8.40 per dollar. The quintal is 220 pounds. The honey was, therefore, selling at Genoa at 27 cents per pound. Whether this honey was from North America, the West Indies, or the Spanish-American republics is not mentioned.

When we realize that transatlantic rates are soaring beyond all reason and that the risks of transportation make marine insurance very high, perhaps this price of honey is not more than would necessarily be expected.

Beekeepers' Conventions

Formerly it was the custom of the bee journals to give extended accounts of the various meetings of beekeepers. This is no longer possible, because the number of conventions has increased to the point where to do so would occupy all the available space in the Journal. Where there were formerly but a dozen or two conventions of importance in the entire country, now more than that number are held within the limits of a single State. We are always glad to receive notes concerning the various meetings, but would call the attention of the correspondents to the necessity of making the accounts as brief as possible.

Securing Sugar For Feeding Bees

From early reports coming in where bees have had a good flight and it has been warm enough to make a superficial investigation, it appears that bees have consumed a large proportion of their winter stores already and that feeding will have to be done early and in quantity.

The shortage of sugar is acute, but we believe that beekeepers will have no trouble in getting such sugar as they will need if they take the matter up with their grocer or with their nearest wholesale house, executing affidavit as below and explaining the

STATE OF _____ ss.
County of _____

I, _____, being duly sworn, state upon oath (or affirm) that the following statements are true:

I am the owner or have in my possession _____ colonies of bees. The bees above mentioned will need sugar for food in order to live or be in suitable condition for gathering surplus honey during the season of 1918. I estimate that I will need _____ pounds of granulated sugar for the purpose of feeding. If I am permitted to secure this sugar or any part of it, I will use it for food for the bees and for no other purpose and if any remains unused at the beginning of the surplus honey flow, I will return it to the dealer from whom I purchased it or to whomever the Federal Food Administrator shall direct.

My commission expires _____

The above affidavit must be executed before a Notary Public or other officer qualified to administer oaths.

Food and the War

The need of saving food is imperative if America is to win in the world war. Pork, wheat and sugar are the most available food for transport to feed the armies, because they are readily preserved and easily carried. We can live without discomfort on such products as cannot be sent abroad. To make the most of what we have will require readjustment of the food habits of the average American family, but there will be no complaint on the part of the loyal citizen intent on making any necessary sacrifice in order to support our soldiers in the field.

To give the housewife the best available information concerning the work of the food administration and suggestions providing the best possible

matter thoroughly. The Food Administration has expressed its desire to see that all beekeepers are supplied with sufficient sugar.

If you are unable to get sugar locally, execute affidavit as below and send it at once to your State Bee Inspector so that he may take the matter up at once and do what he can to get the sugar.

If desired, he will furnish copies of this affidavit free. However, we urge every beekeeper not to wait, but to make proper affidavit and take the matter up at once. A week or two may make it too late.

Following is copy of affidavit:

food for her family, while at the same time saving the foods designated, we have arranged for a series of articles on "Food and the War," by Mrs. Mary G. Phillips. Living in Washington, Mrs. Phillips has an excellent opportunity to keep in touch with the work of the government. We commend these articles to the attention of the ladies.

Honey Production in British Columbia

The Bulletin on honey production in British Columbia shows reports of 382 beekeepers owning 1,685 colonies with a crop per colony of 51 pounds.

The harvesting of honey-dew by their bees in 1916 resulted in a winter loss of about 40 per cent.

GROWING SWEET CLOVER

Cultural Requirements of the Plant Under Field Crop Conditions

IT frequently happens that, having seen sweet clover growing along roadsides, on gravelly banks and other unpromising situations, we are surprised to fail in getting a stand in a well prepared field. Sweet clover requires a firm seed bed, and will not succeed on land where the soil has been deeply stirred and left in a loose condition. It is well to scratch the surface with a tool that does not penetrate deeply, leaving the surface loose for an inch or so, and compact below. While it will succeed on a great variety of soils, it requires that they be in well settled condition and not freshly plowed to a depth of several inches, such as best suits many forage plants. This condition probably accounts for more failures in getting a stand of sweet clover than any other cause.

Sowing the seed on top of the ground or on the snow in winter, will often secure a good stand with no cultivation at all. Good results

The time of sowing will depend much upon the manner in which the crop is to be handled. Where it is desired to sow the seed on old meadows or pastures without plowing, it will probably be best to scatter it in winter or early spring. The freezing and thawing have a tendency to soften the hard coat of the seed, as well as to cover it with earth. As a field crop, the writer's limited experience would indicate that spring sowing, with a nurse crop that can be cut early, will be best.

There is a great diversity of opinion as to the proper amount of seed to sow. Where it is used to thicken up meadows or pastures a smaller amount is needed than where sown as a field crop on newly prepared land. Some growers say that 4 pounds of good unhulled seed per acre is sufficient to sow on grass lands. As high as twenty pounds of hulled seed per acre is advocated by some for a

field crop. The seed covering is very hard, and, unless treated, only about half of it will grow the first year. If the seed is scarified the hard coat is scratched until it germinates readily, and much less seed is necessary to secure a stand than otherwise. Ten pounds of hulled and scarified seed per acre should be sufficient on good land.

It is often difficult to get a stand on old land which is deficient in lime, for lack of the nitrogen-gathering bacteria that thrive on the roots of the clovers. It is sometimes necessary to treat a small area with a good coat of manure, and sometimes with crushed lime. After the sweet clover is growing well on this land the area can be gradually extended.

Utilizing the Crop

Probably there is no forage crop which will furnish as much pasture per acre as will sweet clover in its second year of growth. It should be allowed to get a good start in spring before stock is turned in, and the area should be sufficiently large for the animals thus kept. Cattle, hogs and horses all eat it with relish after they become familiar with it, and thrive equally on it. It is a common practice to pasture the crop during the first part of the second season and then to turn the stock off and harvest a seed crop. The writer has harvested a very good crop of seed from a limited area, which was pastured lightly through the entire summer until the crop was cut. Of course, it is not possible to pasture heavily after midsummer, and still secure a good crop of seed.

Sweet clover makes a good quality of hay if cut at the proper time and well cured. If a seed crop is to be cut, the first crop of the second season may be cured for hay by cutting high enough to leave some of the small branches on the lower part of the stem. If cut too low at this time the plants will die. Sweet clover hay requires more time to cure properly

TAKING SOIL FOR INOCULATION FROM A SWEET CLOVER PATCH

often come from sowing it with small grain in spring, on land that has been cultivated the previous season. Some succeed by sowing after the last cultivation of corn, the seed germinating to some extent the same season, while some does not sprout until the following spring. The ideal condition is to cover the seed from half an inch to an inch with finely pulverized soil, with a firm soil underneath.

Time of Sowing

Sweet clover may be sowed in winter or early spring, as above stated, or at any time from March until August. It should not be seeded when it is likely to start so late that it will not have time to establish itself firmly before winter. Under the different conditions of soil and climate of this great country, it is difficult to give general directions that will apply everywhere.

CUTTING WHITE SWEET CLOVER

than the clovers with smaller stems, but if piled in small cocks it is little damaged, even though some rain falls on it. If properly cured, it makes a very good winter feed. When cut for hay it should be mown before it begins to bloom to any extent. When it is about two feet high is the right time. The first year it may be cut at almost any time the grower finds it convenient.

Some practice sowing sweet clover with early oats, cutting the oats with a high stubble, and, later, getting a crop of hay.

Saving the Seed

The seed crop sometimes fails because the plants are too thick on the ground. They spread or branch widely as they grow, and where they are too thick the blossoms may drop off without setting a full crop of seed. Usually best results are obtained where a first crop is cut for hay or is pastured until midsummer. The second crop does not grow as high as the first would do if permitted to seed, thus making it easier to handle. Seed is obtained only the second year, and if the first growth of that year is permitted to seed, the plants will die when cut, so that only the one crop can be obtained.

The seed ripens so irregularly that it is not always easy to tell just when it should be cut in order to save the largest amount of seed. At best much of it will shatter off and be lost, since the first to ripen will be ready while there is still a large amount of bloom. The most seed will be secured by cutting when about three-fourths of the seed pods have turned brown. If cut sooner there will be too many blossoms and immature seeds; if cut later too much of the ripe seed will shatter in the harvesting. Usually enough seed shatters off to reseed the land. Some growers have been able to continue the same land in sweet clover for fifteen or twenty years by sowing two years in succession to begin with. After the first year, a crop of seed will ripen every year.

It is something of a problem to harvest the seed without losing a

large portion of it. The writer has cut a small field with an ordinary mower when the plants were wet with dew, and immediately raked it into windrows. This method is hardly to be advised where the seed is to be hauled to a threshing machine, since more of the seed will be wasted than where it is bound into bundles. This small field was threshed by hand with forks. A large sheet of canvas was laid on the ground, and the sweet clover carefully lifted on it, after it was fully dry. By beating with the forks the seed was readily separated from the stalks.

The ordinary grain binder is generally used for this purpose. Where much seed is to be harvested, it is necessary to provide some special pans to catch the seed that shatters off. Corn binders have been used in some cases.

When threshed with a grain separator, the straw is broken up so much that it makes a fair forage for wintering cattle or horses. They will not eat it readily where threshed by hand, since the straw is not broken

up to any extent and the dry stalks are too coarse otherwise.

Those interested in this subject will do well to write to the U. S. Department of Agriculture for Farmer's Bulletins 797, 820 and 836, all of which deal with different phases of the culture of sweet clover. They give in much greater detail information that space will not permit here.

Quadruple Vs. Single Row Winter Cases

By G. C. Greiner.

THE old adage, "Convince a man against his will, he is of the same opinion still," contains more truth than poetry. And this is not strange. After we have spent almost a lifetime using certain appliances and tools it becomes, as it is termed, second nature to us, and with normal, natural abilities we become experts in their application. To make a break in our accustomed habits and adapt ourselves to new methods would not only be up-hill business,

A FIELD OF SWEET CLOVER AT HARVEST TIME.

SWEET CLOVER ON THE LEFT, GRIM ALFALFA ON THE RIGHT

but in many instances would cause heavy expenses and extra labor. The beaten path, crooked as it may be, is always easier traveled than deep snow on a straight line, even if we could save one-half of the distance. In fact, if we should undertake to make a short-cut of this kind, the average people would call us "cranky," no matter how much they would be benefited by our effort in the end.

These conditions we meet in almost all walks of life. It is not only the beekeeper of many years' experience, who thinks his beaten path is the straightest, but all other occupations are laboring under the same deception.

It is not my object to open up any controversy with either the quadruple, the straight row or the single colony advocates. Each one of these three methods has its advantages. This cannot be denied, and it would hardly be advisable for anyone who

is accustomed to his particular kind and has stocked up with an extensive outfit in that line, to make a change. Besides the dollar and cent point of our occupation, contentment of mind is worth a great deal. If we can perform our daily tasks to our own comfort and satisfaction, life becomes a pleasure and is worth the living.

For the benefit of our younger brother beekeepers who have not yet decided which kind of winter case to adopt and are contemplating making a supply during winter for future use, I will enumerate a few pros and cons of the quadruple and straight row case, as I have gathered them up during my many years of experience and observation.

The single one-colony case used by many experienced beekeepers with good satisfaction, we will leave out of consideration, as the preference of the majority of beekeepers seems to be one or the other of the two larger kinds.

When I left my bee-cellar dug into a gentle slope of one of Naples' side-hills nearly twenty years ago and moved to my present location, which is situated on the level plains of Niagara County, the wintering protection problem was uppermost in my mind. Although surrounded by orchards, groves, buildings, etc., the new locality offered no dependable windbreak for my bees, and as wintering out doors had become a much-talked-of subject at that time, I decided to add winter cases to my bee-keeping outfit.

From my earliest beekeeping days I could see almost numberless advantages in keeping bees in straight rows, all facing one way (east or south), and as a natural consequence my choice was the single one-row winter case. Being always cautious when launching out onto new schemes of this sort, wishing to make sure of their practical use, I made only two or three as a trial the first season. In planning my work I made the great mistake of considering the economical side of labor and lumber only, leaving all other, much more important features in the background. I was shortsighted enough to build my cases, or sheds, as I generally call them, for nine colonies, making them as long as 14-foot lumber would allow without waste.

When I moved my sheds to the yard (in sections, of course, for I could not handle them all put together) it dawned upon me at once that I had made a great blunder. Where should I get the bees to fill them? It would take the bees from half way across the yard to do it, and to spread them out again in the spring would be a long, disagreeable task. I did not use the unwieldy things a second time, but before another packing for winter came around I had them cut into two parts, making a five and three-colony case of each one of them. That relieved me in a measure of shifting my bees first towards the large sheds and then back again to their summer stands in the spring.

Since then I have had the five and

three colony sheds as a mixed lot in my yard and find that the smaller ones are by far the most practical and convenient to use, so much so that I have begun to cut down the larger ones to the smaller size, making one-colony cases of the cut-off pieces.

In speaking of the quadruple cases I do not intend to belittle anybody's work or theory. On the contrary, if properly made and rightly managed they give good satisfaction. Some of our best beekeepers use and recommend them, and they know whereof they speak. Economizing heat by way of the enclosed colonies standing side to side and back to back is one of their most important features. In proportion to their cubical capacity they are most economical in regard to the lumber used in their construction, and we all know that it requires less roofing to cover a square than an oblong.

But it is also an undeniable fact that they have some undesirable features. For instance, one-half of their inmates have to face the opposite direction from the others, always exposing one side or the other to the severity of prevailing storms. Another objection is their clustered position. To have access to all four, the operator is obliged to walk constantly from one side to the other and always pass in front of the hives. Besides miles of unnecessary travel during the season it has a tendency to irritate the bees; many attacks may be the direct result of this oversight.

It is very different with the straight row system, if the apiary is ideally laid out. Rows should be at least ten feet apart and hives should have about two feet between in the rows. When doing any beework during the season it is always one step from hive to hive; the operator is always on the same side (the right side of the hive), which makes all manipulations much more convenient; every hive is a seat for the next one and forms a shelf for his tools and at no time is it necessary to come anywhere near hive-entrances.

Our first lessons in geometry taught us that a straight line is the shortest distance between two points. Small and unimportant as this straight line business seems to be, it saves the beekeeper many unnecessary steps during the season. I apply this principle systematically to all my beework, and when extracting time comes around I reap special benefit from its application. In a straight line I take my wheelbarrow with comb baskets to the end of the row, and turning around I have again a straight line back to the honey-house, gathering up combs for the extractor from hive to hive.

When I stand in front of my three-hive winter case and compare the relative positions of the entrance of the three colonies when on their summer stands and in the winter cases, the bee-passages before and after packing are either in the same place or so nearly so, all being on the same level and in the same plane,

that no drifting or confusion will occur when the change is made. Thus the three-colony single-row shed eliminates all necessity of shifting bees in the fall, as well as in the spring, which, to my mind, is an essential feature.

I do not use my hive-stands for the sheds, but they are stacked up and set on little blocks; they will last a life-time if lifted out of the ground in the fall and given a chance to dry during winter. A little repair where needed, a nail here and there, will greatly prolong their service. Some of my stands have been in use over thirty years and are yet in fairly good state of preservation.

La Salle, N. Y.

The word "drifting," used by Friend Greiner in the latter part of the foregoing article, indicates one of the greatest objections (for us) to the use of the quadruple case, or in fact to any case which requires the moving of the colonies together for packing, and we believe that this is one of the strong points in his method.

When colonies are moved together for winter and there is occasion for any of their bees to take flight, there is more or less confusion among them in recognizing the new locations. The result often is that the strong colonies, making more noise, attract the bees of the weaker ones who "drift" to the appeal. We have noticed this, years ago, and that is what dissuaded us from moving the hives at all. But we are inclined to think that perhaps our experience was exceptional. However, lately we have heard so much of colonies "drifting" and the weak ones losing bees to the profit of the powerful ones that we are strengthened in our dislike of moving colonies at all on their stands for winter. Friend Greiner's method avoids the moving, and drifting is not to be feared.—Editor.

Beekeeping in Santo Domingo

By H. Bremser

NEARLY three months in Santo Domingo, I think I can give pretty accurate information about beekeeping conditions here and about land and people. A lady beekeeper in Sanchez made this season from 60 colonies 30 barrels (50 gallons each) of honey. Even now enough nectar is coming in that I could make strong colonies fill a super with honey. My work at present is queen rearing, getting the queens in the supers mated and starting new apiaries with the nuclei.

Sanchez is situated at the north end of a bay 30 miles long and 12 miles wide, northeast of the island. The bay is really the continuation of the river. On the south side of the

bay we located and stocked already with nuclei four new apiaries on land owned by Dr. Maldonado. At the north side of the bay we bought four small pieces of land from five to ten acres each, to which I am bringing nuclei as soon as I have them ready. We also located places on the river as far as we can go up in a motorboat. A railroad runs 31 miles from Sanchez to the interior, and the doctor secured places on it also for apiaries. This is about all in the vicinity of Sanchez. On the north coast the doctor owns considerable land. I went there once over the mountains and came through the towns or villages of Matanzas and Cubreras. On the way we crossed three good-sized rivers (one over a hundred yards wide) in log canoes, the animals swimming behind. In this locality we have 30 colonies in logs and have the hands instructed to buy as many more as they can get hold of. As soon as I have time I will go there, take two breeding queens along in two-frame nuclei, transfer these bees, brood and good comb, to 10-frame supers and start apiaries there as I am doing here now. The native bees are the worst to handle I have ever met with, but very fine cell builders. Five days ago I received from a friend in Porto Rico 13 queens of my stock in two-frame nuclei. The honey here, which I have examined, is lighter in color than the Porto Rican honey and of very good flavor. The country I have seen is thickly wooded or virgin forest and only here and there small patches in fruit and cacao, and very thickly populated. The people are good-natured and peaceful, but do not like to work, and this is one of my main difficulties. Nature produces most anything they need, so it is necessary to pet and coax them, if you want any help. With the rich and cheap land the island has, it is my opinion that as soon as settled times return the small 5 to 10-acre farmer will invade this island from the north, start farming with poultry, bees, dairy, etc., and gain prosperity in no time. If he knows something about mechanics and carpenter work, as we Texas farmers do, he will be almost independent and his independence secured. It is certainly amazing when I relate to my friends here the stories circulating in the States and even in Porto Rico about the unsafety of Santo Domingo and the wild and uncivilized population. On my trip to the north coast, which lasted 13 hours, the few people we met always saluted first and gave very polite information. In the few huts we saw and entered we had to rest and accept coffee and fruit. My friends told me that even in the revolutionary times they only cut each other's throats and did not harm the stranger who kept out of politics. We have direct mail and passenger service from New York to Sanchez twice or three times each month. To visit in the future the apiaries situated near the water we are going to use a small motor-boat, which the doctor has already ordered. I could narrate some very in-

teresting incidents, which I had on my trip over the mountains and in crossing the flooded rivers and the trouble we had with the animals, especially the pack mules. On the water we once had a rough sea and had to return, bees and all, as the motor was flooded and did not work. For the next load I took a sailing boat and had better luck.

Sanchez, Santo Domingo.

The Hubbard Feeder

HUBBARD Brothers, of Boyne Falls, Mich., seldom resort to feeding, since the shallow combs which they use over their comb-honey supers furnish a reserve supply of stores for every colony. However, in the best regulated api-

THE HUBBARD FEEDER IS SAFE FROM ROBBERS.

ary there will occasionally be a colony which for one reason or another must be fed. For this purpose they have devised a feeder which is attached to the back of the hive, as shown in the picture. An inch auger hole in the hive-body, which is opposite a similar hole in the feeder, gives the bees access to the syrup. The feeder has a metal cover which fits very tight and thus prevents rainwater from dripping in, or robbers from getting a taste. A piece of wire cloth, which slants across the feeder from top to bottom, enables the bees to get the last drop without danger of drowning.

This feeder can be filled at any time without disturbing the bees, as it is not necessary to open the hive or interfere with the normal flight of the bees at the entrance.

Strained Honey

By J. E. Crane

STRAINED honey! What memories cluster about these words! Again I see the old one-story wood-colored house, with its huge chimney and fireplace, where I was born and lived my childhood life, with father and mother, brothers and sisters. And back of the house the

orchard, and the well, with its old-fashioned sweep for lifting the buckets of water from between the walls of stone. Near by was the beehouse, for no one thought of keeping bees, in those days, without a bee-house. This house was really a shed with one roof sloping to the north, and boarded up on the north side and open on the south side, so the sun warmed the bees in winter, causing many to fly out in cold weather and get lost, or making it so hot in summer as sometimes to melt down the combs. And then there were the long, golden autumn days and frosty nights. Then father would say it was time to "take up" the bees, for "the brood was all out of the combs." Mother and brothers and sisters were all interested as father melted some sulphur on a shovel by the kitchen fire and prepared some great "matches," as he called them. Then we went to the yard in front of the bee-house and with a spade cut out a hole in the ground ten or twelve inches square and ten inches deep, sticking three or four "matches" in the bottom. After much knocking or thumping on the hives to discover which were lightest and not likely to winter, the matches were lighted and the hives set over the burning sulphur one after another. How sorry I felt for the poor bees to be smothered in this way when they had done nothing to merit such a fate. Soon the hives father had decided to "take up" were all silent and taken to the large kitchen and the combs cut out; some of the whitest were saved for company and the rest piled into great wooden bowls for "strained honey." Later, when the little mother had time, a milk pan holding six or eight quarts was taken, two sticks laid across the top and another pan punched full of holes laid on the sticks, into which the combs of honey were placed after cutting them crosswise and lengthwise and every way, to drain for "strained honey." I can almost hear that honey today as it dripped into the empty pan. How good it looked as the lower pan slowly filled with the pure honey free from the dark comb. And once, I remember, when the little mother was out of the room, and I thought no one would see me, I helped myself. Surely "stolen waters are sweet and bread eaten in secret is pleasant," but did ever a morsel pass juvenile lips and taste more delicious than the scrap of wax besmeared and dripping with amber honey? As the honey ceased to drain the old combs were stirred and placed in the oven warm enough to melt the combs, and the golden wax ran over the honey. How wonderful it seemed in those far-away days! Yet how slow the process; but in those days we cut our grass with a scythe and our wheat with a sickle and threshed it with a flail. Today we have our mowers and reapers, our threshers and seeders, our autos and even our flying machines. But how about strained honey? We do not need to strain honey these days, someone will say, for we have the

"extractor," a wonderful invention that has revolutionized beekeeping. Yes, we have the extractor, but there is yet much honey to strain or separate from the wax. There are the cappings, removed to make the combs ready for the extractor. Then we have more or less sections that get broken in handling or injured so as to be unfit to market, for accidents will happen in the best of families, as well as with beekeepers who have to depend on inexperienced help. And then there are more or less combs that are ill-shaped, or where the starters have fallen down. More or less may granulate before 't is shipped to a distant market, or gets broken in transit. We recently had nearly a hundred cases sent us from the city that had been shipped in by different beekeepers; the most of it had to be strained, or the wax separated from the honey and got into shape to market. When we think of the large amount of cappings that will accumulate where the honey is extracted from several hundred hives, or even one hundred, the old way seems quite too slow, and we may find it to our advantage to have a box or a number of boxes three or four feet long by eighteen inches wide and ten or twelve inches deep with a galvanized wire cloth screen with one-fourth inch mesh nailed to the bottom, beneath which a metal bottom will conduct the dripping into a vessel below. Into such a box the cappings and broken or injured combs may be thrown, and, if it sets in a warm room and is stirred a few times, most of the honey will drain out and be in no way inferior to that which comes direct from the extractor. After a few days it will cease dripping, or nearly so; then they may be thrown into a barrel and the box again filled with cappings to drain, or they may be treated at once with a melter. As the little mother long ago treated the combs to a strong heat, strong enough to melt the wax, to get all the honey, so we must now treat the cappings and combs to heat sufficient to melt the wax if we would get it all. It is rather surprising how much honey remains in the cappings after the honey has ceased to drain out, probably twice the weight of the cappings. There are various ways of separating the last of the honey from the cappings, but I believe none so good as a melter designed especially for this purpose. I have recently had one made for my own use that suits me well. A pan of galvanized iron three feet long by eighteen inches wide and four inches deep is made. Into this an extra bottom is soldered, extending from one end to within four inches of the other end, where it turns up as high as the edges of the pan. This makes a water jacket one inch deep over the bottom of our pan with opening at one end for filling with water and escape of steam. Small holes are drilled through the end opposite the opening for the escape of the melted wax and honey.

The pan is set in a wooden frame so the ends may be raised or lowered to suit our convenience. A small oil stove underneath gives necessary heat.

My Experience With Bees Shipped in Combless Packages

By John Kneser

Read at Wisconsin State Convention, December, 1917.

BRIEFLY I wish to give my experience in purchasing bees in combless packages.

When bees are purchased in this manner the orders should, of course, be placed early in the season, and in packages no smaller than at least two pounds; and it is further essential that they be received before fruit bloom. The purchasing of bees in combless packages, while not so advisable where purchasers have not hives and drawn combs, is recommended as being highly desirable and profitable, especially so in view of the present price of honey. In the event that purchasers have no hives or empty combs, it is advisable to buy the colonies outright.

When following the above suggestions, purchasers should secure bees from the South during the months of April and May, and under ordinary favorable conditions they can build up strong colonies, for the June and July flow.

There may be a prevailing opinion among some beekeepers that when purchasing bees from the South in combless packages there is a likelihood of their having foulbrood, and possibly, therefore, transmitting the disease to healthy bees. The opinions of overwhelming authorities are to the contrary; that foulbrood is not usually transmitted by purchasing bees as outlined.

About five or six years ago I tried the experiment by sending for different sizes of combless packages of bees with queens. I was well pleased with the results. Further, during the month of May, 1916, I received twelve two-pound packages with an untested queen in each package. These packages arrived in good condition and just in time for the clover flow, which commenced late in June. These bees produced more honey than the average of my other colonies. During the spring of 1917, because of conditions wholly beyond my control, the purchasing of combless bees was not very satisfactory, for the reason, first of all, that the bees arrived in poor condition, the loss being about 60 per cent. In addition to that several other factors entered into this unsuccessful venture: The congested condition under which they were expressed; exceedingly hot weather during shipment and during preparation for shipment; too great a proportion of old bees and inferior queens and virgins sent.

Although I had losses, nevertheless, taking the mean between the two, the profits realized are far more satisfactory than by any other method known to me.

Milwaukee, Wisconsin.

Early Spring Suggestions

By Frank F. France.

MR. BEEKEEPER, what plans are you making for the coming season? It is now time to think over every detail necessary for the work of 1918. If you have a business system, your work will be a pleasure. It is a very good plan to take an inventory of everything, the number of colonies, the number of supers of good worker comb, extracting combs, extra frames with foundation, worker combs full of honey for spring feeding, number of extra bottoms and covers, and storage cans. How is the condition of your auto or truck? Does it need repairs or overhauling? If so, now is the time to have it done by your service station. It can be done cheaper and better at this time of the year than when the rush of the season is at hand.

Time is the most important factor today. Let every minute of your time count, just as every factor counts in this great war. Your new supplies should be all ready for the coming season. Clean up all surplus combs of excess wax and have them graded as to kind and quality, namely, drone and worker comb. The importance of extra combs in the spring, summer and fall means the same as money on interest and when filled with brood or honey they are forms of security bonds in readiness for your crop. All old, broken comb, cappings and scrapings send to the wax-rendering specialist. It will save you time, fuel and money.

What about your equipment; is it standard? Do you know that this war's greatest lesson is standardization? Not only does it apply to war supplies but to everything else. If you have all kinds of hives and frames of different sizes, you spend half the time fitting parts together. This is lack of standardization. Keep all parts of one size and make, so they be interchangeable. Make standardization one of your policies and you will be insured a good return for your investment. Standardization is also economy. It is simple, it is reliable, it is free of complications. If you have good standard hives of the same size and make it is also easier to control disease.

What will become of the business of the young beekeepers who are in the war or may go to it? Many have gone to the training camps, some to Europe and a great many more are on the draft list, not knowing whether they will or will not be exempted. The United States is going, sooner or later, to adopt a universal military training system whereby all young men physically able will be trained. If we beekeepers were a unit to help one another, it would be easy to find someone to care for

the bees of the soldier boy, but now, if he cannot find a person, his business will be a total ruin. I may be one of the many thousands to join the colors, if not exempted, but I am, with the rest of the boys, ready to go at any time to help press out German militarism. The wartime appeal is to help Uncle Sam first and ourselves last.

I do not think many beekeepers understand the tin can situation. The price of cans will probably not be any greater than last fall, as the government, I am informed, has tin prices under control. It is the supply of cans that is limited, and whether we can get them at all will be the question. Also how long after we order them will the shipment arrive, since war freight is to have the right of way, so that all other freight not perishable will move slowly? Of course the transportation system depends largely on what will happen to the Kaiser this spring and summer. Our transportation system and our home power plants will largely need the motor truck, which may be the future means of carriage.

Platteville, Wis.

Suggested New Antiseptic Treatment for Bee Diseases

By W. J. Sheppard.

A NEW antiseptic known as "flavine" that has been found highly successful in the treatment of wounds and disease on the battlefields of Europe seems likely to be of benefit to beekeepers as a remedy for bee diseases. It is reported that experiments have been made with it in England during the past season in the case of a few colonies having Isle of Wight disease, and that it has effected a cure. If that is so, there would appear to be no reason why it should not be equally efficacious in the treatment of other bacterial diseases of bees, American foulbrood, European foulbrood and sacbrood. From enquiries made by the writer as to whether it had been actually tried as a remedy for foulbrood as well, he was informed that up to the present it had only been experimented with in one instance and that the result was satisfactory.

The difficulty hitherto experienced in treating bee diseases antiseptically has been that antiseptics powerful enough to destroy disease germs have, as a rule, been harmful to the bees, and generally highly injurious, or fatal, to the unsealed brood.

It is stated that the essential qualifications for an ideal antiseptic are that "it should be non-poisonous and non-irritant to any tissue of the body, harmless to the phagocytes (the white warrior cells of the blood), potent to kill disease germs in the presence of blood serum, and stimulating to repairing tissue." It is claimed that "flavine" comes near-

er to this standard than any other antiseptic at present known.

For the treatment of bee diseases, if further tests prove its efficacy, it possesses several advantages that are obvious. It is inexpensive and easy of application. Five grammes, equaling 77 grains, costs only 32 cents. For the treatment of Isle of Wight disease in spring and summer one grain is dissolved in one quart of warm water and sprayed into the hive with an atomizer, so that the eggs, larvae, bees, combs, floor-board, etc., are thoroughly dampened. A second application is given after five days. If the weather prevents the opening of the hive, one pound of honey, or sugar, is dissolved in one pint of the fluid and fed rapidly, and followed by spraying when weather permits. For autumn treatment a stronger spray is recommended, consisting of one grain of flavine to 16 ounces of warm water to commence with. Also soft candy medicated with one grain of flavine to the pound. Probably similar treatment would be suitable for foulbrood and sacbrood.

It is said that it is safe to use combs over again that have been in contact with diseased colonies if they are sprayed with the fluid of the first mentioned strength by means of a mist sprayer of sufficient power so that it penetrates to the bottoms of the cells. The fluid has a greenish fluorescent tinge so that its penetration is easily perceptible. There are two preparations of "flavine," called acriflavine and proflavine, the former being slightly more expensive than the latter. Possibly this treatment will be given a trial next season at some of the experiment stations on this side of the water, as it seems to give great promise of good results.

Nelson, B. C.

Advertising Honey

By Jay Smith.

AT the present time, honey is almost selling itself, but the time will come again when it will be necessary for the beekeeper to do some hustling if he expects to get rid of his honey at remunerative prices.

"It pays to advertise." Every one will tell you so, and it does, but it must be of the right sort. If a person is not careful in advertising he will find it an easy matter to lose money thereby.

One should sell his honey locally if possible, for not only can he get a better price but he will save the middleman's profit, freight charges, etc.

For a number of years I have bottled honey and sold it to the grocers. The average grocer will take a few bottles out of the case and set them on the shelf, but no one will know what it is. It may be jelly, apple butter or most anything as far as the purchaser can tell. Then many storekeepers are not salesmen and many of them employ cheap clerks, who are not salesmen. A customer comes into the store and the clerk says, "What will you have?" The customer tells him, buys it and goes out. The customer did not say, "I will have some honey, please," because he did not know that the storekeeper had honey for sale. In making my rounds to sell honey, a grocer frequently has said, "I have still on hand some that you sold me a year ago." He only bought one case the year before, and sold part of it when someone called for it, when the baby had the "croup."

I tried to get grocers to mention that they have honey, and when a customer comes in, ask if he wants some fine honey, but grocers have

HONEY MUST BE ATTRACTIVELY PACKED TO BOOST SALES.

hundreds of things to sell, and of course cannot go over the entire list.

I tried advertising in the daily papers, but found I could sink a lot of money in this way; the sales of honey from the groceries would not pay the advertising bill. It did not pay me to advertise this way.

Finally I hit upon a plan which was worked out so well that I give it here believing that many who live near the larger towns can use it to advantage, and the expense in advertising is nothing.

I go into a grocery store and say to the proprietor: "I have a honey proposition to make which I believe will interest you. If you can spare the use of your show window for a few days, I will put in a window display of fine extracted honey in jars of various sizes. I am not going to ask you to buy any honey. Simply place this display in your window with the prices marked on the different size bottles, watch the people stop, look at it and then come in and buy. After the display has been here as long as you wish to keep it, I will take the honey away and you can pay for what has been sold and as much more as you want to keep on hand."

The grocer usually says there is no use trying to sell the larger packages, the half-gallon and the gallon sizes. The ten-cent and twenty-cent sizes are as big as he can sell. In making this deal, however, I never contradict the grocer, for he naturally feels he knows far more about his business than I do, so I say, "That is true, but the gallon and the half-gallon make such an attractive display. They will help sell the smaller sizes." I know well enough, however, that the reason the larger ones have not sold is because people do not see them. Let people once get sight of the beautiful extracted honey and many of them will want a gallon.

The grocer always accepts this proposition because he is not asked to put any money into it that he is not sure of getting back at once. He has nothing to lose, no risk to take, and a new window display is always an attraction, so I am allowed to arrange a display similar to the one shown in the photograph.

People who come by the window stop and look at the display. Many come in and buy. Children look a long time at it and then go home to begin work on their mothers to get some of "that honey."

I first tried this at one of the largest groceries in the city, a dealer in fancy groceries. When I came to remove the display there was not much left to remove. He sold more honey in that week than he had sold in a year before. I put a display in a number of other stores soon after, with the same results. The honey sold like hot cakes.

One grocer has said, "You can put in the display if you want to, but do not expect too much. We have never sold extracted honey here. We can sell comb honey all right, but not

the strained." I put in the display and it worked just as I knew it would, but it surprised the grocer. He left it in his window three weeks and I had to fill it in several times as the stock sold out.

I always explain to the grocers that after the display has been in the window and people know they can get honey there, it will build up for them a permanent demand for honey. This has proved to be true.

This scheme is the best of anything I have ever tried. If the producer has on hand plenty of honey, he may better have it in the show window advertising itself than to have it stored away in his honey-house.

Vincennes, Indiana.

Woman's Work in Food Conservation

By Mary G. Phillips.

IT is true that at last the woman in the kitchen has come into her own. For years our families have come to the table three times a day, have eaten with relish the good meals there, and have gone away without once thinking that in half an hour they have demolished what it took hours to plan, prepare and cook. Three bountiful meals have been taken for granted like sunshine and air, but now, at last, we are confronted with a new idea. We have suddenly waked to the fact that the health of the family depends absolutely upon the woman who plans what we shall eat, and prepares and cooks it. If you look around among your friends you will see that the children in one family are strong, vigorous and energetic, while those in another are weak, thin and unambitious. It may be that the mother, although a "good provider," has not for years given the children the food they need for proper growth and strength. I know of a family where the youngsters are given no milk (a most important food for children), and the chief meat is pork, a food exceedingly difficult for youthful stomachs to digest. No wonder that these boys and girls are undersized—they are undernourished.

Now, we housekeepers of today are not only recognized as the keepers of the family health, but we have a bigger responsibility even than that. We must keep our families healthy at home at the same time that we are sending all the food possible abroad. We are to help win the war! Isn't it a splendid feeling to know that we are a part of the United States army of women in a great drive every day, winning the war? "There is no magic way to make food win the war," says Mr. Hoover, "it can be done in but one way, the way of voluntary and eager resolution and action of the whole people in every shop and every kitchen and at every table in the land." Our trenches are our kitchens, our weapons the market basket and saucepan, and our ally cornmeal, but our victories are as real as though we flourished bayonets. So arm yourselves, house-

wives, and let us do our whole duty to our families and our country!

Of course every beekeeper is bending his energies toward the production of a maximum crop in 1918—that is part of his patriotic duty. The beekeeper's wife has her patriotic obligation, and I wish that the things which comprise her whole duty might be painted on every kitchen wall:

1. Keep the family well by the wise use of the right foods.
2. Save food for others by using less wheat, meat and sugar.
3. Waste nothing.
4. Prepare and cook food with thought and care.

The object of this article is to help the families of beekeepers to do these things and it should not be forgotten that every member of the family can help—it does not depend alone upon the mother, who does the planning and cooking. For instance, if Mother decides to have carrots for dinner and Father refuses to eat them, declaring they are nothing but rabbit food, he is hindering Mother's work and doing an unpatriotic act. What difference does it make whether he likes carrots or not? He can learn to eat them and be that much better off. Children can do their part by following the gospel of the clean plate, and they will, if they have been trained to like all wholesome foods. It is often difficult in after life to overcome food prejudices formed in youth, and now that we have an incentive by appealing to a child's patriotism, it will be possible to help them to form good food habits.

The need is immediate, and so urgent that we should set about our task now, not relaxing one day until the time comes when people are not starving by hundreds and thousands while we have plenty. Professor Jager, that splendid beeman of Minnesota, came back from Serbia recently, and the stories he told of the hungry people there make one ashamed to use wheat, and more ashamed to grumble over having to use cornmeal. Just imagine, if you can, having nothing to eat for three years but a piece of bread daily as big as your fist, with a red pepper; bread so black and gritty that the teeth that bite on it become worn down to the gums. That is what thousands of Serbs are living on while we feel it a hardship to have one wheatless day a week! The workers in the Food Administration realize so fully that the saving of lives and the winning of the war can be accomplished by limiting our use of wheat, that one man there has insisted upon his family forgoing the use of wheat entirely, that there may be more for others. But after all, that man's sacrifice and his entire work of the Food Administration will go for naught, as will the work of all the missions helping to carry food abroad, unless we housewives do our utmost to co-operate. We must take hold of the food problem as we find it in the homes which we manage, and that means that we have three things to study—our

families, to find out what they need; our source of supply, to find out what we may use, and government publications, which will give us light on both. Aside from government bulletins, there is a mass of literature flooding the country today, which should be used cautiously, common sense dictating what to assimilate and what to disregard. Too frequently such literature is put together hastily by inexperienced "food experts," and this is no time for experiments. Food, we know, is scarce, and experiments often costly, therefore tried and tested methods that you know, are the best to use, unless you are sure of your source of information. Above all, let us use common sense. Here, for example, is a paper containing recipes for meat substitutes. In one wheat is used, elaborate preparation is necessary, and two hours' cooking is required, therefore much fuel. That sort of thing our common sense teaches us not to try, a good general rule being to have simple meals which require the least time in preparation, the least fuel to cook, and the least use of meat, wheat and sugar, yet conforming to the family needs.

Most of us are willing and earnest in our efforts toward food conservation, but the difficult part is to keep up the effort day after day. It is easy to plan a meatless day and a wheatless day for a few weeks, but the strain comes when, without hope of receiving medals of honor, we have it to do week after week. The men in the trenches are relieved every few days and go behind the lines for rest. Our part is to keep on the firing line until the war is over. All honor to the housewife who does it cheerfully and gladly!

Washington, D. C.

My Neighbor's Garden

By C. D. Stuart.

STRAIT from the neighborhood of her garden flew my bees. I listened to catch some message from her in their gossipy murmurings, even as whiffs of fragrance, from magic-carpeted fields just beyond, came to me on the pinions of a brisk March wind. I could close my eyes and see that absurd little garden with its young gardener—my neighbor's daughter, and the apple of his eye—fussing over the one rose bush I myself had given to her, as Mother Eve might have tended the first infant in the world.

But all my mental tiptoeing failed to bring the message.

"We must be about our neighbor's business," those busy honey-gatherers ruled, thus cleverly passing back to me the problem of bridging the hostile trenches of parental jurisdiction.

One spinster bee, rather brazenly, I thought, dragged into a hive two bulging suit cases the color of new tan shoes. One could see at a glance that they had been stolen from a poppy field and that they had been tightly packed with crystals from the

hearts of the poppies. I know the very place. In one corner of the field stands a live oak. There the young gardener and I met (quite by accident) and had worshipped the "land of fire" as the Spanish mariners who sailed up and down the coast in the early days, described the "flame" of *Escholtzia Californica*.

Of course, the bees do not mention the California poppy in botanical

WHITE OR FIELD MUSTARD. Sometimes called "Wild Turnip."
(Photographed by John R. Douglass.)

terms. Even the gardener feels more at home with its everyday name. But as that spinster bee, together with other spinsters, continued to drag into the hive other spick and span bulging suit cases, one could distinctly overhear in their excited humming, unanxious approval of the poppy, which only a poet may interpret.

"... Not all proud Seeba's queenly offerings
Could match the golden marvel of thy bloom..."

Brimmed with the golden vintage of the sun."

Other spinsters, more decorous, with nectar hidden from public view, were drowsily chanting of the lupine intermingled with the poppies—"snowy and amethystine in seas of red bloom."

But only the gardener knows the intimate history of our flower which is kith and kin to that other flower whose essence has enslaved an entire nation, although she claims that our poppy has never been guilty of a greater offense than giving the Indian a few hours of happy forgetfulness, or, possibly, raising the hopes of certain elderly Spanish Californians who were wont to put their faith in a hair-restorer distilled from it.

It is clear, then, that bees, like other specialists, are limited by their occupations, as flowers appear to mean only nectar and pollen to them. On the other hand, the young gardener's fund of half-forgotten lore concerning all growing things, apparently is inexhaustible.

"The mustard's in bloom!" she had exclaimed only a few days before.

I smiled indulgently and looked in the direction of her gaze. Sure enough, a yellow haze was just beginning to tinge the orchards.

"The kind one buys with a ham sandwich?" I teased.

"Sandwich mustard grows taller and blooms much later," she corrected, and at once took my education firmly in hand.

"What's the difference?" I demanded. "Smells the same."

She broke off a piece and held it up to me. It had a brittle, reedy stalk and smooth, pale leaves. "Field or white mustard," she called it, and added, "Some know it as wild turnip."

"Then what's this?" I triumphantly held up to her a plant with rough, hairy leaves, but with the same pale yellow flowers.

"Migra, or black mustard," she

ESCHOLTZIA CALIFORNICA

"On hills and plains, lifting, exultant, every kingly cup."

promptly retorted, and informed me that it was much used by our pioneer grandmothers as early "greens," and that in a similar manner the native Indians, long before pioneer days, had used the herbage of the California poppy.

But that is not all my young gardener knows. I say **my** gardener, for I am resolved that no other shall ever invade the walled garden of my bachelor heart. She has seen the poppies unfold, and laughed at the red-winged blackbird plunging down into the feathery depths of the mustard's lace-like foliage, or tilting about on the slender stems. She has watched the fields of pale green change into a magic carpet of "golden dust," as the flowers opened in the spring sunshine. She knows that but for the amber liquid distilled from those blossoms, young bees hatching in March would often go hungry to bed, or more probably would never hatch at all. Numbers of spinsters, the coveted liquid concealed on their persons, were, at that very moment, hurrying from her father's orchard back to the nursery.

Still another thing she knows. That wise little gardener is perfectly aware that they are my bees. We had once stolen out and watched the invaders taking their buccaneering way across the valley, plundered flowers swooning in their wake. I wondered if she ever watched my bees now. If only I could be certain! But why not find out? Surely one has the right to follow one's own property!

So I followed my bees, quickly, lest I should falter in traversing the intervening mile to the poppies, then on a little further to the mustard.

And there, knee-deep, in that magic carpet of inextricable fragrant network, stood my gardener—my magic girl with erect golden head matching the pale yellow flowers that filled her arms, waiting for the magic words she wished me to speak and that I had only been waiting the courage to pour into her small pink ear to perfect the magic of that wonderful spring day.

All around us hummed my bees. But we remained unobserved. Romance like ours is not for the Marthas of beddom. Los Gatos, Calif.

The Nutrition of the Honeybee

By R. Adams Dutcher

Division of Agricultural Biochemistry, University of Minnesota.

IF you had gone to the average biologist a few years ago and asked him the question "What are the facts regarding the nutrition of the honeybee?" the chances are ten to one that he would have answered, "That is a chemical question; I am interested in the biological field and cannot answer your question." Had you then sought an answer to the same question from the chemist of that day he probably would have answered, "I am not acquainted with the anatomy and physiology of insects and it is a question upon which I have no

knowledge. I am a chemist, not a biologist."

This viewpoint is fast disappearing, for, through the development of biological chemistry during the past few years the chemist is becoming more thoroughly a biologist and the biologist is becoming better versed in the fundamental sciences.

Our knowledge regarding the food of the honeybee and its functions is relatively meagre; in the short time allotted for this paper I shall merely indicate a few facts regarding our present knowledge of nutrition as applied to the higher animals and bring to your attention a few facts which may be of importance in the development of the honeybee.

Chemical analysis shows all living organisms to be composed of complex chemical substances which are being continuously broken down and rebuilt during the life of the organism. In order that the organism may best perform its natural functions it is necessary that the right kind of chemical materials be furnished in correct proportions and in sufficient quantity. The food is the source of these chemical materials.

The chemical substances which are present in the food materials of higher animals and which must be present for normal growth and development are (1) the protein, (2) the fats, (3) the carbohydrates, (4) mineral salts, and (5) growth-stimulating substances sometimes known as vitamins.

The Proteins

This class of chemical compounds is characterized by a large proportion of nitrogen, which is valuable in building of muscle, nervous tissue, bone, cartilage, hair, and in the case of insects, the hard, shell-like coat to which the softer tissues are attached. In Table I will be found a list of the important foods used by man and domestic animals in which the content of protein is expressed in per cent.

Table I—Protein Content of Some Common Foods

Human Foods—	Per cent.
Meat	16.00 to 20.00
Eggs	12.00 to 13.00
Cheese	24.00 to 26.00
Wheat	10.70 to 13.30
Rice	7.00 to 8.00
Potatoes	1.80 to 2.20
Milk	2.00 to 6.00
Stock Foods—	
Alfalfa Hay	14.00 to 18.00
Cottonseed Meal	40.00 to 42.00
Wheat Bran	14.00 to 16.00
Timothy Hay	2.50 to 3.50
Soy Beans	34.00 to 35.00
Bee Foods—	
Pollen	17.00 to 27.00
Honey	0.10 to 0.50

The Fats

These chemical substances function in the animal body as fuel materials, furnishing heat and energy. The typical fats used as human food are butter, lard, oleomargarine and the vegetable oils. It will be noted that the foods listed in Table II contain relatively small quantities of fat. This is not of great importance, for the animal is capable of manufacturing fats from carbohydrates.

Table II—Fat Content of Foods and Feeds

	Per cent
Milk	1.60 to 6.60
Beef	8.00 to 20.00
Fruits	0.20 to 1.50
Vegetables	0.10 to 0.70
Cereals	1.00 to 7.00

The Carbohydrates

This class of chemical substances also serves as fuel material in the animal body. The sugars, starches and gums are the most valuable carbohydrates and are found in the following foods:

Table III—Carbohydrate Content of Foods

	Per cent
Fruits	6.00 to 25.00
Vegetables	5.00 to 28.00
Corn Starch	89.00 to 91.00

A CALIFORNIA POPPY FIELD.

Cereals -----	65.00 to 78.00
Sugar (cane) -----	100.00
Maple Sugar -----	92.00 to 93.00
Honey -----	75.00 to 81.00

The Mineral Salts

In order to obtain the mineral elements necessary for normal life processes, the animal must receive a varied diet, for many foods are actually deficient in mineral matter. The mineral content of some common foods is given in Table IV.

Table IV—Mineral Content of Foods and Feeds

	Per cent
Corn -----	1.50
Starch -----	0.30
Sugar -----	None
Wheat -----	1.80
Wheat Flour -----	0.60
Rice Hulls -----	18.00
	(96% is silica)
Oil Meals -----	5.00 to 8.00
Alfalfa Hay -----	7.40
Honey -----	0.18

Vitamines or Accessory Food Substances

In the last few years it has been found that certain food mixtures which contain sufficient quantities of protein, fat, carbohydrate and mineral matter, will not permit an animal to grow well unless certain chemical compounds are present. The nature of these substances is still unknown, but it has been found that such foods as butter fat, egg fat, milk, vegetables, fruits and certain grains contain these mysterious substances in relatively large amounts.

The Food of the Honeybee

In general, there are two types of food utilized by the honeybee, honey and pollen. Honey is manufactured by the bee from floral nectar and honeydew, the former being the more important from the commercial standpoint. The amount of nectar produced by the single flowers is very small and has led to much speculation regarding the number of flowers necessary to produce one pound of honey. The evidence would indicate that 50,000 to 1,000,000 flowers are required for this purpose.

Some of the older scientists studied the amount of honey carried by a single bee and concluded that a bee would have to make 2,500,000 trips to produce a pound of honey. Mr. Dadant has called my attention to the fact that this figure is much too high. He is of the opinion that a bee does not require more than 25,000 trips to accomplish this result, and this is in agreement with statements in ABC and XYZ of Beekeeping. According to the figures of Collin submitted by Mr. Dadant, the number of trips should be about 26,700; but this is assuming that the bee is carrying the concentrated honey. Analyses of floral nectars show the per cent of water to vary from that of honey (17 per cent) to more than 80 per cent. If the nectar contained 76 per cent of water, as indicated in Table V, the number of trips necessary to produce a pound of honey would be 3,46 times 26,700, or 92,382 trips. It is therefore safe to say that the bee will average (in round num-

bers) about 60,000 trips to produce a pound of honey.

Analyses of nectars from two different sources are given in Table V.

Table V.

	Invert	Cane	Ash
	Sugar.	Sugar.	Sugar. Etc.
Nectar. Hoya Carnosa	59.23	4.99	35.65
Honey Suckle	76.00	9.00	12.00

Table VI shows the total sugar content in Sainfoin nectar and the resulting honey.

Table VI.

	Cane	Invert
	Sugar.	Sugar.
Sainfoin Nectar -----	57.20	42.80
Sainfoin Honey -----	8.20	91.80

There are two important changes which must take place before the nectar may be termed honey. First, the water content must be lowered by evaporation, and, Second (as shown in Table VI), the cane sugar must be broken down to the two simple sugars, glucose and fructose. This mixture of simple sugars is commonly known as invert sugar, or reducing sugar. The changing of sucrose or cane sugar to invert sugar is brought about by enzymes or ferments in the body of the bee.

(To be concluded in our next issue.)

Moving Bees

SEASONS like 1917, when but a few miles difference in location determined whether the crop was good or a failure, demonstrate very forcibly the importance of being prepared to move an apiary on short notice. To the beekeeper who is fully equipped, moving is not a serious matter, provided he has a suitable location to which he may go.

The replacing of the horse by the automobile has removed the most serious element of danger. Nine in every ten cases of misfortune in moving bees have been caused by the bees stinging the horses. If the hives get broken open on an auto,

there is no trouble because of the necessity of unhitching frightened horses.

While in cases of long moves, it is necessary to use a freight car, most of the apiaries nowadays are moved by means of autos. A distance of fifty to a hundred miles can be covered at a less cost by motor truck than by freight, with a saving of time and with less injury to the bees. If the bees are to go into a car, it is necessary to haul them to the car, and again on unloading to haul them to the apiary site, so that they must be handled much oftener.

It is rather a simple matter to move an apiary by auto. However, two things must be looked after carefully, ventilation to prevent possible smothering of the bees, and protection from the effect of jarring, which might break the combs or throw them together in such a way as to crush the bees. To make sure of proper ventilation, every apiary should be provided with a sufficient number of moving screens for one load of hives. The moving screen is made of a shallow frame about an inch and a half in depth, just the size of the top of the hive, covered with wire netting the same as used for fly screens. In moving, the top is removed from the hive and the screen put on its place and fastened with staples made for the purpose. With the entire top open, and a clustering space an inch or more in depth, there is little danger of smothering except in extremely hot weather. At such times it may be desirable to put a similar screen on the bottom of the hive in place of the regular bottom-board, and leave a small space between the hive and the bed of the auto. Strips should be across the hives before a second tier is piled on them, to provide for a sufficient circulation of air. Piled up in this way, the bees can be moved on a hot day with little dan-

AN APIARY THAT WAS MOVED FIFTY MILES BY OUR STAFF CORRESPONDENT WITHOUT LOSING A COLONY OR BREAKING A COMB.

ger, since there is a current of air as soon as the car is on the move.

A still better and safer plan, when the bees are to be handled by people who may not be aware of the danger of smothering them or of tearing the screen and allowing them to escape and perhaps cause accidents, is to nail over the screen, at each end, strips an inch in width and thickness, and over these strips nail a board which will thus protect the screen and also shade the bees from the direct rays of the sun, in case the hive was exposed to them at any time. The ventilation then comes over the screen from both sides. A similar protection may be used at the bottom. There is then no danger of the bees being smothered by the too close piling of the hives on one another.

After trying various plans of fastening the frames to prevent jarring, the writer prefers the use of paper, as suggested by J. L. Byer, of Canada. Where the Hoffman self-spacing frames are used, it is an easy matter to move, since the frames will be sufficiently rigid without special preparation. Loose hanging frames would very quickly be loosened by the motion, and disaster would attend the moving if they were left unfastened. If a pile of old newspapers is handy, one can prepare a hive in a very few minutes by crushing a small roll of paper into the spaces between the tops of the frames. It is surprising how solid they will be if paper is placed between the frames at each end, and how nicely they will take a long journey. The apiary shown on the big truck in the illustration was moved fifty miles, without the loss of a single colony or damage to a single comb.

In loading the hives on the truck, the frames should be placed crosswise of the car, as the jar will be from sidewise motion. In loading a freight car the frames should run endwise of the car, since the jar will come from bumping the cars from the ends.

If one has new hives and good moving screens, it is a simple matter to close up the hives in preparation for moving. If the hives are old and the screens do not fit well, newspapers come into play to close up all holes, and serve the purpose admirably. It is well to put on all moving screens the afternoon before the bees are to be moved, and leave the entrances of the hives open as usual. After the bees have stopped flying at night, the entrances can be closed, and the bees will be ready for an early start the following morning.

When releasing bees in a new spot, it is very important that they should realize the change of location, so they may reconnoiter, in a manner similar to the first flight of the young bees, and learn the location of their new abode. When they have been transported long distances they realize the unnatural conditions and make the usual circles about the entrance. But if carried only a short distance

with much care, and if they have been set down upon their new stand at night, some of them may, the next day, take flight without looking behind. To avoid this we use a slanting board or some other obstruction in front of the entrance, so that they may at once notice that things are not as they were. After the first flight there will be no danger.

Efficiency in Beekeeping

By Morley Pettit.

THERE is a word to conjure by in production. It nearly won the war for Germany; humanly speaking, it will win the war for the Allies. That word is **Efficiency**.

The idea has revolutionized manufacturing and business. It is now revolutionizing beekeeping. What is it?

A negro went to the bush for wood. He stopped his mule-wagon ten feet from the pile while he loaded it, walking back and forth. When he had enough in the box for his old woman to get dinner, he drove home. That was not efficiency. To drive close and eliminate carrying, to load well and avoid extra trips would be a step in that direction.

Every task requires certain operations and each operation certain motions. To study to reduce the number of operations and of motions, thus saving time and energy, is the mechanical side of efficiency. Every thoughtful beekeeper is doing it more or less. He calls the result "short cuts." Sometimes they are not the surest way home.

Carried to its extreme, efficiency makes machines of men. Repeating the same operation day after day and week after week destroys constructive thought and separates the daily task from the joy-of-doing which should accompany it. In beekeeping this cannot be. Seasonal changes make it impossible. Varying conditions make even good system difficult, but all the more desirable. Systematically performed, the daily tasks of beekeeping become a joy of constructive thought and of purposes accomplished. Even when reasonable conditions spoil results, plans and preparations immediately go forward to "next year," when better returns are expected.

At its worst, commercial beekeeping is a series of little pottering jobs done to scores or hundreds of colonies. At its best, it is a system by which each colony is intelligently given necessary attention at regular intervals being determined by the beekeeper's judgment of seasonal weather and colony conditions. The beekeeping expert is the doctor and each colony is a patient. The doctor must have his science and his system and then vary the application of them to individual needs. He may employ several pairs of unskilled hands in the process, to lift and fetch and carry, but his part cannot be well done by rule or proxy.

In other words, beekeeping efficiency is very different from me-

chanical efficiency. Very few operations in the actual care of bees have been successfully standardized or reduced to rule of thumb. That is where the novice fails when he reads how Mr. — does so and so. He tries to do likewise, misses important points which Mr. — probably observed unconsciously and failed to record, and mentally charges Mr. — with incompetency. The real reason for his failure might be charged to lack of experience. It might also be charged to lack of analysis and proper expression on the part of Mr. —.

When beekeepers learn "experience" instead of, or experience with, methods, they learn to judge the methods of others and to devise methods which will suit their own conditions best. They also learn to vary from colony to colony and from day to day, yes, and from season to season, the application of their standard methods according to conditions which are found to exist.

This "experience" is known to be of paramount importance, and according to tradition, is to be had only after many years of unprofitable labor, by allowing a very small apiary to grow only as experience grows. However that may be, it is the fundamental knowledge on which all successful beekeeping practice is based. Not many who have obtained it by the laborious process are able to reduce it to language. They are like the old cook who was asked for the recipe of a certain delicious cake she made. "Wall, honey," she said, "if you-all put in the things that I put in, and mix them the way I mix them, you'll have as good cakes as I make." They attempt to convey their experience in terms of methods and appliances, and they succeed to a limited extent in the hearing of other experienced beekeepers.

If all the experience or knowledge of bees and the conditions related to their "keeping" now in the minds, mostly subconsciously, of successful beekeepers were reduced to language abstracted from unimportant details of multifarious methods, if this were published and every honey producer led to read and digest it, the development of the industry would be phenomenal.

Let me put this in another way. Beekeeping is keeping bees—delicate insects, extremely complex organisms, highly sensitive to stimuli such as light, temperature, humidity, electricity, vibration, air currents, odors—to a thousand phases of environment not named or not determined. Their activities are subject to these and to numerous physiological and colony conditions which multiply variations of behavior and complicate control.

Man has not learned to change appreciably bee-nature by breeding. The multitude of individuals and the brief life-span of each precludes any attempt at training bees, were such a thing possible. In common parlance my bees do not "get to know me." I try to know something about them. The extent of my knowledge

of them limits my success in "keeping" them.

Efficiency in beekeeping, then, falls under two heads: on the one hand a knowledge of bee-nature, with the means of preventing undesirable behavior, such as swarming or dying in winter, and of promoting behavior which is to be desired; on the other hand, the simplifying of these "means" so as to obtain the best results with the least expenditure of time and energy.

I have said that methods of bee management cannot be standardized. I will say now that they **must** be standardized. Before the busy season opens I must have definite plans as to how I am going to proceed to control or prevent every phase of undesirable behavior, and to promote all bee behavior which is to be desired. That every colony may have its fair share of attention the days for visiting each apiary at regular intervals must be arranged by the **calendar** well in advance. Even internal conditions which may be found in various colonies on different periodical examinations may be classified and the treatment each shall receive determined. It is true that these conditions will shade off into one another and that their treatment will depend on conditions and trends of the season; but the previously thought out plans will be a guide, though not a rule, of action.

Efficiency in a seasonal occupation like beekeeping makes the most of

each season in turn. In the swarming season, for instance, swarm-prevention has the pre-eminence. I have no time to extract during a northern clover flow. If I spent half my time extracting then I would know that with an adequate supply of supers I might manage almost twice as many bees with a chance of doubling my crop. I would be sure that tiering up would improve my honey, besides distributing the labor. A study of the average beekeeper's season would show that much of the work of his busy time could be done before and after.

Efficiency seeks definite knowledge and mastery of the situation. I can learn to judge of colony conditions to a limited extent by studying the flight of bees at the entrance. But diagnosis is uncertain, leading to haphazard methods or a wholesale application of radical treatment, both of which are undesirable. A thorough examination of each colony at stated intervals gives individual attention and provides the occasion for all the manipulations necessary for securing a crop and leaving each in the best condition for winter.

Hives, buildings and appliances are tools used in the production of honey. They are as important as the tools used in the factory or on the farm. Hives deserve special consideration because bees use them as well as men.

Georgetown, Ontario.

things are right—you must **know** they are!

JOSEPHINE MORSE,
In Country Gentleman.

Honey Gingerbread

½ cup sour milk.
1 cup extracted honey.
1½ teaspoons soda.
1 level tablespoonful ginger.
½ cup lard or fat.
2 eggs well beaten.

Flour to make thin batter. Mix soda with sour milk and add rest as listed. Bake in moderate oven 45 to 60 minutes, in shallow pan.

If when making light bread, by omitting lard and sugar and using the same amount of honey, you will find a great improvement in flavor.

MRS. MARY KING.

Nourishment in Honey

(Mary A. Porter, in "Good Health.")

In early times, until cane sugar was introduced from the tropics, honey was the most common sweet substance available for food in the temperate zone. Before beekeeping gave a better and more economical supply, the wild honey found in rock crevices and in old trees was highly prized. Wild honey is still gathered in some countries, and in Peru it is an important export. Floral or normal honey is made from nectar, a sweet liquid secreted by flowers. The flavor and aroma of the honey depend upon the blossoms from which the bees extract the nectar. Each flower secretes its own combination of oils and substances, which give the blossoms their special fragrance. This peculiar flavor is detected in the honey—clover, buckwheat, fruit blossoms, etc. There is a choice variety of French honey from Narbonne which has the flavor of wild thyme and other mints. In districts where oranges grow, we get an orange blossom honey.

It is the custom of dealers to mix several honeys in order to produce a blend that is usually more satisfactory than an unmixed honey of pronounced flavor.

Honey extracted from the comb is easily adulterated, but the pure food legislation has made such adulteration dangerous and unprofitable, and for this reason the strained honey on the market is largely pure.

Like most foods, honey varies more or less from its average composition. The syrup contains about four parts sugar to one of water. There are several kinds of sugars present in honey, for the most part grape sugar and fruit sugar.

Honey also contains a small amount of magnesia, lime, phosphoric acid, iron and protein; however, the sugar so largely predominates that the food value of the other ingredients need not be considered.

In choosing honey, too much importance should not be attached to lightness of color, for some of the best varieties are dark.

How to Keep It

Honey should be kept in a dry place in the house, otherwise it is likely to absorb moisture and spoil.

BEE-KEEPING FOR WOMEN

Conducted by Miss EMMA M. WILSON, Marengo, Ill.

Racing the Stingers

While speaking of stings I want to tell an adventure I had several summers ago, no repetition of which is desired. It was at a time when the main honey flows in this vicinity were over and there would be a period of three to four weeks with nothing doing until goldenrod and asters came into bloom.

So I conceived the idea of taking one hive to a location six miles away beside a large pond surrounded with clethra, commonly known as white alder or pepper bush.

This bush secretes a large amount of nectar, of which the bees are very fond, and was just starting to bloom.

So I closed the entrance of a hive tight and secure, as I thought, hoisted it into the back of a buggy and started off alone. I had gone about a quarter of a mile when I felt a sting on the back of my neck. Leaning back, what was my horror to see the bees tumbling out through a small opening in the entrance, which must have been made by something joggling loose as we drove along.

I tried my best to throw a light laprobe over the hive, but by that time the bees were beginning to get acquainted with the horse, with the

result that I had to devote my attention to the reins. I couldn't stop to take out the hive because it was only by galloping the horse that the bees could be kept at all at bay.

Even at that, they hurled themselves like little javelins at us. Afterward thirty-eight stings were counted on the back of my neck!

I knew if I slowed up they were likely to get the upper hand and perhaps sting us both to death. So on we went, finally swinging round a circle in a neighbor's yard and heading for home. Luckily a man was beside the roadside pump in front of the stable, and it took only a jiffy to throw a blanket over the now crazy, plunging horse, unharness and rush him into the stable and shut everything up.

Those bees continued to rage riotously all morning, issuing from the hive in streams.

Later I managed, all bundled up in coats, bloomers and gloves, to get them back to their old stand.

It was a more fortunate ending than I deserved for such carelessness, but at any rate I learned from that experience that to be a successful beekeeper you must not just **think**

It should not be kept in a cold place, and never in the refrigerator.

The chemical change effected by the bee in the sugars of the nectar is the same as that produced by digestive ferments. The honey sugar has, therefore, undergone the first stage of digestion. It is because of this predigestion that honey is more wholesome than cane sugar. Eating too much honey will upset digestion, but not so soon as when too much ordinary sugar is eaten. Too much of either should, of course, be avoided.

Whether strained honey or comb honey is eaten, is a matter of choice. For those with delicate digestion, the particles of wax in comb honey may cause trouble, but for normal persons such small bits of wax as may be swallowed are as harmless as are the particles of indigestible material in many other foods.

Honey has a mildly laxative effect. Bran biscuits made with honey are more laxative than the ordinary bran biscuit. Older writers have claimed medicinal properties for honey, but this is largely a matter of tradition. Honey is a food and not a medicine. It is worthy of much more extended use, especially in cooking, because of its agreeable and economical features as well as because of its wholesomeness.

The simplest way of using honey is to serve it like jam or syrup with bread, breakfast cereals, rice, pancakes and other mild-flavored foods. When used on bread, an ounce of honey spreads as many slices as an ounce of jam. When it is to be used as a syrup on cakes, etc., it diluted with a little hot water, it is less sweet and also easier to pour.

Honey can be satisfactorily used for sweetening lemonade and other fruit drinks. Syrup of any kind is more convenient for this purpose than undissolved sugar. Honey can be used in place of sugar for some kinds of preserving, and fruits cooked in it keep very well, indeed.

With Currants

Currants cooked in honey served with cream cheese and crackers or bread make a delicious lunch dish that is also very nutritious. Honey may be substituted for molasses in cookery, as it is slightly acid. It can be used in place of molasses in all kinds of breads, muffins and cakes, and it makes a more delicately flavored product.

A cupful of honey will sweeten a dish just about the same as a cupful of sugar. As there is about one-fourth of a cupful of water in a cup of honey, one should use one-fourth less liquid than the recipe calls for when using honey in place of sugar. No special honey recipes are necessary for making cake, as the substitution of honey for sugar is all that is necessary. And honey used in the place of sugar keeps the cake moist longer. A honey cake made with butter will keep its quality until the butter grows rancid, while one made without butter will keep fresh for months and even improve its flavor. What is true of the cakes, is also true of the dough; it can be kept almost indefinitely.

Many recipes for making cake with honey in the older cook books are very elaborate, and usually direct the honey be brought to the boiling point and then skimmed and cooled. This custom of boiling probably was necessary when the honey was much less carefully prepared than at present, and when it contained impurities of many kinds. As a matter of fact, a cake made by stirring flour directly into cold honey is in no way inferior to cakes made with honey that has been heated.

Icing made with honey, or with part honey and part sugar has the same advantage that honey cakes have. It keeps soft and in good condition for a long time. Honey is not often used in bread making, but there is no reason why it may not be used in place of molasses or sugar in varieties of bread that call for such sweetening.

A few honey recipes are here given, all of them highly nutritious and suitable for children as well as for adults:

Baked Honey Custard

5 eggs.
 $\frac{1}{2}$ cup honey.
 4 cups scalded milk.
 $\frac{1}{8}$ teaspoonful powdered cinnamon.
 $\frac{1}{4}$ teaspoon salt.

Beat the eggs sufficiently to unite the yolks and whites, but not enough to make them foamy. Add the other ingredients and bake in cups or in a large pan in a moderate oven. The baking dishes should be set in water.

Boiled Honey Custard

2 cups milk.
 3 egg yolks.
 1-3 cup honey.
 $\frac{1}{4}$ teaspoon salt.

Mix the honey, eggs and salt. Scald the milk and pour it over the eggs. Cook in a double boiler until the mixture thickens. This custard is suitable for use in place of cream on gelatin desserts, or to be poured over sliced oranges or stewed fruit.

Honey Pudding

$\frac{1}{2}$ cup honey.
 6 oz. bread crumbs.
 $\frac{1}{2}$ cup milk.
 Rind of half a lemon.
 $\frac{1}{2}$ teaspoon ginger.
 2 egg yolks.
 2 tablespoons butter.
 Two egg whites.

Mix the honey and the bread crumbs and add the milk, seasonings and yolks of the eggs. Beat the mixture thoroughly and then add the butter and the whites of the eggs well beaten. Steam for about two hours in a pudding mold which is not more than three-quarters full.

Rolled Honey Wafers

$\frac{1}{4}$ cup butter.
 $\frac{7}{8}$ cup flour.
 $\frac{3}{4}$ cup honey.
 Mix together the butter and honey and add the flour, sifted with the spice. Spread out very thin with a broad, long-bladed knife or spatula on a buttered, inverted dripping pan, or on flat tins made for the purpose. Mark off in three-inch squares and bake in a slow oven until delicately browned. While warm, roll in tubular shape and hold until they are cool and, if necessary, until they harden

into shape. Honey wafers are not quite so tender as those made with sugar.

Honey Mousse

4 eggs.
 1 pint cream.
 1 cup hot, delicately flavored honey.
 Beat the eggs slightly, and slowly pour over them the hot honey. Cook until the mixture thickens. When it is cool, add the cream whipped. Put the mixture into a mold, pack in salt and ice, and let it stand three or four hours.

Yellow Honey Cake

$\frac{1}{2}$ cup sugar.
 2 egg yolks.
 2-3 cup honey.
 $\frac{1}{4}$ teaspoon cinnamon.
 $\frac{1}{2}$ cups flour.
 Sift together the flour and the spice. Mix the sugar and egg yolks, add the honey, and then the flour gradually. Roll out thin, moisten the surface with egg white, and mark into small squares. Bake in a moderate oven.

Honey Sponge* Cake

$\frac{1}{2}$ cup sugar.
 $\frac{1}{2}$ cup honey.
 4 eggs.
 1 cup sifted flour.
 Mix the sugar and honey and boil until the syrup will spin a thread when dropped from the spoon. Pour the syrup over the yolks of the eggs, which have been beaten until light. Beat this mixture until cold; then add the flour, and cut and fold the beaten whites of the eggs into the mixture. Bake for forty or fifty minutes in a pan lined with buttered paper, in a slow oven.

This cake can be made with a cupful of unheated honey in place of the honey and syrup, but the quality is not quite so good.

Breakfast Marmalades

(Sugarless)

As a butter saver, Americans might adopt the English custom of serving marmalade with toast or hot bread for breakfast. Let the fruit supply the sugar to be used in making these marmalades. Their virtue lies in the tartness of the fruit and the fact that they contain only what nature put in the fruits.

Apple-Raisin Marmalade

To one cup ground seeded raisins add one cup chopped apples and one cup of water. Cook until thickened. A little orange and lemon juice and grated rind may be added if liked.

Cooked dried fruit, as apricots, pears, peaches, or prunes may be used in combination with the ground raisins in any proportion desired, and three fruits combined as apricots, apples and raisins.

Catsup added to the marmalades makes a simple fruit relish to serve with cold meat.

Date-Prune Jam

Wash one pound prunes, soak overnight; cook in same water and remove stones. Remove stones from one pound dates and cut in small pieces. Cook with prunes until mixture is thick. Add small amount of lemon juice.

Prune-Apricot Butter

Wash one pound prunes and one-

half pound apricots; soak over night; stew until very soft in same water; rub through colander; return to sauce pan and cook slowly until

thick like apple butter, being careful that it does not burn. Do not add sugar.

LEGAL SERVICE DEPARTMENT

In what way are taxes on bees assessed in Iowa? How much per colony? IOWA.

Under the Iowa law ten colonies of bees are exempt from taxation. Any number above ten colonies are given in to the assessor the same as other property, and they are taxed according to their value. The assessor fixes the valuation. The rate of taxation varies according to the levy of your county.

Can you give me information regarding the present law relating to foulbrood? IOWA.

The new Iowa law relating to bee inspectors reads:

"Upon written request of one or more beekeepers in any county of the State, said apiarist shall examine the bees in that locality suspected of being affected with foulbrood or any other contagious or infectious disease common to bees. If, upon examination, the said apiarist finds said bees to be diseased, he shall furnish the owner or person in charge of said apiary with full written instructions as to the nature of the disease and the best method of treating same, which information shall be without cost to the owner.

"Sec. 3. Anyone who knowingly sells, barter or gives away, moves or allows to be moved, a diseased colony or colonies of bees without the consent of the State Apiarist, or exposes any infected honey or infected appliances to the bees, or who willfully fails or neglects to give proper treatment to diseased colonies shall be deemed guilty of misdemeanor, and upon conviction thereof before any justice of peace of the county, shall be fined not exceeding the sum of fifty dollars, or imprisonment in the county jail not exceeding thirty days."

Mr. Eric Millen, Ames, Iowa, is the State Apiarist in charge of this work, and all letters of enquiry should be addressed to him.

Agreement for Working Bees on Shares

Will you give a working agreement to cover the following:

I am to work bees on shares next year, the owner to furnish the bees just as they are. I do all the work, furnish my own tools, provide my own board, etc. All honey and beeswax is to be shared half and half, each to furnish containers for his own share. The owner of the bees is to furnish all extra supers necessary. All natural increase is to be equally divided, each to furnish one-half of the necessary hives.

It is very desirable that such agreements as the above be reduced to writing and that each party shall retain a copy to avoid possible misunderstanding. This seems to be a case where everything is explicitly provided for. The following is a simple form:

This agreement, made on this 10th day of December, 1917, by and between John Smith and Stephen Brown, witnesseth:

That the said John Smith hereby agrees to lease to Stephen Brown 200 colonies of bees together with the hives and equipment and to furnish such extra supers as may be necessary to harvest the crop, for the season of 1918.

The said Stephen Brown agrees to give careful and prompt attention to the said bees, to use due care to guard against disease, and if disease be found at any time to give proper treatment therefor; to use diligence in saving all swarms that may issue, to provide necessary stores for needy colonies, and to perform all other necessary labor in the harvesting of the honey crop and attending to the usual work of the apiary. At the close of the season he further agrees to return to John Smith the full number of colonies provided with sufficient stores for the coming winter; provided, however, that he shall not be responsible for losses caused by tornadoes, storms or other causes beyond his control.

It is further mutually agreed that all surplus honey and wax shall be equally divided between John Smith and Stephen Brown, and that each shall furnish the necessary containers for his own portion; also that all increase shall be likewise equally divided and that each shall furnish one-half of the necessary hives therefor, and that the said Stephen Brown shall furnish his own tools, provide for his own board and other expenses and that the said John Smith shall not be held liable for any expenses except as herein provided.

Signed this 10th day of December, 1917.

JOHN SMITH.
STEPHEN BROWN.

Leffingwell, Allen; Vice President, Clyde Godfrey, Jonesville; Secretary-Treasurer, Vern Haskins, Osseo.

Oakland County—President, Arthur Houghton, Pontiac; Vice President, W. L. Lovejoy, Clarkston; Secretary-Treasurer, Miss A. S. Sly, Birmingham.

Washtenaw County—President, Floyd Markham, Ypsilanti; Vice President, E. B. Manwaring, Ann Arbor; Secretary-Treasurer, E. Ewell, Ypsilanti.

A number of other county organizations have been formed previously. The following places are scheduled for meetings during the rest of the month: Jackson, E. Lansing, Grand Rapids, Scottville, Big Bear Lake, Elk Rapids, Traverse City, Tawas City, Caro, Bay City, Saginaw and Owosso.

The severe storms experienced here have interfered somewhat with the attendance, but all meetings have been held as scheduled. The attendance has been very satisfactory. The matter of organization has been taken up enthusiastically and the fact that interested and public-spirited beekeepers have been made the officers of the associations insures the success of the organizations. In many places beekeepers have taken part on the programs. Mr. Erbaugh and the State Inspector have spoken on "Wintering," "Spring Management," "Swarm Control," "The Necessity of Increased Production," "Foulbrood" and "Extracted Honey Production." Beekeepers have been urged to increase their production through more efficient methods, by increasing their number of colonies, by buying or renting unproductive colonies, by producing extracted honey instead of comb, by proper winter protection and proper attention during the spring time and by co-operating in the control of bee diseases.

The results of these meetings are of permanent value to the State. Many beekeepers have been brought to the meetings who have never before attended a meeting where apicultural subjects have been discussed. All have been urged to ask questions and to discuss fundamental problems freely, with the result that many persons attending expressed their determination to increase their efficiency and profit by the new ideas gained. It will be necessary to discontinue these meetings during the month of February because the State Inspector also teaches Apiculture in the Agricultural College. The work will be taken up again in March.

B. F. KINDIG,
State Inspector of Apiaries.

MISCELLANEOUS NEWS ITEMS

Bee Meetings in Michigan.—Mr. P. W. Erbaugh, a former deputy of the office of the State Inspector of Apiaries, now a Special Agent of the Federal Bureau of Entomology, has been assigned to work in Michigan for the time being. In co-operation with him a series of county meetings were arranged for January. To date we have held meetings at the follow-

ing places: Marshall, Mason, Williamston, Munieth, Adrian, Hillsdale, Coldwater, White Pigeon, Fenton, Birmingham and Ypsilanti. One of the objects of these meetings is the organization of County Beekeepers' Associations. The following counties organized associations with officers as follows:

Hillsdale County—President, E. A.

Sweet Clover Seed in Demand.—According to the "Seed Reporter" of the Bureau of Markets, Department of Agriculture, Washington, D. C., sweet clover seed is scarce this year, and the prices rule high. The reporter says: "The crop is reported very short and dealers have been scouring the country for available supplies, with but little forthcoming. The stocks on hand are very low and inadequate to meet the spring demand. Hulled white sweet clover seed is being quoted in a limited

way at from \$20 to \$25 per hundred pounds."

What a change in a few years. The poor, despised sweet clover is at last coming into its own. The time should not be far off when beekeepers will begin to notice the effect of the increased plantings by additional forage for their bees. This is true already in the South and many parts of the west. Should this clover supplant the red clover, it will become true almost everywhere.

West Virginia Meeting.—The Pan Handle Beekeepers' Association will hold their spring meeting March 27, Market Auditorium, Wheeling, W. Va., and in all probability the West Virginia State Beekeepers will hold their annual meeting at the same place on March 28, which will make a two-day meeting. The following persons will be present to address the meetings: Mr. T. K. Massie, President of the West Virginia State Association will have and demonstrate the Massie hive. Mr. Adam J. Yahn will have a Langstroth hive and will demonstrate the proper way of putting the Langstroth together. Mr. Yahn is one of our deputy inspectors and he tells me that it is surprising how many people do not know how to assemble a Langstroth hive. Mr. W. E. Seaman will give us a talk on sweet clover, the benefit it is to the beekeeper, how the farmer can get bigger and better crops by growing sweet clover, its qualities for rebuilding our already too poor farms.

W. C. GRIFFITH, Sec'y.

Tupelo Honey Exchange.—In our January number we gave an account of the formation of the Tupelo Honey Exchange in Florida. Since then we have received added information which we give to our readers.

It takes the form of a stock company, its members owning the majority of stock.

They have applied for charter under the laws of Florida with main office at Wenwahitchka, at which place a majority of the producers live, and a branch office at Cordele, Ga., which is the main shipping point of tupelo honey of the South.

The object of this organization is to sell its output through one medium or seller and at a uniform price. If beekeeping has a great future in the South it is in this tupelo gum section and it is hoped through the efforts of this organization to promote it greatly.

In the past, beekeepers living remote knew but little about the honey market and they sold for what they were offered, all the way from 5c to 10c per pound. This has had its effect on the industry there which was very serious and accounts for the slow progress until a few years ago. But its growth has been wonderful of late and with this help it is hoped many more locations in this great belt will be stocked with bees, even by those who are already in the field.

Tupelo gum honey never granu-

lates. Added to this feature its quality for domestic use cannot be excelled by any southern honey.

W. M. Whitney Dead.—We failed to chronicle the death of Mr. W. M. Whitney, of Evanston, which occurred on November 21, last, at the advanced age of 89 years.

Mr. Whitney was a familiar figure at the Northwestern Association meetings in Chicago each year, where

THE LATE W. M. WHITNEY

he took prominent part in the discussions.

Always an enthusiastic beekeeper, and to the last a progressive one, he will be missed from the ranks of his profession. He had been a beekeeper for many years.

Extracted or Comb?—Professor L. V. France, of the University of Minnesota, sends us the following information concerning the courses of beekeeping at the Agricultural College and the opinions expressed by the students concerning the desirability of comb versus extracted honey production. Thirty-seven students were given the question, "Shall I produce comb or extracted honey?" The replies were as follows:

Before 1918—	
For comb honey	11
For extracted	26
For 1918—	
For comb honey	2
For extracted	35

Mr. France adds: "These students appreciate not only the advantages of extracted honey production over that of comb honey, but also the special present war situation requiring the increased production of extracted honey."

Pushing Extension Work.—The new office of State Apiarist in Iowa is getting the work well started. The beekeepers of that State asked for extension work for four years before they could get it. When the new inspection law was passed it provided for extension work also. Prof. F. E. Millen was appointed State Apiarist and has all such work in charge. He has been holding meetings at numer-

ous points in the State during the past weeks, including a short course at the college during the Farmers' week roundup. A correspondence course is announced to reach those not in position to take advantage of the regular courses. Iowa beekeepers are much gratified with the way the new official is taking hold of the work. A series of field meetings and apiary demonstrations are planned for next summer. Any Iowa beekeeper who wishes an apiary demonstration held in his neighborhood should communicate with Prof. Millen, at Ames, as early as possible, since he will have a busy season.

A Michigan Meeting.—The beekeepers of Branch county gathered at the court house at Coldwater, Mich., on January 10 for a one-day beekeeping school. The speakers were B. F. Kindig, State Inspector; Mr. Leffingwell, of Allen, and Mr. Erbaugh, of the extension service. Mr. Kindig spoke on feeding and how to secure sugar for feeding bees; he also talked on foulbrood. Mr. Leffingwell spoke on the production of extracted honey and Mr. Erbaugh on wintering and swarming. About forty were present. CHAS. GALLOP.

New Man at Ames.—Mr. E. M. Atkins has resigned his position with Prof. Webster at the Iowa Agricultural College to enter extension work in the government service. Mr. Wallace Park, of Manhattan, Kans., has been appointed to succeed him in charge of experimental work in apiculture and has already started with the work.

UNITED STATES DEPARTMENT OF AGRICULTURE

Bureau of Markets

Semi-Monthly Market News Bulletin

Honey arrivals since last report:
Medina, Ohio.—1,789 pounds Michigan.

Keokuk, Iowa.—No fresh arrivals.

Hamilton, Ill.—No fresh arrivals.

Markets—Jobbing Prices

(In many markets in the honey trade the term "jobber" is commonly applied to the original receiver who buys direct from the grower in carlot quantities. However, in these reports we use the term "wholesale carlot receiver" to designate the carlot purchaser, while the term "jobber" refers to the dealer who buys in less than carlot quantities from the carlot receiver and who sells direct to retailers. The prices quoted in this report represent the prices at which the "wholesale carlot receivers" sell to the "jobbers.")

Note: Arrivals include receipts during preceding two weeks. Prices represent current quotations.

St. Louis.—Comb honey: No supplies; extracted, supplies light. Cans, bright amber 16-18c per pound; dark amber 15c. Beeswax; no sales reported.

Denver.—Comb honey: receipts very light. Extracted, approximately 27,000 pounds arrived. Comb honey: sup

plies practically exhausted; no sales reported. Extracted honey: demand and movement good; white to light amber 16-17c per pound. Beeswax: receipts light; price to producer, yellow, 38c per pound.

New York.—Arrivals: 30 barrels, 25 casks Porto Rico, 3 barrels Santo Domingo, 675 barrels Cuba, 177 barrels Chile, report probably incomplete. Local demand moderate, market steady; export demand good, but hard to secure ship space. Extracted honey: domestic light, best 20-22c per pound; West Indian light, 19-20c; dark, 17-18c per pound. Beeswax: 104 bags, 12 boxes Porto Rico, 5 bags South American arrived; demand good, market strengthening. West Indian, yellow, 39-40c per pound; dark, 37½-38½c.

Cincinnati.—Extracted honey: one California arrived; local receipts very light; demand good, market firm, movement moderate on account of high prices; domestic, light amber 17-18c; orange and white sage, 22c. Comb honey: supplies practically exhausted; demand and movement good, market strong; fancy white heavy, \$5.50; No. 1 white heavy, \$5.25 per 24-sectional case. Beeswax: demand and movement good; market strong; average yellow, 43-45c per pound.

Chicago.—No fresh carlot arrivals. Receipts very light. Supplies very light. Stock from nearby States: Comb honey, best 23-25c per pound. Extracted honey, best 17-18c per pound.

Philadelphia.—360 cases comb from Vermont arrived. Practically no demand or movement; market very strong; very few sales. Comb honey: Vermont, amber \$5 per 24-section; case; dark amber, \$4.75. Extracted honey: no arrivals; no sales reported. Beeswax: No arrivals; no sales.

Kansas City.—No carlot shipments arriving. Demand limited; movement slow; market strong; few sales, all sales in small lots. Extracted honey: jobbing prices, California and Colorado, white and light amber, 17-18c; dark, 14½-15½c. Comb honey: sales direct to retailers, Californias, 24-section cases, No. 1, \$5.50; native 24-section flat cases, No. 1, mostly \$6. Beeswax: no fresh arrivals. Buyers paying 35-40c per pound.

Minneapolis.—No arrivals. Supplies very light. Demand moderate; market firm. Comb honey: 24-section cases Minnesota white, best, few sales at 18-19c, mostly 18c per pound; Colorado white, mostly at \$5.50. Extracted honey: Minnesota, 60-lb. cans, best mostly 19c per pound. Beeswax: no sales.

St. Paul.—No arrivals reported. Supplies very light. Demand moderate; market firm. Comb honey: Minnesota, 24-section cases, fancy white, \$5.50; No. 1 mostly at \$5. Extracted honey: no sales reported. Beeswax: no sales.

Manual of North Carolina Association.—The first manual of the North Carolina State Beekeepers' Association is just out. It is a pamphlet of 24-pages giving a history of the for-

MEMBERS IN ATTENDANCE AT THE NORTH CAROLINA MEETING. THIS STATE IS FAST BECOMING A "PROGRESSIVE" IN BEEKEEPING RANKS.

mation of the association, its constitution and by-laws, recommendations and general information.

The association unqualifiedly indorsed movable-frame hives, Italian bees, extension work, more care of bees, bee clubs for boys, specialization in one branch of beekeeping.

There is then given a summary of educational extension work done, list of dealers where standard supplies can be obtained, names of bee journals and bee-book publishers, a plan of meetings, and list of members of the association.

North Carolina ranks among the first of States in number of bees. Up to the last year or two very few of these bees, however, were in anything but box-hives. With the wide-awake organization they have now and with such men as Franklin Sherman, Bruce Anderson, C. L. Sams and others pushing, North Carolina should in time assume her place as a honey producer of the first rank.

Feed and Save the Bees

To the Beekeepers of Massachusetts:

The honey market is experiencing unprecedented demands. More honey should be produced in 1918; hence, save your bees and prepare for maximum production.

Colonies in various localities of the State, by force of circumstances, have insufficient stores to enable them to survive the winter. (To winter a colony in Massachusetts requires at least 30 pounds of stores; calculate in proportion the emergency needs.) By arrangement, candy stores to save the bees become available about January 15, through the co-operation of the Sugar Division of the Massachusetts Food Administration which—

"Realizes the value and importance of beekeeping and has prepared to support by suitable arrangements the measures now being undertaken by the Massachusetts State Board of Agriculture for the relief of the beekeepers throughout the Commonwealth."

It is Necessary to Act at Once

First. See what further stores your colonies immediately require. It not

being wise to try to feed sugar syrup during winter, try to supply additional stores in the form of candy. This, in the emergency, becomes available about January 15, at distributing centers as below.

Second. Then if your colonies are not protected and packed to keep them warm, do this at once. (Information will be sent upon request.)

Distributing Centers

It having been impossible to arrange sugar distribution for home candy making, the Board of Agriculture has designated the following as distributors of soft candy for bees during the emergency:

Boston—H. H. Jepson, 182 Friend street.

Springfield—A. C. Andrews, Box 1474.

Worcester—Ross Bros.' Company, 90 Front street.

Orders, which will be accepted only from Massachusetts beekeepers, should be sent to your nearest distributor, accompanied by cash, and for the least possible candy necessary. Later in the season further supplies of candy should be available, hence, please do not stock up with more than you must use at present.

The number of colonies to be fed should be stated with your order.

Directions for Feeding

Candy is procurable in paper pie plates or paper dishes. These are to be inverted (candy side down) directly over the bees, on top of the frames, in an empty super. A two-pound package is estimated to serve a colony about three weeks. One or more slabs of candy may thus be placed in a super and replaced as often as necessary. Over the candy, fill the super with insulative packing (any dry, warm material) in order to conserve all the heat possible. Keep everything dry.

If it is a cold day, work rapidly, but feed rather than to starve your bees. Do not delay feeding.

Very truly yours,

BURTON N. GATES,

Inspector of Apiaries and Collaborator U. S. Bureau of Entomology, Bee Culture Investigation.

DR. MILLER'S ANSWERS

Send Questions either to the office of the American Bee Journal or direct to
DR. C. C. MILLER, MARENGO, ILL.
He does NOT answer bee-keeping questions by mail.

Making a Colony Queenless—Demaree Plan

1. In my locality where little honey is coming in after July, and the bees consume a portion of the stores left on for winter, my colonies are in 2, 3 and 4-story hives by the last of July, full of bees, and the hives average from 5 to 16 frames of brood to the colony. As the bees raised from the eggs laid by the queen after the 10th to the 15th of June will be of little value to gather the clover flow and be too old for the best results in wintering, why not take away the queen about the 10th or the 15th of June. If she is a good one save her to increase or requeen and let the colonies raise a new queen, which will help in swarming, do away with the bees that would hatch in time to be consumers, and those raised from the new queen would be in better shape for winter.

Where the flow depends most on the clover would there be any objection to this system?

2. Where can I find the Demaree plan of bee management?

INDIANA.

ANSWERS. 1. I don't know. On the face of it it would look as if your scheme would work out all right; yet it very often happens that a thing that looks good in theory doesn't at all pan out so well when submitted to the bees. The thing to do is to try part of your bees in that way, and see how they compare with the rest. You may find that when the queen is gone the bees will not gather so well.

2. The Demaree plan has been given a number of times in this department, and you will find it in "A Thousand Answers," under the head of "Swarm Prevention."

Here is the plan: When a colony becomes strong at the time when swarms may be expected, and especially when it has started queen-cells, put all but one frame of brood in the second story, leaving in the brood-chamber, or lower story, one frame of brood with the queen, and fill up the empty space with drawn-out combs or frames filled with foundation, having a queen-excluder between the two stories. At the time of doing this, destroy all queen-cells, and 7 to 10 days later destroy any that may be started in the second story. That's the Demaree plan, and it may be used even after a swarm has issued and is returned.

Banat Bees—Buckeye Hives

1. Please give me a description of the Banat bee.

2. Do any extensive beekeepers keep them?

3. Would also like a description of the Albino bees.

4. Do many large beekeepers use the Buckeye hives.

OKLAHOMA.

ANSWERS.—1. Banats look a good deal like common blacks, but with whitish rings. They have the reputation of being very gentle.

2. I don't know; but I think not in large numbers.

3. Albinos are a shade lighter in color than Italians and like Albinos of the human race, are likely to be inferior in vigor, and so not the best gatherers.

4. They fly, but I don't know.

Roasting Out American Foulbrood

To kill the germs at America's foulbrood by roasting the frames with lye, the water warps the wood and the lyce eats the nails. I roast the frames in the oven up to 400 degrees F., over a pan. The pan gets the wax, the heat

gets the germs. The frames get light brown, but not enough to hurt.

OREGON

ANSWER.—Water warps wood, to be sure, but I've cleaned hundreds of frames by boiling them in a solution of concentrated lyce, and found them all right to use afterward. They were of straight-grained pine. If made of basswood—although frames should never be made of basswood—the wet frames might be weighted down in straight piles to dry.

Lye eats nails, yes, and so does water under proper conditions; but I never found the nails in any frames hurt in the solution of lyce. The wax can be saved, too, when you boil.

But your plan of roasting is better if only a few frames are to be treated. If the number is large, I'd rather boil them in a big kettle.

Miller Queen Nursery

Last year I bought about twelve Rauchfuss queen-cages which, according to my opinion would fulfill the purpose of queen nursery.

However, they did not work. It was necessary to put the queen-cells in the cages just one day before emerging, when the bees had loosened the caps of the cells already. Then the virgin could not be kept longer than about a day.

Looking for a substitute I closed a regular frame on one side with a thin board, made about twelve apartments and closed the other side with perforated zinc, so that the bees had access to the cells, but the virgin could not be released. I was very successful this time.

Now, my dear Doctor, if you, in your "queen-nursery," would close one side with perforated zinc instead of using wire-cloth, or if you would cut your eight tiny 10x2 of perforated zinc, you will overcome all the disadvantages of your "queen-nursery." In my nursery I put cells in before they are "ripe."

What do you think about my opinion?

WISCONSIN.

ANSWER.—I could tell better what to think of your opinion if that opinion had been more fully expressed. You think perforated zinc instead of wire-cloth would overcome all the disadvantages of my queen-nursery, but you do not say what those disadvantages are, and I can think of only one. Perforated zinc has been in use for years for queen-nurseries, and more than one disadvantage is connected with its use. Virgins make desperate efforts to get through the perforations, and I've had them die upon being wedged in the openings. Of course, that could not happen with wire-cloth. With perforated zinc the bees may tear down the cells or steal the food and let the baby-queens starve. Of course this will not happen if the nursery is kept in a queenless colony, and is not likely to happen if it is in an upper story over an excluder, but it is often convenient to have a nursery in the same story with a laying queen, and with wire-cloth this is safe. Another point is that if a cell is in any way mutilated the bees will inevitably destroy it if perforations allow them to attack it. Many a time I have cut apart two cells so close together that one of them would have an opening in it, and the queen would mature apparently as good as any, whereas she would have been surely doomed if perforated zinc had been used.

I said I knew of but one disadvantage of the wire-cloth, which is the same as saying one advantage of the perforated zinc. It is that the bees can get into close contact with

the cells. I don't know how much advantage that is. One would hardly think that in the middle of the brood-nest a thermometer would show a higher temperature in a little compartment containing bees than in one without them. Yet even if there be no difference in temperatures, it is possible that the very contact of the bodies of the bees closely surrounding a cell may have some subtle influence of real advantage to the occupant of the cell. Admitting that there is such an influence—and I am quite inclined to think there may be—it may be so little that it will be overbalanced by the several disadvantages named. On the other hand, it may be sufficient to overbalance them all. I don't know.

Requeening—Wintering

1. I want to requeen two colonies; when would be the best time to do so?

2. How long after removing the old queen should the new one be introduced?

3. Should I be unable to find the old queen on the first attempt, how long could I keep the new queen in her cage without any bad effects? Should it be necessary to defer the search until the next day, where should I keep the caged queen?

4. What is the most practicable and safe method of introducing the new queen?

5. Having handled three colonies last summer, hiving two of them, but never having seen a queen, would you advise me to use much smoke in the cages?

6. When a queen is shipped are there any bees shipped with her? If so, what should be done with these bees when the queen is introduced?

7. I am wintering out doors, packing the super with burlap and building a box all around the hive with a 4-inch space on all sides, top and bottom, packing this space with maple leaves, putting on a board cover with rubberoid roofing. I put the regular cover over the super and am beginning to think I should have left it off. Should I?

8. How soon in the spring should I remove the burlap in the super and the winter packing around the hive?

ILLINOIS.

ANSWERS.—1. That depends somewhat on when the question is asked. All things considered, probably there is no letter time than toward the close of the honey harvest. Yet if you want to introduce a pure queen so as to rear queens from her, it will be better not to wait so late, for if you should you would rear no queens from her the same season. So in that case it would be better to replace a very poor one, it will be better not to wait till fall.

2. There is not entire agreement about this. Some introduce the new queen at the time the old queen is removed; some introduce her a day or two after the removal of the queen; and perhaps the larger number put the caged queen into the hive upon removal of the old queen, but have the cage canded so that the queen will not be released by the bees until a day or two later. Some take the still further precaution to give the caged queen upon removal of the old one, but have the candy protected from the bees for a day or two before allowing them to eat it.

3. The new queen can be kept in her cage two or three weeks if there is plenty of food, and she may be kept wherever there is no danger of being chilled, say above 60 degrees, but about the best place to keep her is in the hive into which she is to be introduced, but not allowing the bees to get at the candy to release her.

4. Oh, my! It would take quite a book to tell all the ways that are claimed as best. Perhaps no way is more generally in use than with a provisioned cage in one of the ways mentioned in second answer.

5. There is hardly any way you can make more sure you will not find the queen that to deluge the bees with smoke. Use just as little as possible to keep the bees from flying at

you. If you do not find the queen after looking over the combs once or twice, close the hive and look again an hour or more later.

6. Yes; ten or more workers are in the cage with the nucen, and you pay no attention to them, allowing them to stay in the cage and come out when the queen does.

7. Some say leave the cover on, but the most part would say it is better to leave it off.

8. Better not till bees are flying every day, or even until late in May, unless you are afraid the bees are running short of stores.

Requeening

I have thirty colonies of black bees in my home yard, and I want to Italianize them. Do you think I can do so by buying a pure breeder and requeening them in early May, then requeening again in September with the same breeder in the same yard? Would all the black drones be gone by that time?

In my locality I can rear good queens in May and September. ALABAMA.

ANSWER.—Yes, if in May you replace your black queens with daughters of a pure queen, there would most likely be nothing but pure drones left in your apiary in September. But would it be necessary to requeen in September? Would not the chances for pure stock be just as good if you should wait till the next year to requeen? You seem to take it for granted that there will be no trouble from drones in surrounding apiaries, but that's a matter to be reckoned with unless nothing but pure stock is to be found within something like two miles of you.

Moving Bees

I bought 12 colonies of bees and am going to move them about twenty miles. Is it advisable to remove the packing and cover them over with screen cloth? Of course it will be in the spring when I move them.

LONG ISLAND.

ANSWER.—On a very hot day it would be desirable, and perhaps absolutely necessary to replace the cover with a screen, but on an ordinary spring day it would not be necessary.

Damage in Moving—Age of Queen—Feeding

1. I bought a few swarms of bees on frames not wired, but joined together. In moving them I broke the combs and some of the honey is running out. How would you treat the bees, now or in the spring? They are in furnace cellar now.

2. How do you tell the age of a queen?

3. How much and at what time do you begin stimulative feeding in spring?

4. How much should an 8-frame hive weigh when it is taken out in spring?

5. Would it be better to feed the required amount of honey or syrup at one time?

6. How much sugar does it take to equal a pound of honey fed to bees?

7. How much water do you feed to bees to a pound of sugar. IOWA.

ANSWERS.—1. Let them entirely alone while they are in the cellar, and even till fruit-bloom. Then lift out some or all of the frames that are freely movable, and cut apart the combs that are joined together, where possible crowding each comb into place in its own frame. If the combs are too badly broken down for this,

then you will treat the case the same as in box-hives.

2. By looking in my book to see when she was born or clipped. There is no way by which you can be sure of the age of a queen by her looks, although as you gain experience you can make a pretty good guess by the more or less shiny look of an old queen, and by her slower movements on the comb.

3. I don't begin stimulative feeding in the spring or any other time. I see that abundance of food is present, and that's all the stimulation the bees need. There are places where there is a dearth of pasturage in the spring for so long a time that stimulative feeding is necessary to make the queen lay; but that doesn't happen here, and I don't believe it does in Iowa.

4. That varies. A hive may weigh 40 pounds and contain plenty of honey, while another of the same weight allows the bees to starve. The first has new combs that are light, with little pollen, while the second has heavy old combs loaded with pollen.

5. Generally it is better. 6. Any time early in the season you can feed sugar and water, half and half, but in feeding late for winter use 2½ parts sugar (either by weight or measure) to one of water.

Now, look here; seeing it's you, I'm willing to give you a little friendly advice: Don't go to fooling with sugar for bee-feed. Use honey and save sugar for the allies. Every time you do that you're hitting the Kaiser a whack on the "snout," and goodness knows he needs all

Crop Report and Market Conditions

Honey

Stocks of honey are dwindling to such an extent as to be considered almost negligible. One large bottling firm is now paying 17 cents for good white honey where it can find it, and with but few offerings.

Still a few beekeepers are holding small quantities, "just to see what the market will do." One advises that he has about fifty cases of fancy extracted for which he is willing "at present" to take 20 cents per pound.

A letter from a British subscriber states that the British Beekeepers' Association has recommended a price of 60 cents per section for comb honey at retail and 40 cents per pound for extracted at retail. This, of course, is caused by the extreme demand for honey there owing to shortage of sugar.

Unless our food committees regulate the prices to be received for honey, or unless the war ends in the meantime, we cannot see where the price of honey in this country can drop very low, during 1918.

WINTER LOSSES

Reports from Texas are not very encouraging. Following two seasons of drought and short crop, many colonies have died, probably a larger proportion than in any recent years, and the outlook is anything but rosy. Many beekeepers are abandoning beekeeping altogether and melting up combs rather than pay the prices asked for sugar, which is also hard to obtain.

Only a few reports are coming in from the central sections and from the north. These differ widely. Where bees went into the winter in good shape with plenty of stores and ample protection, the losses seem to be about average.

There is some loss from starvation already and several reports of losses from poor food, combined with long confinement.

MARCH REPORT IN FULL

For our April number we expect to make a detailed report of conditions as reported to us by reporters over the country.

Wax Rendering a Specialty

the whacks you can give him. Then, when the war is over continue the same plan, because honey is better for bees than sugar. "Haven't any honey." Well, that's bad, and you'll have to use sugar. But don't let it happen again. Each year save up enough combs of sealed honey so that you will have an abundance to give to any colony that needs it, and unless your hives are large you will find that most of your colonies will be better for one or more extra combs each spring.

Receiving Shipped Queens

1. I want to send South for some queens for requeening next spring, which I want to do as early as possible. Now, suppose I order queens to be delivered about April 20 and we should happen to get some bad weather for some days so I cannot open the hives, what can I do to save the queens?

2. How long can a queen be kept alive away from other bees?

3. Does it make any difference how far I send South for my queens, or is it better to get them as far North as possible? If so, how far North will they have queens ready for shipment April 15? MICHIGAN.

ANSWERS.—1. Keep them in the house where it will not be colder than 60 degrees, making sure that the food is not exhausted. But I wouldn't think you would want them before at least a month later.

2. I don't know how long without any bees at all; but with the usual escort she would likely be all right for two or three weeks.

3. I don't think it makes any difference how far South you send. You would hardly get queens April 15 without sending south of 35 degrees.

Feeding Honey

We are having severe weather here and my bees will need a little feed in April. Can I feed honey that has soured, next spring, after the bees have a flight?

ANSWER.—After bees are flying daily there is no harm in feeding such honey. But it should not be fed in the fall.

Sugar Candy

1. Would bees live on a cake of sugar if it was placed over the brood frames in the winter or spring?

2. Will bees live on common dry granulated sugar? ILLINOIS.

ANSWERS.—1. They will live on a cake of sugar candy, but I doubt if wetting granulated sugar and letting it dry will make a good cake of candy. You must boil it first.

2. I think not.

Carniolans

I want to keep bees this spring, but I cannot decide what kind to get. I would rather keep Carniolans, because I understand they are the best honey gatherers. Because of their large size, I think the ordinary wax foundations and bee supplies are too small for them. Please tell me if this is so. I want to run for extracted honey alone, and use the Dadant's big hive. Do you think they would do well? WISCONSIN.

ANSWER.—You have been wrongly informed as to the size of Carniolan bees. Ordinary supplies, including foundation, are used with them, and I don't think you could get foundation of larger size if you wanted it. If you had them side by side with Italians I don't think you would see any difference in size. Most beekeepers prefer Italians. Comb foundation of the usual size is used in the big Dadant hives.

A BOOK FOR BEGINNERS

"First Lessons in Beekeeping," written by the editor of this magazine, is intended primarily for the use of beginners in beekeeping. You should have it. Price, postpaid, \$1, or clubbed with the American Bee Journal, one year for \$1.75.

American Bee Journal, Hamilton, Ill.

Queens That Will Please

Over 20 Years of Careful Selecting and Breeding

They are bred from **Imported** stock, the very best for honey gathering and gentleness. They are not given to swarming and are highly resistant to diseases. Give me your order, and after you have given my queens a fair trial, if you are not satisfied in every way that they are as good as any you have ever used, just return them and I will send you queens to take their place or return your money with any postage you have paid out on returning the queens.

Prices April 1 to June 15

	1	6	12

BEEES AND QUEENS

FOR SALE—First-class Italian queens and bees in season. Send for price list. Free from disease; safe arrival and satisfaction guaranteed. M. Bates, Greenville, Ala., R. 4.

BREEDING QUEENS—I have a few extra choice Italian breeders for spring delivery. Price \$5 each. J. E. Wing, 155 Schiele Ave., San Jose, Calif.

OUR BRIGHT ITALIAN QUEENS will be ready to ship after April 15. Untested, 75c each, \$8 per doz., or \$65 per 100. Safe arrival guaranteed. Tillery Bros., Georgiana, Ala., Route 5.

FOR SALE—Fine Italian queens at 90c each, \$9 per doz. Ready April 31. Safe arrival guaranteed. T. J. Talley, Route 3, Greenville, Ala.

THREE-BAND ITALIANS ONLY—Queens, packages and nuclei. Untested queens, each \$1, 6 \$4.25, 12 \$8.25. Write for price list. In later lots, also nucleus and packages; booking orders now. If you consider quality, pure mating and low prices I am your queen-breeder. I have adopted Gleanings Code for the sale of bees and queens. H. G. Dunn, The Willow, San Jose, Calif.

GOLDENS THAT ARE TRUE TO NAME—Queens, nuclei and bees by the pound; we receive hundreds of testimonials annually. Write for list. Untested queens, each \$1, 6 \$4.25, 12 \$8.25. Write for prices in lots. We are now booking orders for early delivery. We have adopted Gleanings code for the sale of bees and queens. Garden City Apiaries, San Jose, Calif.

FOR SALE—Bees. April 15 is the date on which we can ship you the best three-banded bees and queens on the market; we have been in the bee business continually for twenty-four years and have been striving to secure the best three-banded bees and queens that could be had. We have been judging from the many letters we have received from our satisfied customers, we have succeeded in our efforts. We believe we can furnish you with the best honey-gatherers to be found anywhere. You will find our nuclei better filled with bees and brood than any other nuclei you can buy. All our bees are on standard, wired, Hoffman frames; full sheets of foundation. File your orders now, sending money when you want the bees shipped. Satisfaction and safe arrival guaranteed. We quote you, without queen, as follows: Three-frame nuclei, \$2.75; two-frame nuclei, \$2.25; one-frame nuclei, \$1.75; three pounds bees, \$8.75; two pounds bees, \$7.75; one pound be, \$2.00. If queens are wanted with bees, add price of queen wanted. Young untested queens, 75c; young tested, \$1. The Hyde Bee Company, Floresville, Texas.

BEEES AND QUEENS from my New Jersey apiary. J. H. M. Cook, 84 Cortland St., New York City.

TESTED leather-covered queens, \$2.00; after June 1, \$1.50; untested, \$1.00 per doz. A. W. Yates, 3 Chapman St., Hartford, Conn.

GOLDEN Italian Queens, bred strictly to produce Golden bees of the best honey-gathering strain; untested, each, \$1, 6, \$4.25; 12, \$8.25; 100, \$60. Satisfaction guaranteed. L. J. Pfeiffer, Route A, Los Gatos, Calif.

GOLDEN Italian Queens, untested queens, \$1 each; six, \$4.25; \$8.25 per doz., 50, \$32.50; \$60 per 100. Tested queen, \$1.50; one frame nucleus, no queen, \$1.25; 2-frame, \$2.25; 3-frame, \$2; breeders, \$5 and \$10. L. J. Dunn, 54 Broadway Ave., San Jose, Cal.

WANTED—10 to 100 swarms of bees not over 50 miles from Bellevue, Ohio. N. B. Querin, Route No. 7.

FOR SALE—I still have for sale some of the high grade Italian bees, I advertised in the February issue of the American Bee Journal, a year ago. They are in good eight-frame hives. Price, with one super, \$5. Still too many bees in town. Only one block from main street, reason for selling. G. F. Schilling, State Center, Iowa.

FOR SALE—Warranted queens from one of Dr. Miller's breeders; also limited number of package bees. Write for prices. Geo. A. Hummer & Sons, Prairie Point, Miss.

FOR SALE—Mott's strain Italian queens. Plans, "How to Introduce Queens and Increase," 25c. E. E. Mott, Glenwood, Mich.

THREE-BANDED Italian Queens, untested, one, \$1; doz., \$9; nuclei and packages with fine queens, 2-fr., \$3.75; 3-fr., \$4.50; 1 lb., \$2.50; 2 lbs., \$3.50; 3 lbs., \$4.50; June 1. A. E. Crandall & Son, Berlin, Conn.

THE best Italian stock, three-bands and goldens at \$2.50 per pound, without queen; 2 pounds, with queen, \$4. Rosedale Apiary. J. B. Marshall & Son, Big Bend, La.

BOTH Italians and hybrid bees at \$2.50 per pound with untested queen; 2 pounds, with queen, at \$4. Mrs. T. H. Carruth, Big Bend, La.

FOR SALE—Golden Italian bees; 1-lb. pkg., with queen, \$2.50; 2-lb. pkg., with queen, \$4; 2-frame nuclei, with queen, \$3.50. L. J. Bond, Big Bend, La.

HAVE YOU, Mr. Producer, been getting all for your honey that you could expect? If the price you have been getting has been less than the largest price you have read about, let the Domestic Beekeeper, Northstar, Mich., help you dispose of your 1918 crop. Investigate.

GOLDEN QUEENS that produce Golden workers of the brightest kind. I will challenge the world on my Goldens and their honey-getting qualities. Price, \$1 each; tested, \$2; breeders, \$6 and \$10. J. B. Brockwell, Barnetts, Va.

THREE-Banded and Golden Italian Queens and pound packages in spring, from the Sunny Southland. Grant Anderson, Rio Hondo, Texas.

PURE 3-banded Italian queens, untested but warranted, \$1, 6, \$5; tested, \$1.50; 6, \$8. Last year's tested queens, clipped, \$1. Good fat nuclei and full colonies in abundance. Write for price list. J. F. Diemer, Liberty, Mo.

BEEES WANTED—From one to 100 colonies within 200 miles; also used equipment. John P. Geiger, Syracuse, Kans.

BEEES AND QUEENS—What a pleasure when you know and I know and the bees know that you have placed your order to be shipped to you in April and May; no war prices. Write to S. Mason, Hatch, N. M.

THREE-BANDED Italians; untested queens in April and May, one, \$1, 6, \$5; 12, \$9. Tested, \$1.50 each. One-pound packages of bees, \$1.50 each; two-pound packages, \$2.60 each. Add price of queens if wanted. If you want as many as 60 packages write for prices and discounts on early orders. Safe arrival and satisfaction guaranteed. No disease, and all queens purely mated. Cotton Belt Apiaries, Box 83, Roxton, Texas.

GOLDEN and 3-banded Italian queens will be our specialty. We can also furnish Carniolans. Tested, \$1 untested 75c each, \$1.50 per pound, \$1.50; nuclei, per frame, \$1.50. Send your order for bees early. C. B. Bankston & Co., Buffalo, Leon So. Tex.

HONEY AND BEESWAX

FOR SALE—Two barrels amber honey, honest, smartwaxed and goldenrod; 104 gallons in lot, and best offer takes it. J. F. Archdekin, Bordeloville, La.

WANTED—Shipments of old comb and capings for rendering. We pay the highest cash and trade prices, charging but 5c a pound for wax rendered. The Fred W. Muth Co., 204 Walnut St., Cincinnati, Ohio.

WANTED—White or light amber extracted honey in any quantity. Kindly send sample, tell how your honey is packed and your lowest cash price; also buy beeswax. E. B. Rosa, Monroe, Wis.

FOR SALE—Alfalfa white extracted honey in new 60-lb. cans; if interested quote me a price. Sample, 10c. J. M. Mirkes, Box 112, Basin, Wyo.

WANTED—Comb, extracted honey, and beeswax. R. A. Burnett & Co., 6A121 173 S. Water St., Chicago, Ill.

WANTED—Beeswax at all times in any quantity, for cash or in exchange for supplies. Dadant & Sons, Hamilton, Ill.

SUPPLIES

ARE YOU keeping well posted on the crop condition and price prospects for your 1918 crop of honey? If not, you would! The Domestic Beekeeper, Northstar, Mich., will keep you posted on crop condition and price prospects as recommended by the Committee of the Chicago Northwestern Bee Association. This committee, through the Domestic Beekeeper, saved producers a half million dollars on their 1917 crop of honey and expects to do even better on their 1918 crop. Are you one who is not taking advantage of an opportunity never before offered to secure all your crop of honey is worth? This opportunity is worth investigating.

CONSERVATION PASTE—Costs less than 1c per pint; will stick your label on anything any time; easily and quickly made; no boiling; simple ingredients; ready for use in 30 seconds. Send 25c for formula. Money refunded if not satisfactory. Sunnyside Apiaries, Fromberg, Mont.

NORTHWESTERN BEEKEEPERS—Save time and freight charges by ordering supplies near home. Best standard goods, factory prices. Send list of wants, and I will quote lowest prices. Catalog upon request. George E. Webster, Valley View Farm Apiary, Sioux Falls, S. Dak.

FOR SALE—One thousand beehives with supers; three-fourth dovetailed, balance halved together at corners and nailed both ways. Hoffman frames throughout. We will guarantee them to be sound and free from disease. Will sell all or any part at about half what new hives will cost. Apply to The Hyde Bee Co., Floresville, Texas.

200 VEGETABLE PLANTS, \$1, including tomatoes, peppers, egg plants, lettuce, celery, cabbage; 100 flowering plants \$1; choice assortment R. I. Red eggs; day-old chicks, bees, queens, honey. Grubb, Box B 14, Woodmont, Mont. Co., Pa.

"BEST QUALITY" comb foundation for L. or H. frames; 20-pound lot; med. brood, 55c; light brood, 60c. Pure natural beeswax, not "weed" product. J. J. Angus, Grand Haven, Mich.

\$1,200 for the best comb-honey outfit in central Iowa. Box 42, Colo, Iowa.

FOR SALE—A lot of comb-honey supers, 25 and 35 cents each; mostly with sections and foundation; no disease. Also a large show-case 40 in. long, 36 in. high and 24 in. wide; glass on all four sides; price, \$5. A light scale and other supplies. Chester E. Keister, Clarno, Wis.

FOR SALE—Cedar or pine dovetailed hives, also full line of supplies, including Dadant's foundation. Write for catalog. E. Burdick, Sunnyside, Wash.

HONEY LABELS

HONEY LABELS—We have just issued a new and up-to-date catalog of honey labels and stationery. Write for your copy. Neat labels and quick delivery guaranteed. American Bee Journal, Hamilton, Ill.

SOUVENIR Bee Postal Cards, 5 for 10c; "Songs of Beedom" (10 songs), 20c, all postpaid. George York, Sandpoint, Idaho.

WANTED

WANTED—50 to 200 colonies of bees, preferably near home.
H. G. Quirin, Bellevue, Ohio.

WANTED—White sweet clover seed; send sample; state quantity and your lowest price in first letter.
Dadant & Sons, Hamilton, Ill.

WANTED—300 or less colonies of bees for cash and spring delivery. Correspondence, with full particulars, solicited.
A. W. Smith, Birmingham, Mich.

WANTED—Bees: 1 to 100 colonies.
C. O. Smith 5446 Cornell Ave., Chicago.

WANTED—Bees to work on shares or rent; have good location and experience. Write for particulars.
J. H. Waibel, Kawkalin, Mich.

WANTED—To buy a two or four-frame extractor. State condition and price.
Addison Gould, Buckhannon, W. Va.

WANTED—Your old combs, cappings or slurrum to render into beeswax by our high steam pressure wax press.
Dadant & Sons, Hamilton, Ill.

WANTED—We are looking for old bee-books, back numbers of the Bee Journals, listed prior to 1907, and copies of our subscribers who wish to complete libraries of beekeeping literature. Just now we want especially copies of Alley's Beekeepers' Handy Book, the second volume of Cheshire on Beekeeping, and copies of Harrison's and Widman's books. Readers having old beebooks or bee journals which they no longer care for will please write us fully what they have to offer, with prices asked.
America, Bee Journal, Hamilton, Ill.

SITUATIONS

WANTED—Position as student helper in large bee business. Have had some experience. Can give best of reference as to my character and reputation.
Henry Eggers, Eau Claire, Wis., R. F. D. No. 1.

HELP WANTED—Will give experience and fair wage to active young man who is not afraid of work, for help in large, well-equipped apiaries for season starting in April. State present occupation; also age, weight and why exempted.
Morley Pettit, The Pettit Apiaries, Georgetown, Ont. Can.

YOUNG LADY, refined, educated, good worker, desires season on commercial apiary in Southern States; some knowledge of poultry and green-house work.
R. A. F., care Fifth Ave. Bank, New York City.

WANTED—Man to work with bees, season 1918; state age, experience and wages on basis of board furnished by us. Address:
The Rocky Mountain Bee Co., Billings, Mont.

WANTED—By middle-aged man, with experience, 100 to 150 colonies of healthy bees, equipped for extracted honey, to work on shares.
M. Knudsen, Albert Lea, Minn.

WOULD YOU like to receive four or five hundred dollar per hundred more for your 1918 crop of honey than the big buyers will offer you? The Domestic Beekeeper, which will cost you but \$1 per year, will show you how. This is no guesswork; we have done this very thing with hundreds of our subscribers on their 1917 crop, and are willing to do the same by others. You will make your greatest 1918 mistake if you do not, every one of you investigate the work of the Domestic Beekeeper is doing for its subscribers, along the line of buying and selling for them.

WANTED—One or more men of some experience in the handling of bees. Prefer them to be under or past military age and morally of good habits. A good chance for the right party or parties to earn fair wages and learn queen-breeding, the package business and honey production.
M. C. Berry & Co., Hayneville, Ala.

WANTED—Young man for season of 1918, as helper, and learn bee business; experience not required. Board and good wages to right man.
A. J. McCarty, 712 Coffman St., Longmont, Colo.

WANTED—Can take two students for season of 1918; board given in exchange for work, and more if season is good; running ten apiaries.
R. F. Holtermann, Brantford, Ontario, Can.

WANTED—Industrious young man, fast worker, as a student helper in our large bee business for 1918 season. Truck used for out-yards and hauling. Apiaries located near summer resorts. Will give results of long experience and board and small wages. Give age, weight, experience and wages in first letter.
W. A. Latschaw Co., Clarion, Mich.

WANTED—Expert comb-honey man, with references, to handle 700 stands of bees. Good proposition to right man.
Hagerman Valley Bee and Honey Co., Hagerman, Idaho.

FOR SALE

FOR SALE—Wishing to retire from active business, I offer for sale 200 colonies bees in 8 and 10-frame L. hives; 750 full depth extracting supers, with combs; 400 section honey supers; 300 honey boards; 75 escape boards; eight-frame power extractor, with honey pump; four H. P. gasoline engine, saw with dado, planer heads and attachments for making supplies; a complete apiary in No. 1 condition; good location. 1917 crop was 15 tons honey. Will also sell my home place of ten acres, 5-room house and No. 1 improvements, near to a \$5,000 schoolhouse. Will sell home separately and give terms.
J. R. Marlow, R. D. No. 1, Weiser, Idaho.

FOR SALE—Small fruit farm and bees, cheap.
W. H. Gray, Chillicothe, Ill.

PATENTED Jan. 1, 1918, the C. B. Saunders Bee Feeder, a bee feeder which is made to go down into the brood-chamber. If any manufacturing company or companies are interested in the patent write,
Chas. Boone Saunders, Barrington, Ill.

LAST FALL, Mr. Smith asked us our advice on when best to sell his crop of 15,000 lbs. of clover extracted honey. We answered him by advising that he hold until May, unless he got a good round price for it before. He could at that time have taken something like 12c per pound for it. He held it. At our Michigan State Convention last December, he again asked what we thought about the future price of honey. He could then get 17c per pound for it. We advised him to hold. He sold the entire crop the other day on board the cars for 18½c per pound. Mr. Smith's case is only one in hundreds of cases where producers have done well by following the advice of the Domestic Beekeeper. We want every beekeeper who has honey to sell to send in his dollar for the Domestic Beekeeper during 1918. We have the back numbers, you can begin your subscription with the January number, thus making your volume complete. Do it today, and at the end of the year get your dollar back if you think you have not received its worth.

I Am Ready to Book Orders Now

for spring delivery for Italian bees in pound packages at \$1.40 per pound. Tested queens, \$1.25. Untested, 90c. 6 for \$5.00. Satisfaction guaranteed. Free from disease.
C. H. COBB, Bellevue, Ark

“Somewhere in the U. S.”

There are thousands of beekeepers who have not ordered their supplies for this season. The U. S. Government asks an increased production of honey to relieve the sugar shortage.

The Kretschmer factory has been working steadily all winter filling its own warehouses and rented storage space. A number of our workmen have been with us for years—they know how to make the kind of supplies you want for your bees.

As a result of careful tests extending over a long period of years, actual tests under all climatic and weather conditions, we make our **Hive Bottoms of SOUTHERN CYPRESS**, the decay-resisting wood, the **Bodies or Brood Chambers and Supers of NORTHERN WHITE PINE** (it holds paint, finishes well, and does not check or split), and the **Lock Cap Covers of California Redwood**.

If you haven't received a copy of our new green catalog, a regular **BEEKEEPERS' DEPARTMENT STORE**, send for it at once.

By all means get your order in without one bit of unnecessary delay. You don't want to lose any high-priced honey this year on account of getting your supplies too late. If you'll mail us the order now, we'll do the rest.

QUEENS **BEES** **QUEENS**

Three Banded and Golden Italians; the best of either

They are hustlers; gentle to handle; cap their honey white; are very resistant to European foulbrood. We have added Mr. B. M. Carraway's queen-rearing outfit to ours and have with us one of his assistants, so can fill all orders promptly. Had fine success shipping bees last season in our newly devised cage and method of feeding, a number of shipments going as far as Idaho and Wyoming. Mr. R. B. Mills, Corinth, N. Y., wrote, "Bees arrived in fine shape, not 50 dead bees to the cage, 2-lb. size." Satisfaction and safe delivery guaranteed. Get your order in early reference: The Guaranty State Bank, Robstown, Texas, or the City National Bank, Corpus Christi, Texas.

Buyers of EXTRACTED and COMB HONEY
Shippers and Exporters of HONEY

[The WORLD is Our Market]

A Simple Problem That = Much

The simple problem (yet often missed) that presents itself to every beekeeper is the buying of queens. "Easy," you say; "anyone can do that." It is true everyone can buy queens, BUT DOES EVERYONE GET GOOD QUEENS? And if you don't, what HAPPENS?

TRY
FOREHAND'S
THREE BANDS

THE THRIFTY KIND
and be sure

Over a quarter of a century of select breeding makes them thrifty, hardy, gentle and beautiful.

Ours are the Imported Queens, Americanized. This makes them light in color, but they still retain the fine qualities of their imported mothers.

We have placed these Queens on the market for over a quarter of a century, and every year the demand increases.

Doesn't this prove that they are good Queens?

Deposit your order now and insure prompt delivery. Only one-fourth cash down, to insure you of prompt delivery and us of your good faith. We begin shipping April 1. We guarantee pure mating, safe arrival, and satisfaction.

A Beekeeper's Letter, Dated May, 1917

" a large dealer in the south recently told me that many beekeepers are asking for cypress hives and saying that they do not want anything else. This is so often the case that nearly all the supply dealers are now listing cypress as well as.

I recently bought several hundred dollars worth of hives for my personal use from a firm which has never offered anything in cypress. I insisted on cypress bottoms and they had to be made especially to fill my order. I feel very sure that the use of cypress for bee hives, hive bottoms and hive stands will very largely increase as beekeepers learn more of the non-rot qualities of the all-heart wood of this species, which should be specified in all cases.

Trusting that the above facts may be the means of saving you many future replacements, I am

Very truly yours,"
(Signed)

NOTE: All our hives are made of this competing wood rather than injure it.

GET A BOOK = IT IS FREE

There are 12 volumes in the internationally famous Cypress Pocket Library, and each is authoritative in its field, and all are FREE. Vol. 1 is the U. S. Gov't Report on Cypress—that is a good authority, surely. Vol. 4 is the Barn Book, with plans and specifications for Building. Vol. 36 is the Carpentry Book, making easy a dozen hard jobs of carpentry. Vol. 19 is the Canoe and Boat Book. Vol. 27 is the Silo Book. Vol. 3 is the GREENHOUSE Book. All are free for the asking. Suppose you ask for one or a dozen, right away.

WORTH INVESTIGATING

This Cypress wood matter is worth investigating. Just write our "All's and Helps Department."

WINTER PROBLEM SOLVED BY Woodman's Improved Protection Hive

"THE HIVE WITH AN INNER OVERCOAT"

100% Perfect Protection by Tests, Winters of 1916-17-18

The Inner Overcoat Did It

Without any special preparation we have wintered bees in these hives without loss. It is a joy to see the condition they are in, when compared with other styles of hives and wintering methods. The INNER OVERCOAT is telescoped down over the brood nest, in between the outer and inner hive walls, when preparing them for winter. In the spring it is removed and stored away in the K. D. flat. Not more than two minutes are required to pack or unpack a hive by this method. The INNER OVERCOAT affords more protection than several inches of ordinary packing material. Send for a special circular showing 10 large illustrations.

Tin Honey Packages

SIXTY-POUND CANS, in cases or in bulk, are being sold by us at prices considerably below general market prices. Send us an estimate of your requirements and let us quote prices.

FRICTION TOP PAILS, any size furnished, and in quantities as you may desire. Send us a list of your requirements and let us quote prices, as we can save you money. The tin can factories are rushed with orders, the tin plate situation is serious and transportation slow, so it will be wise to place your orders early.

A. G. WOODMAN CO., Grand Rapids, Mich.

"falcon"

THINGS THAT ARE NECESSARY FOR YOUR APIARY

1. There must be a good location for the apiary.
2. Queens must be healthy and vigorous to put life into the hives. (Our queens are the best to be had and at reasonable prices.)
3. Your bees cannot do the work they should if you do not give them the best with which to work. If they have ample storage space, if they can work all the time without slack motion, they will be more contented and swarmless. To accomplish this, you must give them ample storage space, that is, the **RIGHT HIVES AND SUPPLIES. "falcon"**

Beekeepers should be placing their orders early for their early needs. He who waits is apt to suffer. These late beekeepers who want their goods in such a hurry at the last minute will lose some of the honey crop by not furnishing their bees with ample storing space. Railroad embargoes and rush business make deliveries slow.

Our famous "falcon" supplies will please you. Do not wait. Order now and strike while the iron is hot. "falcon" means the best, the standard of perfection. Red Catalog and Simplified Beekeeping upon request. Dealers everywhere.

HIGHEST GRADE EXTRACTED HONEY

R. 1

LaCrescent, Minn.

191

Dadant & Sons,
Hamilton, Illinois.

Gentlemen:

Have shipped you today, by freight prepaid, 82 pounds of No. 1 Quality Yellow Beeswax. Enclosed find bill of lading. Please work same into medium brood foundation, pack in 3 or 5 lb. paper cartons and ship by freight to Mound Prairie, my nearest freight office. Let me know at once how much the charges are and I will send check by return mail.

Wish to tell you that Dadant's Foundation is far ahead of any other kind I ever tried; no trouble to get bees to accept it and make into beautiful combs. You surely hit the nail on the head when you say it excels. Hereafter, as long as I can get Dadant's Foundation, I shall use no other kind.

G. A. BARBISCH,
Mound Prairie, Houston Co., Minn.

Feb. 20/18.

When ordering of your dealer, insist on Dadant's Foundation. If he hasn't it, order from us.

DADANT & SONS

Produce More Honey FOR WAR FOOD

A Glorious Opportunity for Beekeeping

NEVER BEFORE has beekeeping had such an opportunity to prove its usefulness. Beekeeping is the only means of saving the tons of honey now wasted. Every beekeeper must help, but the commercial producers can do most.

WHAT DOES IT MEAN when beekeepers are permitted to buy sugar during a sugar shortage in order that their bees may not starve? **Why** do the beekeeping supply factories run on fuelless days? Honey is an important food.

More Honey is Needed

There must be an increase in the production of all foods, but the shortage of sweets is especially acute. There must be more Honey.

HOW CAN IT BE PRODUCED? The Nectar supply of 1918 is still uncertain. However, a failure of the crop is more frequent than a failure of the nectar supply. The beekeeper must have his bees ready to get all the Nectar.

NOW IS THE CRITICAL TIME. The good beekeeper does two things:
He has colonies strong before the honey-flow.
He prevents swarming by division.

THE GREATEST LOSS is through failure to have bees ready on time. **Now** is the time to begin plans and preparations for the honey-flow. Delay may decrease the crop one-half.

WHAT BEES NEED. To reach maximum strength early, bees need only three things:

- Plenty of stores.
- Plenty of room for breeding.
- Plenty of protection from cold and wind.

Most beekeeping failures are due to neglect in preparation for the honey-flow. Each colony should have ten frames of brood when it begins.

OTHER PREPARATIONS. Buy or lease unproductive colonies. There may be a thousand in your county. Order necessary supplies at once. Watch for brood diseases this summer.

MARKET the crop intelligently, after studying the bulletins of the Bureau of Markets.

Keep More Bees

Can the Department Help You? There are several offices in the Department of Agriculture which are anxious to help beekeepers increase their honey crops this year. There are in many of the States, Inspectors and Extension Beekeepers who are at your service. The Department can tell you who they are.

Keep Bees Better

If your bees are unproductive, place them in the hands of a good beekeeper and let them do their share.

U. S. DEPARTMENT OF AGRICULTURE

WASHINGTON, D. C.

[This space donated by THE G. B. LEWIS CO., Makers of Beeware, Watertown, Wisconsin]

THE EVOLUTION OF THE BEEHIVE

The First of a Series of Articles Showing the Development of Hive Construction Since 1780

BY THE EDITOR

ALTHOUGH nothing is so important in beekeeping as the bee itself, the beehive and its ease of manipulation are next.

Bee economy was a closed book and the most important facts of bee physiology were unknown until a little over a century ago. The trunks of trees and hollow caves were the abodes of the bees. Swarms were hived in "skeps" made of rushes, osier, straw, clay, earthen ware and logs split and hollowed out. The Caucasian views of apiaries so kindly sent to us by the Caucasian Beekeepers' Association, of which we have already published several, are very good illustrations of the various receptacles used for bees.

As observers noticed that the bees built their combs side by side, the idea was evolved to have them built on separate racks or frames for the easier removal of a part of the contents.

If we tried to tell our readers just when the first progressive changes were made in beehives we would probably deceive them unwittingly, for improvements were made, from time to time, and abandoned, to be again resumed later in better and more practical form.

We can probably best interest our readers by giving them copies of actual improvements made about 130 years ago. We have in our possession a three-volume "Complete Treatise on Bees" by L' Abbe Della Rocca, Vicar-general at Syra, one of the Cyclades, an island in the Mediterranean. His book bears the date of 1790.

Plate 1 shows a house apiary, built of stone, with straw roof. The hives, 6 of clay and 2 of wood, are inserted into the structure and project

through to the other side. The clay hives show their posterior end, closed by an earthen disk. The wooden show their front, with entrances of metallic plates perforated for the egress of the bees. In order to har-

vest the honey from these hives commodiously, it was necessary that the combs be built crosswise. Then by the removal of the disks or of the rear plank, the combs containing honey could be cut out with the knife shown at fig. 10, plate 2. This knife or chisel is made with a curve on one end and a straight edge on the other. In order not to crush the bees, when drawing out the combs, a rounded frame, fig. 11, was used on which to drop the combs of honey. The bees could then be brushed off both sides before putting the comb into a jar.

Figs. 4 and 5 show methods of supporting pieces of combs within the hives in the proper position to form a guide for the bees to start their building. The little fork was fastened upright and removed as soon as the guide was sufficiently built in by the wax-workers. The author very judiciously remarks that the rounded foot of the other support, fig. 5, was not well adapted to use in a circular earthen hive, and advises the making of square supports. Later he manufactured a support for three "bait combs" an inch and a half apart from center to center.

Fig. 1 will be recognized by our readers as intended to exhibit worker, drone and queen brood. If this cut is quite crude, we must remember that it was made over 120 years ago, when printing and engraving were far from their present artistic condition. However, if we could now teach those artists some valuable improvements, they could still show us how to bind books properly. This edition, bound in calf, is still prettier and more lasting than books bound at great expense forty years ago.

Fig. 6 represents a small tree limb

The Improved Slat Hive devised by L'Abbe Della Rocca

Plate 1. A House Apiary built of stone, with straw roof

used in hiving swarms. A few bees were made to alight upon it, by shaking them gently from the main swarm. Then, after removing the limb to which the swarm hung, this was hung in its place and the returning bees were easily carried to the hive to join their sisters. Or the limb was used for the swarm to settle upon, by shaking the bees from the limb on which they hung and covering the latter with a shield or a cloth. Figures 7 and 8 were "swarm catchers," though a little heavier than the metal frames of the present day. Fig. 9 represents a hook to draw down the limbs on which the swarms might be hanging. Fig. 2 represents an earthen hive, one foot high and 2 feet long, with, at one end, a wooden disk notched for the passage of the bees; at the other end an earthen disk, to be removed only when wanting to take away the honey. Fig. 3 represents a similar disk with entrances for the bees. Fig. 12 shows the Della Rocca clay beesmoker. Hot coals and fuel were supplied at the big end and the smoke expelled at the little end. Small holes at the bottom furnished air for the combustion of the fuel. The author remarked that this instrument was "more proper than any other, to smoke bees." Fig. 13 exhibits a small straw skep to be used in hiving bees.

The next plate shows the improved slat hive devised by L'Abbe Della Rocca. And, by the way, let us say that he considered as proper the distance between combs of an inch and a half from center to center, for his frame supports were placed at that distance.

From time to time we will give our readers more facts on the "evolution of the beehive."

Sugar Shortage is Honey's Opportunity

By Chilton Gano.

IF there has been, since the United States entered the war, one reaction of the country's business that has been more noticeable than any others, it has surely been the effort of every kind of business to adjust itself to war-time conditions—to find the silver lining of the war cloud.

For instance, no sooner had the Government asked the co-operation of housewives in conserving animal fats and dairy products than every manufacturer of vegetable cooking and salad oils began to push his products more aggressively than ever before. Nobody knew who or what "Mazola" was, in February, though it had been on the market for three years. But the Government edict was surely the proper signal for the Corn Products Company to lift this product into the limelight. They did so with a national newspaper campaign. Results were so tremendous that the company has had to double the capacity of its Argo refinery, which was already the largest of its kind in the world, to supply the new demand for this cooking and salad oil.

Later came the sugar crisis, and this same company saw another big opportunity for increasing its corn syrup business, urging corn syrup as

a substitute for cane sugar. Karo has long been advertised in a big way, but probably never at so great an expense as today, when full-page advertisements are being run in newspapers all over the country.

These are only two of many scores of food campaigns which have dovetailed their appeal with that of Mr. Hoover and have proved through their great successes that such patriotic appeals are the strongest that could possibly be made to Americans at this time.

Honey's Opportunity

The writer has written several articles for the American Bee Journal on the possibilities that lie in co-operative national advertising of honey by beekeepers. But, of course, most thorough national organization of the industry would have to be the first step, and to urge national advertising as an immediate step would be highly impracticable for that reason alone. It would also be impracticable, probably, for several other reasons, the primary one being that national advertising of honey at this time would create a bigger demand for the product than could possibly be filled.

Yet every beekeeper must be fully awake to the remarkable opportunity afforded by the sugar crisis. Every beekeeper must realize that there never was a better time for honey to come into its own than right now. There never was a time, and probably never will be again, after this war is over, when a public demand for sugar substitutes will be so imperious. Surely the beekeepers will hardly feel like sitting back and doing nothing while the raisin growers are shouting from the housetops of the fruit sugar in raisins and the corn syrup people are telling in huge advertisements of the food calories in corn syrup. Every sugar substitute will surely make the most of the opportunity. Honey must surely do so, too. For there are many food experts who state that honey is the most wholesome sweet of all, and much to be preferred to sugar.

The common sense of the people will lead them to turn to honey, in a limited degree, and the honey market is no doubt today a bull market. But the American people have become an advertisement-led people. No really great movement on their part in favor of any commodity can be expected unless it is definitely engineered by the producers of the product.

What to Do

What has been said now calls for a constructive suggestion, though it has no doubt set the reader to thinking along constructive lines. The writer's suggestion would be that honey producers do all in their power to increase their production of honey to the highest possible maximum. There is no telling how long the war will last or how much more acute the sugar shortage may become.

But increasing of production will be only half the battle, if it is successful in a marked degree. It will then be necessary to increase the

Plate 2. Some of the implements used for beekeeping in olden times. Notice, at Fig. 12, the bee smoker

public demand for honey. Under conditions such as now prevail this increasing of demand will be the simplest matter imaginable. It will not call for national advertising, but it will call for some sort of advertising, sorts that have been done already to some extent, for instance, and even more ambitious local campaigns.

Let us suppose, for example, that members of such an organization as the Colorado Honey Producers' Association set to work and doubled their output, and that, on trying to market it in the usual way they found that yields had also been increased in many sections and the market was dull. With their organization it would be a very simple matter to assess the members a small amount per case of honey and to do a little newspaper advertising in Denver. Remember, honey is not a generally used product. It is treated more like fruit or candy than like a staple. A recent article in the *American Bee Journal* stated that it ought to be easy to double the consumption of honey in this country. But that is a very conservative estimate of what could be done for honey with the right kind of advertising. Especially at this time a very modest campaign in Denver should easily quadruple that city's consumption of honey. How many housewives know more than two or three ways of using honey? Yet a Department of Agriculture Bulletin gives 55 different uses for honey in the home, and every one of them would appeal to the patriotic housewife desirous of conserving the sugar supply. They would also appeal to the palates of herself and her family.

What has been supposed in the case of the Colorado organization would be almost as easily accomplishable by any county, sectional, or State beekeepers' association. It might be a little outside of the regular routine of such association, but war times call for unusual decisions. Many of the existing associations—and no doubt associations exist in nearly every State—have already among their objects the influencing of market conditions. One of the objects of the Western New York Honey Producers' Association is given as "to promote the most modern methods of packing and marketing its products."

Again, the Chicago Northwestern Beekeepers' Association, at its 1917 convention, passed a resolution urging the greater advertising of honey as a food.

Such campaigns in selected cities or sections can be put on very quickly, especially if handled through an advertising agency. Such agencies are to be found in all fair-sized cities. They have the facilities for prompt action, know how to make the appeal, and attend to practically all the details. Their services cost next to nothing also, as the publications allow the agencies a fixed percentage of the cost of the advertising space, as they find it most convenient to handle business coming from experienced agencies.

Appetizing copy, accompanied by a recipe book offer, could not fail of the desired result. And the plan has the double virtue of both promoting a great national industry and serving a truly patriotic purpose. The effects of such work would be lasting—permanently salutary to the industry. New users of honey would continue to be users for the rest of their lives, and the effect of the marketing co-operation on the associations would be to concentrate their attention on the possibilities in co-operative marketing, with the result that permanent marketing programs like that of the Colorado organization would be adopted.

Chicago, Ill.

Faults of the Express Companies

By J. F. Archdekin
ALLOW me, in the first place, to say that the express companies of the United States, as they are at present operated, are one of the greatest impositions that the people put up with. It is to be hoped by everyone that the time is at hand when this really useless and at the same time indispensable organization will be put out of business and supplanted by a special form of parcel post. There is absolutely no excuse for the existence of the express companies since the usefulness of the parcel post has been demonstrated.

In view of the urgent need for the people to economize, I feel that this is a form of waste that can and should be eliminated as soon as possible, that it is a form of waste is plain to anyone who has had much dealing with the express companies. Especially do the shippers of pound packages of bees understand this.

A package of bees should be sent by the shortest and most direct route between the point of origin and the point of destination, and should not be subject to delays at transfer points. In a word, bees should be

treated as perishable property, which they are, and handled accordingly.

Instead of this, the company receiving the shipment will endeavor to transfer it over its own lines as far as possible. This is done in order that the receiving company may get the largest share of the charges. By this means shipments are frequently carried hundreds of miles off the direct route, delayed at transfer points and only turned over to another line after the receiving company has carried them as near to the destination as it can, if the destination is on another line. Especially is this true in the case of a long haul.

Then there is the carelessness of the express employees and their utter disregard of instructions on the packages.

A railroad depot platform would not appear natural were it not for the express trucks piled high with packages waiting for a particular train. These trucks will often stand for hours, or perhaps all day, in the glaring sun and woe be it to any luckless shipments of bees that are on that truck. It is the most heartless thing that can be imagined and it is the death of countless bees and the cause of numerous disappointments. By the direct point of origin to point of destination route most of these difficulties could be overcome.

The express men seem to regard packages and other matter which they handle as they would deadly enemies with whom they are engaged in mortal combat. This frame of mind, in the case of bee shipments, has a tendency to reduce them to junk.

Shipments which are injured by rough handling and leaking bees are probably kicked out of the car door after the train pulls out. Such shipments are known as "lost," and after a complaint from the customer and some more time passed by, a second shipment is sent out. These are some of the perplexities of the package man versus the express companies.

Evolution in beekeeping may still be practiced in modern times. Notice the two split-log hives, with entrance at the end. There are many of these in Russia

IMPORTANT NOTICE

THE SUBSCRIPTION PRICE of this Journal is \$1.00 per year in the United States of America and Mexico; 3 years, \$2.50; 5 years, \$4.00; in Canada, 15c extra, and in all other countries in the Postal Union, 25 cents a year extra for postage. Sample copy free.

THE WRAPPER LABEL DATE indicates the end of the month to which subscription is paid. For instance, "dec13" on your label shows that it is paid to the end of December, 1918.

SUBSCRIPTION RECEIPTS.—We do not send a receipt for money sent us to pay subscription, but change the date on your address, which show that the money has been received and credited. In case of errors, please write us.

(Copyright: 1917, by C. P. Dadant.)

up variations of different plans of breeding queens, all of which have a significant value and may suit in turn many individual beekeepers.

Besides this, of course, he gives the standard methods of queen-rearing, in concise form. The Doolittle, Swarthmore, Miller and other methods are all explained. This new book, which is now in the press, will contain over 100 pages and will be cloth bound, with many cuts from original photographs. It is to sell for \$1.00 postpaid, and should be ready for delivery by the time this issue of the American Bee Journal is in the mails.

THE EDITOR'S VIEWPOINT

Boosting Honey Production

An eight-page pamphlet has been issued by the Department of Agriculture at Washington giving the situation of honey in the "Agricultural Situation of 1918."

Now, if ever, we beekeepers should strain ourselves to the utmost to increase the output of honey. It will act as a supplement to sugar in these times of sugar scarcity.

The booklet rightly points out that myriads of pounds of honey go to waste in parts of the United States in flowers scarcely visited by bees, and that the expansion of beekeeping to take up a part of this waste will be a net gain to humanity.

Our production of honey at present is in the neighborhood of 250,000,000 pounds annually, or only about 2½ pounds for each man, woman and child in the country.

Copies of this booklet may be obtained by asking for part 4, Circular 87, of the Department of Agriculture, Washington, D. C.

The Bee and Queen Situation

Never before has there been such a demand for bees and queens at this season of the year. Queen breeders are in many instances having to turn down some large orders so as to be able to take care of the ordinary trade.

To offset this, however, the season is much more promising with queen breeders than a year ago. Bees seem to be in excellent shape in the south-east and honey is coming in sufficiently to incite egg laying so that colonies are fast becoming populous.

The only section which cannot

show favorably in queen breeding is Texas, which has been hard hit in the past two years, so that some of her breeders have discontinued the business entirely. Fortunately, this condition does not exist over the whole State, and many of the breeders are already getting in shape to fill orders as before.

There is, however, one source of bees which we think is too little considered by the beekeeper who wants to increase, and that is the unproductive bees in his own neighborhood, or at least in his surrounding country. There are thousands of colonies in the country today which yield hardly a pound of surplus from one season to the other. They have no attention and in many instances are allowed to "swarm themselves away" by their owners who quite frequently think that the zenith of beekeeping is to have many swarms.

Now is your chance to buy up many of these colonies and make them produce. If bought early and gotten in condition during fruit bloom, they will in many instances more than pay for themselves and your trouble the first honey flow.

Practical Queen-rearing

Mr. Frank C. Pellett has just finished a new book entitled "Practical Queen Rearing." As its name implies, this book is for the practical beekeeper who expects to rear some of his own queens, but it will be found of use to the experienced queen-breeder as well.

Through his numerous visits to beekeepers of note, and to practically all the larger queen-breeders in the South, Mr. Pellett has picked

Bibliography

Several interesting bulletins are upon our desk. Among them we find the following:

"Insect Pollination of Timberline Flowers in Colorado," by L. A. Kenoyer. Professor Kenoyer has inspected flowers above the tree line in the Colorado mountains and found many insects upon the blossoms. He mentions a number of plants and of insects which would interest the students. His conclusions are that flowers above the timber line are as much visited by insects as those of lower altitudes.

"The Weather and Honey Production," by the same author. It was through the records made by J. L. Strong, of Clarinda, Iowa, during 29 years of meteorological data and weights of a hive of bees daily, that Mr. Kenoyer secured this most interesting information. His conclusions confirm the opinion current among old beekeepers, that rather abundant rain is favorable for large honey production; that south winds are apparently more favorable than winds from any other direction, that the clear days just preceding a rain show greater increase than the days immediately following. He also confirms our opinion, based on past experience, that "a winter of heavy snowfall is, in the great majority of cases, followed by a large honey yield." This, we believe, is due to the melting snow soaking the ground more thoroughly than spring rains.

"Environment Influences on Nectar Secretion," by the same writer. This is a very learned dissertation on the subject of nectar secretion, the writer quoting 28 other experimenters and students. A review of it would be difficult. Let us mention only two important points: "The optimum con-

dition for sugar secretion is an alternation of low and high temperatures. The more favorable all conditions for growth and the more vigorous the plant, the greater is the amount of sugar secreted." This is probably why we have greater crops of white clover honey when this plant sows itself again in our pastures, after several years of scarcity.

The above three contributions show Professor Kenoyer to be a careful observer and a methodical student. We may look for more of this useful work from him in the future.

Dirty Water Cause of Disease

In our interesting contemporary bee weekly, the *British Bee Journal*, we find a suggestion by Dr. A. Z. Abushady, worth quoting:

"If *Nosema Apis* is the real offender (in *Isle of Wight* disease), and if it is true that it has very resisting spores, which are often present in stagnant pools, etc., two questions at once arise. The first is a thorough testing of all the known modern non-toxic antiseptics that seem suitable to use in the apiary, with the view of determining the least noxious and the most effective one in dealing with this offender. The other is to consider the improvement of the water supply to the bees. It is useless to be content with giving advice regarding the cleanliness of the apiary and the use of a clean water fountain when every observant beekeeper will honestly testify to the fact that the bees will reject the fountain water, even if warm, in preference to that from a heap of manure. I have rarely seen any of my bees calling at the water fountain in my garden, though placed in a conspicuous position; yet I have repeatedly noticed many of them go to the roof of the gutter, presumably to drink from the rain water. I cannot believe that it is a difficult contrivance to give the bees their pure water supply inside the hive itself. When I make this suggestion, and many others, I trust I may be pardoned by those conservatives who never believe in new methods; for I might be led astray by the progressive spirit of my profession, which is always in a revolutionary state."

We know that bees do drink from fountains of pure water, but we also know that they often drink water "from a heap of manure." Whether this has anything to do with some of

the diseases of the adult bee is a matter that may require investigation. Constipation, paralysis, May disease and *Isle of Wight* disease, which do only occasional harm in this country, are still in the domain of the unknown, though some of our friends are sure that they are due solely to soured honey or pollen. And why not give the bees water in the hive? We might save many an adult from being chilled in cool spring days.

Drone Comb in the Hive

Remember that if you do not wish an excess of drones in your hives, April and May are the months in which the drone combs may best be removed, throughout all the northern part of our country. Remember that if you cut out drone comb and do not replace it with worker comb or comb foundation, the bees are likely to build drone comb again in the same spot.

Remember that it costs as much to rear 3 drones as it costs to rear 5 workers. The workers produce honey while the drones consume it. Rear your drones only in colonies which you consider as good breeders. You cannot entirely prevent the rearing of drones in undesirable colonies but you can greatly curtail their production. The difference in honey spent in producing 2,000 drones instead of 200, per colony, would pay the cost of supplying the bees with worker combs, over and over, every year. If you fail to attend to this, you are neglecting a 100% investment.

Behaving drone brood to destroy it, is equal to killing the rats after they have made holes all through your sack of flour. It is better than letting them live, but after the bees have cleaned out this dead brood the queen will fill the comb all over again with brood, unless the workers can get ahead of her and fill the combs with honey.

Treating Bee-Diseases With Drugs

It seems quite the natural thing for the inexperienced beekeeper to think there should be some drug that might be advantageously used in the treatment of diseases that affect bees and their brood. Indeed success has been from time to time claimed for many different drugs, especially in England and on the European continent. Although one after another they may sink into disuse, new candidates are

constantly appearing. In the latest *British Bee Journal* to hand is found advertised "Naphthaforma Tablets, the Germ-killing Remedy for Foul-brood"; also "Bacterol, the Successful Cure for 'Isle of Wight' Disease." Another advertisement says, "Izal, the Modern High-power Germicide, is a reliable remedy against Foul-brood and *Isle of Wight* Disease." Flavine is the latest, which is mentioned as "gaining friends." Yet, when one reads from time to time in the same journal of the somewhat hopeless struggle against disease, it doesn't look as if the drugs mentioned had been very efficacious.

For some reason, less faith has been put in drug treatment on this side of the water, and among American beekeepers of experience it seems a general belief that no drug exists powerful enough to affect the disease and at the same time prove harmless to bees and brood. It might be presumptuous to say such a drug never will be found; yet in the light of the past it is pretty safe to advise the inexperienced to waste no time in trying drugs, no matter what the claims for them may be.

Sugar Arrangements for Illinois

We wrote a letter a few days ago to the Illinois Department of Food Administration asking if it were not possible to facilitate the getting of sugar by the beekeepers of the State when local grocers were slow in allowing sales on the basis of the affidavit, copy of which we gave in our March issue. Their letter follows:

"Referring to your letter of March 11, we beg to advise that some two weeks ago we sent out a general bulletin advising all of our local administrators, situated in 800 townships throughout the State, to give publicity to the fact that beekeepers should be supplied with the necessary amount of sugar required for feeding their bees until the natural feeding season commences. You may therefore take this as your authority to deliver sugar against the affidavits which you have prepared, beginning at once.

"Very truly yours,
"U. S. FOOD ADMINISTRATION.
"Chicago, Ill., Branch."

Beekeeping for Women

We have in mind to present more material of special interest to the ladies. We have some good things on hand, but want more. If women who keep bees would only write and tell us about their experiences in starting, their successes and their failures, we would be glad. Pictures of their apiaries, equipment, especially to lighten their labor, and other interesting subjects will be welcome.

On the Supply Maker's Trail--- No. 2 Smokers and Un- capping Knives

By Frank C. Pellett.

READERS of Uncle Tom's Cabin will remember that Topsy "just grew" and that she had no idea that she ever had any parents. So it was with the Woodman Company, of Michigan, it just grew, also, without any definite intention of establishing a supply house, on the part of its founder. Not only did it grow in the beginning, but it kept on growing, and still continues to grow.

A. G. Woodman was engaged in beekeeping, in combination with fruit growing on a farm near Grand Rapids. He used to start to town before 3 o'clock in the morning, so as to get his load of fruit on the market by the time the first buyers appeared. Whether he was more a fruit grower or a beekeeper would be hard to tell, since he grew up in daily contact with both. As his bee business grew, he found it necessary to buy supplies in quantity, in order to insure that he would always be ready when the honey-flow came. Some of his neighbors were less provident, and made no provision for securing supplies until they were urgently needed. They soon found that Woodman always had them on hand anyway, and that he never refused to meet their urgent needs. He soon found that nearby beekeepers were looking to him for supplies, and increased the amount of his orders. Every year the number of his customers increased, until he began to get small orders from other towns. Thus it was that the Woodman Company "just grew," without special effort on the part of anybody.

It was not long until the barn on the farm was no longer big enough

for a warehouse, and it was too much of a task to haul all the supplies out to the farm, repack them for shipment, and take them back to town to the freight depot. It accordingly became necessary to choose between his farming and going to town. Woodman was a farm boy who had married a farm girl; they were doing well with their fruit and bees and liked the life. The problem, however, was what to do with the business which "just grew." Since it had outgrown the farm and had developed with so little effort, there seemed to be no way to get rid of it, so they decided to leave the bees on the farm and take the business to town. It looked much easier to run out to the farm to care for the bees than to keep the supply business in the country, and so it proved.

Once the business had been moved to town it was no longer allowed to "just grow," but it was pushed with all the energy that heretofore had been expended in growing fruit and producing honey. The proprietor decided that the best opportunity in the supply field lay in the pushing of specialties. As a practical beekeeper he had developed a double-walled hive which he named the "Protection Hive." For a time he occupied himself particularly with introducing this hive, which has since become so generally known as to require no description here. Later he offered the section fixer, which has been very generally used for folding, and putting foundation in sections.

When the late T. F. Bingham was ready to retire he selected Woodman as the man to continue the manufacture of Bingham smokers and knives, which are known among beekeepers the world over. Mr. Bingham made the first really practical bee-smoker in 1878, and, although it has been improved from time to time, it is still recognized as one of the best in the market.

A. G. WOODMAN STILL LIKES TO GET OUT TO THE ORCHARD AS WELL AS TO THE APIARY.

When a fellow buys a bee-smoker he gets a good deal for his money. If we stop for a moment to think how much we owe to the smoker, we will appreciate what Bingham and those who came after have done for us. By its use we can control the bees so nicely, that the necessity for veil and gloves is done away with at certain times. We not only are able to work with more comfort and satisfaction, but an immense amount of time is saved, because we can control conditions within the hive. Hundreds of bees are saved, which would be crushed in spite of our utmost care. If one will try to work without the smoker for only half an hour during the height of the season, he will wonder how it was ever possible to produce honey successfully before its invention. Beekeeping, as we know it now, was not possible prior to the invention of the smoker and a few other contrivances which were developed at about the same time.

Then the cost of the smoker is insignificant, entirely out of proportion to its importance in the apiary. If they cost ten dollars each instead of a dollar, we would have to buy them. Yes, if they cost twenty dollars, I am sure that no commercial honey producer would do without one. If we take time to look one over carefully, we will wonder how it is possible to make it and sell it so cheaply. The price is accounted for by the fact of its universal use. Any article can be made at a low price if there is a demand for enough of them. Each of the pieces that enter into the finished article is made by hundreds and even thousands. The legs are stamped out of sheet metal faster than one can

THE APIARY THAT WOODMAN LEFT ON THE FARM; 250 COLONIES IN PROTECTION HIVES.

count. Another machine stamps out the metal just the right size to make the barrel. Another operation punches the holes where the legs are to be attached, and the grates are cut out by a die in a similar manner. Each machine cuts out its particular part, and enough of these parts to make hundreds of smokers are turned out in an hour's time. When the parts come to the man who is to assemble them, he begins by picking up the flat sheet of metal that is to compose the barrel. By feeding it between rollers it comes out the right shape. The bottoms are then crimped on and other parts attached, one after another. With every part cut to fit, a skilled man can turn out the finished smokers very rapidly. Unless one has given a thought to the number of beekeepers who must have these implements, the size of the shipments will amaze him. Here are little packages each containing a single smoker going out to beekeepers in widely separated locations. Here again one finds a box holding half a wagon load, consigned to a dealer. Not long since, I happened to see several of these big boxes of bee-smokers on a depot platform away down in Mississippi. It is because so many other beekeepers are buying tools, at the same time, that the manufacturer can afford to invest the hundreds of dollars in machines necessary to turn them out fast enough to enable them to sell to us at a dollar. Although the maker gets only a few pennies of profit on each smoker, if he can sell enough of them, the total makes a satisfactory business. There never was a time in the history of the world when the price of a day's labor would buy so many useful things as has been the case since the invention of our modern labor-saving machines.

The Bingham uncapping knife has

maintained its leadership from the first. The men who make these knives for Woodman now began making them for Bingham more than thirty-five years ago. A certain amount of hand labor is necessary to the making of a good knife. The metal is stamped out the right size by a machine, but it is then ready for the critical operation of finishing, which must be done by hand. Each one of the thousands of these knives that have been turned out every year for a generation, has been examined by the same pair of eyes and ground down to a fine finish on a big stone by the same man, who has continued to turn them out year after year. The steam knife is made in just the same way as the cold knife, with the addition of a copper jacket soldered along the top, to provide a cavity to hold the steam. How much this one man working away in a dingy room has done to lighten the labor of the beekeepers of America, no one can estimate. Without uncapping knives and smokers extracted honey production would be very unsatisfactory, if not impossible.

Unsanitary Conditions and Unwholesome Methods Surrounding the Manipulation, Packing and Marketing of Honey

By Emil F. Lein.

ACTION was taken at the last annual meeting of the New York State Association of Beekeepers' Societies to standardize the marketing of section honey and, for sanitary reasons, requiring its encasement in cartons.

Such action, if its execution is ultimately enforced, will inure to the benefit of the beekeeping profession,

and is a protection to the consumer, in so far as it shields the combs against dirt, filth and germs from the moment of their encasement in these cartons, but, unfortunately, is no guaranty against prior infection, or contamination of these combs caused under the management of the filthy, careless or indifferent comb-honey producing beekeeper.

Even though the reader has no personal knowledge of unclean and unwholesome conditions pertaining to the handling of honey among beekeepers, let him not assume that they do not exist. A little incident which came under the personal observation of the writer last year may suffice to prove that at least isolated cases of unsanitary conditions may be found of a nature so shocking that if the facts were known by the general public they would not promote the sale of section honey. Many an innocent consumer might hesitate before being tempted again to purchase his favorite sweet in the form of snowy-white and apparently pure combs in sections, without further assurance that the producer had taken care of these combs with at least ordinary regard to cleanliness.

It is not the purpose of this article to injure the sale of comb honey. But regardless of the effect a disclosure of actual conditions might produce, at least the beekeeping fraternity should be aware of them.

We have in mind a visit last autumn to a beekeeper in another locality. Here we were confronted by conditions such as we had never expected to find among beekeepers anywhere. Before our eyes was unfolded a scene which impressed itself upon us indelibly. On a dirty floor, fairly littered with rags, tools, clothing, household articles, etc., in the most chaotic fashion, were scattered several supers filled with white comb honey, one super of which was partly covered with dusty woolen rags on which a cat with a litter of kittens had made her bed. Apparently disturbed by our entry, some of the kittens crawled over several supers, to the distress of their mother.

We shall have no difficulty in pointing out evils fully as great among the producers of extracted honey, most of which have reference to the careless and indifferent handling of the product and others to the undependable methods of packing adopted by them.

Imagine our feelings, after opening the first few cases of a large shipment of so-called "white" honey, upon realizing that we had before us rusty cans, the upper surfaces of which were corroded and covered with filth, intermixed with granulated honey; that a ring of buckwheat honey was plainly visible around the inside of the screw top; that upon unscrewing the caps we again discovered the presence of buckwheat honey on the inner screw thread, indicating that these old cans had previously contained buckwheat honey and without being cleaned had been used for clover honey; imagine our resentment upon discovering that the liners in some caps were so

A. G. WOODMAN VISITING WITH JAY COWERING AT JENISON, MICH. MR. COWERING HAS 300 COLONIES IN PROTECTION HIVES.

deteriorated by age as to have acquired an unwholesome and repulsive odor; that a number of these cans contained from one to ten dead bees, which floated out first when the liquefied honey was being poured out, and which contained so much sediment that some of it required straining; and last, but not least, that the cans were not marked as to the amount of their contents, but sold upon the basis of containing 60 pounds of honey, and that some of them were short in weight as much as 1 3/4 pounds!

Now, what would you say if you were told that this shipment of honey had been received from one of the largest producers of extracted honey?

Such management, methods and conditions surrounding the marketing of honey should be checked by federal law, inasmuch as a State law would be only a local remedy and not sufficiently far-reaching unless enacted by all the States.

But even a State law on such a basis would have a salutary effect. Bee inspectors could be required to report violations.

There is absolutely no excuse for marketing dead bees and sediment intermixed with an article sold as pure extracted honey. Neither is there an excuse for placing white honey in cans which are not absolutely clean inside and not free from all traces of buckwheat honey previously packed in them, and selling the article for pure white honey.

While the use of old cans should be permissible, provided they are absolutely clean on the inside, it would seem that their use should not be permitted unless they are also made to appear clean on the outside. With a little cleansing powder and a moist or wet cloth a rusty can may in a little while be given the appearance of a new and clean can.

Unclean cans, be the cans old or new, should not be tolerated, and this restriction should apply also to the outside of the cans.

It is an easy matter to polish rusty cans in fairly good condition. Cans should be free on the outside from all accumulations of honey, dirt and rust. If these are permitted the inference is, and the chances are, that some of the honey poured out will become soiled.

Honey, when properly handled, is a wholesome health food, worthy of a clean container.

Buffalo, N. Y.

The Cycle of Seasons in Different Apiaries--In Florida

By J. J. Wilder.

THERE is no problem in Southern beekeeping so intricate as that of the rounds of seasons in different apiaries for general work.

We might place the word "When?" in front of each of the following phrases and study them a while and be greatly benefited thereby.

When to first examine bees, equalize stores, spread brood, put on su-

pers, expect swarming, take off honey, to expect next flow, to super again, to transfer, re-queen, finally remove supers for winter, prepare for winter, unite, to sell the crop, to take vacation, and other questions, the time of which comes and goes in many apiaries located in different localities.

As the season's cycle revolves the arrow point turns toward these words, one at a time, until its entire round is made.

To undertake a job out of season would mean loss, in most cases, so we must be on the alert to do the things necessary at the proper time.

I have seen bees transferred during winter. I have seen them fed in the spring when this should have been done in early fall. I have seen api-

sults will not be so bad, but far worse if done entirely out of season.

It can almost be said of the South that the sources of honey change every ten miles; that entirely different honey plants come in and go out as one passes across the country. So there is no one great source of honey, but, instead, many, many small ones, and as many as five or six of these are found in a single location, coming in bloom from very early spring till late fall.

This fact alone makes it very difficult, or almost impossible, to properly instruct all inquirers or give out definite information for general apary work that would be proper for all. So we have to deal with every one separately in his own location.

The editors of our bee papers fully

Wilder Apiary in the Balmly South

arists go off on vacations and on their return find the bees crowded for storing room. Some leave them in early winter and the forest fires burn them up. I have seen supers put on in the dead of winter, just after the honey-flow and honey removed during winter. Swarming-time overlooked, bees moved in mid-winter, completely closed up and suffocated, and combs, honey and bees lost.

The majority of the bees are never examined; stores not equalized; no knowledge of but one honey-flow; supers left on for winter, and many other things done entirely out of season, with results disastrous.

Is it any wonder we fail? Is it any wonder we succeed when we do things at the proper time?

It is easy to be timely in our work, if we only refresh our memory with past experiences, and keep close watch of the bees and the plants as they bloom out in the forest.

It is just a matter of a little application. If we are not expert apiarists and don't do the general apary work just right, but do it at the proper time, in most cases re-

realize this peculiar and difficult situation and on account of it are slow to offer information, because it would often be misleading. Only progressive beekeepers scattered around over this great section can give it.

This accounts for the fact that although in the South we have the bulk of the bees of our great country, yet the amount of honey produced is small, and returns very light.

Suggestions

Southern Florida.—We may expect a flow here by January 1, mostly from pennyroyal. So bees must be left in the very best of shape at the close of the last flow, which is from goldenrod, early in November. All weak colonies should be united and all headed with good queens. Ready-built comb should be given the bees to store this early honey, for they will not build much comb during its flow. About February 15 this flow stops and the citrus comes. Extract and give combs back for this flow.

About March 10 a little increase may be made, transferring, etc., done. This flow stops the first of May, when all extracting should be done,

but not too closely, as the next flow comes about June 1. It is saw palmetto and mango. During this time a little more increase can be made and extra combs can be built. In July cabbage palmetto may yield, giving a light extracting, but at this time plenty of honey must be left in the hives, for the fall flow is a long ways off, which is from goldenrod and a few other fall flowers, but the flow is not certain by any means, and if stores are low bees will go down and only wholesale feeding will save them. So plenty of stores should be left from the saw palmetto flow, which may be later removed if the other flows come.

Jacksonville, Fla., is one-third of the way between the extreme southern point in the State and Washington, D. C. This gives some idea of the length of this narrow strip of land lying between the Atlantic and the Gulf. Florida also extends westward nearly as far in a narrow strip.

Another Wilder Apiary

In this narrow border of country we have just as widely different conditions to contend with.

In the central and eastern sections conditions are similar. Here we have no very early honey-flow, as we are out of the citrus section. The long period of breeding in early spring consumes lots of stores. So the bees must be left very heavy with stores or else they will collapse before the flow comes, which is mostly from saw palmetto and a little gallberry. The bees should be strong here for the main flow, which is never very heavy. But a light flow follows it either from cabbage palmetto or partridge pea. So the honey may be extracted closely from the supers when there is a lot of honey in the brood-nest. Apiary work should start here the first of April and increase made in May. After July 15 the bees should be looked after for wintering.

Northern Florida.—The flow comes on here the first of March, in the

more watered sections from titi. Here bees need but little stores left on for winter. I have heard beekeepers here say they have never known bees to perish.

Apiary work should begin here in February. Tupelo gum thinly scattered along small streams follows with light yield, also some gallberry. In summer and late fall bees live in a hand to mouth manner.

In flat, wooded sections gallberry gives a good flow in May, and a glimmering flow follows from scattering partridge pea.

The High Sand Ridge Section.—Here the early flow is from chincapin, which comes in April, but this shrub covers only a small area. In other localities gallberry comes in May, but in most parts is not an early honey plant. With these exceptions, the main flow comes in July, from partridge pea. So it is very important to see that bees have plenty of stores for winter, and spring, too; but for-

after its close, a light flow comes on from snow vine. Here beginners do not do much at beekeeping, because conditions are not so favorable for the inexperienced; but here is where our best apiarists keep bees, and they do not reach fame until advanced in years.

Let me say before I quit Florida that I have not mentioned all honey plants here, but only the main ones. Ask the natives about certain plants and in most cases they can point out every variety to you. By all means know them, what you may expect from them and when. Watch the bees.

Bradentown, Fla.

Garden Flowers That Beautify the Home and Many of which Provide a Wealth of Pollen for the Bees

By W. J. Sheppard, Nelson, B. C.

A GOOD selection of varieties of flowers will keep up a constant succession of bloom in the garden from early spring to late fall. While making this selection the preferences of the bees can at the same time be studied and administered to. What is more delightful than to quietly stroll around to admire a well arranged and well cared for and beautiful garden, filled with choice and fragrant flowers, and to listen to the restful and contented hum of the bees engaged in their daily task of sipping the nectar, or gathering the pollen from the blossoms?

In early spring, crocuses and the blue scillas, or squills, are the first of the garden flowers here to open and attract the bees. A little later on white arabias, yellow allysum and the lovely azure-blue forget-me-nots make their appearance, all of which are great favorites and assiduously visited. We have tried wallflowers, but have always lost them through the snow breaking them down in winter. Some of the flowering shrubs that begin to open at about this time are a great source of attraction. Many of these make a splendid background for the flower borders. The different varieties of the flowering currants are continually crowded with bees. Then there are the Siberian pea tree, berberis, in variety, white and yellow broom, oleaster, furze, or corse, single lilacs, weigelas in variety, etc.

As a general rule perennials are to be preferred in the flower borders, as when once planted and established they come up year after year and do not require very much attention, except staking and tying up. The perennial larkspurs, or delphiniums, are splendid and make a grand show. The colors—white, pale yellow and various shades of blue—ranging from lovely sky blue to dark indigo and purple shades, are always to be admired. The belladonna, which are of medium height, and the little dwarf butterfly variety remain in

tunately the summer farewell gives a flow here until frost, which always leaves bees in good condition for winter.

Increase should be made and combs built if possible during chincapin or gallberry flow, so as to make harvest as heavy as possible during the main flow, for during it there is a great scarcity of pollen, and bees slack up brood-rearing wonderfully. Later pollen comes in and they build up well for winter.

Here beekeeping is easier than in any other section. One good apiarist can care for 500 colonies or more without help.

West Florida.—Here beekeeping seems to be narrowed down to the tupelo gum. They have no fall flow, and bees are wonderfully reduced in strength after winter, and work to get ready for the flow which comes and goes almost in the month of May. Some titi in small streams gives them a wonderful start, then, just

bloom nearly all the summer. The bees are constant visitors to these flowers and they are also a great source of attraction to the tiny, glistening humming-birds that come and go all day long, while they remain with us. It is always interesting and often amusing to watch their many little antics. The campanulas are very decorative and there are endless kinds to choose from. The biennial varieties of the cup-and-saucer type are most favored by the bees, as the anthers are simply smothered with pollen. The little catmint makes a nice little plant for the extreme edge of the borders.

Lilies of all kinds are noted for their wealth of pollen and the oriental poppies have also quite a lot. The latter make a gorgeous show, as they are now to be had in colors of all tints, ranging from pure white to all shades of pinks, salmons and the most beautiful reds and crimson. One can scarcely afford to leave out the iris family, aptly termed the "poor man's orchid," as although not of much, or indeed any, value to the bees, no garden is complete without them. There is a long-continued sequence of most beautiful and quaint flowers if all the various types are grown, viz., the Spanish, English, German, Siberian and Japanese forms. Phloxes are in the same category as the iris family, in not being visited by the bees, but are favorites for the humming-birds, which frequently hover over them. These make such a grand show and flower for so long a period that they are an absolute necessity in every garden, and are sweetly scented. The dwarf Alpine varieties are well adapted for the rocky. The long-spurred columbines, too, must be remembered. These have been greatly improved of recent years. The humming-birds are fond of them, as with their long tongues they have no difficulty in reaching the nectar. Of course no garden would be complete without roses, the queen of flowers. The double kinds are of no service to the bees, but the single-flowered varieties, of which there are so many lovely kinds, and the briars, yield a certain amount of pollen. I almost forget to mention the peonies, that succeed so splendidly here. There is an endless array of beautiful kinds. The single-flowered ones have quantities of pollen. The stately hollyhocks should also be found a place, the single forms of which the bees are very fond of. The bergamot, the horse-mint of Texas (variety Cambridge Scarlet) is very striking and flowers all summer and is a great attraction to the humming-birds.

Of all the annuals that are grown there's nothing the bees are so fond of as mignonette, for which room should always be provided, if only on account of its sweet and constant perfume. The bees simply revel in the blossoms and are to be found there every day when they are able to fly. *Phacelia tanacetifolia*, belonging to a small genus of Californian annuals, is well worth growing. A place should be set aside for Shirley

and other kinds of poppies, as these yield bounteous supplies of pollen and also help to make the garden gay. Nasturtiums of different kinds also deserve to be grown, as the bees repeatedly visit them.

For late summer and early fall there are the perennial asters, or Michaelmas daisies, of which the newer varieties of some are a great advance on older kinds, and are rich in both pollen and nectar. The Japanese anemones, or wind flowers, bloom at this period and are very pretty and graceful.

Queen Efficiency

By P. C. Chadwick

FOR some time I have given the thought of queen efficiency more than the usual amount of study. The fact that in some parts of California, as well as some of the Southern States, winter breeding is not only frequent but excessive, gave rise to the thought, is excessive winter breeding desirable? From the standpoint of consumption of stores it is reasonable to believe that where winter breeding is in progress to any extent, there is also a flow of nectar that is causing the breeding, which we will assume is sufficient to meet the needs of the colony for that purpose. But the effect on the life and energy of the queen seems of more importance than the mere fact that the colony is breeding during the winter months. There is a period in the life of the queen when she may be said to have reached the "peak" of her energy. The question then arises, how can we secure the best results from her or can we so arrange her career as to secure her services in honey production when she is at the "peak" of her career? In some locations it is doubtful if this can be accomplished, yet it might be.

My observation on the life and en-

ergy of queens is that the first season after their mating is the best of their life, or, in other words, they pass the "peak" of their energy at that time, in California. In the east, where the winters cause a long period of rest, as well as being more or less inactive during the autumn, the situation is somewhat different. But even there I have observed that where a long breeding season, say from apple bloom to the close of a long white clover flow comes, the energy of the queen by the next season is waning. In California the breeding under normal conditions in all parts of the State should begin in earnest by mid-February, and if the season is a good one we may expect the breeding to continue almost unabated until well through July, thus giving five months of continual and excessive activity. A queen mated the July previous will have passed her "peak" of usefulness, during the twelve months, under these conditions.

The amount of breeding space given a colony is a factor, for if the queen is confined to an eight-frame hive in the brood-chamber proper, or other small breeding space, she will be efficient much longer than the queen that is given a ten-frame brood-chamber and allowed to lay freely in the extracting-super also, for in the ten-frame hive, with the extracting super, she will have eighteen frames available for brood, while in the eight, her limit would be the eight frames.

If a queen mated in July is placed under conditions that cause her to lay continually through the summer, autumn and winter, it is possible for her to have passed her best before the close of the season the spring following. Hence, it would seem that if breeding could be kept to a minimum during the winter months, the response in the spring would be more rapid and a greater force of young bees could be secured of the

A Wilder apiary in the overflowed region of Florida

proper age to gather in the nectar when the season had also reached its "peak" for nectar.

In 1916 every queen in my yard was replaced with a virgin that mated from the full colony. This I consider the most desirable way to requeen. By August of 1917 I had lost more than a dozen colonies from queenlessness, while doubtless many of my 1917 queens had been replaced by supersedure unknown to me. I mention this for the reason that, having requeened under what I consider ideal conditions, I found many of my queens gone by the end of the following season. The ideal time for requeening, in my opinion, would be in September or October, for then, even with much winter laying the greatest energy of the queen would not have been passed. But there are so many years when conditions are such that requeening at that time is almost impossible, owing to a dearth of honey, it is found necessary to requeen when opportunity offers and not wait for conditions that may not come. Immediately following the main honey flow is preferable, when a dearth of nectar may be expected later.

Redlands, Calif.

A Talk for Young Folks

By Harry Lathrop

A SHORT time ago there passed away, at Denver, Colo., one who was the full realization of the ideal scout and pioneer—"Buffalo Bill," or speaking more correctly, William F. Cody. "Buffalo Bill," as we love to speak of him, represented a class that will be known no more in our country except in history and romance.

In like manner is passing a class of men who were pioneers in the realm of modern and scientific beekeeping. They were a noble band of men and their names will also live on the

pages of history. They will be honored and revered by other enthusiasts who will take up beekeeping for the love of it in the days to come.

What was it that gave the pioneers and plainsmen their power and efficiency? Was it not their ability to read intelligently and unerringly the language of nature and the wilds among which they lived? Like the Indians, they were good sign readers.

What is it that has enabled beekeepers to so control the activities of our interesting little friends, that the result is remarkable in comparison with primitive and unintelligent methods? I think it is the ability to hear the language of the bees and the understanding that bees will uniformly do certain things under certain conditions. Thus the conditions are met and men reap the benefit of the unerring skill of the little workers.

Among all living beings, including plants, there is a strong instinct toward reproduction, or in other words, self-preservation of the race. Notice how many, many seeds are produced by trees and plants. Some trees, like the maple, produce seed pods with wings so they can fly to distant parts. The dandelion uses a balloon or airship to scatter its seeds afar. Among insects, eggs are produced by the millions, and thus some, like the grasshoppers, become a menace to man.

Among higher animals some are not so persistent and in many cases certain families become extinct. The beautiful passenger pigeon, which was plentiful up to about 1882, belonged to this class. The mother bird laid only two eggs at a sitting and the birds refused to breed unless they were in large colonies. History tells about the great pigeon roosts of former years in which there were acres and acres of timber so loaded with nests that some of the branches would break from the trees.

The roosts were broken up by the ruthless hand of man, great inroads were made in the flocks by the means of shotguns and nets, and the scattered individuals were discouraged and allowed themselves to die without attempting to breed.

In order to illustrate the strong impulse toward self-preservation on the part of bees, I am going to tell you a little story of what I saw in my own bee-yard last summer. About the beginning of the white clover yield I noticed a hive that was strong in bees and brood and in which several queen-cells were already started. I thought it would be a good thing to divide this colony lest the bees should swarm when I was not looking. The colony had two eight-frame bodies for a brood-chamber, and one super of store combs over an excluder. I procured another hive and placed it on another stand about ten feet distant. Then I proposed to take all of the brood and some of the bees out of the parent hive and place them over in the other hive, leaving the queen in the parent hive, which I would fill with clean brood-combs. I was sure the bees would go to work in each hive, and give me a good crop of honey at the close of the season.

The division was made, and as I took out the combs of brood and placed them over in the new hive I kept a sharp lookout for the queen. I failed to see her and simply took it for granted that she was left in the broodless hive. The bees knew better and they soon told me so in language which the bee-master knows very well. You see it is this power to understand the language of bees that makes a beekeeper. I had evidently taken the queen with the brood, and the bees, in the now queenless and broodless hive, manifested the most unmistakable signs of distress. Such distress on the part of humans would be heartrending.

I had taken away their last hope of perpetuating the colony. Now bees don't care so much for an individual, it is the good of the colony (community) they are looking after. They are great socialists, indeed. But to return to the hives; what should I do to make matters right so that the discontented colony would go to work, clean house and begin storing operations? I will tell you what I did. Without taking the time to look up the queen, I just lifted out one comb having brood and a few queen-cells, from the new colony, and placed it in the parent hive. Almost instantly the bees quieted down and gave out that contented, musical hum that the beekeeper so loves to hear.

What I did gave them the means whereby they could rear another queen, or mother bee, and thus go on as a living family and not miserably die out as they would have done.

What of the results? I do not have much time to give to my bee-yard on account of other duties, so these hives were not looked at again till it came time to extract the crop. The first one gave 150 pounds of nice, white clover honey. I really expect-

In Florida, some of the apiaries have to be put up on platforms for protection in the lowlands

ed the other would be weak, but it gave the same amount, so the colony that was divided really paid me \$30 for the season. Not so bad, considering the little time I gave them.

From what we have learned from the bees and in other ways, I am sure it is proper to say that the most important requirement is to guard carefully those things that have to do with our lives and our home. The bees would not allow their home to be broken up contrary to the laws of their being. So should we guard with the greatest care the things that are most important. It is fine that we can learn to understand bee language; they can teach many lessons and give us interest in good things and fellowship with good men and women. We can follow in the path marked out by the pioneers and it is an honor to do so.

Bridgeport, Wis.

Foods We Need, and the Foods to Use

By Mary G. Phillips.

IT is a regrettable fact that although most of us women are willing to let our families go undarned and buttonless, while we sew on Red Cross bed shirts, and are willing to sit up until midnight finishing a Red Cross sweater, we are not so willing to make the real personal sacrifice which following the letter of the Food Administration law entails. It is neither pleasant nor easy to omit eating between meals at afternoon gatherings, it is hard to give up the favorite dish of toast for breakfast, and hardest of all comes the knowledge that the strain upon one's already overburdened pocketbook is increased somewhat by keeping the food pledge. There are entirely too many families where the food pledge, although signed, is not strictly kept, although here and there in every community will be found a family, and perhaps it will be the one least suspected of being capable of real sacrifice, which is bending its whole daily energy to winning the war. That is the family which realizes that until every man, woman and child in the country accepts a personal responsibility in following the directions of the government, the war will go on. Here is where we women have a special opportunity for service—in controlling the kitchen, thus deciding what and how much the family shall eat, we are directly responsible for the keeping of the food pledge. More than that, have you ever noticed that it is the mother who sets the tone of the household? By setting an example in sacrifice, as well as by making the children understand the necessity for eating cheerfully, not what we like, but what the soldiers do not need, it is generally the mother who sets the standard of conduct.

We must not forget, however, that the Government is not asking us to give up one article of our diet which we actually need to keep the body in good health. We are not so much

to "do without," as we are to "substitute," but to do that intelligently we must know a little about the various foods and what they do for us. Most housewives are frightened by the use of such terms as "protein," "calories," "carbohydrates, etc., when, after all, the fingers of one hand are enough to tabulate all the terms we need to know. The foods required to keep the body in proper condition may be grouped under five heads:

Group I.—Meats and other protein-rich foods.

Group II.—Cereals and other starchy foods.

Group III.—Sweets.

Group IV.—Fats.

Group V.—Body-regulators, fruits and vegetables.

We need foods from all five of these groups every day, and if we can once get them fixed firmly in mind, it almost becomes second nature in planning meals to choose something from each group.

cottage cheese, fish, nuts, peas and beans.

Group II, containing the foods rich in starch, is most important, as it contains that vital factor in the war—wheat. Whole cereals come near to being complete foods, since they contain protein and other needed elements as well as starch, and in most countries they supply more of the nourishment than any other kind of food. Wheat, rye and barley are the three cereals which can be used in making bread as we know it, and the progress in luxury and prosperity of a country can be gauged by which of these cereals is used. Uncivilized peoples, begin with barley, but as the race becomes more prosperous it discards barley for rye, then later, rye is discarded for wheat, which makes a bread that is whiter, lighter and finer in texture. The nutritive value, however, of these three grains is practically the same. The French are the greatest eaters of white

In some localities the dearth of pollen in spring holds back brood-rearing. Above are two buckets partly filled with corn chop, with bees working on it.

The foods in Group I are chiefly for the building of new tissue, and naturally people who live an active life, which breaks down and uses up tissues rapidly, need more protein than sedentary folks. That is why our soldiers consume such great quantities of pork and beef, they are leading far more strenuous lives than they did as civilians. Actively growing children must have considerable protein food, but fortunately, the form best adapted to their needs is whole milk. With regard to this kind of food, the Government asks us in the new home card, not to eat any meat on Tuesdays, to omit all pork (which includes lard) on Tuesdays and Saturdays, and to have one meatless meal each day. This does not mean that our families should go without the proper amount of protein each day, but it does mean that we must substitute for bacon, beef, mutton and pork, the following protein-rich foods: milk, poultry, eggs,

bread in the world, for 52 per cent of their total food is wheat bread. They do not eat rice, oats, corn, barley nor rye, and it would mean an entire change of diet for them to adopt these cereals. Shall we ask the women of France to use these almost unknown foods, when they are already so overburdened and harassed or shall we, who know and like these substitutes, use them and give to the French their much needed wheat? The noble, uncomplaining French women are not only managing their different homes, sending packages of food to their soldier prisoners in Germany, caring for the tubercular and infirm at home, but they are likewise doing all the agricultural work of the country, some of them being even harnessed to the plow!

Every time we use some cereal other than white flour we are helping these magnificent women abroad. Here are the starch-giving foods from which we may choose: Corn-

meal, rice, barley, potatoes (sweet and white), rye, tapioca.

Group III consists of foods containing sugar, the fuel which, together with fats, supplies the energy of the body. Here beekeepers' wives have an unusual opportunity to help supply the needed sugar for the allies. For we are familiar with honey and know how to use it in cooking, therefore let us use honey entirely for sweetening, if we have any of the crop left. Of course this does not excuse us from being as sparing as possible in our use of sweets of any kind, and for the sake of variety as well as to supply the needed sugar without encroaching upon that which may be shipped, it is wise to substitute dates, raisins, figs and prunes, all of which are rich in sugar.

Group IV consists of fats, "the most precious thing in this war," for not only do fats supply energy for the body, but they are needed in the making of explosives. We are not

war a nation which eats more fruit and vegetables, instead of the excessive meat eaters we have been. It is from fruits and vegetables that we get mineral salts, certain acids and bulk, or "roughage," all of which help to keep the body in good health. As most of these foods are perishable, we are not asked to restrict ourselves in their use, and I think that we will find our families all the better for a larger supply of them in our meals.

It seems as if it should be an easy matter to plan meals with all these foods to choose from, and if we put our whole energy into the task, it is not especially difficult. The woman is fortunate who has her cellar stocked with home products and who has her poultry and eggs in the back yard. Those of us who are city dwellers and who find that the grocer is just out of the very things we planned to eat on a certain day, may have to make the meals a little one-

Apiary Buildings and Their Equipment

By Morley Pettit.

A BEEKEEPER'S buildings and equipment will depend on his general system of management. If he moves his extracting machinery from apiary to apiary he can use vacant houses or temporary structures which can be made fairly bee-proof at moderate cost. A complete extracting outfit at each yard will involve more expense for equipment; and if he brings all supers home to extract, a good central plant will practically replace all outapiary buildings.

All three systems have their advantages and disadvantages, and each beekeeper must choose the one which in his case has the most of the former and the fewest of the latter.

Before the days of power machinery and motor transportation, one of the outyard arrangements seemed the best. The hand extractor was easily moved and set up, or a complete set of extractors was not expensive. The smaller output with hand machinery simplified the handling of the honey and getting it all home each night. On the other hand, teaming supers home and back again was slow, costly and dangerous.

In one way the introduction of the automobile made this arrangement more desirable by shortening the time on the road and leaving more time for work or recreation each day. But outapiaries have to be moved sometimes; temporary arrangements are little more than a makeshift, and one tires of always working under these conditions.

Then came the more general use of power extractors with increased capacity which complicated the matter of moving and setting up machinery and increased the difficulty of clarifying, filling and taking home all honey at the end of each day's work. Some advanced beekeepers immediately bought motor trucks, as the lighter ones were then coming on the market, and started taking all supers home to extract. The high cost of trucking at that time deterred most of us from following their example; but I have not heard of anyone going back on that system after once testing it thoroughly. The present facilities for converting light cars into trucks at low expense are increasing the number of satisfied users of the central extracting plant.

I do not believe the advertising manager of the American Bee Journal will object to the following expression of an idea prevalent among advanced beekeepers, that Henry Ford has made commercial beekeeping in its present advanced state possible. Without perpetrating a new Fliver joke, I wish to express a desire that his name be placed beside those of the inventors of the movable frame hive, the extractor and comb foundation, and that he be made an honorary member of the National Beekeepers' Association.

Advantages of Central Plant

When apiaries are all managed

A House Apiary in Sweden. We little realize what it is to be crowded for bee locations

asked to do without fat—part of our duty is to keep the people at home in prime condition—but we are asked not to waste a single ounce and not to use any more than we need. We certainly do not need pie every day, nor fried foods, and we can substitute vegetable oils largely for the animal fats we have always used. There is one precaution to be observed, however, in using oleomargarine or other butter substitutes. None of the fats which take the place of butter contain certain chemical substances (which have not yet been named) which seem to be necessary for the growth of children, and which are found in butter. You will notice in all the government bulletins that we are warned not to cut down the children's butter ration, so even though you may pay the price for butter with a groan, it is better than paying a doctor to tell you that your child is suffering from malnutrition.

Group V, the body regulators, form an important part of our meals which is too often neglected. It is to be hoped that we come out of this

sided that day; but one can readily shift the balance in the other direction the next day. And the best part of putting one's whole heart into the task of providing a balanced ration, is the sure reward of bright eyes and rosy cheeks in the family.

Washington, D. C.

A House Apiary

By Frank M. Pillsbury

THE cut shows a house apiary belonging to Mr. H. Jonsson, in Sweden. He has only black bees and does not favor the Italians, having tried them and discarded them in favor of the blacks. He has handled these without veil or gloves for years. The house contains forty-eight colonies, as can be seen, with twelve colonies in each ell. Entrances are painted different colors. Formerly skeps were used, but the change to hives has been very satisfactory, since it is no longer necessary to sulphur the bees.

Rochester, N. Y.

from one central plant the advantages may be listed as follows:

1. A thoroughly suitable building may be erected on the beekeeper's own property where machinery can be permanently installed. A systematic person will then gather around him all sorts of labor-saving devices and conveniences which take time to accumulate and which frequent moving to outapiaries completely disorganize. I am referring especially to the tools one uses only occasionally which must have regular places and be kept in them or they can never be found when wanted.

2. There is less expense for equipment than where each apiary is equipped, and less wear on machinery than where one outfit is torn up, moved, fastened down and torn up again from time to time.

3. Larger and better machinery will be used, and it will be installed in a much more substantial manner when it is going in to stay.

4. More pounds per day will be extracted because of the improved machinery.

5. The work of extracting and caring for honey and cappings is done at home, where meals and hours can be regular, and if the beekeeper wishes to fit machinery or do other chores before and after hours he is there to do it, instead of traveling on the road. This matter of regular hours is very important in keeping help.

6. Honey can be left in store-tanks for a few days to clarify, free itself of air bubbles from the extractor, and blend before filling into selling packages.

Rear view of Pettit Apiary Building

7. The work of extracting, once started, can be carried through more systematically.

8. At the end of the season all supers are at home for the overhauling or painting many of them will need.

No doubt the advocates of this system will know other advantages I have missed.

The disadvantages of bringing supers home to extract are:

1. The expense of hauling full supers home and empty ones out, including some risk of breaking combs. This includes first cost, upkeep and depreciation of truck; also the time of driver. Against this

must be balanced the fact that a light truck is practically indispensable anyway; almost as many trips to the outapiaries would be needed to go to work as to bring supers home, especially as the honey and wax have to come home in any case, and the moving and setting up of machinery take considerable time.

2. The trouble with robbers when wet combs are taken to a yard in the absence of a flow. This is serious, but could be overcome by going with them at night, as a last resort.

3. A more serious objection is the danger of spreading disease, and I would advise going slowly until it is pretty well eradicated from all apiaries concerned. The danger can be overcome by extreme care to prevent robbing at every step. The home garage should be in the same building as the extracting room and equally bee-tight, so that each load of supers is under cover all the time at home except when actually moving in or out. Also all supers from each apiary should be kept by themselves, with no mixing. Extreme care with reference to infection all along the line will not only prevent spread from one apiary to another, but should eradicate American foul-brood entirely.

The Pettit Apiary Building

After several years of moving machinery, first the hand extractor and capping can in a one-horse wagon; then the power extractor, engine and capping melter with a team, and later in a motor truck, I have become a convert to the central apiary building idea. I have built one and have, or will incorporate in it some ideas based on modern principles of factory equipment. The building is 24x40 ft., with walls 16 ft. to the plate, and a gable roof. It is built on a concrete foundation and is two stories high, with a 4-in. cement floor down stairs and a pine floor on 10-in. joist overhead. The joist are 12 ft. long and meet on a middle partition, making a floor strong enough to carry almost any weight that is likely to be put on it.

The ground floor is divided by the

middle partition, which stops 11 ft. from one end for a garage, running across the building and extending 6 ft. in front. This garage, being about 11x30 ft., has room for a truck and an automobile, or two light trucks, as required. The other two rooms, each 12x29 ft., are the extracting room and honey room, respectively. It is 10 feet from the lower to the upper floor, giving a ceiling 9 feet in the clear. The cement foundation on all walls rises four inches above the cement floor, which slopes toward the middle of each room, where a bell-trap connects with the sewer. This makes washing down the floor with hose and brush after each day's extracting, or other mussy work, a pleasure to anticipate. The extracting room also has a washing sink with draining table against the middle partition near the door of the honey room. Running water, hot and cold, and steam will be on tap at the sink.

The upstairs will contain the office of the business, a lavatory with closet and a shower for the men, the carpenter shop, paint shop, foundation room, storeroom, etc. As far as possible, I aim to have a room devoted to each line of work, and use it for nothing else. Then machinery and appliances once installed need not be moved, but can be left all ready for use at a moment's notice. It will be a lot of space, but that is cheaper than man-time, which is about the most expensive commodity there is in production today.

The stairs go up beside the middle partition and open from the garage. They are of easy grade for climbing, but no wider than is necessary for one person to go up or down. They are not intended for carrying things up, as all material goes through a trap door in the ceiling over the garage. This is 6x4 ft. and may be fitted with a simple hoist, although it is easy to hand light things up or down from the back of a truck standing on the garage floor beneath. This is particularly convenient when loads come in or go out; all material being handled in the garage under

Apiary side of central apiary building at the Pettit Apiaries at Georgetown, Ontario. Garage door on this side allows truck to be backed out between rows of hives for bringing in supers. Extracting room downstairs; office and carpenter shop upstairs

cover. At present heavy boxes are taken up with block and tackle.

It will be seen by the illustration that a large percentage of the outside wall space is glass. This abundance of light relieves the depressing effect which indoor work so often has. It also allows machinery to be placed or supers to be piled wherever convenient, regardless of the location of windows. The ceiling downstairs is 9 feet in the clear and all windows will be screened, giving plenty of air.

(To be concluded).

The Nutrition of the Honeybee

By R. Adams Dutcher.

Division of Agricultural Biochemistry, University of Minnesota.

(Continued from March number).

HONEYDEW, the other material from which honey is made, is found on leaves of trees and shrubs and is supposed to be excreted or rejected by plant lice which feed upon a portion of the leaf sap. Honeydew made from this material are generally considered inferior to those made from floral nectar. Table VII shows an analysis of honeydew from the pine tree.

Table VII

Water	54.41
Cane Sugar	8.16
Invert Sugar	17.44
Gums	19.19

Comparison of nectar and honeydew analyses shows the honeydew to be high in gummy materials which are known to be digested with difficulty by the bee.

Honey, which makes up a very large part of the bee dietary, has the following composition:

Table VIII.—The Composition of Honey

	Per cent.
Water	17.00
Invert Sugar	75.00
Cane Sugar	1.90
Dextrin (a gum)	1.80
Protein30
Ash18
Undetermined (pollen, dirt, hair, etc.)	3.68

It is readily seen by examining Table VIII that honey is a carbohydrate food composed almost entirely of invert sugar and can furnish little or no nitrogen for the building of tissue.

Another very important food for the bee is pollen obtained during the flowering season and deposited in the comb as beebread. This beebread is a storage material and is drawn upon as needed for the feeding of the queen and larva. It should be noted that the worker bee eats comparatively no pollen, but confines herself to an almost protein-free diet of honey. There is little wonder that she lives but a few weeks or months. The queen bee, whose diet is very well balanced in every way, lives for several years. Table IX shows the protein content of some Canadian pollens:

Table IX.—Result of the Analysis of Samples of Pollen

Pollen from—	Moisture	Nitrogen in free substance	Equivalent to Protein
	Pct.	Pct.	Pct.
Yellow box and mesmate	23.50	3.56	22.25
Blue stringy bark	25.15	4.39	27.43
Mesmate	20.80	4.29	26.81
Black wattle, etc.	24.25	3.87	24.18
Cucumber	20.17	3.66	22.87
Flat weed	22.80	2.77	17.31

(Analyses of corn pollen made at this laboratory show a protein content of 24.20 per cent.)

The Use of Food by the Honeybee

From what has preceded we are forced to conclude that food is used by the bee for two purposes: (1) to build protein tissues, and (2) to furnish heat and energy. This explains why the larvæ receive such large quantities of pollen, for in the brief space of 21 days all of the protein tissue of the bee's body is manufactured. The larvæ are fairly "stuffed" with nitrogenous food. The same is true of the queen; not only is she required to repair old tissue, but she is required to manufacture thousands of eggs, and yet she lives for several years. Her diet is highly nitrogenous. Table X shows the composition of larval foods:

Table X.—Composition of Larval Foods

	Drones.		Workers.	
	Queen	Under 4 Days	Under 4 Days	Over 4 Days
Protein	45.15	55.91	31.67	27.87
Fat	13.55	11.90	4.74	8.38
Sugar	20.39	9.57	38.49	18.09

(These results were obtained a great many years ago and may not be correct. However, they are comparable.)

With these facts in mind certain questions immediately present themselves. Can we lengthen the life of the worker bee by insuring high protein larval food of the right type when pollen supplies are low? Is there any relationship between the composition of the larval food and the strength of the colony? Would it be possible to feed the worker bee a small quantity of easily digestible protein material (in the honey or syrup) which will not cause a large accumulation of feces during the winter months? Table IX shows that pollens from different sources vary in protein content and the question might be raised, are all pollens equally valuable for larval foods? Can we find a cheap substitute for pollen and bring on brood rearing earlier, in order that we may have a larger colony for work by the time flowering season comes on? These and many other questions

are being considered by the Divisions of Bee Culture and Agricultural Biochemistry at the University of Minnesota, and preliminary experiments are now being carried out along these lines. From a practical standpoint, it would be worth thousands of dollars to the honey industry to be able to put more bees and stronger colonies into the field during the honey season.

At present honey and cane sugar are the winter stores used for wintering bees, and it is known that colonies often come out very weak in the spring on such diets, especially if the colony was composed largely of old bees when going into winter quarters.

Analysis of the bee's body reveals appreciable quantities of mineral elements, such as calcium, sulphur, phosphorus, chlorine and other elements. Do these play an important role? This question will be studied also.

We have one experimental colony in a greenhouse which contains no vegetation. These bees are being fed honey and corn pollen. Analysis of the pollen, beebread and larval food should shed some light as to the changes through which these important substances pass.

Various substances for pollen have been used with varying success. No suggestions can be made at present in this regard, but we have one colony raising brood in the cellar at this time (Dec 5) on a cane sugar diet containing powdered casein, a milk protein. Whether this is due to the casein or reserve of pollen stores remains to be seen. The matter of protein food for the honeybee is of real practical importance, for honey is an important article of food in times of peace, and now that sugar is not plentiful, the allies are shipping loads of honey from this and other countries to use as a sugar substitute. One consignment alone amounted to 2,000 tons. If we can increase this amount ever so little, we will have accomplished something not only for the nation, but for the honey industry.

The Flowers of California

By W. A. Ryal.

I HOPE I may be excused for appearing a bit egotistical when I refer to my past writings on the honey-secreting flowers of California. Having been brought up among trees and plants (my father having been one of the pioneer nurserymen and fruit growers of this state), I naturally grew up among garden surroundings. And having been on the place since the days of 1865, I, too, learned about these insects when I was a little fellow. And at an early date I learned to investigate the source of the nectar they brought to the hives. This I was prompted to do more especially as I had noticed that some honey was much lighter and finer flavored than other grades. Then, after some years, I began to read the periodical bee literature of America and, I think, it was in 1876

or '77 that I began to write for the press.

Some time in 1877, when a student of the University of California, I received a clipping from a Los Angeles paper asserting that the flowers of a certain variety of Eucalyptus in or near that city were so poisonous to bees that thousands of them were found dead beneath the branches of the tree. The said clipping was referred to me by Mr. E. J. Wickson, the editor of the Pacific Rural Press, a gentleman who shortly afterward became one of the professors of the University of California, and who is, I believe, still connected with the Agricultural Department of the University. I was asked to write what I knew upon the matter. My reply was that I had never known bees being injured by quaffing the nectar of any variety of the tree in question; that I never saw any bees that were destroyed by gathering nectar or pollen from any tree or plant whatever.

The Los Angeles paper, through its correspondent, N. Levering, still persisted that bees were killed by such nectar, at least, by this particular tree. However, some forty years have since passed and the Eucalypti "tribe" are considered the most valuable honey-secreting trees introduced into California; they still fill a void that would otherwise be largely nectarless, thus keeping many a colony from starving during November and the winter months.

The Yucca

Upon the mountains and in some of the desert places through the lower or southern counties of California, one meets the Yucca (*Hesperoyucca whipplei*) and at times specimens thereof are pretty and interesting, especially when they are in bloom, usually during June and July. Besides its native haunts, it may be occasionally seen in public parks and gardens in various portions of the State. The nectar is attractive to bees and, where it grows numerously, a good grade of light honey is secured from it. Something over a quarter of a century ago, the late W. W. Bliss, of Durate, Los Angeles

County, made a bee-brush from the leaf of this plant by securing a quantity of the fiber attached to the trunk. It made a soft fan-shaped brush that had some sale for a few years.

To call a plant out of its established botanical name, even if such name is a long one and hard to remember, is to give it a vulgar name, and the Yucca has many. It might appear to the casual reader irrelevant to say "Our Lord's Candle," "Roman Candle," or "Mountain Queen" are "vulgar," but to these can be added "Spanish Bayonet" and "Spanish Dagger," which rather strongly contrast with the former. There are about a dozen species growing in the southwestern portion of the United States, and in adjacent Mexico. Very recently it has been reported

that this plant is now used to make brooms. Another species is being manufactured into surgical splints. And also it is being experimented with in the making of artificial limbs.

The clump of Yuccas here illustrated I photographed one excessively hot day in July, 1915, when with my wife I was motoring toward Los Angeles. It is a true yucca (*Y. arborescens*) and is commonly called Tree Yucca and Palm Yucca. We had left the mountainous ranges where the first-mentioned genus abounds, and after passing a small place called Fairmont, a sort of oasis on the edge of the Mojave desert, we traveled for some distance along a stretch of dry, sandy soil on which grew little other than scrubby brush, cactus and Yuccas. Oakland, Calif.

A Pound of Bees Not Enough

I differ with Dr. Miller on the fourth question asked by Washington, in January number. A pound of bees supposed to contain 5,000 bees, say one-fourth remain in the hive as nurse bees, that would allow a good queen to do only one-fourth of her duty. A queen worth keeping will fill a comb with eggs in a day. It will be 21 days before more nurses can emerge, and as some bees are lost every day, less than two pounds, or, better, three pounds, is sufficient to build up a colony readily in the cool weather of spring.

M. F. PERRY,
Bradentown, Fla.

Memory Joggers

A record book with notes giving a brief record of each colony is almost a necessity. As an aid to getting odd

jobs about the apiary done, I find the memory joggers just the thing.

At your printing office get some bright colored cardboard and have it cut into squares two and a half inches each way. Punch a small hole in the corner of each card. With a piece of string tie each card to a two-inch harness ring. Carry a few of these in the tool basket and when a colony needs attention make a note on one of the red flags with date when colony will need attention. Thus: 5-7, examine brood; 6-11, swarm due, etc. Slip the ring under hive cover, letting the red flag dangle at front of hive. They are conspicuous, convenient and facilitate prompt work.

Wrapping Hives for Outside Wintering

When it is desired to wrap hives for outside wintering it is unnecessary to use building, roofing or other expensive paper. Use newspapers for all except the outside layer, which should be a fair quality of wrapping paper, such as the merchants buy in rolls for wrapping goods. This can be bought in almost any desired width. After all is in place tie down firmly and with a paint brush give a coat of the following mixture: kerosene oil, two parts, and raw linseed oil, one part. This will waterproof the paper so thoroughly that it will stand exposure to rain and sun for a year or two.

L. A. GREELEY,
Morenci, Mich.

Uniting Weak Colonies

For uniting weak colonies I make a division board of strips that fit tightly to the bottom board as well as the ends, and even with top of hive. Both sides of the skeleton frame are covered with wire cloth

Yucca Trees in California

to prevent the bees from fighting through it. I move three or four frames with the bees to one side and put in the division board. The entrance is closed at night and an oil-cloth cover placed over the frames. The colony is then moved to the stand of the one with which it is to be united. The frames from the entrance to that side is left open, since it is on the stand of that colony. After three or four days the division board is removed and all the bees released, when they unite without trouble. FRANK HAACK, Marion, Ore.

A Sure Way to Find a Queen

I fasten a perforated metal cage over the entrance so that the bees cannot shift it. The frames are then removed one by one and the bees brushed off in front of hive. Replace the frames as shaken. The queen will readily be found trying to get through the entrance. When brood-rearing is about over in the fall one is almost sure to find the queen by taking out the three frames from the middle of the hive and shaking them in this way.

J. H. SEIFFERT,
North Bruce, Ontario.

The South Wales Apiary of W. Thomas

From South Wales

'Our average is from 50 to 60 lbs. in this part of the country, but our honey is fine. It doesn't need blending. All our bees are the German brown race.

W. THOMAS,
Swindburg, Mydrim, S. Wales.

to pieces of wood and by means of a sawing motion the candy can be easily cut into perfect cubes or other desired shapes. The friction will heat the wire so that the candied honey can be cut rapidly.

If ordinary chocolate is used to cover the cubes of honey, the chocolate will assume a semi-liquid condition on standing for a time. To overcome this something must be added to the chocolate to give the required texture. The method of procedure is as follows. Liquefy the chocolate in the usual way and to the liquid add about 5 per cent of its volume of beeswax. A little experimentation will enable one to determine the amount needed for best results. If too much wax is used the beeswax can be tasted, but if just the proper amount is used it cannot be detected in any way. The mixture should be stirred carefully so that the beeswax will be evenly incorporated with the chocolate.

The mixture must not be allowed to cool while dipping the candied honey. If allowed to cool, the beeswax will separate. To prevent this set the containing vessel in hot water while dipping in the candied honey. The candied honey is dipped into the mixture by means of a piece of wire or long pin. The pin is inserted into the cube of honey and dipped into the mixture. If the temperature of the mixture is quite high it may not cover the candied honey as thickly as is desired, and in that case the cubes must be dipped more than once.

Nuts can be used in connection with this method to advantage. The pieces of nut (walnuts, pecans, etc.,) can be pressed into the cubes before dipping, or pressed into chocolate on the cubes prior to cooling. However, as the chocolate cools very quickly, considerable practice must be indulged in before the latter method becomes a success.

The slight taste of beeswax imparted is pleasing rather than displeasing. Another addition to the long list of its uses helps our industry, since beekeepers could advertise the use of beeswax in this connection when making honey sales.

BEE-KEEPING FOR WOMEN

Conducted by MISS EMMA M. WILSON, Marengo, Ill.

Honey-Sweetened Whipped Cream

When whipping cream try adding a teaspoonful of strained honey instead of sugar. It not only gives the cream a delightful flavor, but causes it to stay whipped and firm all day.

How to Make Honey Candy From Candied Extracted Honey or From Candied Comb Honey

By Mrs. C. W. Aeppler.

In making honey candy, either from candied extracted honey or from candied comb honey, the obstacle to overcome is the semi-liquefaction of the chocolate that is used

after the candy has been made and allowed to stand in a warm room.

This matter was for a long time quite a problem, but after some experimentation the following method was adopted, which, if followed, will give excellent results:

If candied extracted honey is used, the honey should be entirely candied and not be in a semi-candied condition. The candied extracted or comb honey should be cut into suitable pieces, half an inch each way is a good size. To do this, use number 30 wire, such is used in wiring brood frames. The wire is fastened

Apiary of J. H. Seiffert, or North Bruce, Ont.

This candy is strictly honey candy, and contains nothing but the products of the hive, with the addition of the chocolate. It has many advantages over candies made from cane sugar. In fact, there is real food value in honey candy. It can be eaten by children and no harm re-

sult, such as might result on eating large quantities of candy made from sucrose.

In short, candy made in this way is perfectly delicious. But it must be remembered that the secret lies in the addition of the 5 per cent of beeswax.

have become more and more restricted, the bees are well provided for. The entire success of the latter enterprise is due to the efforts of the Central Beekeepers' Association. If it were not for this powerful organization, Swiss beekeeping would no doubt have perished ere this under the heel of war's ruination. The wholesale price of sugar in January, 1918, was 11.2c per pound, which is, of course much higher than we are forced to pay.

C. W. AEPPLER.

LEGAL SERVICE DEPARTMENT

Leasing Apiary Sites

I am starting a new apiary on leased ground and have made arrangements with the owner of the land as follows: The lease is to run for a period of twenty years at a yearly rental of \$15, with an additional rental of 50 pounds of honey annually, providing the crop amounts to 1,000 pounds or more. He is to give access to the land by means of an already established road. I am to fence the apiary site against stock. Such buildings as I construct are to remain my property, to be removed if desired at the termination of the lease. Can you give a legal form of lease to cover the above agreement?

Answer—In the following form the land owner is the party of the first part and the renter the second party. It is not necessary that any special form of wording be followed to make a contract binding, provided that the terms of the agreement are clearly set forth. The usual form is something similar to the following:

This article of agreement made and entered into on the 8th day of December, 1917, by and between John Jones, party of the first part, and Frank Smith, party of the second part, witnesses:

That in consideration of the sum of one dollar in hand paid by the said second party and the stipulations and agreements hereinafter

mentioned, the said first party hereby agrees to lease to the said second party the following lands, to-wit: One acre in the northwest corner of his farm in section 34, township 35, range 8, Dent County, Missouri, known as the Simmons place, for a term of twenty years.

It is hereby mutually agreed that the said land shall be used as an apiary site and for no other purpose, except as may be necessary in the care of the bees and the production and marketing of honey and wax.

The second party hereby agrees to pay to the first party the sum of fifteen dollars annually on or before the first day of July, as rental for said premises, with an additional rental of fifty pounds of honey each season that the total production of surplus honey from said apiary shall amount to one thousand pounds or more.

Said second party hereby agrees to build a suitable fence to protect said apiary from live stock at his own expense and to keep same in repair during the life of his agreement.

It is further agreed that said second party shall have access to said premises by way of an already established road; that he shall have the privilege of erecting buildings thereon for his own use in connection with the said apiary and that such buildings shall remain the property of the said second party and he shall retain the right to remove them at any time that he shall have occasion to do so.

Signed in duplicate this day of 1917.

JOHN JONES
FRANK SMITH.

MISCELLANEOUS NEWS ITEMS

New England Pioneer Dead.—Old subscribers of the American Bee Journal who were with us in 1916 will recall our April number, which was devoted almost exclusively to New England.

In it was given a description of New England's oldest beekeeper, Mr. Joseph H. Chase, who has just died, in his 91st year.

Not only was Mr. Chase a pioneer beekeeper, but he was noted as a horticulturist, having taken prizes for many years at the annual horticultural show of his State. His specialty was grapes, as well as bees, and he was also noted for his varieties of peonies.

Conditions Abroad.—In the November and December, 1917, also January numbers, of the "Schweizerische Bienen-Zeitung" (Swiss Bee Journal), I find the following of interest:

Beeswax is now bringing 59c per

pound in Switzerland. The foundation manufacturers are troubled no little in getting raw material.

In the January number of the American Bee Journal I reported the average production of honey per colony to be 5 Kg. This should now be modified, as the latest report of the Swiss Beekeepers' Association shows an average production of 8.0 Kg. (17.6 pounds) for 1917. In 1916 the average production was 5.2 Kg., in 1915 9.9 Kg., and in 1914 4.1 Kg. The total value of the honey crop in 1917 is given as \$1,397,500. However, on account of the increased prices of supplies and sugar, no profit has been left the average beekeeper for his season's work. The Swiss do not enjoy the large production per colony as we do here in the United States.

The war department has allowed a maximum of 4 Kg. (8.8 pounds) per colony for spring feeding. Even though the importations of sugar

Illinois River Valley Beekeepers.—At a meeting held at Pekin, Ill., called by W. H. Williams, of Pekin, more than 50 beekeepers were present. Dr. A. C. Baxter, President of the State Society, gave an address, as did C. P. Dadant. A local organization was formed under the name of Illinois River Valley Beekeepers' Association, with the following officers: President, W. H. Williams, Pekin; Secretary, F. R. Irenberg, Pekin; Vice President, O. S. Biggs, San Jose, Ill. The large attendance at this meeting shows what good advertising will do.

Correspondence Course in Beekeeping at Iowa State College.—The Iowa State College is making special efforts to induce Iowa beekeepers to produce a maximum crop of honey this year. In order that a large number of beekeepers may be aided, a correspondence course in practical beekeeping has been prepared. The course includes ten lesson outlines, which will be sent out throughout the season as needed. Two reference books on beekeeping will be included with the lesson outlines.

A fee of three dollars will be charged, to cover the cost of the books, and will be the only charge to the beekeepers taking this course.

Any beekeeper with one or more colonies will find it profitable to enroll for this course, and younger members of the family are urged to undertake the care of the apiary for the coming season, where the usual attendant is too busy.

The world has realized, as never before, that the final success of a nation depends upon its food supply. To increase the supply of most foods, extra labor, machinery, ground and seed are required. With honey, however, a much greater crop can be secured by means of preparedness and a little attention to the bees at the right time. Give the bees a chance to do their bit. Nature provides the nectar, your country needs it. Join the correspondence course and harvest it. Following is a list of lecture topics, with dates of mailing.

March 1—I. General outline of course, suggestions for reading and preparation for crop, and definitions of bee terms.

April 1—II. Spring management of bees.

April 15—III. Diseases of bees and treatment.

May 1—IV. Transferring bees.

May 15—V. Swarming, control and methods of increase.

June 1—VI. Comb-honey production.

June 15—VII. Extracted honey production.

July 1—VIII. Preparation and marketing of honey.

August 1—IX. Fall management of bees.

September 1—X. Wintering of bees.

F. ERIC MILLEN,
Ames, Iowa.

Nebraska Meetings.—At the January meeting, held at the University State Farm in conjunction with the Organized Agriculture meetings, the following officers were elected: President, F. J. Harris, of Lincoln; Vice President, Geo. O. Olson, of Wahoo, Secretary and Treasurer, O. E. Timm, of Bennington. Also a committee of four was elected for the purpose of getting new members and stirring up a greater interest in the association.

It was decided to hold a meeting on Thursday, at 9 a. m. during the State Fair. At this meeting will be given several instructive talks on the needs of co-operation in beekeeping, etc. Also it is expected to hear a report of the committee on their work done.

On February 2 the officers held their meeting at Omaha and certain changes concerning the State Fair exhibit were recommended before the Board of Agriculture.

Also it was decided by the Association that they will care for all exhibits sent in to the State Fair by members who cannot personally be there to care for their exhibit. This was made especially for beginner exhibitors who can have only a few entries.

Any exhibitor who wants to take advantage of this offer must write the Secretary at least six weeks before the Fair.

O. E. TIMM, Sec'y.

The National Meeting at Burlington.—The meeting of 1918 was one of the smallest in attendance and one of the most harmonious and interesting in discussions that the National ever had. The small attendance was due to lack of early information as to the date of meeting and program, some members stating that they had received a copy of the program only a day ahead of the date of the meeting.

President Jager was present only on the first day, being called back to St. Paul by a telegram, for urgent business. He asked the editor of the American Bee Journal to preside at the meeting until after the election of new officers. The Vice President elected in 1917, Mr. Polhemus, died within a week after his election, so that the absence of President Jager left the meeting without a presiding officer.

The Secretary, John C. Bull, was also absent and Hamlin B. Miller, of Marshalltown, Secretary of the Iowa State Association, was appointed as secretary pro tem. Before leaving, President Jager called the attention of the members to the fact that one

of the most weighty actions the National Association was ever called upon to perform was perpetrated in 1917, when he and several others appeared before the officials of the National Agricultural Department to solicit the establishment of extension work. By the influence brought to bear, fourteen extension workers were appointed to visit the different States, and Dr. Phillips stated that they were holding not less than nine meetings of local organizations daily in different parts of the country, so that the education of uninformed beekeepers is now going on at a rate which will increase greatly the knowledge concerning bees and will check diseases while increasing production.

Very interesting information was supplied by Dr. Phillips concerning the number of circulars sent to beekeepers by the Bureau of Entomology and the replies received showing increased interest. There are over 800,000 beekeepers in the United States and nevertheless it is proven that much more honey wastes unharvested than the total amount of sweets of different kinds produced.

Steps have been taken by the Food Administration to supply sugar for feeding bees wherever it is necessary. Also help is extended in getting the delivery of both lumber and coal for the making of apiary implements.

Resolutions were passed commending the work of the Bureau of Entomology and asking for its continuance and extension.

A resolution was also passed asking that the Postoffice Department take means to enable the shipping of bees in combless packages through the parcel post.

The matter of purchase of combless packages of bees was discussed at length and indiscriminate purchase censured. It was the consensus of opinion among the different members that this business of buying and shipping bees from the South in combless packages be confined to supplying only hives full of combs at the proper time. Otherwise more loss than profit would be derived from this business.

Numerous papers were read and much information elicited.

The officers elected for the ensuing year are:

President—David Running, Filion, Mich.

Vice-President—Hamlin B. Miller, Marshalltown, Iowa.

Secretary—Floyd Markham, Ypsilanti, Mich.

Directors—David Running, Floyd Markham, John C. Bull, of Valparaiso, Ind., and Professor Francis Jager, of St. Paul, Minn.

The marketing of honey, the making of honey a staple, were discussed at length. The following resolution was passed:

"Resolved, That we view with satisfaction the progress already being made and the wonderful efficiency already attained by the teaching of economic uses of honey by our State colleges and high schools. The National Beekeepers' Association endorses this work and desires in this

manner to encourage its continuance."

All the sessions were held in the banquet room of the Hotel Burlington, a very convenient place in the extremely cold weather prevailing at the time.

Although no place of meeting was selected for 1919, the election of both President and Secretary in the State of Michigan indicates a tendency to hold the next meeting in some central spot of the Middle West.

In spite of the small income, the treasury was shown to have a balance of \$133.10 after paying expenses.

Professor F. E. Millen, in charge of apiculture at Ames, made the statement that about 30 of our agricultural colleges are now having courses in beekeeping regularly.

Ontario Short Course.—The short course in beekeeping was a great success and our program was carried out without a mishap of any kind. Sixteen attended the lectures on the opening day of the course and the class gradually increased in numbers until one day forty-nine people were present. In arranging the program the more elementary work was dealt with at the first of the course, to form a foundation for the more advanced work to follow. The last half of the course was of particular interest to the more advanced and experienced beekeepers, although every detail was explained as clearly as possible for the benefit of the beginners. Special subjects were assigned to special days so that those unable to attend all lectures could spend their time here to the greatest advantage. Mr. John A. McKinnon, St. Eugene, Ont., handled the subject of queen rearing. Mr. D. Anguish, of Lambeth, at one time a prominent exhibitor of honey at the Canadian exhibitions, delivered the lectures on Comb-Honey Production, Grading and Marketing. Principles were mentioned rather than methods, but in every case a method was described, to more firmly fix the principles in the minds of the class. G. B. Gooderham, B. S. A., Central Experimental Farm, Ottawa, spoke about American foulbrood. Mr. Sladen, Apiarist, Dominion Experimental Farms, was here for the first week of the course.

I very much regretted the unavoidable absence of Mr. Jas. Armstrong, President of the Ontario Beekeepers' Association. He has assisted with his practical talks at many of our courses, but illness prevented him attending. Mr. J. F. Dunn, Ridge-way, assisted me for the greater part of the time and proved a valuable utility man. Mr. Hershiser was also present and gave two very practical lectures.

The teaching of this course will spread over a large area, some members of the class coming from New Brunswick, Pennsylvania, and one from Saskatchewan. They were all enthused with the urgent need for the production of more honey to help relieve the sugar shortage.

Generally speaking, the prospects of a crop are fairly good in Ontario,

providing the bees come through the winter in good shape. We had several very cold days—20 to 30 degrees below zero—and in many cases the high price of honey induced the beekeepers to extract rather too closely and the high cost of feeding may have stunted the bees' winter stores and large loss may result from starvation.

GEO. F. KINGSMILL.
Toronto, Ont.

California Conditions.—Just as the hopes of the California beekeepers had reached almost the lowest possible ebb, it suddenly rained, Feb. 17. Now we are all at sea as to the future. Many believe that regardless of the amount of rain that may come, we will not secure a crop from the sages. Personally I do not share the opinion of those who think so. By the time this reaches the readers of this journal we will know more of the season conditions, but I venture the opinion that, should good rains follow through March, with sufficient in April to sustain the moisture through May and June, we may expect a flow from the sages. In fact I should not be surprised to see one of the best sage crops for a number of years if those conditions should prevail. But, on the other hand, if the rains should be very light from now on (March 1), we may expect little from the sages, or indeed any wild flora. There are two factors that, to my mind, have played in our favor, the thorough drying out of the sage being one, the other that there had been so little rain previous to Feb. 17 that the plants were perfectly dormant, the rain having come just at the time the sage should begin its spring growth under normal conditions. It will be all the more vigorous for that reason and will have escaped any great danger of frost.

P. C. CHADWICK.

P. S. Much rain has fallen since this was written.—Ed.

**UNITED STATES DEPARTMENT
OF AGRICULTURE
Bureau of Markets
Semi-Monthly Market News Bulletin**

Honey arrivals since last report:

Keokuk, Iowa.—No arrivals.

Hamilton, Ill.—No arrivals.

Medina, Ohio.—50,900 pounds from Minnesota.

**Telegraphic Markets from Today's
Markets—Jobbing Prices**

(In many markets in the honey trade the term "jobber" is commonly applied to the original receiver who buys direct from the grower in carlot quantities. However, in these reports we use the term "wholesale carlot receiver" to designate the carlot purchaser, while the term "jobber" refers to the dealer who buys in less than carlot quantities from the carlot receiver and who sells direct to retailers. The prices quoted in this report represent the prices at which the "wholesale carlot receivers" sell to the "jobbers.")

Note.—Arrivals include receipts during preceding two weeks. Prices represent current quotations.

Philadelphia.—No fresh arrivals. Practically no demand or movement; market strong, very few sales. Extracted: no sales. Comb honey: very few sales, light amber, No. 2, 22c per pound. Beeswax: no fresh arrivals, no sales.

Minneapolis.—No fresh arrivals. Supplies very light. Demand good, market strong. Comb honey: 24-section cases Minneapolis best white, 20c per pound; Colorado white, supplies cleaned up, \$5.75-6.00 per case. Extracted: no sales reported. Beeswax: no sales reported.

St. Paul.—No fresh arrivals. Demand moderate, but exceeds supply; market very strong. Comb honey: Minnesota and Wisconsin: No. 1, light, 24-section cases, few sales 25c per pound. Beeswax: no sales reported.

Kansas City.—No fresh arrivals. Demand limited, movement moderate, market firm; very few sales; all sales in small lots. Comb honey: no sales reported. Extracted honey: Colorado and California white to light amber, 16-18c per pound. Beeswax: no sales reported.

Denver.—No fresh arrivals. Demand

moderate, market strong, jobbing, no sales reported. Sales direct to retailers: few sales, comb honey \$5.50 per 24 section case. Beeswax: receipts light; price to producer 38c per pound.

Cincinnati.—No fresh arrivals. Extracted honey: demand good, movement fair, market firm; domestic 17-19c per pound; orange and white sage, 22c per pound. Comb honey: supplies cleaned up. Beeswax: demand good, market steady. Average yellow, 43-45c per pound.

New York.—Arrivals, 1,019 barrels Cuba. Demand good, market strong. Extracted honey: domestic, yellow, supplies light, 20-22c per pound; West Indian, light, 18-19c; dark, 17-18c per pound. Beeswax: 279 bags Cuba arrived. Supplies very light. Demand good, market strong. Yellow, 40-41½c per pound; dark 37½-38½c per pound.

St. Louis.—No fresh arrivals. Comb honey: no sales reported. Extracted honey in cans, supplies light; bright, 17-18c per pound; dark, 16-16½c per pound. Beeswax: prime, 39c per pound.

Chicago.—Unreported.

Send Questions either to the office of the American Bee Journal or direct to
Dr. C. C. MILLER, MARENGO, ILL.
He does NOT answer bee-keeping questions by mail.

Clean Sections

I have a small apiary of 50 hives, producing comb honey only. I find it is a great deal of work in our part of the country to clean the sections of propolis, so it looks well to put on the market.

1. Is there anything on the market to place on these sections, on top, while they are being filed in the super, to keep this gum off the wood? It seems to me that a piece of tin to lay on top of the section, of the same shape as the slat where the section rests on would save an immense lot of work on cleaning honey for the market.

2. Is there any preparation made that you could put on to take the yellow stain off from the wood and make it as white as it comes from the factory? OREGON

ANSWERS.—1. I have never known anything of the kind entirely satisfactory. Even if you should cover them, as you suggest, you would find that the bees would thrust glue between the section and the covering.

2. I doubt there being anything practical in that line.

I have produced many thousands of sections, some covered with wood or oilcloth, but most of them with tops and bottoms entirely exposed to the bees, and I prefer these latter. The tops and bottoms are cleaned *en masse*, taking a superful at a time, first scraped with some steel tool, and then sandpapered, finishing up the edges afterward, as fully explained in "Fifty Years Among the Bees," and a thousand a day is no hard task.

Starting Pound Packages

I want to buy some bees and don't know how to get them started in empty hives without stores. Do you have any circulars that describe the method of taking care of bees bought in packages? I have "First Lessons in Beekeeping" and "Dr. Miller's Thousand Answers."

1. Can one buy, say, 1 pound of bees and a queen and put them in an empty hive, say April 20, and not give them any stores, and if

they need stores, how much would he need, and what would be best to give them?

2. Should there be foundation starters or full sheets on the brood frames?

3. I have six empty hives and wonder if it would be profitable to buy bees to fill them.

4. I have only one stand of bees and they are very weak and in a box-hive. I want to put them in a frame hive; would it be advisable to move them into the frames now, as I have them in the cellar?

5. How would it be to buy some bees, say 1 pound, to put in with them? IOWA.

ANSWERS.—1. To put bees in a hive without stores April 20, or indeed any time before they can gather, is pretty certainly to invite total loss. Better not to get them before fruit bloom, and, indeed, it may be better not to get them, in your locality, before June. It will be more likely to your interest to get two pounds rather than one. Whether they can gather or not, it is better to give them some stores. The best thing is honey from bees that you know to be free from disease. Likely you haven't that. Then feed syrup of granulated sugar, equal parts of sugar and water; no need to cook it if it is thoroughly dissolved. Let them have two or three pounds ahead, so that there may be no danger of starving if there are a few days when they cannot gather.

2. Give them frames filled with foundation. You can give small starters, but will lose money by it.

3. Yes, there's big money in it if you manage all right and have a bumper season. But if you have had as little experience as I suspect, you better go a little slowly and try only two or three this year.

4. Don't think of transferring into frames before fruit bloom, and it may be still better to wait until the bees swarm.

5. Yes, it may be all right, if you don't furnish the thing.

Making Hives

Would it be unlawful for me to build beehives for my own use the same size as the 10-frame Tri-State hive, and of the same pattern as the Dadant hive? MISSOURI.

ANSWER.—I don't think there is any patent to prevent it.

Doesn't Want Increase

1. I have ten tier swarms of bees, and as my time is limited, I would like to know how best to manage them to save time, make no increase, and secure a good crop of extracted honey. I have an extractor, three bee-escape boards, sufficient queen-excluders and necessary tools. My bees are in eight double-walled Hilton hives, some containing 8 and some 9 Langstroth frames, and one home-made hive similar to the Hilton hive, and one Protection hive. My greatest trouble so long as I have had bees is that they increase too fast. For instance, last spring I had four colonies to start with and before the end of July I had nine (the tenth one I found in the woods), and about 600 pounds of honey.

2. I have two shallow extracting supers and have been thinking of getting enough more to have one for each hive to give to the queen for more brood-rearing room. What do you think of this?

3. How many supers should I have for these ten hives? I use the deep, or rather, regular Langstroth frames in the supers for extracting.

P. S. It might be well to remark that my hives face the east, and all morning they seem to work good till afternoon, when the entrance is shaded, then they begin to hang out, every day a little more, till in about two weeks, or maybe three, then they will swarm. It seems to me they have enough room. They stand under a large hawwood tree.

MICHIGAN.

ANSWERS.—1. It seems you had at least one afterswarm. You can prevent afterswarming in the way so often given in this department. When a prime swarm issues, set it in place of the old colony, placing the old colony close beside it, facing the same way. A week later move the old colony to a new stand 6 feet or more away. That's all; there should be no afterswarm. To prevent the first swarm is not so easy a matter, although I've done something at it, particulars of which are given very fully in my book, "Fifty Years Among Bees." But it may suit you better to keep down increase by doubling up. In the fall unite so that there shall be no weak colony left over winter. Then at the beginning of the next season unite until there are no more colonies than you desire, making sure to unite first any colonies that may be weak.

2. It may work well. Try it with part of your colonies, so as to compare. It might not be bad at the same time to try one or two colonies with two stories containing 8 full frames each.

3. Two extracting-supers for each colony would do if you extract often enough; if you don't extract till the close of the season you will need three or more, even up to six if you have a big yield.

Sweet Clover

1. Will sweet clover grow in Texas? The soil is poor and sandy.

2. Will it grow if sown on waste land among weeds, without covering the seed with soil?

3. When should it be sown and how much seed per acre?

4. Will sweet clover pay if sown for pasturage and then cut for hay?

5. Will sweet clover die the second year of its growth and leave seed again?

TEXAS.

ANSWERS.—1. There are very few places in which sweet clover will not grow, and it will probably grow in your locality, only there may be such a thing as having the soil too sandy.

2. Yes; but it will do a good deal better if the seed be tramped in by stock than if it merely lies loose upon the surface.

3. It may be sown in the spring, or indeed, almost any old time, sowing about 15 pounds to the acre.

4. It is very profitable in some places. But the idea of having it do its fullest for bees and at the same time doing its best for hay cannot be carried too far. If you sow it this year, and it does well, you can cut it for hay without interfering with the bees, for it does not bloom the first year anyway. The next year, if you leave it until the bees have had the full benefit of the bloom, it will not make good hay, being mostly sticks; but you may cut it before it is in bloom and then let the bees have the blossoms of the second growth. 5. Yes.

Bee Outfit From Diseased Colony

1. Would you advise using queen-excluders again that have been on hives that had American foulbrood?

2. Will it be necessary to destroy supers and drawn comb that have been used on diseased colonies?

3. Do bees stay, as a rule, in hives that have been burned out with a blow-torch?

MICHIGAN.

ANSWERS.—1. If my bees were entirely free from the disease I should hardly want to use an excluder that had ever been used by a foulbrood colony, even though the risk might be small. If I had used an excluder over a diseased colony in my own yard last year I should not hesitate to use the same excluder again next year.

2. Yes; combs, but not supers.

3. Yes.

Swarming

One day last summer I had a swarm and before I had it hived another swarm came out from another hive and joined this one. This happened three times. Such butchering of bees and queens I never saw before. By night I had four swarms in hives, but half of the bees returned to their original hives. What is the meaning of this? Do Italians act like that, and would sprinkling them have helped any? MINNESOTA.

ANSWER.—Bees sometimes seem to have a crazy spell of uniting when they swarm, and one is at a loss to account for it or prevent it, no matter whether the bees be Italian or black. Showering with water might have helped, and possibly it might have done little good.

Drones

I have 27 swarms of bees, one of which has a hybrid queen which produces a pure Italian drone. There are other hybrids in the apiary which throw pure drones, but are inferior in every way to this one. While the season was a poor one here, this one swarm produced nearly 100 pounds of comb honey and filled ten frames from the late fall flow, while the next best in the apiary produced about one-half as much. They are also wintering better than any of the others. Could I not use this queen to rear drones from next summer, when I plan to Italianize at the beginning of the honey flow, caging the drones from all other hives? KANSAS.

ANSWER.—Yes, you can encourage drones in this best colony and cage those of the other colonies, but instead of allowing drones to be reared and then caging them it may be better to shave the heads off all drones before they have time to emerge from their cells, and it may not be a bad plan to cut out the drone-comb and replace it with worker-comb or foundation.

Disposing of Honey in Broken Combs

I have about fifty 2-story, 10-frame size colonies of bees that are old and have been badly handled for several years, and last year nothing was done to them. I intend to transfer into new cases and frames with full sheet foundation in the spring. On account of bad handling it will be impossible to extract the honey from the frames, as they are more or less broken, and in what I call a bad mess. I find nothing in any of three or four bee books that I have that deals with a method to get

the honey out of chunk comb. Can you put me right in the American Bee Journal columns or refer me to some book that deals with proper method? MISSISSIPPI.

ANSWER.—It isn't the easiest thing to find a way that you will think entirely satisfactory. One way is to set out the combs in question, giving the bees free play to rob out the honey. A good way, if neighboring bees don't get too big a share. You can melt the combs and use the honey for cooking, or make it into vinegar. Indeed, if carefully melted so as not to burn the honey, it may be fed back to the bees at any time when it would not be taken into the surplus supers. Sorry not to give you something more convenient.

Requening—Distance to Place Hives

1. When a hive is made useless, how long would you wait before introducing another queen?

2. Someone estimated that a single bee would only gather about a teaspoonful of honey in a season, providing it lived six or seven months, and was able to work all the time. What is your guess?

3. How many miles would that bee fly in all its rounds in that season to gather that honey?

4. My hives are in rows 10 ft. apart and the rows are 12 ft. apart. Is that far enough apart? ILLINOIS.

ANSWERS.—1. Not more than a day or so. Indeed, it may be better to put in the new queen at the same time the old one is removed, planning, however, that she will not be released from the cage until a day or two later.

2. Hard to make any guess. If we assume 25,000 field bees in a colony, and that it gathers 100 pounds surplus and 200 pounds for its own stores, making 300 pounds in all; then dividing that 300 pounds among 25,000 bees, roughly figuring would make about a fifth of an ounce for each bee. But that's counting that each bee spends several months gathering, whereas it spends less than a month.

3. I don't know enough to make an intelligent guess, but I know it might vary very greatly in different places and different years. Even from the same hive on the same day one bee might travel three times as much as another in getting a load.

4. There ought to be no danger to young queens from having hives all facing one way when they are placed so far apart, especially if there are trees or other objects to help mark location. And you can just as well make double the number on the same ground, with no more danger, by putting the hives in pairs, the two hives of each pair almost touching each other.

Enlarging Broodchambers—Transferring

1. I would like to try a super on hive-body to enlarge brood-chambers. In your answer to "Pennsylvania," April, 1916, you say "It is best to put empty super on bottom." Why? Will it do any good this season for me to enlarge brood-chamber when I unpack, say April. I use 10-frame hives. And is it necessary to exchange them, first one on top and then the other?

2. Have a colony that was hived on only seven full sheets of foundation, the other frames being empty. Want to put them into another hive, as there are so many drones. What shall I do to save the brood in the frames that had no foundation? M. E. B.

ANSWERS.—1. The matter referred to is giving a second story early in the season for the sake of allowing more room for brood-rearing. For years I have practiced this, giving the second story as soon as the first story was filled with brood, and then reducing to one story when it came time to give surplus-supers. My general practice is to put the second story under the first, and this for two reasons. It is at a time of year when it is desirable to conserve the heat as much as possible, and if the additional story be given above the whole

of this story it must be kept warm, whereas, if it be given below, no more of it need be kept warm than the bees occupy as they gradually work down. It is also more natural for bees to extend their brood downward, and the bees are slower about starting brood above. No need to exchange stories.

2. One way is to put the new hive under or over the old one, an excluder between (of course the queen will be in the new hive) leaving them thus at least until the worker-brood has emerged.

Swarm Prevention—Full Sheets of Foundation

1. Removing queen from colonies determined to swarm and cutting out all cells after hearing of first virgin, what per cent of colonies would you expect to go ahead all right (in your locality), with no further effort at swarming?

2. Would this prove a very satisfactory method of control?

3. With Hoffman frames and using full sheets of foundation there is a space of about one-half to five eighths of an inch not filled at the bottom. Is not this poor judgment, and why do not foundation makers make same a trifle wider?

4. Do you believe in all the principles of the Dzierzon theory? If not, which ones do you reject? OHIO.

ANSWERS.—1. About 100 cent; at least they would make no further attempt to swarm for some time, although a few might do so a few weeks later.

2. Yes, provided you have no better stock with which to replace the queen.

3. Because if the foundation comes clear down to the bottom-bar the foundation will stretch enough to buckle and make bad work. But by using foundation-splints you may have the foundation touch the bottom-bar without any buckling. Foundation makers are glad to make foundation full depth if you so order it.

4. I do not now think of anything in the Dzierzon theory to which I would take exception.

Does Frozen Honey Granulate?

Referring to your answer to "Ontario" question 2, page 84. I presume you are aware that in this northern country honey does not granulate if kept frozen all winter. I keep a few boxes of comb honey in shallow frames every year and it does not granulate till May, and on those few occasions when I have been compelled to leave extracting till freeze-up, even the extracted in 60-pound cans do not granulate if left in the honey house. Of course, many parts of Ontario have a thaw or two, but we get steady cold from the end of October till the end of March. Excuse me butting in. I always thought it was the freezing that kept it from granulating, but might be wrong. MANITOBA.

ANSWER.—Glad to have you "butt in." You have raised an interesting question, the question whether honey that is kept frozen granulate or not. I think it is generally believed that frequent freezing and thawing tends toward granulation more rapidly than steady cold, and I've always supposed that even though it might not granulate so readily in a very cold temperature steadily maintained as it would in a frequently changing cold temperature, yet a uniform cold temperature favored granulation more than one uniformly warm. I'm pretty certain it will be found that severe freezing will crack the comb, no matter how steady the temperature. All this refers to comb honey. The case is different with honey subjected to extra ripening, as when it has remained in a hot attic throughout the summer. In that case it will not granulate, neither will the combs crack, no matter how low the temperature nor how much it changes. It is possible that your honey has been ripened more than usual. It is possible, also that I am mistaken about ordinary honey granulating so long as it is kept frozen.

BEEES AND QUEENS

FOR SALE—Three-band Italians; queens from best honey-gathering obtainable. Untested queens, \$1 each; 6, \$5; 12, \$9. Safe arrival and satisfaction guaranteed.

W. T. Perdue, Ft. Deposit, Ala.

OUR select bred mated queens winter well. Honey-moon Apiaries, Yakima, Wash.

FOR SALE—First-class Italian queens and bees in season. Send for price list. Free from disease; safe arrival and satisfaction guaranteed. M. Bates, Greenville, Ala., R. 4.

BREEDING QUEENS—I have a few extra 'c' oice Italian breeders for spring delivery. Price \$5 each.

OUR BRIGHT ITALIAN QUEENS will be ready to ship after April 15. Untested, 75c each, \$8 per doz., or \$65 per 100. Safe arrival guaranteed.

FOR SALE—Fine Italian queens at 90c each, \$9 per doz. Ready April 15. Safe arrival guaranteed.

THREE-BAND ITALIANS ONLY—Queens, packages and nuclei. Untested queens, each \$1, 6 \$4.25, 12 \$8.25. Write for prices in larger lots, also nucleus and packages; booking orders now. If you consider quality, pure mating and low prices I am your queen-breeder. I have adopted Gleanings Code for the sale of bees and queens. H. G. Dunn, The Willow, San Jose, Calif.

GOLDENS THAT ARE TRUE TO NAME—Queens, nuclei and bees by the pound; we receive hundreds of testimonials annually. Write for list. Untested queens, each \$1, 6 \$4.25, 12 \$8.25. Write for prices in lots. We are now booking orders for early delivery. We have adopted Gleanings code for the sale of bees and queens.

Garden City Apiaries, San Jose, Calif.

BEEES AND QUEENS from my New Jersey apiary. J. H. M. Cook, 141f 84 Cortland St., New York City.

TESTED leather-colored queens, \$2.00; after June 1, \$1.50; untested, \$1.00; 10 per doz. A. W. Yates, 3 Chapman St., Hartford, Conn.

GOLDEN Italian Queens, bred strictly to produce Golden bees of the best honey-gathering strain; untested, each, \$1; 6, \$4.25; 12, \$8.25; 100, \$60. Satisfaction guaranteed.

L. J. Pfeiffer, Route A, Los Gatos, Calif.

GOLDEN Italian Queens, untested queens, \$1 each; six, \$4.25; \$8.25 per doz. 50, \$32.50; \$60 per 100. Tested queen, \$1.50; one frame nucleus, no queen, \$1.25; 2-frame, \$2.25; 3-frame, \$3; breeders, \$5 and \$10.

L. J. Dunn, 54 Broadway-Ave., San Jose, Cal.

WANTED—10 to 100 swarms of bees not over 50 miles from Bellevue, Ohio.

N. B. Querin, Route No. 7.

THREE-BANDED Italian Queens, untested, one, \$1; doz., \$9; nuclei and packages with fine queens, 2-fr., \$3.75; 3-fr., \$4.50; 1 lb., \$2.50; 2 lbs., \$3.50; 3 lbs., \$4.50; June 1.

A. E. Grandall & Son, Berlin, Conn.

THE best Italian stock, three-bands and goldens at \$2.50 per lb., with untested queen; 2 pounds, with queen, \$4.

J. B. Marshall & Son, Big Bend, La.

BOTH Italians and hybrid bees at \$2.50 per queen, with untested queen; 2 pounds, with queen, \$4.

Mrs. T. H. Carruth, Big Bend, La.

FOR SALE—Golden Italian bees; 1-lb. pkg., with queen, \$2.50; 2-lb. pkg., with queen, \$4; 2-frame nuclei, with queen, \$3.50.

L. J. Bond, Big Bend, La.

GOLDEN ITALIAN QUEENS—No better honey gatherers anywhere at any price. Untested, \$1; tested, \$2.

Wallace R. Beaver, Lincoln, Ill.

FOR SALE—Mott's strain Italian queens. Plans, "How to Introduce Queens and Increase," 25c. E. E. Mott, Glenwood, Mich.

HAVE YOU, Mr. Producer, been getting all for your honey that you could expect? If the price you have been getting has been less than the largest price you have read about, let the Domestic Beekeeper, Northstar, Mich., help you dispose of your 1918 crop. Investigate.

WARRANTED QUEENS from one of Dr. Miller's breeders, \$1 each; \$10 per doz. Package bees, \$1.75 per pound, \$3 per 3 pounds. Add price of queen wanted.

Geo. A. Hummer & Sons, Prairie Point, Miss.

QUEENS—H. D. Murry's strain of 3-banded Italians; reared by the Doolittle method. Prices untested, 1 for \$1, 6 for \$5, 12 for \$9. No disease. Safe arrival and satisfaction guaranteed.

O. D. Rivers, Route 4, Honey Grove, Texas.

GOLDEN ITALIAN QUEENS—About May 1; good honey gatherers; no foulbrood; select tested, \$1.50; tested, \$1.25; untested 85c, 6 \$4.75, 12 \$9. No nuclei or bees for sale.

D. T. Gaster, Rt. 2, Randleman, N. C.

THE Sinking Creek Queen Introducing Cape; 5 years' test of absolute success; indispensable for introduction of valuable queens; also several queens can be kept in one hive in perfect harmony; small and works on the brood comb; especially adapted for queen breeders. Price 60c per doz., 2 doz. for \$1; post paid. Sinking Creek Apiaries, Gimlet, Ky.

SWARTS GOLDEN QUEENS produce golden bees of the highest quality; satisfaction guaranteed. Mated \$1, 6 for \$5; tested \$2.

D. L. Swarts, Lancaster, O., Rt. 2.

SAVE THAT QUEENLESS COLONY!—Introduce a vigorous tested queen. We can supply them by return mail for \$1.25; \$14 per doz. Queens were reared last fall and bred in four-frame nuclei. Three-band Italians only. Never a case of foulbrood in every locality. Satisfaction guaranteed on every queen.

J. W. K. Shaw & Co., Loreauville, La.

FINEST ITALIAN QUEENS, June 1 to November, \$1 each; 6 for \$5. My circular gives safe methods; free. J. W. Romberger, 3113 Locust St., St. Joseph, Mo.

ABOUT APRIL 15 I will again be ready to fill orders for untested queens of my fine strain of leather-colored Italians. I breed no other race. Choice tested and breeding queens at all times. Satisfaction guaranteed. Circular free. Untested queens \$1 each, \$9 doz.; choice tested \$1.50 each; fine breeders \$5 each.

C. S. Engle, Beeville, Bee Co., Texas.

FOR SALE—One to fifty colonies of Italian bees in ten-frame hives. Bees and hives are in A 1 shape; no disease. Price \$10 per colony.

John C. Bull, 234 Indiana Ave., Hammond, Ind.

GOLDEN QUEENS that produce Golden workers of the brightest kind. I will challenge the world on my Golden and their honey-getting qualities. Price, \$1 each; tested, \$2; breeders, \$5 and \$10.

J. B. Brockwell, Barnetts, Va.

FOR SALE—8-frame colonies, extra fine strain Italian bees, with queens, \$7 each; all free from disease, with cores for winter; standard full depth self-spacing Hoffman frames; all straight combs in new one-story single-wall hives; o b here.

Wilder Clarke, Earlville, Mad. Co., N. Y.

PURE 3-banded Italian queens, untested but warranted, \$1; 6, \$5; tested, 6, \$8. Last year's tested queens, clipped, \$1. Good fat nuclei and full colonies in abundance.

Write for price list. J. E. Dwyer, Liberty, Mo.

Vegetable
GARDEN 25c

Lettuce, Cucumber, Radish, Beet, Carrot, Parsnip, Peas and Beans. Enough for your garden, postpaid.

Order early. Pine Tree Nursery, Round Pond, Me

GOLDEN and 3-banded Italian queens will be our specialty. We can also furnish Carniolians. Tested \$1, untested 75c each. Bees per pound, \$1.50; nuclei, per frame, \$1.50. Send your order for bees early.
C. B. Bankston & Co., Buffalo, Leon So., Tex.

THREE-BANDED Italians; untested queens in April and May, one, \$1; 6, \$5; 12, \$9. Tested, \$1.50 each. One-pound packages of bees, \$1.60 each; two-pound packages, \$2.50 each. Add price of queens if wanted. If you want as many as 50 packages write for prices and discounts on early orders. Safe arrival and satisfaction guaranteed. No disease, and all queens perfectly mated.
Cotton Belt Apiaries, Box 83, Roxton, Texas.

THREE-Banded and Golden Italian Queens and pound packages in spring, from the Sunny Southland.
Grant Anderson, Rio Hondo, Texas.

FOR SALE—One and two-pound packages with Italian queens; April and May.
E. Eggeman, Alleville, Ala.

FOR SALE—Good Italian queens, tested, \$1, six for \$5.40; untested 75c, six for \$4.25; nuclei with untested queen, 2 frames \$3.25, 3 frames \$4.25; with tested queen, 2 frames \$3.50, 3 frames \$4.50; 1-lb. package, with untested queen, \$2.25; 2-lb. package, \$3.25; with tested queen, 1-lb. package, \$2.50; 2-lb. package, \$3.50.
G.W. Moon, 1904 Park Ave., Little Rock, Ark.

GRAY CAUCASIANS—Gray Carniolians, 3-banded Italians; gentle, hardy, prolific; cap beautifully white; are "Mendelian" bred to superior drones, from choicest mothers; results are obvious. Apiaries widely separated. Quinn's queens of quality have no superiors. "There's a reason." Chas W. Quinn, 609 W. 17th Ave., Houston Heights, Texas.

FOR SALE—The very best three-hand Italian bees that money and skill can produce. If it is a bargain you are looking for send your order this way. All our bees are on standard size Hoffman frames, wired and full sheets foundation. Extra prolific and good honey gatherers; free from disease. Safe arrival and satisfaction guaranteed. We quote you without queen as follows: Three-frame nuclei, \$2.75; two-frame nuclei, \$2.25; three-pound package bees, \$3.75; two-pound package bees, \$2.75; one-pound package, \$2. If queen is wanted add her price to bees wanted. Young untested queens, \$1 each; young tested queens, \$1.25 each. Full-depth ten-frame bodies filled with full-drawn combs. \$2 each. Ideal supers, 5 1/2-16 inches deep, 10-frame full drawn combs, \$1.25 each. The Hyde Bee Company, Floresville, Tex.

SELECT bred mated queens, \$1 each, prepaid. Bred from the selected stock of eleven yards totaling over 1,500 colonies of bees run for commercial honey production. Only one grade of queens—no culls sold, \$10 per dozen, prepaid.
Honeymoon Apiaries, 402 N. Fifth Ave., Yakima, Wash.

HONEY AND BEESWAX

FOR SALE—Two barrels amber honey, honest, smartweed and goldenrod; 104 gallons in lot, and best offer take it.
J. F. Archdekin, Bordeloville, La.

WANTED—Shipments of old comb and cap-pings for rendering. We pay the highest cash and trade prices, charging but 5c a pound for wax rendered. The Fred W. Muth Co., 204 Walnut St., Cincinnati, Ohio.

WANTED—White or light amber extracted honey in any quantity. Kindly send sample, tell how your honey is packed and your lowest cash price; also buy beeswax.

Dadant & Sons, Hamilton, Ill.

SUPPLIES

ARE YOU keeping well posted on the crop condition and price prospects for your 1918 crop of honey? If not, you should! The Domestic Beekeeper, Northstar, Mich., will keep you posted on crop condition and price prospects as recommended by the Committee of the Chicago Northwestern Association. This committee, through the Domestic Beekeeper, saved producers a half million dollars on their 1917 crop of honey and expects to do even better on their 1918 crop. Are you one who is not taking advantage of an opportunity never before offered to secure all your crop of honey is worth? This opportunity is worth investigating.

FOR SALE—200 wire queen excluders, 55c each.
D. G. Little, Hartley, Iowa.

[The WORLD is Our Market]

"Practical Queen-Rearing"

Is the title of the new bee book, cloth bound, 100 pages, which has just been written by Mr. Frank C. Pellett, who is well known to our readers.

For many years there has been a demand for a book which would give in concise form the many different methods of queen rearing, as the Doolittle, Pratt, Dines, Miller, Alley and others with variations as practiced by different large breeders.

You have this in the new book which is just out. Send for your copy now and get informed as to your best method of rearing queens from your best colonies. Good pointer in it also for the large beekeeper and veteran queen breeder.

Price, postpaid, only \$1.

By special arrangement we can offer it and a year's subscription to the **American Bee Journal** for only \$1.75.

(Canadian orders 15 cents extra.)

AMERICAN BEE JOURNAL, Hamilton, Illinois

Queens That Will Please

Over 20 Years of Careful Selecting and Breeding

They are bred from **Imported** stock, the very best for honey gathering and gentleness. They are not given to swarming and are highly resistant to diseases. Give me your order, and after you have given my queens a fair trial, if you are not satisfied in every way that they are as good as any you have ever used, just return them and I will send you queens to take their place or return your money with any postage you have paid out on returning the queens.

Prices April 1 to June 15

	1	6	12
Untested -----	\$1.00	\$ 5.00	\$ 9.00
Selected untested -----	1.15	6.00	10.00
Tested -----	1.50	8.00	17.00
Selected tested -----	2.00	11.00	20.00

Guarantee.—You take no risk in buying my queens, for I guarantee every queen to reach you in first-class condition, to be purely mated, and to give perfect satisfaction.

L. L. FOREHAND, Ft. Deposit, Ala.

The Severin Steam Capping Melter

And Separator combined. The best on the market. Five working parts in one. Though compact, has almost 5 feet of melting surface, with surplus steam to run your knives. Has an upper screen for melting wax when running white honey; also slumgum basket in separator for amber.

Manufactured by F. J. SEVERIN, Imperial, Calif.

FOR SALE—Two-frame Cowan reversible extractor, cheap; too small.

F. O'Donnell, Rush City, Minn.

SWARMING CONTROLLED—No additional fixtures needed; unnecessary to clip queens; done solely by manipulation. Successfully used eight years. For particulars address:

Trimble & Thompson, Wapello, Iowa.

CONSERVATION PASTE—Costs less than 1c per pint; will stick your label on anything any time; easily and quickly made; no boiling; simple ingredients; ready for use in 30 seconds. Send 25c for formula. Money refunded if not satisfactory.

Sunnyside Apiaries, Fromberg, Mont.

NORTHWESTERN BEEKEEPERS—Save time and freight charges by ordering supplies near home. Best standard goods, factory prices. Send list of wants, and I will quote lowest prices. Catalog upon request.

George E. Webster, Valley View Farm Apiary, Sioux Falls, S. Dak.

FOR SALE—One thousand beehives with supers; three-fourth dovetailed, balance halved together at corners and nailed both ways. Hoffman frames throughout. We will guarantee them to be sound and free from disease. Will sell all or any part at about half what new hives will cost. Apply to The Hyde Bee Co., Floresville, Texas.

"BEST QUALITY" comb foundation for L. or H. frames; 20-pound lot; med. brood, 55c; light brood, 60c. Pure natural beeswax, not "Weed process."

J. J. Angus, Grand Haven, Mich.

FOR SALE—Cedar or pine dovetailed hives; also full line of supplies, including Dadant's foundation. Write for catalog.

A. E. Burdick, Sunnyside, Wash.

HONEY LABELS

SOUVENIR Bee Postal Cards, 5 for 10c; "Songs of Beedom" (10 songs), 20c, all postpaid. George York, Sandpoint, Idaho.

Constance, Ky.

SOUTHERN BEEKEEPERS, save money on comb foundation. Send me your beeswax to be worked, for cash or on shares. Terms the lowest, and satisfaction guaranteed. Send for terms.

E. S. Robinson, Ft. Myers, Fla.

WANTED—Two bee men for comb honey for 1918. State age, wages and experience. B. F. Smith, Jr., Fromberg, Mont.

BEEKEEPERS, LOOK HERE!—Young man 26, of good habits, with theoretical but no practical experience, has some capital to invest with service. If you want an energetic, interested partner, get this fellow.

H. Hermansen,
3232 1st Ave. S., Minneapolis, Minn.

WANTED—Man to work with bees, season 1918; state age, experience and wages on basis of board furnished by us. Address The Rocky Mountain Bee Co., Billings, Mont.

WOULD YOU like to receive four or five hundred dollars per hundred more for your 1918 crop of honey than the big buyers will offer you? The Domestic Beekeeper, which will cost you but \$2 per year, will show you how. This is no guesswork; we have done this very thing with hundreds of our subscribers on their 1917 crop, and are willing to do the same for you. You will make your greatest 1918 mistake if you do not, every one of you investigate the work the Domestic Beekeeper is doing for its subscribers, along the line of buying and selling for them.

WANTED—Can take two students for season of 1918; board given in exchange for work, and more if season is good; running ten apiaries. R. F. Holtermann, Brantford, Ontario, Can.

WANTED—Indusrious young man, fast worker, as a student helper in our large bee business for 1918 season. Truck used for outdoors and hauling. Apiaries located near summer resorts. Will give results of long experience and board and small wages. Give age, weight, experience and wages in first letter. W. A. Latschaw Co., Clarion, Mich.

WANTED—Expert comb-honey man, with references, to handle 700 stands of bees. Good proposition to right man. Hagerman Valley Bee and Honey Co., Hagerman, Idaho.

FOR SALE

FOR SALE—Wishing to retire from active business, I offer for sale 300 colonies bees in 8 and 10-frame L. hives; 750 full depth extracting supers, with combs; 400 section honey supers; 300 honey boards; 75 escape bees; eight-frame power extractor, with honey pump; four H. P. gasoline engine; saw with dado, planer heads and attachments for making supplies; a complete apiary in No. 1 condition; good location. 1917 crop was 14 tons honey. Will also sell my home place of ten acres, 5-room house and No. 1 improvements, near to a \$5,000 schoolhouse. Will sell home separately and give terms. J. R. Marlow, R. D. No. 1, Weiser, Idaho.

BEAUTIFUL FARM HOME—Improved, rich soil, well located, good buildings, 100 colonies of bees, up to date, best honey-producing location in State; not crowded; average for past seven years 105 lbs; 5 acres of ginseng golden seal, all ages, in fine shape. One-half apiary shade, one-half natural. Will sell a part or all. A wonderful opportunity; a bargain. Poor health reason for selling. W. M. Penrod, Ronneby, Minn.

FOR SALE—Small fruit farm and bees, cheap. W. H. Gray, Chillicothe, Ill.

LAST FALL Mr. Smith asked us our advice on when best to sell his crop of 15,000 lbs. of clover extracted honey. We answered him by advising that he hold until May, unless he got a good round price for it before. He could at that time have taken something like 12c per pound for it. He held it. At our Michigan State Convention last December, he again asked what we thought about the future price of honey. He could then get 17c per pound for it. We advised him to hold. He sold the entire crop the other day on board the cars for 18½c per pound. Mr. Smith's case is only one in hundreds of cases where producers have done well by following the advice of the Domestic Beekeeper. We want every beekeeper to have a hold in the case in his dollar for the Domestic Beekeeper during 1918. We have the back numbers, so can begin your subscription with the January number, thus making your volume complete. Do it today, and at the end of the year get your dollar back if you think you have not received its worth.

Notice to Bee-Keepers

We are booking orders for combless packages, for April, May and June delivery, at the following prices:

- 1-lb. package, \$1.80 each; twenty-five or more, \$1.70.
- 2-lb. package, \$2.90 each; twenty-five or more, \$2.90.
- 3-lb. package, \$3.90 each; twenty-five or more, \$3.80.

If queens are wanted, add 75c each to above prices. We will only have tested and breeding queens to offer until June 1, as we will need all our queens for the package trade.

Price of tested queens, \$1.50 each.
Breeding queens, \$3 each.

The high cost of all material, and labor, compels us to raise the price on our packages. We guarantee safe arrival to your express office. Our bees are free from all disease and are of the best Italian strain.

P. S.—We do not use a frame of brood or any comb at all in our packages, as has been stated by others; this is false.

Did You Get Caught Last Summer?

Today is not one bit too early to order your Bee Supplies. If you should wait until July 1, we would try just as hard to handle your order promptly, but you know what embargoes and freight congestions mean, especially if you were one of thousands whose goods were tied up in transit last year until the honey season was over.

IF WE ALL MAKE ONE GOOD, LONG, STRONG PULL TOGETHER, we won't feel like slackers, and after the war is over we won't feel like sneaking out of sight when war times are mentioned.

Our part is to make supplies as good as we can and as fast as we can—your part is to give your bees the best care you know how to give them, and to make them produce all the honey possible.

To do this **YOU MUST HAVE PLENTY OF HIVES, SUPERS, FRAMES, FOUNDATION, EXTRACTORS, SMOKERS, PLENTY OF EVERYTHING** used in your work, and **YOU MUST HAVE THEM IN TIME TO USE THEM.**

THE GOVERNMENT IS SHIPPING HONEY TO THE BOYS IN FRANCE—IT HELPS KEEP THEM FIT. We're trying to do our part. Let's pull together and help the boys take another trench. Don't wait another day about sending us your order.

Crop Report and Market Conditions

For our reports for April number we sent out the following questions to reporters:

1. How have bees wintered—what percent of loss?
2. Condition of bees—Strength and honey.
3. Honey plant and drought conditions?
4. What amount of increase will be made?
5. Extracted or comb, are many changing?
6. Honey prices—are any buyers offering for 1918?

THE WINTER

Throughout the whole northeast the winter has been exceptionally prolonged this year, bees not getting a flight for nearly two months. This combined with short stores in many instances has led to severe losses, especially with the inexperienced beekeeper. Average run from 5 to 15 per cent loss with the experienced beekeeper up to 75 per cent loss with the inexperienced. One reports 49 lost out of 50.

In the southeast the losses have been small, probably not over 5 per cent, with the exception of Kentucky, which shows a 10 per cent loss.

The central west shows about the same loss as the northeast, with cellar wintered bees in good shape where amply fed before cellaring.

Texas has had big losses, ranging in the estimation of one well informed, at from 25 to 50 per cent, depending upon the locality. Losses here have been caused by a combination of hard winter and extreme starvation, owing to the drought.

The west shows average losses, as docs California, except that one or two reports show larger losses on account of disease among the bees, in itself a bad sign.

CONDITION OF BEES

In the whole section east of the Mississippi River and north of the Ohio, bees are not in normal shape. Many colonies are weak, and a larger number show the effect of poor stores, with a shortage of honey in many instances which will lead to much loss.

In the southeast conditions are the best in many years. The season opened finely, new honey is already coming in and bees are exceptionally strong. This will be a boon to the commercial queen breeders who had such a hard time last year to pay expenses on account of the extremely unfavorable weather all through the spring.

All cellar wintered bees seem strong in the north. This is also the case in Colorado and other western States. The winter has been very mild in Idaho and Washington and bees are in very good shape.

In California bees are a month behind the usual and seem short in stores, besides being weak.

HONEY PLANT AND DROUGHT CONDITIONS

A blanket of snow has covered the whole northern half of the country since early winter, which in itself is conducive to the best growth of clover. Where this snow has melted to allow reporters to judge, clover seems to be in much better shape than counted on last fall, though there is little likelihood that clover will be as abundant as in 1916, except in a few favored localities.

It has been a dry winter in the South and is dry yet. Rain is needed. There have been, recently, rains in Texas that have brightened the outlook there, though much more rain is needed. The spring is very late there.

Colorado has been dry, but prospects are not unfavorable to a good crop. Alfalfa is all right. Sweet clover should have more moisture to put it in the best shape. There has been no drought in Idaho and Montana, as well as Washington, and conditions are "lovely."

California has been very dry, so dry, in fact, that many beekeepers were figuring on a short crop. Recent rains have been copious, however, and though the rainfall at this writing is not up to normal, prospects are more favorable with each day.

INCREASE

In all parts of the country, wherever condition of bees will permit there will be large increase. Certain sections will do well, however, to regain their 1917 strength by such increase while in other sections it is likely that 50 to 75 per cent increase over last year will be made. It would not be far off to assume that there will be at least a 15 per cent increase in holdings of bees the country over, and such increase will be attempted early so as not to interfere with the crop, but rather to greaten it.

COMB TO EXTRACTED

Many are changing. Supply dealers are experiencing a much greater demand in proportion for shallow and deep frames and extracting supers. The change to extracted will occur mainly, however, with the experienced producer. The small beekeeper with only a few colonies will do little changing.

To show the trend, however, one of the larger comb-honey producers of Colorado, who has comb equipment throughout, will run 15 per cent of his bees to extracted this year.

HONEY PRICES AND OFFERS

Comb honey is practically cleaned up, and extracted nearly so. In fact, there is more demand now than could be supplied if every pound of honey in the country were immediately placed on the market. White honey is selling for around 20 cents per pound and finds ready buyers.

Reporters state that one or two large bottlers are already "feeling out" the 1918 situation, but are making no offers. One reporter was offered 10 cents for his whole crop, which he promptly refused. Another stated that he would not sell for less than 16 or 18 cents for white extracted.

Foreign buyers are already active. We know of two inquiries, one for fifty tons and another for one hundred tons, but with no definite prices offered. With the decrease of the submarine menace by fall and the subsequent release of allied shipping space, the demand on the part of our allies should be greater than in 1917.

We see no reason for pessimism on honey prices. They should be the equal of 1917, even if the crop proves to be large, as early indications seem to promise.

One large honey dealer states that he sees nothing to indicate a price of less than 15 cents for average white extracted, and it would be our opinion that it would be a mistake to contract ahead early at a less basis than this. The sugar shortage of our allies and necessarily of ourselves, is far from entirely relieved. Nor is it likely to be in the near future. It behooves every beekeeper to produce to the utmost this season to help relieve the shortage.

QUEENS BEES QUEENS

Three Banded and Golden Italians; the best of either

They are hustlers; gentle to handle; cap their honey white; are very resistant to European foulbrood. We have added Mr. B. M. Carraway's queen-rearing outfit to ours and have with us one of his assistants, so can fill all orders promptly. Had fine success shipping bees last season in our newly devised cage and method of feeding, a number of shipments going as far as Idaho and Wyoming. Mr. R. B. Mills, Corinth, N. Y., wrote, "Bees arrived in fine shape, not 50 dead bees to the cage, 2-lb. size." Satisfaction and safe delivery guaranteed. Get your order in early. BECAUSE IT LASTS

That is One Argument in Favor of Cypress as a Beekeeper's Lumber

There are many qualities that make the value in lumber, depending, of course, on the uses to which they are put. But of all virtues that of **endurance** comes first. The wood that resists rot influences longest, especially when the wood is used in a service by which it is exposed to wet and dry conditions and earth contact—that wood is accredited with being able to give the user the greatest **INVESTMENT VALUE**.

No use tries the lasting qualities of lumber greater than that of Bee Hive construction. It is the very deuce to get lumber that will not too readily rot—unless one gets Cypress lumber. Then there is a good show for endurance that means **real money saved on repairs you don't have to make**. Try it, Mr. Beekeeper.

STUDY THE WOOD QUESTION

There's one way to get at this matter of endurance—through books of authority. Such are the 41 volumes of the internationally famous Cypress Pocket Library. These books are not "advertising"—they are authoritative references on file in the libraries of scores of technical schools and National institutes. Ask for Vol. 1 to start with; it contains the complete U. S. Govt. Rept. on Cypress, "The Wood Eternal," and a full list of the other volumes; then branch out until you cover the subject.

 Bee Catalogue now

Big Money? == Yes == Read How

If your banker said to you, "Mr. Brown, buy that piece of land next to you at \$100 per acre; it will be worth \$2,000 per acre this coming summer," would you buy it today, or wait—well, until later on? We are sure you would not delay one moment.

We offer you the same kind of buy—that is, make \$20 on each \$1 invested. Buy your sections and bee-supplies *now*, for the sections cost less than \$1 per hundred, and next summer, when they are filled with honey, they will be worth \$20—think of it, those same sections that you bought for \$1. The same holds good on other supplies. **ORDER NOW** and tell your neighbors the same, or Mr. Railroad Embargo "will buy that piece of land next to you and you'll be left."

OLD COMB

Ship your old comb and cappings to us for rendering. We charge you 5c per lb. for the wax rendered and pay you the highest market price.

WAX AND HONEY

We always buy Comb and Extracted Honey, as well as Beeswax, so when you have the above to offer, write us and you will be well pleased.

WINTER PROBLEM SOLVED

BY

Woodman's Improved Protection Hive

"THE HIVE WITH AN INNER OVERCOAT"

100% Perfect Protection by Tests, Winters of 1916-17-18

The Inner Overcoat Did It

Without any special preparation we have wintered bees in these hives without loss. It is a joy to see the condition they are in, when compared with other styles of hives and wintering methods. The INNER OVERCOAT is telescoped down over the brood nest, in between the outer and inner hive walls, when preparing them for winter. In the spring it is removed and stored away in the K. D. flat. Not more than two minutes are required to pack or unpack a hive by this method. The INNER OVERCOAT affords more protection than several inches of ordinary packing material. Send for a special circular showing 10 large illustrations.

Tin Honey Packages

SIXTY-POUND CANS, in cases or in bulk, are being sold by us at prices considerably below general market prices. Send us an estimate of your requirements and let us quote prices.

FRICITION TOP PAILS, any size furnished, and in quantities as you may desire. Send us a list of your requirements and let us quote prices, as we can save you money. The tin can factories are rushed with orders, the tin plate situation is serious and transportation slow, so it will be wise to place your orders early.

A. G. WOODMAN CO., Grand Rapids, Mich.

"falcon"

THINGS THAT ARE NECESSARY FOR YOUR APIARY

1. There must be a good location for the apiary.
2. Queens must be healthy and vigorous to put life into the hives. (Our queens are the best to be had and at reasonable prices.)
3. Your bees cannot do the work they should if you do not give them the best with which to work. If they have ample storage space, if they can work all the time without slack motion, they will be more contented and swarmless. To accomplish this, you must give them ample storage space, that is, the **RIGHT HIVES AND SUPPLIES. "falcon"**

Beekeepers should be placing their orders early for their early needs. He who waits is apt to suffer. These late beekeepers who want their goods in such a hurry at the last minute will lose some of the honey crop by not furnishing their bees with ample storing space. Railroad embargoes and rush business make deliveries slow.

Our famous "falcon" supplies will please you. Do not wait. Order now and strike while the iron is hot. "falcon" means the best, the standard of perfection. Red Catalog and Simplified Beekeeping upon request. Dealers everywhere.

THE EVOLUTION OF THE BEEHIVE

The Second of a Series of Articles by the Editor Showing the Development of Hive Construction Since the Earlier Days

IN 1750 a man was born who had great influence upon beekeeping, F. Huber, a Swiss, of Geneva. In his early youth he lost his eyesight; his biographer, De Candolle, attributes this to his too great eagerness to read. He spent days and nights in reading and when his parents deprived him of artificial light at night to compel him to take a rest, he even tried to read by the light of the moon. At 17 he was almost completely blind. He was then engaged to Aimee Marie Lullin, who heroically remained true to him and finally married him seven years after. Through her eyes and those of a faithful servant, F. Burnens, who was also a great observer, he made studies of natural history which finally concentrated upon the inhabitants of the hive. The works of Reaumur and Bonnet drew him to this. He confirmed the discovery of Schirach that the bees can transform any worker egg into a queen by special treatment. He showed that worker bees who were supposed to be neuters could, in most instances, lay eggs that would hatch. He described the combats of queens with each other. He discovered that the queen was fecundated in flight. He studied the causes of swarming, the use of the antennæ, the production of wax, the building of combs, etc.

For these studies he devised what he called "the leaf hive," which opens like the leaves of a book, and on each of which leaves a comb is suspended. He also devised what we now call observing hives, hives with only one comb and glass on both sides, which he called "ruches plates" (flat hives), because of their shape. It was with hives of both these styles that he made the numerous remarks which he recorded in his "Letters to Chas. Bonnet," published in 1792 and republished in 1796 and in

1814 under the title of "Nouvelles Observations sur les Abeilles" (New Observations upon bees). He also published a memoir of the origin of beeswax, in 1804.

The latter memoir was incorporated in the *Nouvelles Observations*, in the last edition, composed of two volumes.

Huber's leaf hive had a popularity which lasted a number of years. The greatest obstacle to its use is the difficulty of bringing together the combs of a populous hive after having taken them apart, for they touch one another in their entire length and depth, except in the spaces left for openings for the passage of the bees. It is difficult to open and close

a hive of this kind without crushing many bees, especially in the busy season. The elder Dadant tried them, and it was after accidentally crushing a queen while closing the hive that he discarded them, for the hanging-frame hive.

D. L. Adair, of Hawesville, Ky., patented a hive similar to that of Huber, in 1867, and gave it publicity in both the early years of the *American Bee Journal* and in his "Annals of Bee Culture" which appeared from 1869 to 1872.

A little later, Moses Quinby abandoned his hanging-frame hive for a hive with "standing frames" somewhat similar to those of the Huber leaf hive. But his frames were held in position by a clamp which was slipped into a groove on the hive bottom. His frames also differed from those of Huber in having full bee spaces at both top and bottom, so that they touched one another only at the perpendicular ends which were made of lumber 1½ inches wide. So the difficulty of manipulation was lessened, since the points of contact were less numerous. The advantage claimed for these hives was that they made a closed body, which was surrounded with another hive body and bees were said to winter in them better than in hives with loose hanging frames, in which the air can circulate around the frames, at the top, bottom and ends.

The Huber leaf method was also followed by Adair in his honey sections, with the only difference that he made the top and bottom bars to overlap on the end bars. The Adair section was soon improved upon and gave birth to our folding honey section. So the Huber hive principle is still in use in our supers with comb-honey production, the difference being that the sections are enclosed in a case, while the Huber leaf hive was

Adair's Section Beehive

formed of the frames brought together, with a dummy at each end.

In the American Bee Journal of July, 1912, we gave on the cover page a view of the apiary of A. B. Anthony, of Sterling, Illinois. The hive invented by Mr. Anthony opens like a book, more literally than the Huber hive. It is a model of ingenuity, for it is arranged to open in such a way that not a single bee can be crushed, the frames not touching each other. But the exactness of the requirements in such a hive has discouraged most people from its use. For popular use, hives must be simple enough to be put into the hands of entirely unskilled workers.

Apiary Buildings and Their Equipment

By Morley Pettit
(Concluded from April)

I HAVE turned over in my mind many ideas for the efficient routing of supers from the hives to the extractor; but the completion of the building in addition to apiary work was all that spare time in 1917 would allow without permanently installing any machinery. So I think I will postpone the publication of definite plans further than to say that the garage has a door in the end

to be taken to the apiary at night, or upstairs for storage, as the case may be. Outapiary supers will, in the spring, be handed down the trap door to the motor truck in the garage.

Extracting Machinery

With good steam pressure and a long-handled knife and well-built combs, one man can uncapp for an 8-frame extractor, and a helper has too easy a time tending it. Where extractors are allowed to do their work thoroughly I believe there should be 16-frame or 18-frame capacity, with one to attend them and two, or at most three, uncappers. I am referring to Langstroth combs. This would call for good large capping melter capacity, a battery of four 4-frame or three 6-frame extractors, a pump and plenty of storage. I would heat the knives and melters with steam brought through well insulated pipes from a boiler in another room. That would remove the most objectionable feature of this part of the extracting, the over-heating and vitiating of the air caused by oil stoves burning in the room, and even steam from knives and melters might be taken care of to advantage by some system of condensation.

I do not know what the daily capacity of such an outfit would be, but would guess at from 7,000 to 10,000 pounds as a conservative estimate. I know that under rather unfavorable conditions, with one 8-frame machine, I uncapped and the helper extracted 3,500 pounds in one day last fall, and he had an easy time. If you say why such haste, I will refer you to the shortness of the time between light and dark honey flows in many sections, the importance of leaving honey on as long as possible for ripening, and the high cost of living.

The knife is a sandwich-knife with straight blade about 10½ in. long. A tinsmith added the copper jacket for

The Huber Leaf Hive

The observing hives (ruches plates) of Huber were undoubtedly the ones which permitted him to make the numerous discoveries which he brought to light. The writer has often followed Huber's teachings with one of these hives. A single-comb observing hive, located within a house, by a window, or outside on a veranda and filled with a comb loaded with bees, is a source of endless study. There is no need of a queen, provided the comb contains brood less than three days old. You can watch the rearing of a queen, the destruction of the supernumerary queen-cells by the first queen hatched, often helped in this work by the neuters. You may even have occasion to notice the combat of queens. There is no end to the amount of experience that may be derived from the use of these "flat hives" with glass on both sides. Even combs built crooked and fastened to the glass will give you amusement and information, by enabling you to see how the bees work in the cells, to deposit honey or pollen or to rear brood.

The life of F. Huber, published in the "Bibliothèque Universelle" of February, 1832, and re-published in 1894 by Ed. Bertrand in the "Revue Internationale D'Apiculture" is interesting reading and we may translate it for our readers some day.

facing the apiary as well as in the front. The hives in the apiary can be arranged so that a motor truck can be backed down the rows and loaded with supers for extracting, as a welcome substitute for the old wheelbarrow.

All supers are removed from the hives with bee-escapes, so the loading on the truck will be easy and rapid. Loads of supers from out-yards, of course, go immediately into the garage at the front door to be unloaded directly to the extracting room. Here the supers can be moved either in piles on small trucks with castor wheels, as milady moves her dinner-wagon, or hung from trolleys on overhead tracks, as carcasses are moved in an abattoir. It might be practical to run the overhead track out into the apiary and along over the rows of hives. A super-lifter for brood-chamber examinations might possibly be combined with this; but so many have been dreaming of super-lifters that I will shut up for the present.

In any case, routing and machinery must be arranged to avoid back-tracking as much as possible. With this end in view the door from the extracting room to the apiary is at the opposite end from the garage. A super-hoist may also be placed at this end. Supers will then come in from the garage, pass through the extractor and rest near the far door,

The Standing Frame of Quinby

steam. The handle is straight with the blade, eliminating the tiresome side-pull of the stock knife, and I wound it with tire tape for a better grip. The next improvement will be some sort of support for the other end to give leverage and save the operator's wrist. A modified bread-cutting machine might answer.

A Revision of Extractor Construction
While we are installing extractors the stock machine of the manufacturer will stand some scrutiny.

The idea of an extractor or battery of extractors built in, as it were, or permanently installed, has not to my

knowledge been published before. If it has I would be obliged to any reader for the reference. All extractors are built for moving about without "taking down" in any way, and have had to suffer in some points on that account. To make them for permanent installation admits of a complete review of extractor construction with a view to revision.

What are the essential parts of an extractor? Among them are baskets for the combs, a reel to whirl them, supports for the reel, a screen to intercept the flying honey and a reservoir to retain it until drained away. For convenience, hand extractors were built in a tin can which combined reel-support, honey-screen and reservoir. Power extractors are built the same way. To overcome vibration caused by uneven loads,

the beekeeper nails this can down and wires it down and sometimes braces it from the ceiling, and it continues to be a flimsy tin can which is no proper support for a real machine. The honey collects in the bottom and cannot be fully drained out without tearing the whole machine from its moorings. One would not expect to find a power machine in any other industry so little removed from its hand prototype.

The comb-basket reel might well have its upper and lower bearings fixed in a steel frame on a concrete base, rigid enough to resist all vibration after ordinary care is taken to balance uneven combs. The honey screen and reservoir is an entirely separate matter, and does not need to be a complete can at all; so long as it catches flying honey and con-

ducts it along channels which will drain automatically and completely into the pump chamber. The latter might be built like a wax-honey separator to keep floating wax and honey from the pump.

I would use a battery of small reels in preference to a large one. They have greater centrifugal force, start and stop easier, and while one is stopped, fewer baskets are idle. The force of vibration from an uneven load in a small reel is less. A number of small reels could be placed in one set with only single partitions between them.

The Honey Pump

I am thankful our building is on level ground so we can pump honey from the extractor to storage with a clear conscience. So many recommend gravity systems, but they all involve stair climbing or lifting combs or supers, which is work for the beekeeper. The pump lets the motor do it, and that is always cheaper. The only effect of the pump is to hasten granulation or if run when not full to cause foam by churning. The latter is easily prevented and the former is an advantage when selling granulated, and does no harm when the honey is to be heated for bottling.

The Honey Room

Ranged around the wall in the honey room are the store tanks to which the honey is pumped through galvanized iron piping with rubber hose on the end for distribution from tank to tank. The capacity of these tanks suits the day's work so that night will not find one only part full. We have enough for at least three days extracting, as that is a minimum time for honey to "steal" before skimming and filling. They are on stands about three feet high, so that filling can be done on a table in a comfortable position. Pails as filled are crated uniformly and stacked in the shipping end of the honey room next the garage, where they are convenient to load into the truck for shipment.

Besides having plenty of light and capacity for two cars, the garage has a floor drain and running water for washing and will be equipped with small work bench and proper tools for all except the most difficult adjustments and repairs.

Things Every Central Apiary Building Should Have

There are many points on which beekeepers will differ in the matter of apiary buildings and equipment; but certain things everyone should have are:

1. Cheerful rooms with high ceilings, large windows close together, and plenty of electric lights where the latter are available.

2. A power plant, gasoline or electric, connected by convenient line-shaft to extractors, honey pump, saw, emery wheel and whatever other power machines may be used.

3. Steam for uncapping, wax rendering, liquefying, feed making, cleaning, and perhaps for heating the building to make inside work independent of weather conditions. Question: How about a steam engine for

The Leaf Principle is used in these

Specially constructed Hives of an American Beekeeper, made to be turned over for examination.

power in view of gasoline shortage and above-mentioned uses for the exhaust?

4. Running water and floors that can be washed down with hose. If necessary, a private water pressure system is a good investment in view of using it in dwelling as well.

5. That the building should be bee-tight goes without saying, and if you build twice as large as you think

you will need it may be large enough.

Honey production has become an established business comparable in permanency and profits with any other branch of agriculture. Perhaps no other branch requires so small an outlay of capital for the same return. The best of practical equipment is not expensive, and the best is none too good.

THE EDITOR'S VIEWPOINT

Laying of Queens— Nurse Bees

Comments by C. C. Miller

In April American Bee Journal, page 130, M. F. Perry says he differs with me as to the number of bees required for a certain thing, I having inclined to the opinion that a pound might answer, and Mr. Perry suggesting 2 or 3 pounds. To be sure, the types make him say "less than 2 pounds, or, better, 3 pounds," but I'm pretty sure the printer or someone else dropped out a "Not," and that "not less than 2 pounds" was meant.

There is a pretty wide difference of opinion when one asks 2 or 3 times as many bees as the other, and it may not be out of place to inquire whether we are both talking about the same thing. To go back to the beginning, on page 28, January number, I was asked, "Assuming that I give a pound of newly-hatched bees and a strong, vigorous queen to a queenless colony with a large force of held bees, would the pound of nurse-bees be enough to nurse all the brood she could produce, say until the first of it be sealed?"

I replied: "I don't know enough to answer definitely. I'm inclined, however, to the opinion that all the brood an average queen could pro-

duce up to the time of the sealing of the first of it would be properly fed if a pound of newly-hatched bees were added. At that it might be hard to prove that some of the fielders did not turn in and help on the feeding."

Mr. Perry says: "A pound of bees, supposed to contain 5000 bees, say one-fourth remain in the hive as nurse-bees, that would allow a good queen to do only one-fourth of her duty." According to that it would take four times as many bees, or four pounds, to allow her to do her full duty, that would make us still farther apart.

But how do you know, Friend Perry, that "one-fourth remain in the hive as nurse-bees?" Isn't the number that remain a very varying quantity? In the early spring I suspect that less than half the bees go afield. I don't know what proportion stays in the hive on a hot day in a big flow; I wish I did. But have you any proof that it is as large as one-fourth?

You say, "A queen worth keeping will fill a comb with eggs in a day." If she keeps that up she will keep 21 combs filled. I've had some excellent queens, but I don't know that I've ever had one that kept 21 combs filled. Have you?

You say, "It will be 21 days before more nurses can emerge," and are evidently talking about feeding for 21 days. I don't know that it makes very much difference, but I wasn't talking about 21 days' feeding, only 8 days, for if you will look again you will see that the question specified "until the first of it be sealed."

You say, "Some bees are lost every day," evidently talking about bees of all ages, but please note that both in the question and the answer "newly-hatched bees" are specified. A newly-hatched bee is supposed to have before it about six weeks of life, so that none of the pound should die within 8 days, or even in 21.

Your conclusion is that not less than 2 or 3 pounds "is sufficient to build up a colony readily in the cool weather of spring." But the question was not how many bees will build up a colony, but how many can feed the product of the queen in 8 days. And I don't see that the cool weather has anything to do with it, for although the weather makes a difference about the number of bees that fly out, cannot a nurse-bee feed just as many babies in a cool day as in a hot one?

If I understand you correctly, you think not less than 2 or 3 pounds of nurse-bees should be added to "a queenless colony with a large force of field bees," in order "to build up a colony readily in the cool weather of spring." Even upon that point I'm afraid we would hardly agree. "A large force of field bees" is rather indefinite, but I would hardly think of it as being less than 25,000. Now, would you think me unreasonable if I should say that there was no need to add a single bee to a field force of 25,000 in order to build up readily in the cool weather of spring. At any rate, that's just what I do believe. Please remember that when a colony comes out of winter quarters there are no young bees, yet the colony builds up all right. You may say that many of the bees are practically young, having merely existed through many weeks without doing any work. Well, then, I'll give you a case where all the bees were field bees, in the fullest sense of the word. One year, a good many years ago, I moved a colony to a new location and set on its stand an empty hive to which the field bees returned, and to these I gave a queen. I cannot give details as to the building up, but I know that that colony, starting with nothing

but field bees, gave one of the largest yields of surplus of the whole apiary.

To answer the questions before us we need to know: 1. How many eggs a queen lays daily. 2. How many larvae each nurse can keep fed. I'd like to know.

Death of R. C. Aikin

Mr. R. C. Aikin, a former beekeeper of Colorado, and a writer of some note on apiculture, was taken ill at his home in Blessing, Texas, on March 11, and was removed to the hospital at Houston, Texas, on the 17th, hoping that he would improve; however, double pneumonia developed and on March 21, 1918 he quietly passed away.

No doubt, our readers will remem-

THE LATE R. C. AIKIN

ber the many writings of Mr. R. C. Aikin in the Bee Journals when he was actively engaged in beekeeping in Colorado, several years ago. At that time he was considered an authority on apiculture and his writings on this subject were read with great interest by all. He and his wife have for the past few years resided in Blessing, Texas, and his death has closed the book for one of the best men it has ever been our privilege to know. We extend our deepest sympathy to the sorrowing wife and other relatives.

Death of J. L. Strong

One of the best known apiarists of Iowa, J. L. Strong, died March 7, after three years of suffering.

Mr. Strong was not only a capable apiarist and a noted queen-grower, but he was a man of great power of observation and method. If our readers will refer to the editorial in the third column of page 118 of the April number, they will see that Professor Kenoyer used the records made by Mr. Strong, during a space of 29 years, of weights of a hive and me-

teorological data. This little item shows the worth of the man. He was 72 years old.

His wife, family and friends have the sympathy of the beekeeping public.

Free Advertising of Honey

Honey never had such free advertising as it is getting nowadays. The March number of "Physical Culture" contains a long article extolling honey for food. It is no more than honey deserves. But there was a time when it might have been difficult to get free encomiums of this kind. As the French say: "A quelque chose malheur est bon," which may be freely translated to "It's an ill wind that blows nobody good." If it were not for the world struggle, which makes food scarce, the public would not be so carefully informed of what may be gained by large honey production and consumption.

Illinois Foulbrood

The 1918 official statement on foulbrood does not contain any report. It contains only instructions on how to treat foulbrood and gives a copy of the law. It is published under the direction of the Illinois Department of Apiculture. It may be had of Charles Adkins, Director, Springfield, or of A. L. Kildow, Inspector. Putnam. Beekeepers who are in doubt about foulbrood should procure this and all other available information.

Death of an Editor

We have received by private advice the news of the death of Mr. F. D'Autemarche, managing editor of "L'Apiculteur," the oldest bee magazine in existence. Mr. Sevalle, editor-in-chief, who has for years stood in the background, is again assuming the management.

The public announcement of the death of D'Autemarche has probably appeared in the November-December, for it is mentioned only incidentally in the January-February number.

Against the Bee Killer

"Contro l'apicidio" is the title of a booklet of 34 pages published in Italy by the Italian Federation of Beekeepers. The author is Emo Perucci and the book is a straight aggression against the people who still kill the bees to get the honey. It contains a very thorough description of the different methods of transferring bees from box-hives to movable frames

and shows the advantages of modern methods.

A similar work would still do some good in the backward counties of many of our most progressive States.

Beekeeping Applied to the Liberty Loan

The Chicago Sunday Tribune of April 14 contained a cartoon showing the dollars of the third Liberty Loan under the shape of the bees of a swarm, making honey in $\frac{3}{4}$ sections at the rate of $4\frac{1}{4}\%$ and stinging the Kaiser.

Weak Colonies in Spring

Now is the time to watch your weak colonies. If you are in a locality where foulbrood is prevalent, such colonies as might have had the disease last fall and were strong enough to withstand the winter, will be in danger of being robbed out this spring, thus spreading the disease to your stronger colonies. Then, too, just before the spring honey-flow commences is the easiest time to discover the disease if it has developed. Work at your colonies when a very light flow has commenced, thus doing away with the dangers of robbing.

Weak colonies which have good queens may be saved if their entrance is narrowed down so as to be easily protected by the bees from ever-alert robbers. Some aid these colonies by the addition of a frame or two of brood from other colonies. But this, if done, should be done only when the weather is sufficiently warm so that the colony can easily keep such extra brood warm, and all brood given, or nearly all, should be sealed.

Queenless colonies, if weak, had best be united with other weak queenright colonies rather than try to save them by buying a queen and running the risk of her being killed by the old bees. If the colony is queenless and yet strong, it may be advisable to introduce a queen fresh from another hive.

Variation of Time of Fruit Bloom in North and South

A letter from Dr. Miller a few days ago suggested that it might be interesting to note the period of the blooming of different fruit trees this year at Marengo and at Hamilton to see what a hundred miles variation in longitude means.

We will have more to say about this later.

Fabre on Parthenogenesis

By the Editor.

THOSE of our readers who have been with us for several years will remember, perhaps, the writings of the celebrated naturalist, Fabre, and his great observations upon the bee-eating wasps, the philanthus apivorus, and his description of the digger-wasps, such as the sphex, the scolia, the pompilus; the scientific way in which these insects sting their prey sufficiently to render it unable to defend itself and yet live until it is eaten by the young larva of the digger-wasp. (American Bee Journal, September and November, 1912.)

Fabre's writings are exceedingly interesting, for although he was a botanist and an entomologist, his descriptions are as devoid of scientific words as he could make them. Besides, he spent but little time describing the anatomy of the insects. Of this he gives just enough to explain their actions. He was really a naturalist, studying the habits and ways of all these insects and describing what he saw in a delightful manner. The reader of his books accompanies him in his researches, so vivid are his descriptions. His entire life was spent watching the small but innumerable world of insects.

I bought his "Souvenirs Entomologiques" in his native language, the French, and am spending many delightful hours with him among the hymenoptera. But although he spent years among the different varieties of bees, the honeybee seems to have been neglected by him, for he mentions only its enemies, the digger-wasps. It was, therefore, with great astonishment that I found, in the last chapter of the 3d volume, a reference to Dzierzon and parthenogenesis. It came in the following way:

In describing the "osmia," a family of mason bees, he explains the repartition of the sexes in the different cells. In this bee, the male is smaller than the female, just the opposite of our honeybee, if we consider the worker or neuters. But as the female osmia are all fully developed females, the comparison between them and their males is not in very great contrast with that of our queens and drones. The females are hatched in cells measuring about one-third more than those in which the males hatch. Fabre wonders, as we do, at what causes the sex of the egg and concludes that it is entirely left to the decision of the mother. But as to what determines her decision he remains ignorant. He writes:

"There remains to be told in what manner is made this facultative determination of the sexes. I know absolutely nothing about it. If I ever learn anything upon this delicate question, it will be due to some happy circumstance for which I must wait. Towards the end of my researches, I became acquainted with a German theory concerning the domestic honeybee and due to the api-

arist, Dzierzon. If I understood it well, according to the incomplete documents before my eyes, the egg, such as it is, supplied by the ovary, already has a sex; always the same; it would be originally male; it is by fecundation that it would become female. The males would be the result of non-fertilized eggs; and the females of fertilized eggs. The queenbee, therefore, would lay female or male eggs according to whether she did or did not fertilize them, as they passed through the oviduct.

"Coming from Germany, this theory inspires me with profound distrust. As it has been admitted, with rash precipitation, even in classic books, I will surmount my repugnance to investigate Teutonic ideas and will submit it, not to the proof of arguments, against which a contrary argumentation may always arise, but to the irreversible test of facts."

HENRI FABRE

Fabre then goes on to explain that, according to the Dzierzon theory, the egg passes by the spermatheca which contains the seminal fluid and may or may not have its sex changed by the action or inaction of this fluid, becoming a female or a male, the sex being thus determined, at the will of the layer, by a pressure upon the spermatheca. Now comes the experience upon which he bases his denial of parthenogenesis:

"The Osmia, born industrious, dies working. When her ovaries are drained, she spends the remainder of her strength in useless labor, partitions, lids, boards of pollen without use. The living machine cannot accept inaction, even when there is nothing to do. It continues its functions in labor without purpose. Let me point these vagaries to the adepts of the reasoning power of beasts.

"Before reaching these useless labors, my belated workers have laid

their last eggs, the location and date of which I know positively. These eggs do not differ in any particulars from their elders. They have the same dimension, form, gloss and appearance of freshness. Their supplies have nothing exceptional, either, and are very well suited to males, closing the laying. And yet, these last eggs do not hatch, they shrink, wilt and dry up on the stores of food. At the terminal egg-laying of some osmia I count 3 or 4 sterile eggs; with another, 2 or 1. Another gives fertile eggs to the last.

"These sterile eggs, touched with death from their first appearance, are too numerous to be unnoticed. Why do they not hatch like the others which they so resemble? They have received from the mother the same care, the same vituals. The investigations of the magnifying glass show nothing that can explain the fatal issue.

"If our mind is free from preconceived ideas, we go straight to the explanation. Those eggs do not hatch because they have not been fertilized. This would perish every animal or vegetable germ that did not receive the vivifying impregnation. Any other explanation is impossible. Do not speak of the lateness of the laying; eggs of the same date from other mothers, are perfectly fertile. Once again, they do not hatch because they have not been fertilized.

"And why have they not been fertilized? Because the seminal bag, so small that it has often escaped my observation, in spite of my vigilance, had exhausted its contents. The mothers whose spermatheca preserved till the end a remnant of the fecundating element had their last eggs as fertile as the first; others with a seminal receptacle too quickly exhausted had their last laying smitten by death. This seems to me clear as daylight.

"If the unfecundated eggs perish without hatching, those that hatch and produce drones are therefore fecundated; and the German theory crumbles.

"What explanation will I then give to account for the marvelous facts which I have exposed? None, absolutely none. I do not explain, I relate. From day to day, more skeptical towards explanations which may be advanced to me, more hesitating towards those that I might advance myself, I see more and more before me rising, in the black cloud of possibilities, an enormous interrogation point."

So the reason for Fabre's positive denial of the Dzierzon theory of parthenogenesis lies in the non-hatching of the last laid eggs of some of his osmia. This looks convincing. Dr. Phillips has himself written that he "found that many eggs laid by drone-laying queens fail to hatch and, in fact, are often removed by the workers." But other facts rise before my mind which seem to indicate a conclusion quite different from that given by Fabre.

On page 13 of the American Bee Journal for January, 1916, I have given an experience of my young days which impressed itself vividly,

because I then knew but little concerning parthenogenesis. Let me repeat the statement, in part:

In my queen-rearing experience, it happened to us once, I believe it was in 1872 or 1873, that we found sale for seven first-class Italian queens, very late in October. The amount offered for those queens, by a lover of good stock, was so enticing that we decided, my father and myself, to sell the queens, which were in very populous colonies, and take the risks of being able to replace them the same season. Queens were not then to be bought as readily as they are now. There were still many drones, as the season had been very prosperous and late. But those queens, hatched early in November, had no opportunity to mate, for the weather turned cold suddenly and the time of their rut passed without any opportunity for flight, even though drones might have been present. The following spring we found ourselves with seven pretty and very prolific drone-layers. Their eggs were laid as regularly as those of fertilized queens, and their progeny hatched in the most uniform way, small drones from worker-cells and large, full-sized drones from drone-cells. I do not remember that any of their eggs failed to hatch. True, some of them might have been removed by the bees, unknown to us, but this does not seem likely. The little drones appeared as able-bodied as the large ones, and, according to the Dzierzon tests, must have been proportionally as good as the large ones. It goes without saying that we promptly replaced the queens with other breeding stock, and never did we have better early matings than that year, since thousands of drones were produced at a time when there are usually very few.

Being then between 21 and 22 years of age, I became very thoroughly impressed with this evidence of the correctness of the Dzierzon theory, which had, up to that date, appeared to me only as a possibility. I have, ever since, called it an established fact. But it is very easy to see why an observer like Fabre, who had no opportunities to make a test of this kind, should denounce the theory as entirely false. And yet it is very likely that the eggs mentioned by him as not hatching were rendered unproductive by some other cause than want of fertilization. In my experience I have seen two or three queens whose eggs did not hatch, but never had an opportunity of ascertaining the cause.

However great the genius of Fabre and his powers of observation, he was, nevertheless, subject to prejudice. Witness his antipathy to Teutonic teachings. Such an antipathy was natural in a Frenchman, writing after the crushing war of 1870, but it should not have led to anticipated prejudice. Besides, Dzierzon, born in Karlsmarkt, eastern Silesia, may have been of Slav descent, a Pole. So even the prejudice against him might have been ill-placed.

In his writings, Fabre constantly criticized Darwin and his theory of evolution, of constant change, slow and steady, due to the struggle for life and the survival of the fittest. Nothing that Fabre saw served to convince him of anything but the immutability of the habits and conditions of the minute beings which he watched so carefully and upon which

he wrote so interestingly. It would have been worth while, if he and Darwin could have been placed face to face for a few hours and urged to discuss their views. They were both accurate naturalists and both after the truth. They were 14 years apart. Darwin was born in 1809 and Fabre in 1823. Neither took things for granted, but while Darwin tried to explain some of the phenomena which he saw, Fabre left, at the end of his studies and his wonderful descriptions, what he himself called "an enormous interrogation point."

C. P. DADANT.

The Cycle of Seasons in Different Apiaries in Georgia

By J. J. Wilder

WE might include in this, almost the entire Dixie land except Florida, as the State of Georgia extends from the low, flat, level coastal lands to the Blue Ridge, and their honey plants, their season of blooming, etc in all the Southern States correspond very nearly with that of Georgia.

There is a clover belt in Alabama which extends up into Tennessee. This particular section I am not familiar with, as I have never kept any bees in it, and what I know is mostly through correspondence.

In this great clover belt is located the largest queen-breeder and shipper of bees in all the South. But few if any great honey producers are located in it. So we might infer that the season is more uniform, beginning early, having a long, almost even season, ending late, except as adverse weather conditions may bring about changes. It may be that the honey-flow never is heavy enough for a great honey harvest, but just enough to keep brood rearing going at a good pitch and some feeding done to keep this up at more adverse times, resulting in lots of bees and only small amounts of honey relatively.

The same condition prevails in northern central Florida in the partridge-pea belt, which has come under my own observation.

Let me go back to general conditions prevailing in Florida. Let no beekeeper think that our country is great for beekeeping because we have so many small honey-flows; that bees will keep strong and colonies continue to exist. Far from it. Our great loss in colonies actually occurs between these honey-flows and our winter losses are almost negligible.

A colony may show up well on a small honey-flow and at its end be very strong in bees and not light in stores, and before the next honey-flow collapse and be lost. There may be no nectar or pollen between. So we have to leave the honey and keep it equalized. Maybe the next flow yields a little and the next a little and so on.

Most of eastern, all of southern Georgia and largely southern Alabama have the same season and about

the same honey plants throughout. Spring tithi and the many different varieties of huckleberry grow widely over this great belt. The first warm days in middle February they bud and by the first of March they are out and the bees are bringing in nectar and pollen every day, weather permitting.

Maple is also out at this time, being very abundant along streams. Now is the beekeeper's chance. In this section it is not a matter of stores, but a matter of brood for the bees and as soon as these honey-plants are well started blooming, all colonies must be looked through carefully and the stronger ones with much sealed honey in the brood-nest must be given empty combs in the center. Bees must be carefully examined each week and as the weaker ones begin to strengthen and the weather gets warmer give them an empty comb, likewise.

On the third round, which is about the 10th of March, the strongest ones will need supers and on the next round general supering will be necessary.

Then we may expect swarming to start, and we are right in the main honey-flow which continues till about May 25, and at which time all the bees not in reach of cotton fields must be left with plenty of stores for summer and fall, or they will dwindle and some colonies be a total loss before winter.

Colonies in easy reach of the cotton fields can be extracted closely, leaving only a few pounds of honey. In late July, cotton and velvet-beans begin yielding and a slow, steady flow is on until the latter part of August, at which time all honey can be removed except 15 or 20 pounds to carry bees over fall, during which time they continue to breed more or less.

The Red Hills

Leaving the low and level country, which is for the most part only a few feet above sea level and better known as the Altamaha Grit Region, with its larger streams in most places lined with white tupelo gum, its smaller ones with tithi and flats all make a mass of gallberry, which extend the honey-flow on up to about June 1, we now pass up into a far more elevated section, which is several hundred feet above sea level, and with this we sweep over the largest section of Georgia. The soil is mostly red and the land for most part badly broken, but in it is some gray and sandy as well as rocky soil, which makes some change in the honey flora. In this region the poplar is the most important honey-plant. It lasts until early June. Here there are plenty of pollen plants and bees must have more stores for winter, say 10 or 15 pounds more. All increase should be made on this flow and at its close plenty of stores should be left in the brood-nest and some besides in supers. The blackberry is also a good yielder here and its flow may be expected towards the latter part of the flow from poplar. Along large streams there is some black tupelo gum which gives the first real honey-flow, and at the

end of which poplar comes. Here brood-rearing should be encouraged early.

In the sandy soil the winter huck-leberry gives a yield which corresponds in amount and time with that of poplar. There is also some gall-berry in the extreme eastern part of the State, but the flow is light and comes at the latter part of the flow from poplar.

In the Red Hills a strange thing occurs with reference to the flow from cotton. In a small part of this territory it yields well, elsewhere not at all, being only a pollen plant. Cotton is extensively grown nearly all over this section, yet it only yields here and there even, apparently, in the same soil and subsoil, and under similar conditions.

Goldenrod and asters grow more or less here and give a light flow just

Locust starts the flow in the latter part of April and gives a good yield for 30 days, though there is no inclination to swarm, so it is not time to make increase. After this, for 25 or 30 days, there is no honey-flow; then the chincapin and chestnut give a very light yield, bees consuming as fast as they gather. About June 20 a heavy flow comes all at once from basswood. Bees swarm and increase can be made and should all be done on this flow. Closely following this, sourwood comes on and a little swarming may be expected at the beginning of this flow, but it should be suppressed, for swarms at this time will not build up sufficiently strong for the winter. This flow lasts for about 40 days and is the best one in all that section and can be counted on for most of the surplus.

At its close a light flow may follow from asters, but it is not to be counted on, so plenty of stores must be left from sourwood.

Cordele, Ga.

Winter Transferring

B. J. F. Diemer

THE final result of the experiment of transferring bees commenced in August and given in the January number of American Bee Journal has turned out very satisfactory. Out of the 38 colonies two failed to winter, one being queenless and the other short of stores in the upper hive. The 36 that were left came through the winter in good condition, plenty of bees, brood and honey. The box hives are still nearly full of honey, as there was plenty in the upper hive for them to winter on. In one of your letters you cautioned me against trying to transfer in winter the 18 that refused to transfer themselves in the fall. I decided that you were right and thought best to drum them up the first warm day in early winter. This I did by placing a hive body over half full of sealed honey and some pollen on the top of the box hive turned upside down. I was surprised at their readiness to go up in the frame hive; there being no brood in the box hive, it only took a few minutes to chase the whole bunch upstairs. I put the bottom-board under the hive body, leaving the inch hole open, so the bees could move the honey from the box-hive if they would. As it was quite warm today, I looked in all of them and found plenty of bees, brood and honey, all in the upper hive; but they haven't moved much honey out of the box yet. Perhaps they will as the weather gets warm. Perhaps some one would like to know how to get this honey out without melting it and having a mess. This part of it is past the experimental stage, as I have proved. Just bore a hole in the back end of the frame hive and a hole in the side of the box-hive and connect the two together with a short piece of rubber hose. The bees will do the rest if they have room to store the honey.

For several years I have bought all the box-hive colonies I could get,

transferred them, gave them an Italian queen and in a few weeks they would look as good as new. A lot of box-hives in a neighborhood is as bad as a case of smallpox in a theater. You may be enjoying the play and at the same time catching the disease. But I am glad to say I have never seen a trace of foulbrood in any of them. Believe me, I am done cutting out old crooked combs and trying to fit them in a good new frame. Of course this has been avoided, but there is still room for improvement. Anyway I had lots of fun out of this job and will be keen to buy more box colonies.

Liberty, Mo.

Co-operative Selling Pays Texas Honey Producers

By Chilton Gano

THAT co-operative marketing can be made to pay right from the start was never better exemplified than in the case of the Texas Honey Producers' Association, which has been in operation only a year and a half and has already learned the secret of securing better prices and saving money in purchasing supplies.

The experience of this organization has been so extraordinarily successful that the writer believes every beekeeper should read about it. To convince readers of American Bee Journal that the story deserves to be carefully read from beginning to end, some specific figures on the success of the association will be given first, and the career of the association sketched afterwards. The instances were cited to the writer in February by Manager LeSturgeon, of the Texas Honey Producers.

A member of the association had 5557 pounds of honey for sale, packed in eight oak barrels. He was offered 8 1-3 cents per pound and was ready and willing to sell it. The association learned of the matter and asked to be permitted to handle the business. The request was granted and the honey sold to a New York firm at 12½ cents per pound.

Another member had several tons of rather strong and unpleasantly flavored honey which he had been willing at one time to sell for 4 or 5 cents per pound, for baking or feeding purposes. He decided to put it in the hands of the association, and it was sold at 10 to 12 cents a pound.

Saved \$76 on Cans

In saving money on purchases of supplies results have been equally good. One member of the association who needed a car of honey cans secured price quotations from his dealers, thus learning the lowest figures at which he could buy through that channel. He then placed the order with the association, and saved \$76 on the transaction.

A non-member of the association not long ago sold 135 pounds of wax to a San Antonio dealer at 28 cents a pound. The association, at the time, was paying 30 cents a pound, at San

J. F. Diemer's method of transferring with the box-hive below

before frost. They are a stimulant, but as a rule no surplus is expected from them.

Blue Ridge Section

Bordering on the Red Hills comes the Blue Ridge section, in which conditions are entirely different. With an elevation thousands of feet above sea level it is almost an unbroken forest and mountains; not so wide, but extending hundreds of miles forming the great water shed of Dixie land. More people keep bees here than anywhere else, according to population, and the bees are mostly in box-hives and log gums. Modern beekeeping is very slowly penetrating. In Tennessee it seems to have developed somewhat. As a rule, bees are naturally in better shape here than elsewhere, and I hope to live to see what beekeeping will be here in the near future.

In this forest bees follow nature more closely. If they are kept requeened, with plenty of stores, the only thing in the way of success is weather conditions.

Antonio, and 35 cents f. o. b. Hamilton.

The San Antonio Express, in a feature article on the association's work, recently made an estimate of the savings that would have been made for the beekeepers of one little town in a year if, instead of purchasing supplies and merchandise in small shipment lots, they had followed the association's co-operative buying plan. The saving on freight alone, in the case of whole car lots, figured out at \$640, and the saving through securing of wholesale prices figured at \$704. The saving from association buying alone would thus have been \$1344 for the season.

Other instances of the kind mentioned will be given in what follows. These are not special instances, but may be considered as typical of what the association is accomplishing.

Co-operation Was Needed

Generally unsatisfactory conditions as regards the marketing of Texas honey was what led the Texas Beekeepers' Association, after twenty-five years of existence as a mere social and educational body, to take up the matter of co-operative marketing.

In July 1916, extracted honey was a drug on the South Texas market, securing around 5 cents per pound, while comb honey could not be sold at 7 cents in the majority of cases. This was in spite of the fact that amber extracted was selling at 7½ cents in California and that Colorado honey grading with the Texas product was 8½ to 11 cents in Denver. In the words of Manager LeSturgeon, "The Texas price was an artificial value, born of ignorance on the part of the producers and a ruinous competition among themselves."

As regards the attitude of the Texas wholesale and retail trade towards Texas honey, it was as discouraging as possible. The handling of honey had been for years a very unsatisfactory business to the grocery trade, with no stability in price and no organized sources of supply. A man might buy a few cases and soon find a competitor far underselling him because of the latter having secured a bargain from a producer ignorant of what a reasonable price should be. There had also been a lack of uniformity in pack and grade, so that many merchants had ceased to handle honey through disgust at the great variety in appearance, flavor and color and inability to secure a steady supply of a uniform grade.

At the time the co-operative idea had been making headway in South Texas, enough farmers having become interested so that action was being secured at the State Capitol in obtaining a law authorizing the formation in Texas of the co-operative form of corporation. To the honey producers it seemed the logical time to do something drastic, and 79 bee-men from 19 counties held a meeting at San Antonio in July to discuss marketing conditions. The result of the meeting was the adoption of a plan whereby every producing center should organize under one head for co-operative purchasing of supplies, co-operative selling through a sales

manager, thus eliminating the brokers, and establishment of a central educational bureau to disseminate market information, teach best methods of packing and shipping, etc. It was decided that the information bureau should serve the entire industry, whether members of the association or not, and that all Texas beekeepers should be eligible to membership.

Opposed by Big Business

The association, which took the name of Texas Honey Producers' Association, did not have entirely smooth sailing at the start. Certain supply interests attempted to discourage the movement by even selling at a loss in order to quote lower prices than the association could quote. For a time cans for honey packing could be purchased in South Texas at a lower price than at any other point in the United States, in instances even lower than the car-load price of the largest manufacturers. The better known bee supply houses, however, did not take part in this unfair competition, and the producers saw through it and presented a united front, as a whole.

They were strengthened in their stand by another result of their first meeting. For an immediate result of their determination to co-operate was the advance of honey prices in Texas 2 cents per pound. This took place within six weeks, and was ac-

companied by no advance whatever in consumer prices.

It may be said, in general, that the first decision to co-operate, in a section where prices are lower than reasonable, can usually be made to advance prices, if the producers stick to their guns. Exactly the same thing happened in California, when the prune growers of Santa Clara Valley organized. The speculators had been selling futures in the east at prices which showed they intended to buy from growers at 3 to 3½ cents. The growers got wind of these prices, and for the first time rebelled. They did not believe the reports of a very large crop circulated by the speculators, and they held a mass meeting and established a bureau to investigate. The investigation proved a normal crop only would be harvested, and the bureau advised growers to hold for 5 cents. Though there was no real organization, except of the flimsiest kind, a majority of growers heeded the advice, at least partially. Most sold at 4 cents or better, at any rate, and in the one season the single recommendation saved the industry half a million dollars. The success led to closer organization for co-operative marketing, and the California Prune and Apricot Growers', Inc., are now fully established and are already advertising "Sunsweet Prunes and Apricots," on a small scale.

(To be Continued.)

The Pussy Willow down by the creek

My Neighbor's Garden

By C. D. Stuart

MANY years ago, my neighbor, although possessed of the conventional garden, is said also to have cornered that huge tract of nature's garden lying just above and beyond my apiary, fenced it, posted it and otherwise prepared it for his own exclusive enjoyment.

"Buckin' natur' right from the start," was the verdict of his old gardener when one morning he descended from where the chimneys of my neighbor's mansion loom like battlements against the sky, to repair a broken fence in the ravine near my beehives. "Just look a' that!" He waved his arm toward the expanse of wooded hills. "Two thousand acres! No man can keep all that land to hisself."

"Not while my surplus honey comes from it," I agreed.

The gardener's eyes widened.

"Pussy willow down by the creek, first. After that the wild blackberry

—not much nectar from it, but plenty of pollen for the brood. That square I sent you Christmas was Ceanothus honey."

"Thought I smelled Wild Lilac when I went into it!" he grinned.

"Same thing," I told him: "a flowering shrub."

"Wild Lilac! You'll have some crop this year; hills are blue with it. That last you gave me was good honey, too.

"It came from poison oak—What are you staring at, man?" I demanded; "your land is covered with it."

"It was covered," he corrected. "I dug out miles of it makin' trails for the Missus. Carried my swollen arms on a pillow for a week after!" He stopped and eyed me blankly. "Say, neighbor, poison oak juice is black, an' just natcherally burns a hole in you wherever it touches; that honey was white. Are you sure it was poison oak?"

"Positive. Nothing else in bloom when the bees made it."

"And I ate it!" Overcome by the

thought, he sat down on a boulder and fumbled for a smoke. Suddenly he laughed. "That's a good one on the boss—takin' all that honey right from under his very nose!"

"Bees don't know they're trespassing. They can't read the old man's signs."

"Nobody reads 'em. Tell me! Why are signs like prohibition?"

"Give it up," I answered.

"Don't prohibit," he roared, his breath redolent with local opinion.

"Your boss owns the land," I reminded him; "if he gets joy—"

"He don't!" interrupted the gardener, and lovingly lit a long, black cigar. "Made 'im simply wild to see anybody else enjoyin' his property, an' he went broke tryin' to enjoy it by hisself."

"Well, he ain't exactly in the bread line," admitted the gardener, in answer to my scarcely-veiled curiosity; "but hog-tight fencin' an' fancy hull pups cost a lot. Then old Miss Riley got bit," he continued, between puffs. "She was pickin' blackberries on his premises, but the Court wanted to know who owned the dog. That one bite cost \$5,000, cash money."

He smoked on, recalling other intimate details.

"Next, Jim McCarty's goats broke in. The dogs investigated, and old Billy landed on him, then went on browsin' just like nothin' had happened. Jim owned right up the goat was his, but pay damages? No, sir. Said no dog's neck was wuth \$500, no matter what his pedigree; an' as fer three acres of Wild Lilac, that was only fit fer goat fodder anyhow—not knowin' it was Ceanothus an' good fer honey. Besides that he said the goat was grazin' on his land that the boss had fened in. Before the Court could decide which was a lyn', along came a fire an' burned the fence. Another \$5,000 went to clear the titles an' buy new fencin'. All that," condescendingly, "was before your time."

I nodded.

"Fences are a lot o' worry," he mused. "Don't last no longer'n it takes to fix 'em. That's what put the old man in the hospital."

It was my turn to stare. My neighbor in the hospital! It seemed but a day since he had passed, peering this way and that as though to make sure the world were in proper order.

"Yep, nervous prostration. 'Course hunters do get in an' shoot a rabbit now an' then," the gardener continued; "but I've found 'em pretty decent sort o' fellows. They," with a last lingering puff, "sure smoke bully cigars."

"But the flowers—ferns and azalias—are they safe?"

He rose and picked up a roll of wire. "The people are harmless—mostly convalescents and lovers explorin' trails, or tourists lookin' fer a view, or mebby a tramp boucarin' round fer a warm place to sleep; or them automobile picnickers always wantin' a spring handy to shade; an'," with a sly wink, "your bees after our poison oak."

Having no cigar and no more honey till the new crop, I merely remarked that it was hard luck when a

Wild Lilac Bordered Trail.—Photograph by John R. Douglass

man couldn't enjoy his own garden. "Too much of it; that's the reason. A cat's got no use fer two tails, an' one sting's a-plenty fer a bee, ain't it?"

"For all practical purposes," I agreed. "But if the bee had nine lives to protect, like the cat—"

The gardener gave the barbed wire an impatient twist. "Can't corner the earth and get away with it, not even if you had twenty lives. It's again' natur'."

The gardener is right. Again the Pussy willow has come and gone. The paths are fringed with clambering blackberry and the feathery bloom of Ceanothus is on the hills; and my bees take their fill, unmolested. There is nothing to remind me that all this beauty is owned by an absent neighbor. It is as though the broad acres were mine instead. Indeed they are mine. Every curve of the shaded roads, every tint of foliage, every song of the streams, the fragrance, the sunshine, the panoramic glimpses of valley and hill and sky, all are mine—mine and the bees.' No man can take them from us, least of all the babbling old man who sits all day in a far-away hotel under the watchful eye of a trained attendant.

Los Gatos, Calif.

Curing or Eradicating, Which?

By F. Dundas Todd

EARLY in the year 1911 I was invited to become a bee inspector for the Province of British Columbia, and my department chief asked me what I intended to do with any cases of foulbrood I happened upon. I asked a little time to consider the question, and this I devoted to going through all my bee literature, reading everything I found upon the matter and making note of results. Altogether I amassed a very considerable amount of data, and I gathered it all into two heaps. A very small one represented the region where it was claimed that foulbrood had been gotten rid of entirely, and remained free for a number of years, ten I think. The other big mass represented the regions where scores of men claimed to be curing foulbrood, but it was apparently still rampant in their districts.

I carried the piles to my chief, and arranged them on his desk, remarking, "This big heap represents the efforts of many men who cure foulbrood, and still have it, this single sheet of paper tells how Belgium got rid of the disease in 10 years, and still remains free of it. I propose to follow the example of Belgium, not pretend to cure it, but to wipe out by fire everything that I find in contact with the disease. Such procedure will probably raise an awful howl, but I am game to see it through, if you think the experiment is worth making." He decided it was, and has loyally stood behind his inspectors from that day until now.

In 1914 I came in contact with American foulbrood for the first time,

and during the last half of the year it kept me quite busy. I need not go into details, as they were given in an article that appeared in the July issue of the American Bee Journal, showing how I stayed by the proposition, stamping it out wherever I found it. Needless to say I got considerable advice as to how I really should have comported myself if I wished to be have according to Hoyle, but it was all carefully neglected.

Well, I now have had four seasons' experience of fighting American foulbrood and am able to give results, and armed with these to do a little talking back, as I think it is a poor game that is played all on one side. So I have gathered together a batch of literature for the second time, and had another good look at the situation.

The human race never gets very far in any particular phase of activity unless it devises a measuring rod adapted to the conditions, so that it can check results. I think if we had a good measuring rod to apply to the foulbrood situation we would not

have been deluged with so much oratory. In looking over the recent magazine articles at my disposal I find only one man, Wesley Foster, who catches a glimmer of its need, for in July Gleanings he says: "In our experience with European foulbrood we find something to learn every day. It is hard to eradicate but easy to cure. What is meant by that is that an individual apiary can be cleaned up readily, but it is difficult to clean up a district comprising 20 apiaries." He states the proposition exactly as I saw it in 1911, so the standard I set for myself was this, in how short a time can I eradicate the disease from an infected district? One of my own beekeepers, a good student of apiculture, evolved the same idea when he learned I was burning infected cases. He said, "All right, I'll give you five years to see what you can do, and if you have no definite results by that time, then I'll want a different policy."

Well, here is a measuring rod provided for me, the combination of the ideas of these two beekeepers. If he

No more Poison Oak for the Missus.—Photograph by John R. Douglass

eradicates foulbrood from an infected district in five years, a foulbrood inspector is to be considered successful, if he does not, he is a failure. I wonder how many bee inspectors will toe the mark on that proposition.

The shaking system to cure foulbrood has been in vogue since 1891, when McEvoy introduced it to this continent; he published details in 1895, twenty-three years ago. It has been tried from Maine to California and from Ontario to the Gulf of Mexico, so let us see what its advocates have to say for themselves.

In the U. S. Department of Agriculture Bulletin No. 75 there is a paper written in 1908 by Dr. Burton N. Gates, on Bee Disease in Massachusetts. On page 30 I find a heading "Brood Diseases Can Be Controlled." Under it he says, "It has been thoroughly demonstrated that by judicious and persistent manipulation both of them can be successfully controlled and suppressed."

Then, to show what really can be accomplished, he says, "The State nearest to Massachusetts is New York, where the annual loss of bees alone is shown in the following figures:

Previous to 1899, in a limited area the loss of bees alone is estimated at	\$39,383
In 1899, when concentrated effort to suppress bee disease was begun, it amounted to.....	25,420
In 1900	20,289
In 1901	10,853
In 1902	5,860
In 1903	4,741
In 1904	2,220
In 1905	1,725

"In the other states the encouraging results of inspection and persistent effort to suppress the inroads of disease are similar."

Observe, this was a concentrated effort, continued for seven years. Yet, in the seventh year foulbrood was still present, in fact the cases of that year apparently amounted to 6.8% of what was present in 1899. There was assuredly no complete eradication in five years in this case, so it fails by the measuring rod provided by Foster and Brookes.

I would like to know the condition of that district today, twelve years afterwards, especially when I read in September Gleanings on page 719 the following note about this very same State of New York: "Chief Inspector Geo. H. Rea drew out the fact that bee disease, both European and American, had wiped out a good many small yards throughout the State. There were not half as many bees as were formerly kept, but inspection was now under way, and he hoped the disease would be brought under control."

After 18 years' experience this is chased the great delusion.

Let us take all the references I find in the bee journals for the past year. In the American Bee Journal for January 1918, I find Mr. Morley Pettit giving a report of a meeting of the Ontario Apiary Inspectors and I am tempted to make a few quotations. The shaking system was begun in Ontario by McEvoy in 1891,

and has been kept up ever since; so it has had 27 years' trial. For a great many years there have been sixteen inspectors in the Province, but it is only fair to say that they do not devote nearly all their time to the work. If curing foulbrood is as effective as it is held to be by its advocates, then in 27 years surely the disease in Ontario would be chiefly conspicuous by its rarity. Let us see.

Mr. Pettit says, "Unfortunately, comparatively few apiaries infected with either disease have been found to be entirely cured, yet it might safely be said that the expenditure of time and money from year to year has not been without benefit, etc." Again, "Seven hundred and seventy-eight apiaries were inspected and 203 of these were found to be diseased with either American or European foulbrood. Eight thousand five hundred and fifty-seven colonies were examined and 1,132 were diseased." That is to say 20 per cent of the apiaries and 13 per cent of the colonies examined were found affected with

in that sentence to indicate that the shaking treatment will eradicate foulbrood from a district in 5 years.

The situation in California is disposed of by P. C. Chadwick on page 924 of December Gleanings in a few words, "California has disease. There is not a county in the State, unless it be very remote, that has not disease." And this is the home of the big professional beekeeper. One of their beemen told me they were shaking all the time.

On page 271 of April Gleanings, I find A. C. Ames remarking about conditions in Iowa, "It is rare when we go through a county one year that we are able to go back in that county the next season; and we all know, if one has much disease, that it is very seldom that one clean-up will get all the infection." In plain English, shaking as practiced in Iowa, cannot possibly eradicate. So the situation is never in hand, and in short cycles the bee inspector begins the weary grind all over again.

Lastly, I want to point out that in

Wild Blackberry thicket.—Photograph by John R. Douglass

foulbrood. This after 27 years of curing.

In July Gleanings, J. F. Byers lets a shaft of light fall on the situation when he says, "European foulbrood is rapidly spreading in Ontario." But in 1911 a searchlight was thrown on the situation in that Province when one of its most famous beekeepers summed up the situation by declaring to me that what Ontario needed was at least 1200 bee inspectors. I am beginning to wonder if the disease has not been shaken all over the Province when the bees were shaken out of the hives.

I began my beekeeping career in Cook county, Illinois, and am naturally interested in conditions in that State, so I read carefully the report of Inspector Kildow on page 961 of December Gleanings. He says, "Notwithstanding more apiaries were examined than ever before last year, less disease was found than during the year before, proving that foulbrood is not only being held in check but that its ravages are being considerably mitigated." I see nothing

the A B C of Bee Culture there is printed U. S. Census Statistics to show that in the whole country there was a drop of one million farmer, that is small, beekeepers between 1900 and 1910, being a loss of about 14 per cent. The heaviest losses occur in the most densely populated States, running from 23 per cent in Pennsylvania to 40 per cent in Vermont. Utah tops the list with a drop of 49.5 per cent.

When in 1911 I looked at similar data as is given above it did not take me long to make up my mind that, as practiced, the shaking treatment was not all that it was cracked up to be. And I could not get away from the clear-cut statement about the condition of little Belgium, foulbrood wiped out in 10 years by fire, and none existing for 10 years or more.

Now for the other side, the test by fire. In 1914 I found American foulbrood in the following districts: Chilliwack, Coquitlam, Point Grey, Vancouver City and South Vancouver. From Chilliwack to Vancouver the

distance is fifty miles, the other districts lie between these two points. As far as I can trace, the disease has been in Vancouver City for over a dozen years, anyhow it was badly scattered over an area six miles by ten, small apiaries being common. In October, 1915, I had a hurry-up call from Nanaimo and found five affected apiaries spread over about ten miles in a straight line.

Each season I followed the situation closely, using what one editor described as heroic methods. I am now able, using Parliamentary language, to report progress. In 1917 I failed to find the disease in any of the districts mentioned, excepting South Vancouver. The heroic treatment by fire apparently will face without flinching the measuring rod of Foster and Brookes.

as a flash he snapped out 'the use of statistics. I statistize everything; knowledge is power, and the throttle valve of every business.'

Since the above was written I find in *Gleanings* of January 1918, on page 27, the following paragraph written by J. F. Crane:

"E. G. Baldwin informs us that they at last have American foulbrood on the east coast of Florida, and considers F. Dundas Todd's article in the *American Bee Journal* as both timely and refreshing. I consider his method of combatting this particular disease quite out of date in this part of the world. I am not denying that his scheme of cremation is a sure remedy for every colony treated. So is burning a barn to rid it of rats a sure cure. The editor of the *American Bee Journal* advocates

I don't care how much wax he has saved, I want to know if he has cleaned up a district, and how long it took him to do the job.

Mr. Editor, I place my cards face up on the table and call for a show-down. I am tired of the generalities that have been printed in the bee journals for years; I want statistics. I want to find out if for twenty or more years the bee world has been chasing a great delusion, or can give solid reasons for the great faith it has shown.

Victoria, B. C.

A Plea for Uniformity

By F. Greiner

A RESOLUTION was passed at the recently held New York State Grange meeting in Syracuse to the effect that manufacturers of agricultural implements be compelled to use standard bolts in the construction of all farm machinery. The beekeepers are not using any bolts in the construction of their honey boxes or other paraphernalia, nevertheless uniformity in and standardizing of the many things apiarists use is of great importance and should receive our most earnest attention. Mr. Dadant says in his recently issued catalog and price list of hives and apicultural implements: "We especially warn beekeepers against trying to invent a new style of hive, as thousands of hives have been invented which are not worth the paper on which the design was printed." I would add to this "and hives are now being invented which are no better."

But let us start with the honey-boxes, the sections. How much better it would be if all comb honey produced was stored in sections of the same size. We could not estimate such an advantage in dollars and cents. We may talk of settling on a certain length of the L-frame top-bar, or on the depth of the frame, its spacing, the uniformity of hives, etc. We may settle these points to our satisfaction and when we have done so the general public will not be affected. But when we unite on the section we will have accomplished something far-reaching as touching thousands and thousands, benefiting hundreds and hundreds of dealers and manufacturers besides benefiting every comb-honey producer in ever so many ways.

It is an idle question if I should ask "What has been gained by contriving the $3\frac{5}{8} \times 5$, the $4\frac{1}{2} \times 4\frac{1}{2}$, or any other odd-sized section?" The answer would be, "Nothing; only confusion has been produced thereby." The only point gained, it may be said, is the advantage of the no-beeway feature. That the $4\frac{1}{4}$ section should be better than any other is not my contention, but, since the most popular frame now in use is the L-frame, and as this frame has as its measuring unit the $4\frac{1}{4}$ square section, being 2 high and 4 wide, and further, since this $4\frac{1}{4}$ square section is the one most in use, I hold that it is the one we should adopt.

It is very true if we did not try out

The Red Bud is one of the earliest of bloomers

Were it possible, I would like to make a statistical comparison of the results attained by the two systems of handling foulbrood; but alas, I cannot lay my hands upon any definite figures published by other inspectors. It seems to me there is a crying want for a uniform system of statistics for bee inspectors, so that the beekeeping world can ultimately develop a system of maximum efficiency, and decide definitely whether shaking or complete extinction is the most efficient and economical in the long run. The following quotation from an article in the *Saturday Evening Post* of January 12 is illuminating. Speaking of the famous Sir Eric Geddes, the writer says: "I once asked him what single rule had been of most service to him. Quick

saving the hives, but why not save the combs and render them into wax?"

My answer is, the purpose of the bee inspectors' work, as I see it, is to eradicate foulbrood, that above all things. If at the same time he can save wax, hives and bees, so much the better, but these are emphatically of secondary consideration. I have a suspicion that in the mind of the average bee inspector the by-product is becoming more important than the regular output. Will Mr. Crane kindly oblige by applying a Foster-Brookes measuring rod to some of the districts in his territory and tell us the results? Let him put the emphasis on his real job, which is the eradication of foulbrood, and talk about the saving of by-products afterwards.

new things, either those of our own invention or as suggested by other thinkers, we would not become wiser, we might stand still and never make any progress. We must do a certain amount of experimenting. I myself have in my yards several styles of hives; one has the jumbo feature, another the standard L, another the half-story frame or interchangeable sectional feature. Yes, and I have used the box-hive. Any of these hives have their valuable feature, but if I might begin beekeeping anew, I would not hesitate one moment but what I would select the regular single-walled Langstroth hive with its tiering up principle. I verily believe that all those successful honey producers who are now using other hives, jumbo-framed or miniature half-story hives, would be equally successful with the L-hive. It is a matter of adapting the management to the hive, that's all. In view of the many advantages that uniformity in hive and hive fixtures affords, it would seem to me that the time is now here for our beekeepers' societies, our apicultural writers, our various bee inspectors and other bee authorities to turn their attention to this subject of uniformity, and particularly to standardizing the section. Mr. S. D. House, in his zeal went so far as to demand that the New York State Association of Beekeepers' Societies at their last session in Syracuse go on record as establishing a standard section, if necessary to ask the legislature at Albany to pass a law making it illegal to offer comb honey for sale in New York State except same is stored in the to-be-adopted section. A committee was appointed at this meeting to have this matter in charge. As chairman of this committee I would ask the co-operation of all beekeepers in this and in other states. Let this subject be discussed from an unbiased standpoint; let us put aside our notions, make concessions for the good of the cause.

Naples, N. Y.

hurrying people, and instead of the faded upholstery of the barouche your eye catches glimpses of shiny enamel as the autos speed past. The sleepy, indolent air of the streets is a thing of the past, swept away by officers in khaki striding by, groups of young business women hurrying along, by sailors, civilians, foreign officers in vari-colored uniforms, all wearing the air of going somewhere with a purpose.

If you follow the stream going south you will find that most of the atoms which make it up are headed for one of the large gray buildings which now form a drab background for the Spanish beauty of the Pan-American building, the classic marble of the home of the D. A. R., and the white simplicity of the Red Cross building. The low, modest, gray structures are unpretentious, and of temporary construction, but what they lack in artistic beauty is made up by what one discovers is going on inside. The streets surrounding the tremendous area which they cover are lined all day with automobiles, and up and down the few steps at the entrances someone is always coming or going. One of these buildings is marked "Food Administration," and the minute one enters, the atmosphere of work is felt—work tremendous in quantity and importance.

Just inside the door are desks as in a hotel lobby, where you inquire for the person you desire to see. He, or she—frequently she—is telephoned to, and a boy acts as guide through a labyrinth of halls, up stairs (there are no elevators), round corners, past innumerable doors, until you find yourself entering a large, light office, where the person you wish to see comes forward cheerfully and courteously, ready to tell you anything you wish to know.

Of course, you wish to know everything, and as you imbibe knowledge your respect and wonder for the great mind at the head of the Food Administration increases by leaps and bounds. You learn that there are many divisions of the Food Administration, each division being divided into sections, each with its staff of specialists from all parts of the country. Every commodity has its section, or if it is specially important, like sugar, it has a division devoted to it. Then there is the Educational Division, which includes a Women's Magazine Section, a Farm Journal Section, a Library Section and many others. As you meet more and more of the workers, each wearing a Food Administration button, you cannot help but feel their tremendous earnestness, their enthusiasm for their work and their devotion and unswerving loyalty to Mr. Hoover.

A young girl in the Farm Journal Section said to me: "You must go upstairs and see the muffin exhibit that was made for the State men when they came here for a conference this week." Of course you know that each State has its food administrator, but do you know that fre-

quently these men come to Washington for personal conference with Mr. Hoover? Those are the days when it is wise to keep away from the Food Administration Building, for no one has time for any individuals who are not "State men." We went upstairs and down long halls until we came to the conference room. At the front of the room someone was talking to a group of twenty or thirty people; at the back stood a camera man photographing muffins with the help of the artist who had made them and who was carefully cutting them in half to show the texture. There, on plates, were at least fifty different kinds of muffins made in the kitchen of the Food Administration, and not one had less than 50% wheat substitutes, many of them contained 75% wheat substitutes, and some were 100% corn flour, rice flour, barley flour or buckwheat flour. And what is more, every one that I tasted was palatable as well as good to look at. They were tender and light and show what we can do if we try. Miss Roberts, who had taken me to see the exhibit, turned to say: "Well, I made chocolate cake with 75% buckwheat flour this week that was delicious, and my mother is now making all her bread with at least 75% wheat substitutes." There is the spirit of the Food Administration workers—they are more than living up to the food pledge! They are not like the woman who was heard to say recently, "All this talk about wheat substitutes passes me by!" And that woman was knitting socks for her nephew at the front, while talk of wheat conservation "passed her by!" It seems incredible that that could have been said in Washington with those thousands of earnest people in the Food Administration so near at hand.

On every office wall in the Food Administration building are posters of food conservation, many of them beautiful pictures, all of them with forceful sentiments—"Food Will Win the War," "Eat Less Wheat, and We'll Beat!" "Serve Simple Food, and Just Enough." Then the walls of the halls are utilized to display posters made by school children of different parts of the country. These are well done and the educational work that they accomplish for food conservation is obvious. Some showed fruits and vegetables in artistic groups with "Eat These" below them; others showed bags of sugar, fat pigs and red cows with "Send These Abroad" beneath. One picture evidently by a small youngster, was a sugar bowl, with "Let Me Alone" printed on it.

The Library Section is a most interesting room where exhibits are prepared for Public Libraries everywhere in the country. While posters carry their message, they may be forgotten, but who can forget an array of tiny toy soldiers with bayonets pointing toward a herd of cows and pigs with the legend, "Back, Meat! Shipping Space All Taken!" Near by is a toy train, labeled "Wheat," with soldiers in a line beside it, saying "Forward, Wheat! We

A Visit to the Food Administration

By Mary G. Phillips

ONE cannot help but be impressed by the change which has come over Washington since war was declared. It used to be that one could stand on the sidewalk outside the historic and picturesque Octagon House for hours at a time and see nothing more exciting pass than an old-fashioned barouche drawn by ancient horses, and driven by a still more ancient colored driver, but now if you stand there for more than a minute or two, you are jostled by the passing throngs of

Will Get You Across;" That was the sentiment expressed by everyone with whom I talked that day—deep regret that the meat which has been saved and was at last on the Atlantic seaboard could not be sent across for lack of ships. Wheat is needed most—that will have to go—the meat, for which there is not adequate storage space, will have to be eaten. Frederick Palmer, Military Censor for the American Expeditionary Force, was undoubtedly right when he said in Washington not long ago, that "every man, woman and child in the country should be talking ships, ships, and yet more ships."

The wheat shortage is more acute than it has been at any time since the war began, one of the saddest parts of it being that in 1917, 11,000,000 bushels of wheat were sunk by German U-boats. That is why the Food Administration's most insistent drive is to save the wheat. If we are to furnish the allies with the necessary proportion of wheat to maintain their war bread from now until the next harvest, and this is a military necessity, we must reduce our consumption to approximately 1½ pounds of wheat products weekly per person. That is 78 pounds per person per year, or about half as much as we have been consuming if we have faithfully followed the food pledge. While up to this time we have been asked merely to limit ourselves to 150 pounds per person per year, the soldiers have been eating wheat at the rate of only 131 pounds per person per year. They must have a full allowance, and it is so little for us to do here at home—merely to eat corn and oats, of which there is a plenty, and to use more potatoes, of which there is a surplus, in order to give our brave soldiers and allies the needed wheat. There are many thousands of families in the country using no wheat products whatever, except a very small amount for cooking purposes, and they are doing so in perfect health.

No doubt every beekeeper's wife is working "from her eyes up" in her efforts to use the substitutes for wheat that are available in her community. If you can get buckwheat and cannot get rye, try out all the buckwheat recipes you can find, and experiment yourself, carefully, of course, using a good bread recipe, and substituting the buckwheat for the greater part of wheat called for. I have tried all the substitutes I could buy, using the same recipes all the time, and although the family like some of the breads better than others, they have eaten them all with relish. If we serve purely wheatless breads two or three days out of the seven we will be doing no more than our share, which should be twice as much as we are asked to do.

The following recipe is a special favorite with my family:

Mush Rolls

1 pint of liquid (generally half milk, half water).
½ cup of white cornmeal.

Cook these together for one hour, then cool until lukewarm. Then add
1 tablespoon of shortening.
1 tablespoon honey.
1 teaspoon salt.
1 yeast cake dissolved in ¼ cup warm water.

Enough flour to make a stiff dough. Knead and let rise until double in bulk (about 3 hours). Knead again and shape into rolls. After the second kneading, they are slow in rising, but if set at night, using only ½ a yeast cake, they are ready for lunch the next day.

On days when the yeast bread gives out and we are ready for a change from corn bread, we like the following:

Oatmeal Mush Bread

2 cups of cold oatmeal porridge.
1 cup of corn meal.
½ pound of dates or raisins.
1 cup of milk.
1 tablespoon of salt.
2 eggs.
2 teaspoons baking powder.

Put the cold oatmeal and milk into a double boiler over the fire. When hot, slowly stir in the corn meal. Cook until the mixture begins to thicken, take from the fire, add the beaten eggs and the baking powder. Pour the mixture in a greased shallow baking pan, the bottom of which has been covered with the chopped dates. Bake in a moderate oven for a half hour.

Another quick bread without wheat is this:

Corn Meal and Hominy Bread

1 cup cooked hominy.
1 cup milk.
1 tablespoon melted butter or vegetable oil.
1 cup white corn meal.
2 eggs.
1½ teaspoons salt.

Mix the ingredients and bake 30 minutes in a moderate oven.

Hominy grits is a most satisfactory form of corn, for it can be used in so many and varied ways. It serves as a breakfast cereal, being specially good when raisins are added. Then it is splendid to use on your meatless day, in the following way:

Baked Hominy Omelet

Soak and boil 1 cup of hominy grits. When well done and white hot, stir in 2 eggs well beaten.

½ cup sweet milk.
¾ tablespoon shortening.
¾ cup of grated cheese.

Season with salt, pepper, paprika. Put in baking dish and bake in hot oven until brown (about twenty minutes). Serve hot.

Hominy Pudding

2 cups cooked hominy.
1 cup molasses.
1 cup raisins.

Bake in a moderate oven about 30 minutes and serve hot with milk or a lemon sauce.

Do not forget that we are on the battle line, and these recipes are part of our ammunition! The enemy must not break through our wheat line!

Washington, D. C.

A Watering Place for Bees

By C. W. Brinhall

THE cut shows a watering place for the bees, made of a half of a paint barrel. It is placed on the back side of the honey house and under an eaves spout, which fills it when it rains. In the barrel is a float made by nailing lath on strips of pine. After nailing, the float is cut

A Good Watering Tub for Bees
C. W. Brinhall

in circular form to fit the barrel. I use two floats so that when one gets water logged it can be set in the sun to dry out, while the other keeps the bees from drowning. In hot weather the barrel should be scrubbed out to keep it fresh. If turned over and cleaned out just before a good shower, it will be promptly filled again.

Schaller, Iowa.

My Experience With European Foulbrood

By F. Kittinger

Read at the Wisconsin State Convention, December, 1917.

I FIRST discovered European foulbrood amongst the bees of my home apiary during the month of May, 1916. The disease developed from a queen purchased during the fall of 1915, from what was supposed to be a reliable source.

The colony that developed the disease happened to be one that was wintered in a house apiary, and as the colonies in the building were well supplied with honey in the fall, they were not examined until late in the spring. When I examined these colonies, I found nearly all more or less diseased.

All colonies that had been wintered in the cellar, and had been set out in this same yard, were examined early in the spring and no signs of disease discovered. After this early examination of the cellar-wintered bees, and before the disease was discovered in the building, I moved colonies from the home yard to both of my out yards. Some of the colonies that were moved had evidently contracted the disease between the time they were examined

early in the spring and the time they were moved, as the next time I examined them I found diseased colonies that had been moved to both out yards.

Several of the colonies in the home yard that were near, or in a direct line of flight with the diseased colonies in the building, showed signs of disease early in the season, while the rest of the yard was comparatively free from disease until later in the season.

As the disease did not show up very bad until after the main honey flow, we secured a fair crop of honey from all but the few that were badly affected—a dozen or so colonies.

As soon as I discovered the disease I killed the queens in all the most badly affected colonies, and ordered young Italian queens from a reliable southern breeder for requeening. All colonies so requeened showed up free from disease in the fall, and were in a No. 1 condition for winter.

Expecting a wild-fire spread of the disease in the spring of 1917, I ordered 100 young Italian queens for delivery during May of this season.

The spring of 1917 found us with something over 300 colonies in fair condition. When these colonies were examined late in April and early in May very few showed any disease. This examination was followed by 7 or 8 days of very unfavorable weather when hardly a bee could fly. As soon as the weather was again favorable several colonies that were marked O. K. at the first examination were again examined. At this time it was found that the disease had spread so that nearly all colonies were affected—some being fairly rotten with the disease.

The first of my southern queens arrived the latter part of April, and about 80 per cent of my order reached me by the end of May. Owing to unfavorable conditions in the South, some twenty queens did not reach me until early in June.

As fast as a batch of queens arrived I killed the queens in the most badly diseased colonies and introduced a young queen at once. Early in the season I paid no attention to queen-cells, never opening a hive until the queen had been in a week or ten days. I think I lost about 15 per cent of the queens so introduced. The greater part of my loss I think was due to the very unfavorable weather for the work at the time.

All diseased colonies that were so requeened early in the season cleaned up the disease and stored a good surplus of honey.

Having been able to requeen only part of the affected colonies early, it was impossible to get up a sufficient field force in a great many colonies. Our average per colony for the season was thus greatly reduced by lack of sufficient field bees during the height of the flow.

I also used another 100 queens this fall, having killed off the old queens just before the end of the basswood flow. Eight days after killing the queens all cells were destroyed, and the colonies allowed to remain queenless until all brood had hatched before requeening.

I lost more queens by this system than where the young queen was introduced at the time the old queen was killed.

For my part, to clean up the disease, I prefer to get young Italian queens the latter part of April or early May. Unless one can do the requeening early, so as to get a good force of workers from the young queens in time for the honey flow, I think it best to double two or three colonies into one. I find there is no use trying to have weak colonies clean up the disease—double them up.

My system of doubling up weak colonies is to haul them to an out-yard and pile two or three high. As soon as they have marked their location shake all bees into one body, and give a young Italian queen. Take all surplus brood-combs and put above a queen excluder over a strong colony. No bees return to the old stand by this system.

Owing to the lack of help it was impossible for me to requeen all colonies this season, but I intend to requeen all that show disease an-

other spring, hoping thereby to have the disease under control.

Franksville, Wis.

[The attention of the reader is called to the following paragraph in the above interesting article:

"Eight days after killing the queens, all cells were destroyed, and the colonies allowed to remain queenless until all brood had hatched before requeening. I lost more queens by this system than where the young queen was introduced at the time the old queen was killed."

The above experience is exactly in line with the editor's own experience. Many people think a colony should be made queenless some days ahead in order to introduce a queen successfully. We believe, and this experience indicates, that the safest introductions with the cage method are achieved where the colonies were not allowed to be without queens for a single minute. It goes without saying that in the present case the colonies needed to be queenless for some days in order to help do away with the disease. But Mr. Kittinger's experience is of value as an object lesson in the matter of queen introduction.—Editor.]

BEE-KEEPING FOR WOMEN

Conducted by MISS EMMA M. WILSON, Marengo, Ill.

Eight and Ten-Frame Hives

Miss Emma Adkins is reported in the Beekeepers' Item as having made special observations this year in apiaries where 8-frame and 10-frame hives were kept side by side. She says, "A good many of the colonies in 10-frame hives made a fair crop even in this worst of all seasons, but those in 8-frame hives did little or nothing."

Sugarless Desserts

Eat less candy; use less sugar in coffee, tea and chocolate; eat more fruit, nuts, popcorn, honey and syrups. A frosted top on a cake is a sign of criminal thoughtlessness at a time when millions of children in Europe are dying of tuberculosis caused by under-nourishment.

Here are some sugarless recipes, worked out by the United States Government, some of them in cooperation with the Universities of Ohio and Missouri:

Hot Rice or hasty pudding (corn-meal mush) served with a sweet sauce makes a simple, wholesome dessert. Chopped raisins or dates added to either, but no sugar is needed.

Honey Sauce

1 cup honey.
 ¼ cup water.
 1 tablespoon butter substitute.
 ¼ teaspoon salt.
 ¼ teaspoon cinnamon.
 A dash of nutmeg.
 Juice of 1 lemon or 2 tablespoons vinegar.

Boil together 15 minutes. The juice of 1 orange and grated peel may be

used instead of lemon and seasoning in this recipe.

Popcorn Candy

1 cup syrup.
 1 tablespoon vinegar.
 2 or 3 quarts of popped corn.
 Boil together the syrup and vinegar until syrup hardens when dropped into balls or fancy shapes for the Christmas tree. Little popcorn men will please the children. Mark in the features and outlines with melted chocolate.

Either honey, maple syrup, molasses, white cane syrup or corn syrup may be used.

Self-Spacing and Loose-Hanging Frames

In the well timed article of G. C. Greiner, page 55, February American Bee Journal, he speaks of giving frames of sealed honey in early spring, such frames having been kept over winter for this purpose, a proceeding which deserves the highest commendation. He says: "Every side-comb of every hive was taken out and glanced over, and when found empty or insufficiently supplied was replaced by one or two combs of honey. In connection with this observation, I wish to emphasize the great convenience of the loose-hanging frame and its superiority over any self-spacing device. A self-spaced frame would have greatly hampered this work and required much more time."

Coming from a man of Mr. Greiner's experience, this expression of opinion would incline one to believe that loose-hanging frames are to be

preferred to those that are self-spacing. Yet "in this locality," where frames of both kinds have been used by the thousands, self-spacers are decidedly preferred. They have the important advantage when placing frames in the hive that not only is the spacing done exactly, but almost instantaneously. With self-spacing frames, even if one had such marvelous eyes that a small fraction of an inch could be measured, each separate frame must be slowly adjusted into place, the whole operation taking many times as long as with self-spacers. And this difference in time occurs every time the frames are handled, so that those who go through their hives many times in summer—and with many good beekeepers it occurs every ten days—will lose very much more time in summer with loose-hanging frames than they can gain in the one operation in question, which occurs only once a year, if it occurs at all.

Even in that one operation, there must be something wrong if there be any real gain with loose-hanging frames. If the self-spacing combs fill the hive quite full, and there is no dummy, then the difficulty of getting out the first frame is so great that one may well prefer loose frames. But there should never be such crowding. There should be a dummy easily withdrawn, after the withdrawal of which the loose hangers have nothing on the self-spacers.

Another item in the case is that with self-spacers the frames are always held square, bottom-bars as well as top-bars being properly spaced. With frames hanging loose, no matter how exactly the top-bars be spaced, there is always a chance for the frames to get out of square, so that occasionally bottom-bars swing so close that the bees glue them together.

What We Eat, and What Happens to It

Under the above title a series of articles is being published in The Ladies' Home Journal, in explanation of which that periodical says:

"Up to now nearly all that we have known of what we eat when the food reaches the human stomach has been learned through the use of the stomach pump, X-ray examinations, or from experiments made on the stomachs of dogs. A direct method, however, has recently been developed in the Department of Physiological Chemistry of the Jefferson Medical College, of Philadelphia, devised by Dr. Martin E. Rehfuess, of Professor Hawk's staff, whereby it is now made possible to follow the transformations of the food that we eat, as it is actually digested by the human stomach, at every stage of the digestion."

The paragraph below is taken from the article in the February Ladies' Home Journal. It contains nothing strikingly new, yet appearing where it does, and meeting the eyes of so many thousands of women who never see a bee journal, it cannot fail of having an important influence. Let us hope that the statement that "Our

children would be better off if we had them eat more honey and less candy" may arrest the attention of many an interested mother:

What Does the Stomach Say to Honey?

"Honey is about 75 per cent sugar, the principal 'sweeteners' present being glucose, fruit sugar and cane sugar, the latter being present in very small amount. The flavor of the honey is due to certain volatile substances which the bee extracts from

the flower. Bread and honey is a combination which looms large in the average juvenile eye. It has good food value and is well digested, provided the child can curb his desire to use more honey than bread. If we take milk along with the bread and honey we have a very satisfactory luncheon. Our children would be better off if we had them eat more honey and less candy. The same is true of the syrups and of molasses; and the more old-fashioned they are in their making, the better."

Short Course at Ames, Iowa—The second annual beekeeping short course will be held on May 13 to 18, 1918, at the Iowa State College, Ames.

In view of the necessity of increased honey production this year, the course will be made very practical and will include phases of management and practice in two apiaries. Several successful commercial apiarists will assist us. If you are really anxious to make a success with bees and want to learn more about them, attend this course.

Opportunities for commercial beekeeping were never better and honey is now regarded as a food, not a luxury. The demand far exceeds the supply.

Many ladies have signified their intention of meeting with us and all are welcome. There are no fees and rooms and meals can be obtained at reasonable rates. The course is open to all interested in beekeeping. Programs can be obtained from F. Eric Millen, Ames, Iowa.

Corrugated Paper—Get large boxes of the heavy mill board, corrugated paper second choice; cut down the corners, lay out flat, paint one side with coal tar; then lay it, tar side down, in front of the hive to kill grass. It is surprising how long it will last.

DR. BONNEY,
King Bee.

Honey by the Ton Going to Waste—One eastern North Carolina county produced 35 tons of honey in 1917, reports Mr. Franklin Sherman. The beekeepers in this county assert that with proper distribution of bee-yards three times as many bees could be kept in the county with equally good results. Even allowing that 1917 was an unusually good honey year, the county could produce 100 tons of honey in average years if it were fully stocked with bees which were managed by good beekeepers. Yet this county does not include 10 per cent of the honey-producing plants of the eastern section—in other words, over 1,000 tons of honey are produced by the native plants of eastern North Carolina in average

years, of which scarcely one-tenth is gathered for the uses of man. Think of what this means when honey is selling for around 15 cents per pound. —Extension Farm News, North Carolina.

The Northern Pennsylvania Beekeepers' Association met in Annual session at Towanda, Feb. 28. The meeting was well attended. The membership now numbers 35. Among the good things on the program was Prof. J. G. Saunders with his movie bee film. Also Chief Apiary Adviser Geo. H. Rea, besides local speakers. The next meeting will be in the nature of a field meeting and picnic combined, to be held in June at the home of the Secretary. All beekeepers welcome.

HARRY W. BEAVER,
Troy, Pa. Secretary.

Massachusetts Federation of Beekeepers' Societies—The following report is interesting from its federation features, aside from the fact that it shows activity on the part of Massachusetts beekeepers. In union there is strength and the example should be followed in every direction:

Each year there is an advance in beekeeping, which now requires the co-ordinate working of beekeepers. To this end, at Worcester, Saturday, March 23, an important gathering of the beekeepers of Massachusetts was held. There was a wide and representative attendance. Among those present were the Presidents of each of the five local beekeepers' societies of the State, together with Secretaries and delegates from these societies. Absolute unity, enthusiasm and earnestness prevailed with but one aim in view, the formation of a "Federated Massachusetts Beekeepers' Association." By-laws were formulated and adopted. It was voted to incorporate. As the business of the meeting was rapidly transacted, the following officers were soon elected:

President—Mr. O. M. Smith, of Florence.

Vice President—Mr. O. F. Fuller, of Blackstone.

Secretary-Treasurer—Miss Dorothy

Quincy Wright, of Ch. msford.

The Presidents of each local Beekeepers' Association being present, announced three delegates to the Federated Association, whose terms of office were, respectively, one, two and three years, and in the order enumerated below:

Berkshire County Beekeepers' Society—Mr. C. M. Musgrove, Pittsfield; Mr. H. E. Hume, Dalton; Mr. L. D. Case, Pittsfield.

Eastern Massachusetts Society of Beekeepers—Mr. W. Schweitzer, Boston; Mrs. R. Goodenough, W. Roxbury; Mr. S. L. Davenport, Hathorne.

Hampshire, Hampden Franklin Beekeepers' Association—Mr. A. C. Andrews, West Springfield; Dr. D. D. Gorton, West Springfield; Mr. O. M. Smith, Florence.

Massachusetts Society of Beekeepers—Mr. H. C. Britton, Middleboro; Miss Dorothy Quincy Wright, Chelmsford; Mr. F. W. Frisbee, North Andover.

Worcester County Beekeepers' Society—Mr. W. E. Parker, West Boylston; Mr. O. F. Fuller, Blackstone; Mr. H. E. Bradish, West Boylston.

The By-Laws provide for a Board of Directors consisting of the following:

Provision is made for the Secretary of the State Board of Agriculture to act as Chairman, with the State Inspector of Apiaries; the President, Vice President and Secretary as the other members.

Members—The Secretary of the State Board of Agriculture and the State Inspector of Apiaries shall be ex-officio members.

Voting members shall consist of three delegates from each of the regularly organized beekeepers' societies of the State. Their dues shall be \$2 annually.

As an associate member, any person who keeps at least one colony of bees is eligible, but associate members have no vote. Their dues shall be 50 cents annually, with an application fee of fifty cents.

After a thorough business session the meeting adjourned, subject to the call of the directors.

BURTON N. GATES,
Acting Sec.

County Inspectors Alive in Texas—One of the most interesting and instructive meetings held recently in Texas was the conference of County Apiary Inspectors at College Station, February 11 and 12. More than 25 county inspectors were present and many valuable papers were read. Among them was a scientific and scholarly treatise on foulbrood by Dr. N. G. LeGear, of Waco. With a high power microscope and a number of slides he exhibited the bacillus of American foulbrood in all its forms and traced its life history.

Monday, Feb. 11, 1918—Forenoon Session—

9:00—The Inspection Service, F. B. Paddock, State Entomologist.

9:30—The College, Dr. W. B. Bizzell, President Texas A. & M. College. 10:00—The Experiment Station, B. Youngblood, Director Experiment Station.

10:30—The Extension Service, T. O. Walton, Assistant Director of Extension service.

11:00—Apicultural Instruction, Prof. S. W. Bilsing, Professor of Entomology Texas A. & M. College.

11:30—Foulbrood Eradication, W. E. Jackson, Assistant Entomologist.

Afternoon Session—

1:30 to 5:30—Fifteen-minute report from each Inspector present of the local work.

Tuesday, Feb. 12, 1918—Forenoon Session—

9:00—Letters of Authorization and Vouchers, F. B. Paddock.

9:30—Reports, W. E. Jackson.

10:00—Laws and Regulations, F. B. Paddock.

10:30—Proposed Work, W. E. Jackson.

11:00—Instruction Book, F. B. Paddock.

Afternoon Session—

1:00—Inspection of College and Experiment Station.

2:30—Foulbrood, N. G. LeGear.

3:00—Sacbrood, T. W. Burleson.

3:30—Inspectors as Advisors, J. B. King.

4:00—County Educational Work, T. A. Bowden.

Evening Session—
Smoker.

It is to the energy of Mr. F. B. Paddock, State Entomologist, that the success of the meeting is largely due. He has prepared to wage an effective battle of eradication this season against our common enemy,

This meeting was held to educate the inspectors as to their duties and powers and to more fully co-relate their work. Strict regulations are to be enforced covering the shipment of honey out of infected areas. Certificates of inspection, showing freedom from disease must accompany bills of lading covering the tender of honey to railway agents for shipment. Texas is fortunate in having a foulbrood law "with teeth in it," and great progress is looked forward to this season. Active work is being done in 28 counties.

E. G. LESTOURGEON.

Inspectors in attendance at the Texas Conference

DR. MILLER'S ANSWERS

Send Questions either to the office of the American Bee Journal or direct to
DR. C. C. MILLER, MARENGO, IL.
He does NOT answer bee-keeping questions by mail.

Queens

1. What is a laying queen?
2. Can I use a virgin queen in a hive with success and will the bees swarm, and also work good the first summer by using a virgin queen?
3. What is an untested queen, and how do you know when you buy a queen whether it is a virgin, tested or untested?
4. Would I have as good a chance to introduce a virgin or an untested queen to a colony of bees as to pay \$2 for a tested queen?
5. Will a virgin queen lay?

SOUTH DAKOTA.

ANSWERS.—1. As soon as a queen begins to lay eggs she is called a laying queen for the rest of her life, even though she may stop laying for weeks or months.

2. You would make a failure with a virgin,

if she should remain a virgin. But after mating she might do excellent work, and would be very unlikely to swarm in her first summer.

3. An untested queen is a laying queen that has been laying so short a time that none of her progeny has yet emerged, and she becomes a tested queen after the markings of her progeny show that she has purely mated. After sufficient experience you can tell with more or less certainty by her looks whether a queen is a virgin or a laying queen; but I wouldn't undertake to tell a beginner how to do it. No one can tell by the looks of a laying queen whether she is tested or untested.

4. A virgin is harder to introduce than a laying queen; but an untested queen is introduced as easily as a tested one.

5. A virgin that fails to mate generally disappears; but sometimes she lays, producing nothing but drones.

Buying Bees

This winter I have lost a colony of three-half Italian bees. These bees were killed through starvation. The bees were thick on the combs and some of them were inside the combs. I want to know if I could buy a colony or a couple of pounds of bees and a queen. Could I use these combs for foundation?

ILLINOIS.

ANSWER.—You can use those combs with decided advantage over using foundation. You would hardly buy a colony to put on the combs, for in the ordinary acceptance of the term, when you buy a colony you buy the combs with it. But if you should buy a colony with its combs, you could use the combs to good advantage in making increase. It would be good policy to buy a 2-pound package of bees with a queen, putting them on your combs. Brush the combs as clean as you can, and put at one side those that are the dirtiest, or that have dead bees in them. If you dry the combs well you may be able to shake out some of the dead bees by holding the comb flat and shaking hard.

Wax Moths in Section Honey

I am bothered with the wax moths hatching out and damaging my section honey after it is cased up ready for the market. What can I do to avoid this trouble? I am satisfied the moth has already deposited the eggs while on the hive.

ARKANSAS.

ANSWER.—You are right that the eggs are already on the sections when taken from the hive. You can fumigate the sections with sulphur a week or two after taking from the hive, and then again two weeks later, and carbon disulfide is still better. The moths are worse with blacks than with Italians.

Chaff Covering

Would a chaff tray of six inches depth be either beneficial or detrimental left on hive all summer, run either for extracted or comb-honey production?

NEW YORK

ANSWER.—It might do some good on cool nights; also on hot days, if hives are exposed to the sun.

Hives in Open

Is the best place for hives in the open, or in a protecting shed with open window, giving free access to outer air?

NEW YORK.

ANSWER.—A protecting shed may be a good thing in winter, but when you come to work with the bees in summer you will find it a good deal handier not to be hampered with a shed. The ideal thing is to have hives sitting under the shade of trees.

Requeening With Ripe Queen-Cell

1. Is it practical to requeen without dequeening by placing a ripe queen cell in the brood chamber in such a way that it will not be torn down?

2. Would the queen be apt to tear it down if it were placed between the frames, say at the back end of the hive?

3. Does a virgin queen usually overcome a laying queen?

4. Do you think this is a good way to requeen with the least amount of work?

5. Is the L frame and the Hoffman frame the same thing and size?

ILLINOIS.

ANSWERS.—1. Sometimes it would succeed; oftener it would not.

2. It would generally be torn down, either by the queen or the workers, or both.

3. That depends. If the virgin has been reared by the bees themselves, she will be victor; although quite often the old queen and the young one will for a time live peaceably

together. But if you attempt to get a virgin into a hive with a laying queen, the virgin is practically certain to be killed, unless the laying queen be so old or poor that the bees are anxious to supersede her.

4. It's hardly a good plan, for if the cell is not torn down its presence will likely make the bees swarm, which you are not likely to want.

5. The Hoffman frame is a Langstroth frame with shoulders that make it self-spacing.

Mold in Hives

1. What causes the mold on the bottom-board and lower parts of the frames? They were packed on all sides with straw and leaves to a thickness of about six inches.

2. What damage will it do to the bees or comb?

3. How can it be remedied?

KANSAS.

ANSWERS.—1. It is likely a combination of dampness and lack of ventilation.

2. That depends on the extent of the trouble. If severe, it may cause diarrhoea. The bees can clean up the combs, even if very bad.

3. Have colonies strong, and give sufficient upward ventilation.

Sulphur for Foulbrood

By putting supers and empty combs in a light room and burning sulphur, will this kill foulbrood?

NEW YORK.

ANSWER.—No, not the least little bit.

Foulbrood

1. Is the sunken surface of brood-cells always a sure sign that either American or European foulbrood is present, or do you sometimes find the surface of cells sunken when no foulbrood is present?

2. In what way does European foulbrood differ from pickled-brood? How can I tell the difference?

3. Do the bees build the comb in sections heavier in cold weather than when it is warmer?

MINNESOTA.

ANSWERS.—1. I think there may be sometimes sunken cells without foulbrood, as also foulbrood without sunken cells.

2. In European foulbrood the diseased larvae have a decidedly yellowish tinge.

3. I don't know; but I hardly think so.

Miscellaneous

1. I made some Doolittle queen-cell cups, and while dipping I fastened to it a pin in a horizontal position so I can easily transfer them on any comb. What do you think of this idea?

2. If I put those cells on the combs in the brood-chamber before swarming will the queen lay eggs in them?

3. What kind of hives do you use?

4. What kind of a double-walled hive do you think is best for ordinary use?

5. Do you know where I can get the old style leveled edge hives?

6. Does any water run in a straight edged hive when it rains? If so how does it do any harm?

7. What is the best way to clip a queen for one that is too nervous and excited to hold them in the fingers?

8. Does it do the bees any harm to handle them often?

9. When is the best time to move bees a short distance of about 50 feet?

ILLINOIS.

ANSWERS.—1. It may work all right.

2. I don't know; I think she might sometimes, but generally not.

3. Eight-frame dovetailed. Ten-frame would probably be better.

4. Probably there isn't much difference; and for ordinary use I should not want double walls.

5. No; their inventor has discarded them, and you would hardly like them if you had them.

6. A very little may go through, but I never could see that it did any harm.

7. I don't know whether it is longer in use;

but at one time there was advertised a device, a sort of tube in which you put a queen, and through openings she would thrust a wing so you could clip it.

8. It may not do any great harm; but at least it binds them in their work, so that they should not be handled without some good reason.

9. A good time is early in spring when they have hardly begun to fly yet.

Bees Flying When There is Snow

1. Should bees be confined to the hive on warm winter days when there is snow on the ground?

2. Would the same number of bees be lost if there wasn't any snow on the ground?

CONNECTICUT.

ANSWERS.—1. Something depends on circumstances. If they had a fight only a week or so before a bright day comes with snow on the ground, then it is well to shade the entrances so they will not fly out and fall into the snow. If they have not had a fight for a considerable time, then let them fly, but throw hay, straw, or something on the ground near the hives so they will not sink in the soft snow never to rise again. It will help if you do nothing more than to tramp down the snow to make it hard.

2. No, there are bees that drop into the snow and perish that would not die if they did not leave the hive.

Wintering

Is it necessary to put bees in the cellar or use winter packing cases in this locality?

Could bees be wintered or stored in a shed as well as in the cellar?

WISCONSIN.

ANSWER.—In Wisconsin it is quite necessary to winter bees in cellar, or else pack them if left outdoors. They may be wintered in an old-fashioned shed, with packing about them; but the majority prefer to have them in a good cellar.

Mailing Queens a Distance

Would queens travel safely to Ireland from the States?

IRELAND.

ANSWER.—There is so much delay and uncertainty nowadays that you would run some risk in having queens shipped at present.

Cellar Wintering

I built two new bee-cellars last fall. They seem to be quite damp, some mold on combs and drops of water on cover; temperature from 44 to 46 degrees. Do you think I ought to warm them up some way? I was in one cellar today; they seem to be quiet. I put away 300 colonies and am quite anxious about them. This is a hard winter up here; 33 below zero this morning, Feb. 1.

MICHIGAN.

ANSWER.—The condition of your cellars would indicate that they do not have enough ventilation. It might be a good plan to warm up the cellar a little, provided the temperature is not raised high enough to excite the bees. I believe that if you can open the doors or windows when the temperature outside is neither too high nor too low, it may help considerably. Mold on the combs is very disagreeable, but not necessarily injurious to the bees. But it would be much better if the air was dry. If the weather is cold, try using a coal oil stove, giving enough ventilation to keep the excess of heat from disturbing the bees. When they are quiet, it is a good sign.

I will gladly answer any other question, if in my power. We want to help our subscribers as much as we can.—Editor.

Increasing

In Pellet's Productive Beekeeping, pages 111-112, a method of making rapid increase by you (Miller) is described. As I understand it you used nine colonies, but made the increase directly each nine days from "Hive No. 2." Ac-

cording to this you would have the following number of hives each period: June 12, 10; June 19, 12; June 26, 14, etc. In other words, an increase of only two each nine days. Now, I have to depend mostly on white clover, and often have no fall flow. White clover is not productive with us, as a rule, after August 1. So I am unable to see where I could get that method even get half the 66 colonies mentioned. Will you please explain? I will look for the answer in the American Bee Journal.

WEST VIRGINIA.

ANSWER.—You will find the story of this increase more fully told in "Fifty Years Among the Bees." There is nothing remarkable about it, seeing the season was excellent, except that it was done with nine very weak colonies. "May 29 there were only 41 combs containing any brood in the nine colonies, counting each comb with brood, even if the patch of brood were no larger than a silver dollar. I doubt if the nine averaged any more than three and a half good frames of brood each."

You are in error in assuming that there was "an increase of only two each nine days." Here are the figures of the actual increase made on each date:

June 12, 1; June 21, 2; June 30, 5; July 8, 4; July 18, 2; July 27, 7; August 4, 8; August 14, 14; August 23, 4.

That was making increase later than you think practicable in your locality, but if the nine colonies had been fairly strong the number probably could have been reached by August 1, and the total number made considerably larger by August 23.

Italianizing an Apiary

I have about 40 colonies of bees; they are all strong and in good shape. Last year I bought two golden Italian queens and was very much pleased with the results obtained from them. Now, I have heard it said, and I have read, that if a man has an Italian queen or two that in a couple of years or so he can Italianize his whole apiary. I would like very much to know how you do it. Do you want to Italianize, destroy the queen, then go to the hive containing the Italian queen and take a frame of brood containing one or more queen-cells and put it in the hive you want to Italianize? By so doing would they raise a young Italian queen? Or, how would it do, by destroying the queen and queen-cells as before stated, to cut out a queen-cell from the Italian hive and insert it carefully in the center of a frame in the hive to be Italianized? Would the bees take care of it and would it hatch out and become a queen for the hive? Will either of these plans work? MICHIGAN.

ANSWER.—Either of the ways you mention should be entirely successful. But don't be too hopeful about having all your colonies pure Italian all at once. So long as other colonies with the wrong kind of bees are within a mile or so, you may expect more or less of your young queens to meet drones from them, and it may take years to be entirely free from black blood.

Poisoned with Propolis

I get poisoned with propolis. My eyes swell shut. I have fevers and in a few days I feel like I had been sunburned. My skin peels off a dozen times or more from one poisoning. I even get poisoned from dust from scraping honey boxes. I sometimes get so sick it affects my heart. Can you tell me of a remedy? MISSOURI.

ANSWER.—I think it is more or less a common thing that beekeepers are troubled with the dust of propolis when scraping sections, although a good many of them may not know it. Their eyes smart and their nose troubles them, but they think it is only a bad cold. There are, however, a few to whom it is a real affliction, as it is in your case. I am very sorry to say I know of no remedy, but am glad to put the matter before beekeepers thus publicly, and if any one knows of a remedy, or even a palliative, he will be doing a public benefit if he will tell us about it.

Bees in Pound Packages

1 Which would you advise, buying bees in one-pound or two-pound packages?

2 At about what date should they arrive in this locality (northeast Missouri)?

3 I have some frames of honey about 5 pounds each. If I order two-pound package of bees delivered about May 1, how many frames would I take to keep them till white clover blooms?

4 Would it be unlawful for me to build hives for my own use the same style as the Dadant hive, but with the same size body as the Tri-State hive? MISSOURI.

ANSWERS.—1. In most cases the result will be more satisfactory with the larger package.

2. You will probably do well if you get them by the middle of May.

3. Two will likely be plenty.

4. No.

Foulbrood—Preventing Burr-Combs

1. At the Pennsylvania State Convention, the method of shaking on full sheets with a drawn comb in the center, as a foulbrood treatment, was strongly advanced. The purpose of the comb is to catch the diseased honey; it is removed after 3 days. Do you consider this treatment effective?

2. I have never heard of anyone recommending the shellacking of brood-frames for the prevention of burr-combs and excessive propolis. All my Hoffman frames have the top and sides of the upper bars, as well as the narrow sides of the end bars, filled with a coat of shellac or wood filler, and a second coat of good varnish, after being sandpapered. Is it considered too much work for the results obtainable? PENNSYLVANIA.

ANSWERS.—1. I should expect good results from the plan, hardly so much because the drawn comb would catch the honey as because it would tend to keep the bees from absconding, which they too often do when nothing but foundation is present.

2. I should not consider the work too much if it would secure permanently the result desired. I should be a little afraid the treatment would lose its effect after two or three years, but possibly not.

Rim on Inner Hive Cover

Why the $\frac{3}{8}$ -in. rim on inner hive-covers? It does not keep them from warping; in fact the Root people put out some with channel irons and no rim. The air space formed by this shallow rim is not enough to do much good, as a heat preventer, and some makers are now leaving off the side strips, so as to get a draft through under the cover. If, as I read, this cover is to be turned over in packing for winter, so as to form a clustering space above the frames, would not a half-inch, three-fourths-inch or even an inch rim be more desirable? Would it not be a good idea to have at least as much space above the frames, with, of course, an abundance of jacking above the brood-chamber? IOWA.

ANSWER.—I haven't bought any hives for some time, so I'm not sure just what you're talking about, but I suspect the idea is to have a $\frac{3}{8}$ in. space over the top-bars, not to allow a place to cluster, but merely to allow the bees to pass readily from one comb to another.

I don't know, but I'm skeptical about an inch space being better. Indeed, I'm a little skeptical about bees clustering above top-bars, and I don't believe they care for any space above their combs. I know they often cluster below their combs, but I think more than room enough above top-bars to allow free passage from one side to the other would be merely giving so much empty space for the bees to keep warm. However, if you say you know they like to cluster above, I'm ready to change my opinion.

Nucleus—Division-Board—Demaree Plan

1. In starting a colony from a nucleus by putting frames, bees and queen into a new

hive and moving to a new stand do you always imprison them for a few days to prevent them from returning to their former stand?

2. After the entrance to a nucleus hive has been stuffed with leaves to prevent the bees from returning to their former stand, why do you stir up the bees by pounding on the hive just before liberating them?

3. When adding frames of brood with adhering bees to these nuclei, do not many of the bees return to the parent hive?

4. Will bees ever carry eggs or young larvae from one frame to another to put into a queen-cell, or do they always build the queen-cell from the liberating side where the egg was deposited by the queen? It seems to me that I have read somewhere of a larva being carried above an excluder.

5. Last year, for lack of frames, I had a 10-frame hive with five frames of bees and foundation on one side of the hive, the other side being entirely empty. Although the foundation in these frames was not yet all drawn out, the bees began building comb in the empty space. Now, as I have never owned or used such a thing, I would like to ask if a division-board placed beside the frames would have prevented this?

6. In this vicinity we depend almost entirely upon white and alsike clover for surplus. Soft maple and dandelion are abundant for building up colonies in early spring, but the small amount of buckwheat and late bloom are a source of minor value for surplus.

Now, I expect to try the Demaree plan next year and I would like to get your advice as to my best way to make increase. I desire to make but slight increase (about 25 per cent), and as there will probably be abundance of late and little for them to do in the latter part of the season, I wish to inquire if it will be best for me—

1st. To divide those large Demaree colonies at the end of the clover harvest, depending on the new colonies to gather their own stores, or

2nd. Let each large colony work as a unit until about September 15 and then divide, also dividing stores with the new colonies and in either case giving a laying queen to the new colony, or

3rd. Will it be better to select colonies in May from which to make increase by the nucleus plan, not expecting these colonies to store any surplus? MICHIGAN.

ANSWERS.—1. That depends. If the bees have been queenless for a few days, and a goodly number is taken, more than enough to cover the combs, then it is not necessary to imprison. Indeed, if the bees are not queenless, but are taken with their own queen, and enough bees taken to allow for the return of part, then imprisonment is not necessary.

2. I don't, as a rule. If the entrance has leaves crammed into it tightly, it should be two or three days before the first bees will squeeze through, and nothing more will be needed to make them stay; but at any time when it is uncertain whether bees will stay, it will do at least a little toward making them mark their location to pound on the hive before freeing them.

3. Likely, unless the bees added are queenless. It is always possible, however, to have the bees queenless.

4. Generally an egg or larva will be used without moving, and for a long time I could not believe that bees would carry eggs or larvae from one cell to another; but I have had cases of queen-cells over an excluder where I could find no explanation but to say the bees had carried up through the excluder the material from which to rear queens.

5. You had just what you should have expected. Bees cluster in something like a sphere, and as part of the sphere fell outside the frames of foundation they would build comb there rather than on the foundation outside the sphere. Very likely the dummy would have confined them to the foundation, and yet if the force of bees was sufficient they might have clustered and built outside the dummy.

6. I'm inclined to think I would prefer your third plan, using a few colonies for the increase.

THIS APIARY OF 62 COLONIES BELONGS TO PROF. J. H. DIEBEL, HIGH SCHOOL PRINCIPAL AT COLUMBUS, OHIO. THE BEES ARE AT HICKSVILLE, OHIO, 150 MILES FROM COLUMBUS.

Catching Swarms

Enclosed I send you a picture of my backyard. There are 62 colonies—the view is through the center. I started with 32 in the spring and I intended to keep them from swarming to a considerable extent. I didn't exactly set any definite limit on the number of new swarms I intended to have. They were nearly all large swarms by the first of June. The season being late, no new swarms appeared until July 1. Just when I was sure that I had the swarming impulse well in hand (with plenty of snipers, etc.) the fun began. Before it was over every colony in the yard had swarmed. I am well located and in spite of this and the unfavorable season, I got 1,500 sections of fine honey. I have much dandelion, 100 acres of raspberry within easy reach, clover, white clover and basswood. The grove that you see in the background of the picture is nearly all basswood. White sweet clover is becoming abundant.

This is all very fine, but what worries me is that this pesky swarming is going to cover the whole plantation with bee hives. I am revolving in my head all sorts of fancy notions as to how I am going to steal a march on those bees next summer. I have a notion to try out a decoy to catch swarms. Would a device shaped like a cone, covered with wire cloth and hung in a tree, attract a swarm? The device could be so arranged that it could be handled like a Manum catcher.

I have noticed that a dark spot formed by a cluster of leaves or branches will attract a swarm. Obviously the flying bees take it for a forming cluster. Two or three of these decoys could be placed in different parts of the yard. They could be suspended in such a manner as to make the manipulation very easy. Has this idea been tried? I am sure you will laugh at this foolish notion. But I want to assure you that this notion is not a bit more foolish than a godly number of other notions I have originated. I must not forget to say that I spent a very pleasant vacation with these insects and I am already waiting for the time to come when I will return to them. You understand, I think, that these bees are at Hicksville, 150 miles from Columbus.

OHIO.

ANSWER.—If I understand correctly, what you are after is something that will offer an inducement to a swarm to settle where it may be easily secured. Yes, something of that kind has been tried, and with considerable success. Years ago a good deal was said about such things. By some a bunch of dried mullein tops was suspended on the top of a pole set in a convenient place. Others used strings of dead bees. Your cone-shaped device hung in a tree might work all right, and I suspect it might work better away from any tree, in full view. A piece of old black comb in it might be an improvement. A swarm is

more likely to settle where some previous swarm has settled. At one time my assistant had a craze for keeping empty hives in or near the apiary, as decoys, each hive containing one or more old combs. Occasionally she caught a swarm, generally a wanderer from away.

Thanks for the fine picture.

Comb Foundation—Diarrhoea

1. I enclose a sample of comb-foundation which I bought last summer and did not use, as it doesn't look yellow in color like the rest I've used. I don't think the bees will work on it. What do you say?

2. One of my colonies was left weak last fall. I fed them sealed white clover honey. Upon examining them later I found everything dark brown all over the frames and combs. The bees are all alive. What disease is this? How is it cured?

MINNESOTA.

ANSWERS.—1. I should call it a sample of excellent foundation. The color of foundation varies according to the wax from which it is made. It may be lighter than your sample and it may be very much darker, and the bees will probably like this as well as the brighter yellow.

2. The trouble is probably diarrhoea, and the cure is to allow the bees a flight as soon as practicable.

Transferring from a Tree

I found a swarm of bees this winter located in a large dead tree stub in the woods. They are in the lower part of the tree; do you think it is possible for me to transfer this swarm to a hive? What method would you advise, and at what time of the year would you think it best to do it?

NEW YORK.

ANSWER.—A good time to operate is when fruit blossoms open. Cut down the tree; cut it off above and below where the bees are, and split open the trunk, then you can cut out the combs of brood and tie them into the frames, upon which the bees can settle after you have put them in the hive, when you can take the bees home. Better not take them home till all bees are in the hives in the evening.

Increase

I am an amateur in the bee business and want to increase. Which method do you recommend, natural swarming or dividing?

CALIFORNIA.

ANSWER.—One who is well up in the business will do better to take the matter of increase into his own hands. One with very little experience may do well to let the bees take their own course. Not entirely, however; for it is seldom desirable to allow each colony to swarm more than once, and it is a rather simple matter for the most inexperienced to prevent all after-swarming. When a swarm is hived, put the swarm on the old stand and let the old hive close up to it, facing the same way. A week later move the old hive to a new place 10 feet or more away. That's all. There is little chance that there will be any second swarm.

Diseased Combs—Shallow Frames Versus Full Depth

1. Would it be safe to use combs on which bees have died of foulbrood for extracted honey above a queen excluder?

2. Which do you prefer for extracted honey, shallow or full depth frames?

VIRGINIA.

ANSWERS.—1. So far as the honey is concerned, it will be all right. But if combs affected with American foulbrood were used there would be danger to the bees in the brood-chamber below. With European foulbrood there would not be much danger. Yet if your apiary is entirely free from both kinds of foulbrood I should advise you to take no chances whatever.

2. Best results are probably obtained with the shallow combs, although many prefer to use the deeper combs on account of the convenience of using the same kind in any story.

“Practical Queen-Rearing”

Is the title of the new bee book, cloth bound, 100 pages, which has just been written by Mr. Frank C. Pellett, who is well known to our readers.

For many years there has been a demand for a book which would give in concise form the many different methods of queen rearing, as the Doolittle, Pratt, Dines, Miller, Alley and others with variations as practiced by different large breeders.

You have this in the new book which is just out. Send for your copy now and get informed as to your best method of rearing queens from your best colonies. Good pointer in it also for the large beekeeper and veteran queen breeder.

Price, postpaid, only \$1.

By special arrangement we can offer it and a year's subscription to the *American Bee Journal* for only \$1.75.

(Canadian orders 15 cents extra.)

AMERICAN BEE JOURNAL, Hamilton, Illinois

Queenless in March

What is the best thing to do when one finds early in March that a colony of his bees is queenless? It is too early at this time of the year to purchase queens, and if a queen is reared from young brood there would be no drones with which to mate her. Is there any remedy, or should the colony be united to one having a queen?

ALABAMA.

ANSWER.—The best thing is to unite the bees with another colony, or with other colonies. If you have a very weak colony with a good queen, unite with that. Otherwise unite with two or more of the weaker colonies.

Bees Cleaning Combs

If I place hives filled with combs from colonies that have died, under strong colonies, so that the bees will clean them out, will it do to leave them there until needed to hive a swarm or for some other purpose? Will the queen go down and lay in them after they are cleaned?

A SUBSCRIBER.

ANSWER.—Yes, it will be all right to leave the combs under the colony until time for surplus supers to be given. The queen will not go down to lay in them unless she really needs the room, in which case you can do nothing better than to let her lay in them.

Natural or Shaken Swarm

Will the plan given on page 280 of the American Bee Journal, for August, 1916, answer equally well for either natural or shaken swarms? I want to do away with the necessity of having on hand a lot of extra hives and frames that would be necessary were I to follow the plan of placing the old hive alongside of the new one for about 3 weeks, and shaking the young bees off the frames occasionally as they emerge.

PENNSYLVANIA.

ANSWER.—Yes, it will be all right to shake the bees off all but one comb, taking away that one comb a week later, giving the brood taken away to weaker colonies. But I hardly see how that will make any fewer frames necessary, although it will take less hives.

BEEES AND QUEENS

NORTHERN BRED ITALIAN QUEENS—Ready May 1, each, \$1; six, \$5.
Allen R. Simmons, Claverack, N. Y.

GOLDENS that are true to name. Untested queens, \$1; 6, \$5; 12, \$9; 50, \$33; 100, \$67.50.
Garden City Apiaries,
San Jose, Calif.

FOR SALE—At the yard, 100 hives of bees; your pick \$6; the run \$5. Empty hives, etc., less than cost.
D. E. Lohmmedieu,
Colo. Story Co., Iowa.

THREE-BANDED ITALIANS ONLY—Untested queens, each \$1; 6, \$5; 12, \$9; 50, \$33; 100, \$67.50.
H. G. Dunn,
The Willows, San Jose, Calif.

WARRANTED QUEENS from one of Dr. Miller's breeders, \$1 each; \$10 per doz. Package bees, without queen, \$3 for 1 lb. package; \$1.75 for 1 lb. package; 25 packages or more, 10c less; add price of queen. Full colonies in 10-frame hives, \$10 each, in 8-frame hives, \$9, in Danzenbaker hives \$8. Tested queens in all colonies.
Geo. A. Hummer & Sons, Prairie Point, Miss.

QUEENS BY RETURN MAIL—Choice tested queens, reared last fall and wintered in 4-frame nuclei, \$1.25; \$14 per doz. Queens of this season's rearing, untested, \$1; \$9 per doz. We breed the 3-banded Italians only and our strain is known for gentleness and honey gathering qualities. Every queen guaranteed. Never a case of foulbrood in our apiaries.
J. W. K. Shaw & Co., Loreauville, La.

A NICE 1-pound package Italian bees with queen, \$2.25; 2-pound package with queen, \$3.25, shipped c. o. d.
W. H. Moses,
Lane City, Texas.

FOR SALE—The largest and best apiary in Western Colorado, for September delivery; also small dairy and fruit ranch. Good building. Cause for selling, asthma.
J. G. Puetz,
Collbran, Colo.

OUR select bred mated queens winter well.
Honey-moon Apiaries, Yakima, Wash.

FOR SALE—First-class Italian queens and bees in season. Send for price list. Free from disease; safe arrival and satisfaction guaranteed. M. Bates, Greenville, Ala., R. 4.

BREEDING QUEENS—I have a few extra c/oice Italian breeders for spring delivery. Price \$5 each.
J. E. Wing, 155 Schiele Ave., San Jose, Calif.

OUR BRIGHT ITALIAN QUEENS will be ready to ship after April 16. Untested, 75c each, \$5 per doz., or \$65 per 100. Safe arrival guaranteed.
Tillery Bros., Georgiana, Ala., Route 5.

FOR SALE—Fine Italian queens at 90c each, \$9 per doz. Ready April 15. Safe arrival guaranteed.
T. J. Talley, Route 3, Greenville, Ala.

BEEES AND QUEENS from my New Jersey apiary.
J. H. M. Cook,
141st 84 Cortland St., New York City.

TESTED leather-colored queens, \$2.00; after June 1, \$1.50; untested, \$1.00; \$10 per doz. A. W. Yates, 3 Chapman St., Hartford, Conn.

GOLDEN Italian Queens, untested queens, \$1 each; six, \$4.25; \$2.25 per doz.; 50, \$29.50; \$60 per 100. Tested queen, \$1.50; one frame nucleus, no queen, \$1.25; 2-frame, \$2.25; 3-frame, \$3; breeders, \$5 and \$10.
L. J. Dunn, 54 Broadway Ave., San Jose, Cal.

WANTED—10 to 100 swarms of bees not over 50 miles from Bellevue, Ohio.
N. B. Querin, Route No. 7.

THE best Italian stock, three-bands and goldens at \$2.50 per lb., with untested queen; 2 pounds, with queen, \$4.
Rosedale Apiary,
J. B. Marshall & Son, Big Bend, La.

BOTH Italians and hybrid bees at \$2.50 per pound with untested queen; 2 pounds, with queen, at \$4.
Mrs. T. H. Carruth, Big Bend, La.

FOR SALE—Golden Italian bees; 1-lb. pkg., with queen, \$2.50; 2-lb. pkg., with queen, \$4; 2-frame nuclei, with queen, \$3.50.
L. J. Bond, Big Bend, La.

GOLDEN ITALIAN QUEENS—No better honey gatherers anywhere at any price. Untested, \$1; tested, \$2.
Wallace R. Beaver, Lincoln, Ill.

GOLDEN ITALIAN QUEENS—About May 1; good honey gatherers; no foulbrood; select tested, \$1.50; tested, \$1.25; untested 85c, 6 \$4.75, 12 \$9. No nuclei or bees for sale.
D. T. Gaster, Rt. 2, Randleman, N. C.

THE Sinking Creek Queen Introducing Cage; 5 years' test of absolute success; indispensable for introduction of valuable queens; also several queens can be kept in one hive in perfect harmony; small and works on the brood comb; especially adapted for queen breeders. Price 60c per doz., 2 doz. for \$1; post paid. Sinking Creek Apiaries, Gimlet, Ky.

SWARTS GOLDEN QUEENS produced golden bees of the highest qualities; satisfaction guaranteed. Mated \$1.6 for \$6; tested \$2.
D. L. Swartz, Lancaster, O., Rt. 2.

FINEST ITALIAN QUEENS, June 1 to November, \$1 each; 6 for \$5. My circular gives safe methods; free. J. W. Romberger,
3113 Locust St., St. Joseph, Mo.

ABOUT APRIL 15 I will again be ready to fill orders for untested queens of my fine strain of leather-colored Italians. I breed no other race. Choice tested and breeding queens at all times. Satisfaction guaranteed. Circular free. Untested queens \$1 each, \$9 doz.; choice tested \$1.60 each; fine breeders \$5 each.
C. S. Engle, Beville, Bee Co., Texas.

QUEENS—H. D. Murry's strain of 3-banded Italians; reared by the Doolittle method. Prices untested, 1 for \$1, 6 for \$5, 12 for \$9. No disease. Safe arrival and satisfaction guaranteed.
O. D. Rivers,
Route 4, Honey Grove, Texas.

HAVE YOU, Mr. Producer, been getting all for your honey that you could expect? If the price you have been getting has been less than the largest price you have read about, let the Domestic Beekeeper, Northstar, Mich., help you dispose of your 1918 crop. Investigate.

FOR SALE—One to fifty colonies of Italian bees in ten-frame hives. Bees and hives are in A 1 shape; no disease. Price \$10 per colony.
John C. Bull,
1013 Calumet Ave., Valparaiso, Ind.

GOLDEN QUEENS that produce Golden workers of the brightest kind. I will challenge the world on my Golden and their honey-getting qualities. Price, \$1 each; tested, \$2; breeders, \$5 and \$10.
2Atf J. B. Brockwell, Barnetts, Va.

Get More Honey from Each Colony

Don't be satisfied with your usual crop. Get a bigger one this year.

There is often enuf honey lost in an apiary, thru lack of enuf supplies at the right time, to pay the entire expense of running that apiary for a whole year.

Don't lose honey that way. Get your supplies now, before it is too late — and be sure to order

SWARMING CONTROLLED—No additional fixtures needed; unnecessary to clip queens; done solely by manipulation. Successfully used eight years. For particulars, address Trimble & Thompson, Wapello, Iowa.

ARE YOU keeping well posted on the crop condition and price prospects for your 1918 crop of honey? If not, you should! The Domestic Beekeeper, Northstar, Mich., will keep you posted on crop condition and price prospects as recommended by the Committee of the Chicago Northwestern Association. This committee, through the Domestic Beekeeper, saved producers a half million dollars on their 1917 crop of honey and expects to do even better on their 1918 crop. Are you one who is not taking advantage of an opportunity never before offered to secure all your crop of honey is worth? This opportunity is worth investigating.

FOR SALE—Second-hand hives; Danzenbaker 8-10-frame hives and frames; 2 empty bodies, 9 bottoms; 11 covers; 10 supers for sec. 4x6x 1 3-8; and fences and sec. holders; sell the lot for \$19.50, free on board Utica, Ill., R. I. & P. R. R. Half price of new; no foulbrood. A. Mottaz, Utica, Ill.

CONSERVATION PASTE—Costs less than 1c per pint; will stick your label on anything any time; easily and quickly made; no boiling; simple ingredients; ready for use in 30 seconds. Send 25c for formula. Money refunded if not satisfactory. Sunnyside Apiaries, Fromberg, Mont.

NORTHWESTERN BEEKEEPERS—Save time and freight charges by ordering supplies near home. Best standard goods, factory prices. Send list of wants, and I will quote lowest prices. Catalog upon request. George E. Webster, Valley View Farm Apiary, Sioux Falls, S. Dak.

FOR SALE—One thousand beehives with supers; three-fourth dovetailed, balance halved together at corners and nailed both ways. Hoffman frames throughout. We will guarantee them to be sound and free from disease. Will sell all or any part at about half what new hives will cost. Apply to The Hyde Bee Co., Floresville, Texas.

WANTED

- WANTED—Two-frame extractor, K. L. Carlock, Baylis, Ill.
- WANTED—May, October and November, 1917, numbers of American Bee Journal and January, 1918, that are in good condition; will pay 10c each. Please mail carefully so the wrapper covers the entire journal. American Bee Journal.
- WANTED—A good honey location to start a line of apiaries; will give a suitable reward for the best reliable information. D. E. Lohmedieu, Colo, Iowa.
- WANTED—A two-frame extractor H. Lefel, Lakewood, Wis.
- WANTED—White sweet clover seed; send sample; state quantity and your lowest price in first letter. Dadant & Sons, Hamilton, Ill.
- WANTED—Bees; 1 to 100 colonies. C. O. Smith 5446 Cornell Ave., Chicago.
- WANTED—Your old combs, cappings or slumgum to render into beeswax by our high steam pressure wax presses. Dadant & Sons, Hamilton, Ill.
- WANTED—Second-hand honey extractors; tell me what you have and price; also wax presses. W. D. Soper, Jackson, Mich. Dealer in all kinds of Bee Supplies.

SITUATIONS

- WANTED—A strong, inexperienced young woman wants work in apiary, preferably in northwest or Colorado. Can begin June 13. Mildred P. Strdevant, Gooding, Idaho.
- WANTED—Extracting outfit in the south or southwest in good location; give full particulars in first letter. A. Carder, Constance, Ky.
- WANTED—Two bee men for comb honey for 1918. State age, wages and experience. B. F. Smith, Jr., Fromberg, Mont.
- WANTED—Man to work with bees, season 1918; state age, experience and wages on basis of board furnished by us. Address The Rocky Mountain Bee Co., Billings, Mont.
- WOULD YOU like to receive four or five hundred dollars per hundred more for your 1918 crop of honey than the big buyers will offer you? The Domestic Beekeeper, which will cost you but \$1 per year, will show you how. This is no guesswork; we have done this very thing with hundreds of our subscribers on their 1917 crop, and are willing to do the same by others. You will make your greatest 1918 mistake if you do not, every one of you investigate the work the Domestic Beekeeper is doing for its subscribers, along the line of buying and selling for them.
- WANTED—Industrious young man, fast worker, as a student helper in our large bee business for 1918 season. Truck used for out-yards and hauling. Apiaries located near summer resorts. Will give results of long experience and board and small wages. Give age, weight, experience and wages in first letter. W. A. Latshaw Co., Clarion, Mich.

FOR SALE

- FOR SALE 200 10-frame new supers complete with beeway sections, at a very low figure. Write. L. W. Mundhenke, East Dubuque, Ill.
- FOR SALE—Full-depth 10-frame bodies filled with full-drawn combs, \$2 each. Ideal supers, 5 11-16 inches deep, 10-frame full drawn combs, \$1.25 each. The Hyde Bee Company, Floresville, Tex.
- FOR SALE—100 comb honey supers, 8 and 10-frame size, painted; in use one year; take the 4 3/4 x 1 1/2 scalloped sections, with sections and drawn comb from full sheets foundation, 50c and 30c apiece, cash. Farnish affidavit that they are sound and free from disease. Chester E. Keister, Clarno, Wis.
- FOR SALE—Sixty moving screens for ten-frame hives; new and unused. In lots of ten or more, 20 cents each. Frank C. Fellett, Atlantic, Iowa.
- FOR SALE—Cedar or pine dovetailed hives; also full line of supplies, including Dadant's foundation. Write for catalog. A. E. Burdick, Sunnyside, Wash.

FOR SALE—Having sold my fruit farm, I offer for sale my entire apiary, consisting of 45 colonies in 8 and 10-frame hives. I examined these colonies this spring and find them free of disease, all in good condition, and each has a laying queen.

Fifty 8 and 10-frame hives; frames are full of comb, built mostly on wired foundation; all straight.

One hundred and seventy-five supers with section-holders; all hives and supers are painted.

One 2-frame Cowan extractor.

The following is new stu" for the present season's use:

Ten 8-frame hives in flat.

Twenty pounds extra thin foundation.

Ten pounds medium brood foundation.

Thirty-five hundred No. 1 sections, size $4\frac{1}{4} \times 1\frac{1}{4}$.

Everything in first-class shape. In order to close out will accept \$400 here for it. No offer for part of it considered.

A. W. Gray, Eldora, Iowa.

FOR SALE—54 stands of bees, all in fine condition. Reason for selling, blindness.

A. Gibson, Coleridge, Nehr.

FOR SALE—Four-frame reversible honey extractors and Superior wax presses. Full description on application. Address, Geo. Stinebring, Shreve, Ohio.

FOR SALE—6 10-frame beehives and combs; 2 8-frame beehives and combs; with supers, sections and appliances. Apply Chas. Nye, Mill Valley, Calif.

BEAUTIFUL FARM HOME—Improved, rich soil, well located, good buildings, 100 colonies of bees, up to date, best honey-producing location in State; not crowded; average for past seven years 105 lbs.; 5 acres of ginseng garden seal, all ages, in fine shape. One-half artificial shade, one-half natural. Will sell a part or all. A wonderful opportunity; a bargain. Poor health reason for selling. W. M. Penrod, Ronneby, Minn.

LAST FALL Mr. Smith asked us our advice on when best to sell his crop of 15,000 lbs. of clover extracted honey. We answered him by advising that he hold until May, unless he got a good round price for it before. He could at that time have taken something like 12c per pound for it. He held it. At our Michigan State Convention last December, he again asked what we thought about the future price of honey. He could then get 17c per pound for it. We advised him to hold. He sold an entire crop the other day on board the cars for 18 $\frac{1}{2}$ c per pound. Mr. Smith's case is only one in hundreds of cases where producers have done well by following the advice of the Domestic Beekeeper. We want every beekeeper who has honey to sell to send in his dollar for the Domestic Beekeeper during 1918. We have the back numbers, so can begin your subscription with the January number, thus making your volume complete. Do it today, and at the end of the year get your dollar back if you think you have not received its worth.

Crop Report and Market Conditions

For our May number we asked the following questions of our reporters:

1. What per cent of loss has there been?
2. In what condition are the bees?
3. Condition of honey plants and prospects?
4. Any offers by buyers on the 1918 crop?
5. What, in your opinion, should extracted honey be worth when the crop begins to be harvested, based on conditions now? Price of comb?

PER CENT OF LOSS

The average loss this year has probably been as high as a year ago, mostly owing to the fact that many colonies went into winter with a short amount of stores, which might have been sufficient for an ordinary winter, but not enough for a protracted cold such as we had. Losses for different sections average about as follows: Maine 20 per cent, Vermont 10 per cent, New York 20 to 50 per cent, Kentucky 30 per cent. Balance of the southeast 5 to 12 per cent, Ohio and Indiana 20 to 30 per cent, Michigan, Wisconsin and Minnesota 12 to 20 per cent, Illinois 15 per cent, Iowa 10 to 30 per cent, Kansas and west Central States 10 per cent; Texas from 25 to 40 per cent, New Mexico and Arizona 3 to 8 per cent, Colorado and Idaho 3 to 8 per cent, Wyoming and Montana 15 per cent, Washington and Oregon 2 to 6 per cent, California 8 to 15 per cent.

CONDITION OF BEES

Bees are probably in a normal condition or above, the country over. Many colonies came out of winter in very poor shape, but have been building up fast, so that they are now in normal condition. Idaho and Washington are very much encouraged, the whole Southwest reports excellent condition of bees. In most other locations reports are that bees are from fair to very strong, with very few reports of bees in poor condition.

HONEY PLANT PROSPECTS

There is much difference in plant conditions compared with a year ago. A few spotted localities report a short crop in prospect, but most localities are looking for a much better flow than a year ago if the weather is favorable from now on.

Georgia and the balance of the South report excellent prospects, except that in Louisiana the spring crop has failed. Michigan and the northern States are possibly a little less than normal, while Illinois, Indiana and other central States are possibly a little above normal. In Iowa the clover is spotted, being completely burned out in some localities, prospects being fair in others.

Some prospects in Texas are poor, but most are good, and so much better than a year ago that everyone is encouraged. More rain is needed, however.

Idaho and Washington report extra fine prospects, while the whole of the Rocky Mountain region is up to normal. California is generally good, with poor reports from restricted areas. Some report extra fine prospects.

In practically all sections the early reports indicate that there are more chances of a crop than a year ago.

OFFERS ON HONEY

Most reporters state that there are many inquiries for honey with but few definite offers. A Georgia producer has been offered 15 cents for his extracted honey in large lots; one in Florida has been offered 16 cents. In Texas the offers have ranged from 13 to 18 cents for extracted honey, depending on the grade. Here there have been inquiries from the British and French governments.

In Colorado and New Mexico buyers have offered to contract, but at no definite price.

One party in California has contracted his whole crop in advance at 15 cents per pound. Many offers are being circulated at 10 and 12 cents, depending on the grade, but the well-informed beekeeper is paying no attention to these. There seems to be no definite price fixed by any one buyer, many offering what they think the beekeeper will take. We have reports of at least a dozen offers made at prices ranging as low as 15 cents up to as high as 17 $\frac{1}{2}$ cents f. o. b. shipping station for white extracted.

PRICES ASKED

No reporter desired to sell his honey at less than 15 cents for extracted, no matter what the grade, while the lowest desired for comb was \$4 per case for No. 1.

In the east and central States beekeepers nearer the market, 20 cents is the average price wanted for white extracted, though very few ventured an idea on prices of comb.

One reporter in Wyoming says he is going to get 20 cents for extracted and 25 cents for comb f. o. b. his station, and one in California is going to hold for 25 cents, owing, he says, to a short crop there.

A bulk of reporters judge that there should be little decline in prices over what buyers were paying for the tail end of the 1917 crop, which would be in the neighborhood of 17, 18 and 19 cents f. o. b. shipping point for white extracted honey.

CONCLUSIONS

The crop should be larger than a year ago.

On the other hand, the demand should be better.

There is one factor which may enter into a determination of the price and that is the facilities for exporting honey. Being a highly concentrated food product and being desired by the governments of our allies as well as by individual firms within these countries, we believe that honey will be given space if at all procurable. Then, too, by fall, the shipping problem will very likely be considerably relieved.

We see no reason for pessimism among beekeepers in disposing of their 1918 crop, and if we were to change our minimum price suggested last month, 15 cents, we would be inclined to increase it rather than lower it, with a minimum on No. 1 comb honey of \$4.50 per case.

There will be need of all the honey we can produce—no one should spare effort to make the crop as large as possible.

Statement of the Ownership, Management, Circulation, Etc., required by the Act of Congress of August 24, 1912, of American Bee Journal, published monthly at Hamilton, Illinois, for April, 1918:

STATE OF ILLINOIS, }
COUNTY OF HANCOCK, } ss.

Before me, a Notary Public in, and for the State and county aforesaid, personally appeared M. G. Dadant, who having been duly sworn according to law, deposes and says that he is the Managing Editor of the American Bee Journal, and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management, etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in Section 418, of the Postal Laws and Regulations, printed on the reverse side of this form, to-wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are:

Publisher, American Bee Journal, Hamilton, Ill.

Editor, C. P. Dadant, Hamilton, Ill.

Managing Editor, M. G. Dadant, Hamilton, Ill.

Business Manager, V. M. Dadant, Hamilton, Ill.

2. That the owners are:
C. P. Dadant, Hamilton, Ill.
H. C. Dadant, Hamilton, Ill.
V. M. Dadant, Hamilton, Ill.
Leon Saugier, Hamilton, Ill.
L. C. Dadant, Hamilton, Ill.
M. G. Dadant, Hamilton, Ill.
Jos. Saugier, Hamilton, Ill.

That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of the total amount of bonds, mortgages, or other securities, are: None.

(Signed) M. G. DADANT.

Sworn to and subscribed before me this 4th day of April, 1918.

H. M. CUERDEN,

My commission expires August 25, 1921.

KEEP INFORMED ON TEXAS CONDITIONS

The **Beekeepers' Item**, a monthly paper edited by Mr. Louis H. Scholl, well known to our older readers, and an authority, has many interesting items which should interest beekeepers, not only in the Southwest, but throughout our country.

In order to allow you to become acquainted with this paper, we offer a special combination of **Beekeepers' Item** one year with **American Bee Journal** for only \$1.25.

Or, if you desire, we can send you your choice of **First Lessons in Beekeeping**, or **Practical Queen Rearing** with the **Item** one year for only \$1.25.

Send all orders to
AMERICAN BEE JOURNAL
HAMILTON, ILL.

QUINN'S QUEENS OF QUALITY

Have no superiors—"There's a reason." Are Mendelian bred, good qualities accentuated. Gray Caucasians, most gentle of all, prolific, hardy, vigorous, disease resistant, white comb builders—they deliver the goods.

ITALIANS, 3-banded, line bred, pedigreed; need no boosting; they speak for themselves. Price—on application at either apary.

CHAS. W. QUINN

Rt. 1, Box 319
Houston, Texas

Box 275
Ft. Myers, Florida

Notice to Bee-Keepers

We are booking orders for combless packages, for April, May and June delivery, at the following prices:

- 1-lb. package, \$1.80 each; twenty-five or more, \$1.70.
- 2-lb. package, \$2.90 each; twenty-five or more, \$2.90.
- 3-lb. package, \$3.90 each; twenty-five or more, \$3.80.

If queens are wanted, add 75c each to above prices. We will only have tested and breeding queens to offer until June 1, as we will need all our queens for the package trade.

Price of tested queens, \$1.50 each.
Breeding queens, \$3 each.

The high cost of all material, and labor, compels us to raise the price on our packages. We guarantee safe arrival to your express office. Our bees are free from all disease and are of the best Italian strain.

P. S.—We do not use a frame of brood or any comb at all in our packages, as has been stated by others; this is false.

Golden Italian Queens

RUSTBURG, VA., R. No. 3, March 18, 1918.

Mr. Ben G. Davis:

Dear Sir—Please find enclosed \$5, for which please send me the very best Golden Queen you can for the money. If you can't ship her at once, please notify me. I ordered one from you 3 years ago last fall that was the best I ever saw. Her bees stored 320 pounds of comb honey the first year. I have several of her daughters that are fine.

Hoping to get a good one again, I am yours truly.

J. W. LAWRENCE.

Sears, Roebuck and Co. Chicago

Multiplies Farm Production and Profits

Amazing discoveries have been made in farming which have completely revolutionized production and profits. The New Way has turned failure land into profit land, has made the difference between small profits and big profits, has solved difficult problems of soil fertility, drainage, plowing, planting—in fact, practically every farming operation, including live stock, dairy, marketing methods and the farm home. You cannot afford to farm the old way when you can secure, for less than seven cents a day, the help of over 100 of America's New Way farmers and farming authorities—each man a specialist in his chosen branch of agriculture. The net result of the experience of these men has been compiled and made instantly available to every farmer through Sears, Roebuck and Company's library of farming practice—

FARM KNOWLEDGE

This splendid work comprises 4 volumes—2000 pages—3000 illustrations. Every chapter written in simple language, easy to understand. The ideas given are so practical that they can be applied at once. Glance at the partial list of contributors—think of having the same men: Glance at the partial list of contents—think of

Special to BEE KEEPERS

Here is just a hint of the nuggets of gold found in FARM KNOWLEDGE of particular interest to beekeepers:

- Getting Started With Bees.
- When to Buy Combless Bees.
- How to Combat Weather Conditions.
- Proper Arrangement of Hives.
- Races and Types of Bees.
- Seasonal Care of the Apiary.
- Seasonal Operations of Bees.
- Artificial Increase of Colonies.
- Feeding of Bees.
- Bee Diseases and Enemies.
- Wintering Bees.
- How to Make Money on the By-products of the Apiary.
- Important Honey Plants and Flowers.
- Marketing Honey.
- Value of Strong Colonies.
- Reasons Why Extracted Honey Can be Produced Cheaper Than Comb Honey.
- How to Rear Queens.
- How to Hive Swarms.
- When to put on "Supers."
- How to Avoid Excessive After-swarms.
- Proper Cutting Away of the Queen Cell.

Space permits giving only a brief list of the other contents of each volume. See the set for yourself at our risk.

- The Beekeeping Industry**
- Vol. 1. Practical Horse Breeding, Care of the Dairy Herd and Beef Herd, How to Raise Hogs, Treatment of Diseases of Farm Animals.
- Vol. 2. Soils, Tillage, Drainage, Plant Enemies and How to Fight Them, How to Grow Crops, Truck Growing, Fruit Growing.
- Vol. 3. Horse-drawn Work Outfits, Farm Machinery, Farm Buildings, Motorcycles and Automobiles, Electricity on the Farm.
- Vol. 4. System in Farming, The Farm Woman, Farm Boys and Girls on the Farm.

Sears, Roebuck and Co., Chicago.

QUEENS

QUEENS

QUEENS

Three Banded and Golden Italians; the best of either

They are hustlers; gentle to handle; cap their honey white; are very resistant to European foulbrood. We have added Mr. B. M. Carraway's queen-rearing outfit to ours and have with us one of his assistants, so can fill all orders promptly. Had fine success shipping bees last season in our newly devised cage and method of feeding, a number of shipments going as far as Idaho and Wyoming. Mr. R. B. Mills, Corinth, N. Y., wrote, "Bees arrived in fine shape, not 50 dead bees to the cage, 2-lb. size." Satisfaction and safe delivery guaranteed. Get your order in early. Reference: The Guaranty State Bank, Robstown, Texas, or the City National Bank, Corpus Christi, Texas.

NOW'S REPAIRING TIME

Don't Replace Rotten Wood with Wood that Will Rot

We have a word to suggest to you practical men of affairs—you who build and maintain Bee Farms. The matter of annual repairs is no trifling consideration. Unless you use a lumber that possesses real INVESTMENT VALUE, these repair bills will eat great holes in the net income of your property. Cypress is so well certified—its character for “staying put” is so thoroughly established—that you are about certain to use it in the early spring repair jobs. Practically all live lumber retailers carry Cypress stocks, so you need have no trouble about getting exactly what you want. If your local dealer has no Cypress in his yard, write us and we will tell you where to get it.

AUTHENTIC INFORMATION = FREE

Write our “All Round Helps” Department if you are at all perplexed about what is best to do in the matter of lumber, for original work or for repairing. There are 41 volumes in the Cypress Pocket Library, covering all sorts of uses for the “Wood Eternal,” and they are free to you. Vol. 1 is a reprint of Bulletin No. 95, Forest Service, Department of Agriculture—a certificate of the U. S. Government. Better get this booklet. Vol. 36 tells how to make easy a dozen hard jobs in Carpentry. Each of the 41 books is free. Vol. 1 contains a list of titles of these books. Start with Vol. 1; it's free to you. Why not write right now?

Big Money? == Yes == Read How

If your banker said to you, "Mr. Brown, buy that piece of land next to you at \$100 per acre; it will be worth \$2,000 per acre this coming summer," would you buy it today, or wait—well, until later on? We are sure you would not delay one moment.

We offer you the same kind of buy—that is, make \$20 on each \$1 invested. Buy your sections and bee-supplies *now*, for the sections cost less than \$1 per hundred, and next summer, when they are filled with honey, they will be worth \$20—think of it, those same sections that you bought for \$1. The same holds good on other supplies. **ORDER NOW** and tell your neighbors the same, or Mr. Railroad Embargo "will buy that piece of land next to you and you'll be left."

OLD COMB

Ship your old comb and cappings to us for rendering. We charge you 5c per lb. for the wax rendered and pay you the highest market price.

WAX AND HONEY

We always buy Comb and Extracted Honey, as well as Beeswax, so when you have the above to offer, write us and you will be well pleased.

WINTER PROBLEM SOLVED

BY

Woodman's Improved Protection Hive

"THE HIVE WITH AN INNER OVERCOAT"

100% Perfect Protection by Tests, Winters of 1916-17-18

The Inner Overcoat Did It

Without any special preparation we have wintered bees in these hives without loss. It is a joy to see the condition they are in, when compared with other styles of hives and wintering methods. The INNER OVERCOAT is telescoped down over the brood nest, in between the outer and inner hive walls, when preparing them for winter. In the spring it is removed and stored away in the K. D. flat. Not more than two minutes are required to pack or unpack a hive by this method. The INNER OVERCOAT affords more protection than several inches of ordinary packing material. Send for a special circular showing 10 large illustrations.

Tin Honey Packages

SIXTY-POUND CANS, in cases or in bulk, are being sold by us at prices considerably below general market prices. Send us an estimate of your requirements and let us quote prices.

FRICION TOP PAILS, any size furnished, and in quantities as you may desire. Send us a list of your requirements and let us quote prices, as we can save you money. The tin can factories are rushed with orders, the tin plate situation is serious and transportation slow, so it will be wise to place your orders early.

A. G. WOODMAN CO., Grand Rapids, Mich.

"falcon"

THINGS THAT ARE NECESSARY FOR YOUR APIARY

1. There must be a good location for the apiary.
2. Queens must be healthy and vigorous to put life into the hives. (Our queens are the best to be had and at reasonable prices.)
3. Your bees cannot do the work they should if you do not give them the best with which to work. If they have ample storage space, if they can work all the time without slack motion, they will be more contented and swarmless. To accomplish this, you must give them ample storage space, that is, the **RIGHT HIVES AND SUPPLIES. "falcon"**

Beekeepers should be placing their orders early for their early needs. He who waits is apt to suffer. These late beekeepers who want their goods in such a hurry at the last minute will lose some of the honey crop by not furnishing their bees with ample storing space. Railroad embargoes and rush business make deliveries slow.

Our famous "falcon" supplies will please you. Do not wait. Order now and strike while the iron is hot. "falcon" means the best, the standard of perfection. Red Catalog and Simplified Beekeeping upon request. Dealers everywhere.

1424 Market Street, Denver, Colo.

A BOOK FOR BEGINNERS

"First Lessons 'n Beekeeping," written by the editor of this magazine, is intended primarily for the use of beginners in beekeeping. You should have it. Price, postpaid, \$1, or clubbed with the American Bee Journal, one year for \$1.75.

American Bee Journal, Hamilton, Ill.

?? WHY ??

Why is it that so many beekeepers prefer Dadant's Foundation? Why does it give such good satisfaction and why is it that when tested side by side with many other makes beekeepers have reported that "they take to DADANT' first."

Do We Use Special Sheeting Machinery? No

We use the Weed process of sheeting our beeswax into endless rolls, and it is the same process as used by nearly all manufacturers.

Do We Use Special Foundation Mills? No

We use the same kind of mills as are used by practically every foundation manufacturer in the world.

Do We Use Special Beeswax? No

We use beeswax such as is produced by beekeepers all over the United States.

THEN WHY?

BECAUSE

Our beeswax is cleaned in such a way that all impurities are removed and all the fine qualities are retained.

BECAUSE

Sulphuric and other acids recommended and used by many manufacturers for cleaning beeswax are not used by us.

BECAUSE

Our motto is and always has been "EVERY SHEET PERFECT"—and we live up to it.

BECAUSE

For FORTY YEARS comb foundation has been, and still is, our *specialty*. When you get DADANT'S FOUNDATION you know that you are getting the best that money can buy. When you send your beeswax to us to be worked into foundation you know that you will get perfect work done. When you ship us your old combs and cappings to render you will get the maximum of wax they contain and, if desired, this wax will be worked into the finest quality of foundation made.

It is UP TO YOU, therefore, to insist on DADANT'S FOUNDATION when you order your goods from your dealer. If you cannot get it from him, then order from us.

DADANT & SONS

HAMILTON, ILLINOIS

Make This a Lewis Year

While you are starting the year's work, getting your bees ready for business, taking stock of supplies on hand and speculating as to what the season's outcome will be,

Make This Resolution

That you will use LEWIS BEEWARE this year—because it means success insurance to you—because it means beehives and parts made of the best material by skillful workmen—because it means goods accurately and systematically packed—because it means sections made of bright lumber, highly polished, accurately dovetailed and scientifically grooved.

Help Your Bees Sting the Kaiser

Order your supplies early, and order standard goods in order to save time and enable us, as manufacturers, to accomplish the most in the shortest possible time. Now, of all times, the Beekeeper should not put off until tomorrow what he can do today. You owe it to your country and to yourself to prepare at once for the gathering of the 1918 crop.

BEES IN THE LOWER RIO GRANDE VALLEY

The First of a Series of Articles on Texas Beekeeping by Frank C. Pellett

TEXAS is a wonderful State with a great diversity of soil and climatic conditions, and with history and traditions peculiar to itself. The naturalist, the botanist, the historian, or the student of beekeeping or other agricultural specialty, can find within the State material for years of investigation. For a stranger to undertake to catalogue its resources, after a brief investigation of those two months, would be but to outline his own limitations, for Texas is too big to be contained within the grasp of any individual.

In order to appreciate the vast stretch of country called Texas, one must study the map of our country and note something of the variety of climate represented within its borders. Orange, Texas, is very nearly

south of Des Moines, Iowa, while El Paso is farther west than Denver, Colo. The northern line of the State is close to southern Kansas, while Brownsville is a long distance south of San Diego, Calif. One might spend a lifetime in one section of Texas and have little idea of the State in general. The casual traveler who visits one corner of the State and comes back to tell you about Texas, may describe an entirely different country from that seen by the visitor to another part. One can describe almost any condition of soil or climate with which he is familiar in any part of the United States, and say with truth that it is like Texas for almost every condition of soil or climate of the rest of the country is to be found somewhere in Texas.

The climate ranges from a winter temperature of some twenty degrees below zero in the panhandle, to an almost frostless condition in the Rio Grande valley. In east Texas, there is a heavy annual rainfall, with a consequent luxuriant vegetation, while in parts of west Texas one finds a desert flora and little rain. At one point we were told there had been no rain for eighteen months, and from the appearance of things we could readily believe it.

When it came to planning a trip to see typical conditions in every honey producing section of Texas in two months, numerous difficulties presented themselves. The job was too big for the time available. Prof. Paddock, the State Entomologist, outlined the trip from beginning to end, and it is doubtful whether it could have been planned better. Numerous well-known beekeepers were missed, and it was not possible to spend as much time as was desirable in some sections, but train schedules, distances to be traveled and opportunities in other places, all had to be considered.

Either W. E. Jackson, chief Bee Inspector, or Prof. Paddock, State Entomologist, accompanied the writer for the entire trip. E. G. LeSturgeon, manager of the Texas Honey Producers' Association, and H. E. Parks, of the Extension Department, also were with the party on part of the journey. At some points, three or four auto loads of local beekeepers would join us for a trip to the country, to visit the apiaries and study the honey plants. The informal discussions of bees and beekeeping, ranging from hive stands to honey flows, were most interesting, and the impromptu field meetings in the various apiaries were very enjoyable. Looking back on such a journey and remembering all the interesting places visited, the many new acquaintances made and the various in-

Fig. 1—Grant Anderson, of Rio Hondo. In many parts of the valley the bees must be lifted off the ground to guard against floods.

Fig. 2.—Semi-tropical vegetation near Brownsville, W. E. Jackson, chief bee inspector in the foreground

cidents along the way, it is hard to decide what is best to fill the limited space in the Journal that can be spared each month to tell about Texas beekeeping. Just to tell about the beekeepers themselves would be worth a volume, for in Texas, as elsewhere, there are many fine personalities among the beekeepers. As the limitation of time made it necessary to miss many interesting places and well known beekeepers, so the limitation of space makes it necessary to omit mention of many interesting incidents in this series of articles.

The Rio Grande valley is the southernmost section of the United States, except for the extreme tip of Florida. As far as beekeeping is concerned, we found conditions in the valley very different from those of any other section of Texas. In fact, Texas seems to be divided into about five natural divisions, as far as honey production is concerned. Each of these divisions has a flora and season peculiar to itself. Moving from one of these sections to another, one would have about as much to learn as though he came from a distant State. The Rio Grande valley has a light flow from one source or another, through most of the year. Several beekeepers told of having swarms as late as December, that gathered sufficient stores to winter successfully. The sources of honey are quite different from those of southwest Texas, where everything that grows has a thorn on it, and where the rainfall is extremely light. The southwest section will be treated in a separate article. North of San Antonio we find another natural division, where cotton becomes the principal source of surplus. The line is well marked, and south of there we were unable to find any beekeepers who reported cotton as important. The soil seems to determine the flow from this plant. The cotton belt will also be treated in a separate article.

East Texas again is a different country entirely, and again demands a separate article. The time was too short to permit the party to visit the panhandle or the high plain country of northwest Texas, so that must be left for a later visit.

The Rio Grande valley, with its mild climate and fertile soil, only requires water in sufficient quantity to become the garden spot of Texas. A small portion of the valley is capable of irrigation, and some of the irrigated tracts show wonderful results.

Land sharks take advantage of the attractions of the country, and prey upon the unsuspecting homeseeker from the north. These are mostly northern men with headquarters in some northern city, who live by taking advantage of their trusting neighbors. There are many opportunities in south Texas, but the poorest way in the world to find them is by joining a land-seekers' excursion and buying from a company. A man who has played the game for eight years confessed to me that they never handle anything for less than a hundred dollars per acre margin. The man who dreams of a home in south Texas should visit the country and get his information from the residents. Few of the people living there will be inclined to deceive him. I heard the native Texans often deplore the way the northern buyer was being "skinned" by the northern land men, and saying that it was having a bad effect on the development of the country.

The valley is subject to extremes of wet and drought. One cannot depend upon the natural rainfall. While the records show an average annual rainfall that would indicate the possibility of profitable cropping, the distribution is uncertain. There may be heavy rains which flood the whole country, and then no rains for months. The country is very level and, sometimes, is flooded for many miles. It accordingly, becomes necessary to keep the bees off the ground over most of the country. Only here and there is a natural rise high enough to be safe in time of extreme high water. (See Fig. 1.)

Fig. 3.—A. Lynn Stephenson and a clump of cactus in his pasture

The variety of flora is extremely interesting. Figure 2 shows a semi-tropical vegetation to be found near Brownsville. In the valley one finds both the desert flora and the valley flora, so that there is a great variety of bloom with something open for the bees every month in the year. The first beekeeper visited was A. Lynn Stephenson, proprietor of the Honeydale apiaries. Our cover pic-

Fig. 4.—The Huisache furnishes plenty of early pollen in the Rio Grande Valley

ture shows his home apiary, which is probably the southernmost apiary in Texas cared for according to approved methods. There is a Mexican apiary a mile or so further south, but it is primitive in the extreme and will be described in another article.

The Stephenson apiary is under Texas ebony trees. These are unlike anything to be found further north. The tree is evergreen and blooms several times during the year. It is a legume and bears beans like the locust pods. (*Siderocarpus flexicaulis*.) It is important for nectar.

Mr. McDonald, the county agent, and Mr. Stephenson both put their time and their cars at our disposal, so there was the finest chance, not only to see everything worth while, but to obtain information at first hand. It was February, and everything at home was in cold storage. Mr. Stephenson picked some fine strawberries and sent to our hotel at a time when coal was at a premium at home, and the thermometer registered 15 or 20 degrees below zero. At that time the bees were working freely on the hackberry and bringing in considerable nectar. The Huisache, pronounced "wesache," was also blooming and furnished pollen in abundance. Many of the plants in that section have Mexican names and the h has the sound of w. There was also a species of mint blooming which furnishes considerable honey some seasons.

Driving to Rio Hondo, we visited

the apiaries of Grant Anderson, which are situated on the banks of the Arroyo, a salt water inlet from the Gulf of Mexico. Mr. Anderson uses a motor boat in traveling to and from his outyards, as described in the Journal some months ago. In even this short distance of about twenty miles, there is quite a difference in the flora. At Brownsville they have a number of plants not found at Rio Hondo, and some at the latter place not found at Brownsville. It certainly behooves a beekeeper to know his locality in Texas. At Mercedes there are a number of good beekeepers who gave us much information about the conditions peculiar to the valley. Claude Armstrong reported the largest average of surplus of which we heard in the valley. He reported that in an average season he had secured as much as 75 pounds per colony in outyards.

L. LaRue considers 40 to 50 pounds a very good yield in his locality. J. D. Kennedy considers 50 pounds as about an average for him. These were rather better reports than were found in other parts of the valley.

At first thought, one would expect this valley to offer a bonanza location for the honey producer, with its great variety of honey flora yielding something practically every month in the year. After looking the ground over, however, one discovers that the brood-rearing season is continued correspondingly, with the result that most of the honey gathered is consumed in brood rearing during the portion of the year when there is little surplus stored. In February, we found the bees in the Honeydale apiary were strong enough for shaking for increase, filling packages, or any other desired manipulation. They apparently averaged about as strong as would be the case in Iowa the middle of May to June 1. It seemed to be the consensus of opinion of the

beekeepers in the valley, that the surplus would not average to exceed 25 pounds per colony for a series of years.

After visiting many beekeepers and asking more questions than four small boys, we were impressed with the fact that the Rio Grande valley is the finest place in America for breeding bees, but rather a poor location (except in a few favored spots) for honey production. It would be possible to fill orders for queens or packages of bees a month to six weeks earlier than in Alabama or Mississippi. Then one could rear queens and mate them successfully for at least ten months in every year and, some years, for the entire twelve months. W. H. Laws, of Beeville, has established some queen yards in the valley, in order to be more independent of poor seasons, and also to add several weeks to the length of his queen-rearing period.

Cactus, commonly called prickly pear, or just "pear," is very common everywhere. It grows in clumps often as high as a man's head. It yields some honey and an abundance of pollen. Apparently, it is of much greater importance in some other sections than in the Rio Grande valley. Beside the cactus, the wild land is covered with a scrubby growth of thorny bushes, such as mesquite, cat-claw, etc. It is difficult for one to walk about through the growth, for although it is not so very dense, the thorns catch in one's clothing and scratch one's flesh. After the first day that a stranger spends walking about in the chaparral, as the bush is often called, he spends most of the night following in scratching for chiggers and ticks. After a time he becomes somewhat immune to the attacks and also learns how to rid himself of the pests.

About 90 per cent of the country is still in the wild, and will be for a long time to come.

Fig. 5.—Rents are not high in the Mexican villages of South Texas. Because of the mild climate, the peons build houses much as the birds build nests, of such material as is ready at hand.

THE EDITOR'S VIEWPOINT

Foulbrood Kill or Cure?

The appearance of friend F. Dundas Todd's article on pages 161-3 of our May issue, sustaining the method of applying fire for the destruction of foulbroody colonies is giving rise to vehement protests. A subscriber asks whether we approve of this method. We do not. Then why did we insert it? Because our friend of British Columbia has a very forcible way of disease might bring it again. If his isolated location, it may be safer to destroy the few cases of the disease found, although one might suggest that the same cause that brought the disease might bring it again. If he followed this method to a finish he would not do for a physician. If you had smallpox or some other contagious disease, he would probably bring you a revolver and a coffin and demand that you put an end to the danger of contagion by self-destruction.

We kept bees some 40 years without seeing a trace of foulbrood any where. Then all at once we found it pretty well disseminated in our apiaries. That was some 10 or 12 years ago. Had we followed friend Todd's method we would probably be out of the bee business by this time. Instead of that we cured the disease and in 1916 harvested a record crop of 125,000 pounds of honey.

If you are a careful beekeeper, reader, and find foulbrood among your bees, do not get frightened, but follow the directions for treatment given everywhere by inspectors and writers. But if you are careless and hesitate to follow instructions, better do as Mr. Todd suggests, build a big

bonfire and destroy that which you do not have the courage to cure.

Fabre and Parthenogenesis

An enquiring subscriber wants to know whether parthenogenesis can be accepted as an established fact, in spite of Fabre's condemnation of it, just because of the editor's experience with unfertilized queens. (See page 156 of the May number.)

We understand the implied criticism and would not expect a novice to accept our assertion without further proof. We might have given this in the May number. Here it is:

There are hundreds of queen breeders who have had experience with drone-laying workers. Many other beekeepers have also found them in queenless hives. Each of them is an evidence of parthenogenesis, for the drone-laying worker is an undeveloped female who has only rudiments of ovaries and an atrophied spermatheca. The fact that she can lay eggs that hatch, without her having been previously mated, is sufficient to affirm the Dzierzon theory. The word "Parthenogenesis" is composed from two Greek words meaning "reproduction from virgin." The drone-laying workers cannot be anything but virgins, since they are incapable of mating.

In the present number will be found an article from our learned Scotch friend, John Anderson, M. A., which reproduces the assertions of two scientists that some African bees have laying workers whose eggs hatch as workers, queens or drones. Either those so-called workers are capable of mating, or they are not. If they are, then they are really fully developed females. If they a

not, and cannot mate, then they give additional evidence of parthenogenesis, though with a variation in the result.

As no evidence of the production of anything but drones from the eggs of laying workers, in the European races, Black, Carniolan, Caucasian, Italian or Cyprian, has ever been given, we must needs be content with the Dzierzon theory, against which so many arguments of all shades have been used.

In a nutshell, this parthenogenesis may be described as follows: The queen and some workers may lay eggs that will hatch without previous mating.

A Notable Work on Honey Plants

H. B. Parks, who has lately moved from Missouri to the Texas College of Agriculture, has completed the most thorough survey of the honey plants of Missouri as yet undertaken in any State. The work was done under direction of Dr. L. Haseman, the State Entomologist who has direct charge of all work in beekeeping in connection with the Missouri institution. Mr. Parks spent much time in field work in various parts of the State and has mapped the flora of Missouri relative to the occurrence of the various honey plants.

A study was made of 225 native and introduced species as to range of the plants, blooming dates and object of the bee visits, whether for honey, pollen or propolis.

There is great need that such work be done in every important honey-producing State, and Missouri is to be congratulated upon being one of the first to complete the survey of her nectar-bearing resources. It is to be hoped that the authorities of the university will see fit to publish the manuscript without delay, as students of similar problems in other States are hampered for lack of references. Its appearance will be awaited with interest.

The Greiner Brothers

We take pleasure in giving to the readers of the American Bee Journal, on another page, pictures of two men who have been constant readers and contributors of the Journal for over 20 years. Messrs. Greiner are both methodical, careful and neat men. They have been successful and are always willing to explain their methods, which are the result of long years of practice. (Editor.)

REMINISCENCES OF EARLY AND LATER DAYS

Recollections of One of New York's Best Beekeepers Since Beginning With Bees

By G. C. Greiner

THE earliest recollections of my beekeeping activities date back to my schoolboy days, when a small lad 8 or 9 years old, in the early fifties. In the city of Bernburg, the capital of Anhalt, with about 15,000 inhabitants, I was by chance introduced to the joys and woes of my earthly existence.

In a small garden, back of a row of closely-built city blocks, grandfather kept in a roughly built shed, from 8 to 10, sometimes as many as a dozen colonies of bees. They were all in the customary straw skeps, the same as all beekeepers used at that time. The usual way and the only possible chance of gathering up the season's surplus crop, was by tipping the skep to one side, driving the bees by means of the blowpipe as much as possible from one of the side combs and cutting this with a long hook-shaped knife from its fastenings. The part I generally played in this operation was to hold the pan while grandfather filled it with what we would call at the present day chunk-

was village teacher about two miles distant from our city. To carry the skep easily, grandfather rigged me up some straps, knapsack fashion, and encouraged by the silver coin, which looked like a fortune in my eyes, I started on my mission. At first, when I started from that village on my home trip, the skep was not much of a load, but it soon began to grow heavy, and the farther I went the heavier it grew, and before I had covered half the distance the load becoming too much for my yet tender constitution, I caved. I do not now remember how my venture finally terminated, but I have a very faint recollection that the hired girl was sent to meet me and assist me home after I had failed to return in proper time.

From the time I left school until 1875 nothing of a beekeeping nature, nor anything of great importance transpired in my life's career, except that in 1862, rather than waste three years' service in the German army, I landed on the shores of this great and glorious republic. At that time I had not the slightest idea that keeping bees and producing honey should ever become the means of earning my daily bread and butter. In fact, I had never heard that the beekeeping industry could assume such paying proportions.

Having had several years of practical experience on one of those large sugar beet farms in Germany, I intended to follow agricultural pursuits for my main dependence in this country. At first this proved a paying investment. During the civil war all farm products had risen to unheard of high prices, which reached their highest pitch just before and after peace had been declared. But things changed quite materially when the discharged armies came home. The large armies of consumers turned into armies of producers, and in a short time a reaction in the prices of all farm products took place. They dropped from year to year; lower and lower they went, until they reached the lowest ever known, and consequently farming did not pay any longer.

About that time I began to look for an opening of a better paying occupation, and an opportunity presented itself in the following way: In 1875 it happened that a neighboring farmer had purchased from a traveling agent, a town and county right for a certain beehive, similar to the jumbo pattern, and intended to engage in its manufacture for his own use as well as for the trade. As I was at leisure during that winter, and somewhat mechanically inclined, this neighbor engaged me to manufacture his hives. This work suited me so well that by spring, in partnership with my younger brother, F.

Greiner, we secured by mutual consent the interest in the manufacture and sale of the above mentioned beehive and prepared to conduct that business as our exclusive occupation. It also happened that my brother, who had come to this country a few years previously for the same reason I did, was a natural born beekeeper, and as part of our season's work consisted of transferring bees for our customers, his natural inclination in that direction proved a valuable acquisition to our business career.

In spite of the fact that we were entirely destitute of any beekeeper's experience, we succeeded from the very first beyond our expectations. Our hives found ready sale and the following seasons favored us with bountiful honey crops. Thus things went along to our complete satisfaction until the disastrous winter of 1880-81, which swept most of the bees in our territory out of existence and blasted all our hopes. It wound up our hive trade, as it seemed, for all future time. But, fortunately, the

G. C. Greiner

honey. Sometimes it would also fall to my lot to hold, and even use, the pipe when grandfather's hands were busy holding the skep and cutting the honey. It always raised me several notches in my boyish estimation to be called upon for such important assistance.

One episode of those early days left indelible marks on my memory even to the present day. I was yet a mere child when grandfather hired me for "einen silbergroschen (about 3 cents) to get one of those straw skeps from a beekeeping friend who

F. Greiner, of New York State

honey crop of the following summer from our own bees that we had left, was an unusually heavy one, which induced us to continue the production of honey as a livelihood for the future.

A little later family conditions made it desirable to change my home from Naples to La Salle, which made it necessary to sever our business connections, each one of us continuing our business on private lines at our own homes. Since then, my brother has followed up Mr. Hutchinson's theory of "more bees," while my ambition has taken for its aim

"more surplus yield," and that both have been reasonably successful is proven by the fact that my brother owns from two to three hundred colonies, while my average yield has been in late years about \$20 per colony, spring count. This, however, does not include our last season's crop. All beekeepers know that, with a few local exceptions, we had almost a complete honey failure all over the United States.

La Salle, N. Y.

Laying Workers Which Produce Female Offspring

By John Anderson, M. A., B. So.
N. Dr. Phillips' Beekeeping (1915).
I there are two references (pp. 187, 203) to a paper by Mr. G. W. Onions in the *Agricultural Journal of South Africa* for May, 1912. Mr. Onions asserted that, among Cape black bees, laying workers occurred very frequently and from their eggs drones, workers and queens were produced. This extraordinary claim seems to have attracted little attention at the time except that one or two Cape beekeepers wrote refusing to believe the story. Mr. Onions, however was not discouraged, and when he removed to Rhodesia he sought the help of the Division of Entomology at Salisbury. Mr. R. P. Jack, F. E. S., undertook the superintendence and checking of fresh experiments in parthenogenesis, to be carried out at Salisbury, but with bees from Cape Colony. A full account of those further experiments, conducted with scientific care, was published in June, 1917, in the *Transactions of the Entomological Society of London*. Mr. Jack is convinced that Mr. Onions has proved his conclusion that workers of the Cape bee "are apt to develop the habit of laying eggs, and that these eggs may produce workers, queens or drones, but do, as a matter of fact, mainly produce workers."

Dr. Phillips, Mr. Onions and Mr. Jack seem to have been unaware that the power of certain worker bees to produce female offspring was noted, and the facts published, many years before the appearance of Mr. Onions' first paper in 1912. The oversight is pardonable in the case of Phillips, Onions and Jack, because such recent writers could hardly be expected to know that valuable papers on beekeeping used to appear in the *Journal of Horticulture*, published at London and edited by Robert Hogg, LL. D., F. L. S. English contributors to the *Journal of Horticulture* included Cheshire, Woodbury, Hewitt, and the two Carrs, while among the Scottish writers were Pettigrew, Thomson, Raitt and McPhedran. Every one of these writers made additions of permanent value to our knowledge of beekeeping, though, with the exceptions of Cheshire and "W. B. C.," their names are scarcely known to the present generation of British beekeepers.

John Hewitt, of Sheffield, England (and his name ought to be mentioned

with those of Schirach, Huber, Dzierzon and the other great masters) made his observations on laying workers more than 30 years ago, and published a brief account of them in the *Journal of Horticulture* for 1892 (August 11, page 134). It was, perhaps, fortunate that the *Journal of Horticulture* was not exclusively a bee journal, and that Dr. Hogg was broad-minded enough to realize that perhaps, after all, Dzierzon had not said the last word on parthenogenesis in the bee. When Hewitt attempted to make his discovery known through the bee press of Britain and America his main conclusions were either suppressed or covered with ridicule. No discoveries might be published which would not fit into the Dzierzon theory. It is thus only by a kind of accident that we can establish priority for the original discoverer of an unsuspected peculiarity in the workers of certain races of the honeybee.

European bees, with which alone Dzierzon was familiar, have one marked defect in their otherwise perfect arrangements for preserving the continuity of the stock. At the time when a virgin queen is ready to be mated there is no other queen in the hive (except perhaps in supersedure) and there is no means of making one. The virgin is the sole hope of the stock, and if she be lost or fails to mate, that stock is doomed.

Hewitt had been working with Punic or Tunisian bees, which he had imported direct from North Africa, and found to differ greatly from the bees of Europe. For example, a stock which had lost its virgin on her mating flight, promptly developed laying workers, and raised queens from the eggs of those workers.

"In one case a number of Punic workers entered a stock of queenless Carniolans and reared a queen from the eggs they laid. This queen is now in the British Museum." (1892.)

It is clear from the narrative that Hewitt had been familiar with the facts for some considerable time, and that his object was to get others to verify observations, of the accuracy of which he entertained no doubt whatever. He proceeds to give directions for inducing Punic bees to rear queens from the eggs of laying workers. The aim is to reproduce as nearly as possible the conditions of a stock that has lost its queen on her mating flight. It must be queenless and broodless with some drones present.

"The bees will soon be busy laying and rearing queen cells. If any of these seem natural, that is not long ones, but just like ordinary queen cells, queens will most certainly be found in them, and not only so, but numbers of worker bees will hatch from worker cells. Hence Punic worker bees have the power to raise both queens and drones from themselves. The instinct seems perfect in the Punic bees; only partly so in Syrians, and it is quite absent in our native bees. I cannot go into the matter just now, but should like as many as possible, who have those bees, to

confirm my discovery, incredible as it may seem."

From these quotations it is quite clear that Hewitt had made the greatest discovery in the natural history of the bee since the time of Dzierzon, and that he anticipated Onions by at least 20 years. The bees of Africa are probably nearer to the ancestral stock, and the workers still retain the power of reverting to the primitive condition when every female was a potential mother. Hewitt's remark that the power is less perfectly developed in the Syrian bee and totally absent in native bees, is highly significant. Dzierzon and his co-workers, being acquainted only with the more specialized bees of Europe, had no chance of making this discovery, and made the very usual mistake of generalizing from insufficient data.

Meantime only the barest facts are mentioned, but it is evident that a new vista has been opened up, and that we must now consider parthenogenesis in the honeybee from quite a different standpoint.

Agricultural College,
Aberdeen, Scotland.

Co-Operative Selling Pays Texas Honey Producers

By Chilton Gano

(Concluded from last issue)

THE story of how poor market conditions for Texas honey led 79 beekeepers to meet and decide on co-operative marketing, and how an immediate result of their uniting was the advance of wholesale honey prices 2 cents per pound, was told in the last issue of *American Bee Journal*.

This price advance took place within six weeks after they had organized, indicating that the mere news that things were to be conducted in a more businesslike way had a good effect on the trade. Then began the work of putting their plan in operation.

The prime purpose of the move was to improve the selling methods. The first step was to adopt an association label. The Lone Star label shown in the illustration was adopted. Six sprays of flowers surrounding the central design are the chief honey plants of Texas, namely, guajillo, catsclaw, mesquite, alfalfa, horsemint and cotton. The blank space is for the kind of honey, comb or extracted, and for a number representing the apiarist who packed it. The Association announced that honey bearing this label is guaranteed, will be distributed at uniform prices, and will be in every way standard.

Instead of establishing an extensive official inspection system to protect the label's good name, the Association withholds a part of the price from the beekeeper until time has been allowed for the purchaser to enter any complaints. This results in the producer being paid as follows: 50 per cent of the value of the

honey, at the current market price on day bills of lading are received; 50 per cent of remaining amount 30 days later, and final settlement within 90 days.

To further protect the purchaser, each member must sign a statement in triplicate to be attached to all bills of lading, guaranteeing that his honey is packed in accordance with Association grading and packing rules, and that he will be responsible for any loss occasioned by failure to put up a standard product.

Members can, on election, sell their honey direct, but it cannot then bear the Lone Star label.

Finding Purchasers

Mr. LeSturgeon outlines the method of selling as follows: "The members of the Association receive on the first of each month a blank form which they are required to fill out. The information which this blank contains gives the manager an idea of the condition of the honey plants,

handling the Texas honey crop. They are relieved entirely of advancing any money on shipments. They are relieved of storing it and of a great deal of bookkeeping. All they do is to take the order for the honey and remit to the Association office upon receipt of bills of lading. Many jobbers are so interested in this plan of marketing that they have offered assistance to the Association, some offering to take stock in the Association in order to guarantee the enterprise."

The ingenuity of the plan is at once apparent. The wholesaler's order-taking machinery is used to get the retailer's orders, but the wholesaler never handles the honey. It is shipped direct to the retailer. This eliminates much breakage, leakage, rehandling charges, etc. Again, having one man in charge of the entire distributing enables him to avoid allowing any market to become glutted.

occurred during the mobilization of troops on the Mexican border. It was impossible to sell honey for army use, because honey was not on the regular army ration nor on the conversion tables of the War Department. The Association took the matter up, and in less than six weeks permission had been granted to add honey to the troops' bill of fare. This opened a market for thousands of pounds at Camp Wilson alone.

A Financial Success

In July the Association will be two years old. That they have been highly successful years is evidenced by the actual figures on higher prices secured for honey and savings on purchases of supplies, given in the first installment of this article. In both its selling and purchasing departments the Association has been financially successful in a very marked degree.

But the mere fact that it has organized the industry has had far-reaching effects. It has earned the respect of the trade, the state and national authorities, and the consuming public, with the result that the Texas honey industry has been resurrected. Producers are no longer cutting each other's prices and undermining each other's security; the trade can get a standard product, uniformly packed, and with satisfaction guaranteed, and the consumer can feel he is buying a product of merit when he asks for Lone Star brand.

In conclusion, a word about the membership rules may be of interest. There are no annual dues. Shares are \$10 each, and ownership of one share entitles the holder to all privileges. One hundred shares is the limit for individual ownership. Profits of the Association are rebated to members in proportion to business done.

Brand used by the Texas Honey Producers' Association in marketing honey

the amount of honey actually on hand, the locations where honey will be available for the market and on what dates; also, kind and how packed. With this information the manager approaches the wholesaler, who can then instruct his traveling salesmen of the price of honey for future delivery, taking orders from consuming points for direct shipment. These orders are mailed back directly to the manager, who in turn directs the honey producers where to send their honey. The honey is shipped direct to the consuming point in the amount desired. Attached to bills of lading is a statement giving the grade, the amount, the manner of packing, and the guarantee. A certain claim period is allowed the purchasing merchant. If the honey is not up to standard, the Association protects the buyer.

"Under this method the manager receives and solicits orders, both great and small, for honey, bees, wax, etc., from all parts of the country, together with the price the prospective customer will pay.

"The jobbers and wholesalers are much pleased with this manner of

Prices are established in April and full publicity on them sent out to the trade.

Advertising of a general nature has not yet been done, but in addition to using a standard label, each case contains a display card for the retailer to use to call attention to the honey.

Influences Legislation

This closer association of the honey interests of the State has also improved their ability to favorably influence legislation affecting their industry. This fact was notably proved when the Texas Senate proposed to lop \$2,000 from the foul-brood appropriation. Within 48 hours the Association had engineered indignant protests from the "folks back home" and prevented the cut.

Again, when the Washington authorities were considering the tin can shortage, and the committee had failed to list honey as a perishable, the Association was able to claim attention for honey and assurance of a supply of honey cans. Here the Association performed a national service for its industry.

A third interesting instance of influence with Government authorities

Centralizing Bee-Yard Control

By J. J. Wilder

WHILE we are learning more and more every season to control our bees, holding them under check and managing more of them with the same help, we must learn to control the group of yards as well as the bees in them.

In the South many outapiaries are now being established making this a timely subject which it pays to look into.

I have looked over our country, picked out locations and established nearly 100 yards and I know what it means to make a mistake in this work; and, on the other hand, what it means to get the proper location.

I once placed a yard on a creek just one mile from the highway, with a rough, crooked road leading to it, and the only way out was to back out to the highway.

While the location on the creek was ideal in surrounding and in distance from other yards, yet the difficulty in reaching it made it a failure. We finally moved this yard near a good road, where we had to pass on our way to other bee-yards,

Another time I located a yard at the end of a settlement road, a mile and a half from a good public road. The settlement road was never kept up, and it was almost impassable at times. This meant a loss of time, and we moved this apiary where it is more easily reached.

Another yard, which was our first outyard established, was placed in an ideal location, and we always obtained a good crop, but there was no available territory beyond, where other yards could be established, and to reach it we had to make a special trip. In consequence it was sometimes badly neglected.

For success we must have yards conveniently located, so we may reach them with the least possible delay. We must centralize as much as possible in order to cut down mileage and allow more time for general apiary work. Of course, good roads have much to do with this subject, whether the distance be covered with teams or with trucks.

It is best to have for the central point of your apiaries, your home yard, or a specially good location for bees. Here you should have a large honey-house and workshop. The bees, at this center point, will be needed to take care of extra combs from outyards, clean up all freshly extracted combs, finish unfinished combs, use up any small amount of honey broken up or rendered unfit for packing, clean out cappings and do many other things that are a great help to the business.

The best stock can be kept here and the yard run as a queen-rearing yard, or much of the increase can be made here, because it is the most convenient yard and can receive daily attention. In consequence, this is a very important yard.

For other locations two and one-half or three miles should be your standard distance between yards.

In the southland we are blessed with abundant water courses. Large branches, creeks and rivers are almost our only salvation in beekeeping. Along these are swamps or low lands which bring about a complete change in the sources of honey, and as a rule bees will not do half so well out of reach of them. So we follow these as closely as the good roads will permit.

The first yard should be located not less than a half mile from a stream and more than 300 feet from a road, so you can drive into the apiary with a wagon or truck.

To establish your other yards, watch your nearby streams closely, at the same time keeping in mind the good roads. Perhaps it will be best to establish all your yards in a direct line, or it will suit better to have them placed in a large circle. All this depends upon the streams and the roads. If in a direct line 25 or 30 miles is as far as your last yard should be from your center point.

Other Central Apiaries

Rather than extend too far from one central point, it is better to establish other centers, placing the groups at least 100 miles away in an

entirely different section, if possible, where the climate has changed somewhat and the honey plants will be of different variety.

The advantage of this is that, should you have a failure or a partial one in one section, such would not be likely to occur in the other apiaries. The main honey flow may come in the spring at one branch and in the summer at another. Then, too, you can shift your packers from one branch to the other, as well as your apiarist, for, as a general rule, the work slacks up in one place when it is just coming on at another. You also have a variety of honeys to offer for sale.

Numerous branches can be established in this manner, always leaving a distance of 100 miles from other branches. These can be established at the same time providing that labor and capital is at hand. It also is very important to have the center point as near as possible to some good shipping point.

The question has been asked, would it be advisable to erect a honey-house and install a packing plant for one yard, which is at considerable distance from the central apiary? We have tried this and found it a failure, for the pasture or range is never strong enough to support a large apiary and it would be too expensive to have a complete outfit for 75 or 100 colonies. The average production of honey in the Southern States is less than 50 pounds surplus per colony and this small amount can easily be carried to a central point for extracting. The supers can be returned as trips are made to and from the yards for general apiary work.

Establishing apiaries and centralizing them as outlined will make work easier, lessen expense and bring success.

Bradentown, Fla.

Santo Domingo Conditions

By H. Brenner

THE pioneer beekeeper in the Republic and old reader of the American Bee Journal is Dr. Maldonado, whose natural leaning is towards entomology. The doctor, a Spanish gentleman, is about 42 years old and a physician of unusual ability. He graduated at the University of Spain and speaks perfectly English, French, Spanish and Esperanto. In my researches about the flora and fauna of the island and in apiculture he is of great help to me through the encyclopedical condition of his knowledge. When I am back from my trips to rest in Sanchez, the evenings, on his verandah, sometimes till 1 and 2 o'clock in the morning, I consider as my best spent time. All his apiaries except in Arenoso are on his own land, and he has picked out over a dozen more sites which will be stocked in fall and next year. Herds of blooded Holstein cattle from imported bulls are grazing in his fenced (barbed wire) pastures. He also is a merchant of great ability,

and a graduated pharmacist, owning a drug store in Sanchez, another in Matanzas, and interest in others in different towns. His agents are all over the Republic. I am glad to say that he will free himself gradually from some of his present enterprises to spend more of his time in apiculture. Another gentleman for whom I predict a future in beekeeping is Captain Dr. Dreyfus, our immigration officer and military physician. The doctor has in his residence an observation hive with a double colony, and intends to buy land on the north coast and go in extensively for beekeeping. The real beekeepers in the Republic are mostly wealthy land owners who are able to buy the materials. The poorer classes and very large majority, have colonies in logs, from which they get honey in place of sugar, and wax to make candles for light. I would like to send some pictures, but I lost my camera in crossing a flooded river in a log canoe; it fell through the negligence of a native boatman, and of course disappeared. I have not yet been able to get another.

A lover of bees in Santo Domingo, Dr. B. Maldonado, Sanchez, R. D.

About a month ago Dr. Maldonado bought a run-down apiary 5 miles from San Francisco de Macoris. We concluded to move the bees and material in the night to the station, load a car and use both in our apiary in Arenoso. The doctor made all the arrangements, etc. We had about 18 mules and horses and only four men. The first trip before midnight went off all right and we reached the station, bees and all, in good condition. After midnight it turned cold and the hands lighted a fire and refused to work, and we had to wait with the remaining colonies till the sun came out, as the doctor and myself could not load the mules ourselves. We tried it, but had to give it up. We had a time when we started, as the mules objected to the bee stings, jumped, kicked, ran against trees and against each other with the colonies tied with ropes on their backs. I

never had such a time before, and never want to see it again. We continually stopped the cracks which opened in the old, rotten hives, with clay, but it did not help much. The richest joke came when we reached town, at about 9 o'clock. We had the streets for ourselves and the bees. We lost ten colonies scattered along the trail. Of course we went back, nailed the boxes together and stopped the cracks with clay and brought them all safe to town and depot.

I am thinking of giving up my actual apiary work here to have more time to follow my real inclinations of researches and investigations, especially in apiculture. There is a large field open here in this respect and hardly a week passes that I do not find something new and unexpected among the bees. Since I am known here, I can well afford it, as every beekeeper will gladly extend his hospitality to me for the little help and advice I can give in return. I also will have more time to inform the readers of the American Bee Journal of my doings, and to put down for our station in Texas my observations in tropical beekeeping.

Questions Answered

With the two last mail steamers I received a number of inquiries from readers of the American Bee Journal which it is impossible to answer separately.

W. Va.—I have not met any bee diseases.

Market for the honey is now New York.

I do not know what honey is worth at present.

No winter in the tropics.

Property is safe here, but they certainly steal honey out of the apiaries if no one lives there.

Nectar is coming in the whole year, more or less. A real flow I have seen at the end of December, January and February. They told me that the main flow is in June, July and part of August.

Ulster, Pa.—I cannot use any U. S. stamps for letters here.

Thank you for your compliments about my articles.

Your other questions do not belong in the American Bee Journal, but if the editor does not mind, I can inform the readers also about quality, price of land, population, etc., as I am going to buy myself. (Will be glad of a short article on this subject.—Editor.)

There are no poisonous snakes here, as far as I know.

There is lots of room for people like you without killing the natives. There is some reason for their laziness; nature produces everything they need. So why should they work?

Dallas, Tex.—I do not know if you can stand the climate here. I never have been sick and my health is improving.

Lots of mosquitoes in some parts, and in some less. I cannot sleep without a mosquito bar.

S. Carolina.—Not advisable for strangers to buy land here. I know several cases where buyers had to pay twice. If you have a friend to advise you it is better.

The bulk of the honey is produced in hollow logs. The natives press it out, brood and all, put it in gasoline cans, stop the opening with a green cornob and sell it in the little country villages to the buyers, who sift it through coarse wire netting into 50-gallon barrels. This is the stuff that is ruining the honey market for the tropics. For about two or three weeks it tastes all right, but after that time it gets a nasty taste and is hardly fit for table use. I send samples of extracted honey to dealers and also to the American Bee Journal.

Sanchez, R. D.

Beekeeping in Jerusalem

By Ph. J. Baldensperger

JUST seventy years ago my father arrived in Jerusalem bent on missionary work among the natives. He had a greater belief in acts than in words. He founded an apiary on old principles on Mt. Zion. After a long and active life he laid down his weary head and now rests, since 1896, not more than a hundred yards from his first apiary, in the cemetery near by. His first apiary resembled all apiaries which have existed in the country for the last three thousand years, without a single change. The pear-shaped hives, manufactured in a pottery inside the city walls, had been copied for generations without number, and faithfully reproduced the patterns no doubt imported from Egypt and Assyria by Jews returning from captivity.

Beekeeping was unknown to the Hebrews before their contact with the ancient civilization on the Nile and Euphrates, as is evident by a passage in Isaiah vii, 17-18: "The Lord shall hiss for the fly that is in the uttermost part of the rivers of Egypt, and for the bee that is in the

land of Assyria. And they shall come and shall rest, all of them, in desolate valleys, and in the holes of the rocks, and upon all thorns and upon all bushes." Hebrew scriptures talk of the "Land flowing with milk and honey," but the error is only from the translation. Milk, or rather sour milk, the Arabic "Labban," is still a dainty among the natives. As for the Dabsch, translated "honey," the article is more widely known yet, and called Dibbs. This syrup is prepared from the boiled juice of grapes. Dibbs is now made, as in the older days, in great abundance in the magnificent vineyards all around Hebron.

Nothing has changed in the Land of Promise since the day of Joshua and Caleb, excepting some religious rites. But we meet everywhere the same people, the same names, the same manners, the same way of living, and, to a great extent, the same language.

Joshua and Caleb, it is stated, came to the brook Esheol and carried away big clusters of grapes to their astonished tribesmen in the wilderness. The Moslem Hebronites of our day raise the luscious fruit in big clusters and offer them for sale in the neighboring villages and as far as Jerusalem. They also boil the grapes into Dibbs, on the same spot at Ain-Askala, in the same way as it was done before the Hebrews, in rock-cut presses. "He made him to suck Dabsch (translated honey) out of the rock." Deut. xxxiii, 13.

There is no doubt for me, who was born and grew up amongst the natives, that they are the closest and most authentic descendants of Canaanites and Hebrews. My plea for them is that when this great war is over they should receive the land promised to them ages ago, a promise now renewed by President Wilson, to dispose of themselves. Faithfully they have clung to the native soil, faithfully they have continued the traditions and to them alone it ought to be reserved.

When I was born, in 1856, near the walls of El-Kuds-esh-Sharif, the ma-

Fig. 1.—Jerusalem. 1, city walls; 2, Zion's school; 3, David's grave; 4, Apiary; 5, cemetery; 6, Miss Baldensperger; 7, Mrs. Baldensperger; 8, H. Baldensperger, Sr., (lived in Jerusalem 1848 to 1896); 9, Henry Baldensperger.

jestic sanctuary, as Jerusalem is called by the natives, the apiary, according to the archaic system, was all tucked up before the solid arch in masonry, with a dark passage behind to work the bees.

Messrs. D. A. Jones and Frank Benton came over from America in search of new races of bees, and under their instructions the dark passages and archways were discarded and the bar-frame hive and American modern methods introduced by their disciples, Baidensperger brothers. (This was in 1880.—Editor.)

And the light was so clear that Ehmud-en-Nahale, our indigenous beemaster, was never heard of again. He continued to knock the coffee in a dark street in Jerusalem, as he and his forefathers had done for generations. Moslems hold fast to their methods. It is profanation to grind the coffee, just as it is profanation to walk into sanctuaries with shoes on. "Take off thy shoes from thy feet, for the ground where thou standest is holy." The good Nahale used to come occasionally in two seasons, swarming and gathering the honey. In April he would gather the swarms, gently showing us the Emire or Duchess, as he called the mother-bee, and in August he took out heavy combs of honey, which he laid on plates with great satisfaction, and a sweet smile. He was very sober in words. 1. "The bees did not like harsh persons." 2. Perhaps he preferred to keep the "secret success" for himself. Quietly he gathered cow's dung, filled with it a small pitcher, put a burning coal to the fuel and patiently blew till a tolerable quantity of smoke gave him security against the bees. He did not live to see our modern inventions, smokers, extractors, comb foundation and the like, and I am afraid he could not have tolerated having his pets taken out of jar hives and introduced into wooden boxes, and in the open air.

Poor Nahale! Dear tradition! Though established on a high and dry plateau, almost in the center of

Henri Baldensperger (Philip's brother) near the old pear-shaped hives piled up under a double rank of arches in the Holy Land

Judea, Jebus, the dry, as the name indicates, was a comparatively good honey region. Big apiaries set up in the old fashion by the Greek monks, in the environs of Jerusalem, gave good crops to the convents. Honey was kept for church grandees there, as it was only known by the better classes in town. There was a time when honey was more abundant in Jerusalem, since there existed still the "Honey-man's street." Haret-el-Assali.

In the American Bee Journal for December, 1917, a list of bee places is given in the United States. Palestine, though very small, has 6 or 7 names reminding one of bees and beekeeping. It measures hardly 25,000 square kilometres and has a population of one million, or thereabouts, whereas the United States, spreading over 9,383,000 square kilometres, with a population of over 100,000,000, has 73 bee places named. The names are spread from Baalbek in the north to the environs of Hebron in the south. 1. Nableh (the bee), near Baalbek; 2. Daburiah (the hornet retreat), near

Nazareth; 3. El Asaliyeh (the honeyed, in the Hauran, beyond Jordan; 4. Deir-en-Nahel (the convent of the bees), near Jaffa Latrone; 5. Asalin (the honey men), near Gath, Deir Imheison, in Philistia; 6. Nahalin (the beekeepers), southwest of Bethlehem; 7. Deir-el-Asal (the convent of the honey), between Gaza and Hebron.

The town of Jerusalem was somewhat protected against the warm east winds by the Mount of Olives, which winds have the faculty or drying up the nectar. The wind known as Sirocco, is more properly called Sharkie by natives. West winds blowing across the Mediterranean bring moisture and clouds which spread Naida, or dew, over the hills and greatly help the honey plants. On rare occasions the hot Sinum (poisoned south wind) blowing from the Sinaitic peninsula, dries up flowers and plants, and the honey season is usually a failure in consequence.

On warm days when the weather is calm, the bees find their way over the valleys of Jehoshaphat, Cedron and Hinnom and forage on all kinds of honey plants on the envining hills of Olivet, Siloam, etc. Olive trees and fig trees, which grow usually all around, have but very little honey, while almond trees around the Mount of Olives and Bethany, as well as down the Cedron, give an early lick in February and March. Hawthorn flowers, a little later, help the bees in their swarming propensities. As the town is built almost on the watershed between the Mediterranean and Dead seas, there are but few springs in the vicinity and they are several miles from the walled enclosure. Bees must look for the necessary water to raise brood in the pools of Hezekiah, Bethesda and Mamilah, as well as in private gardens. The disease-carrying mosquito (Anopheles) lives and thrives about the stagnant waters.

Beekeeping was mostly confined to open spaces against the interior of the walls, either toward the north, or the large gardens on Zion. The

Henri Baldensperger (Philip's father) near his old native apiary in the Holy Land, behind the wall of the fortress.

pine trees, as well as a few olive trees in the Armenian gardens, afford them propolis and a kind of droppings known as miellat (honey-dew), from the pines. Long before this trench-building war, bees knew how to build trenches made of the resin found on leaves and branches, to shelter themselves against hornets or other enemies who tried to enter the hives. Small lizards and sometimes serpents, mice, snails, enter the hives, or would enter but for the propolis with which the bees entrench themselves against their enemies. The death-head moth (*Sphinx atropos*) swarms about the hives in autumn. If it gets into the hive easily it is often too greedy, and too swollen with the honey pilfered inside, and is killed by the furious bees. The skeletons are sometimes found by dozens at the bottom of the hives, embalmed in the resinous matter. Every portable fragment has already been carried out before propolizing.

(To be Continued.)

Packages for Extracted Honey

By Morley Pettit

TYPES of packages used for extracted honey will depend on the form in which the ultimate consumer wishes to receive it. While capable of some education, that individual is something like a bee in that she (gender used advisedly), is the final judge as to whether the behavior of the beekeeper is acceptable or not. He who would sell honey must study the consumer, and as success in beekeeping depends on a knowledge of bee-behavior, so the successful disposal of the crop depends on a knowledge of the preferences of those to whom the sale is to be made.

Consumers may be classified as fastidious small buyers, and careful buyers of quantities. The former are mostly city dwellers, where similar foods in glass containers compete; they want liquid honey in glass. The quantity buyers in cities also want honey in liquid; but will buy in larger packages of tin. In cities where the sale of well liquefied honey has not been pushed, granulated honey will retail in tin or paper, or even in glass to a limited extent; but the majority of people, when given a choice, will buy honey which has been well liquefied in preference to that which is in the granulated form. The latter finds its largest sale among farmers whose wives have ample kitchen facilities and can liquefy it when they choose without much trouble. This is a satisfactory arrangement while supply falls so far short of demand, and because granulated honey ships more safely. When the need arises I am sure that the careful liquefying of all honey just before it goes to the consumer will greatly increase the demand.

Storage Containers for Liquefying

The usual storage containers for liquefying or for sale to re-filling concerns is the 60-pound tin, because

of the ease with which it is handled and heated. It can only be filled once with any degree of satisfaction, on account of leakage, rust and disease, and becomes a rather expensive package except for home use only. The alternative is a used wooden barrel. When emptied of glucose, alcohol, or some other materials, these can be steamed out, coopered, parafined inside and used for honey.

My personal experience with barrels has been confined to those which had previously been filled with glucose. They cost me one dollar each a couple of years ago, although I used to get them for half that price. They are made of white wood, iron-hooped, hold 650 pounds to 700 pounds when filled, and are not so hard to handle as one would think. There is a "knack" in handling them, and two men who have it will roll them almost anywhere with a rope and some planks.

The first lot of barrels I ever filled had not been coopered since they were emptied and must have been damp. The sun shone through the windows on them, and its heat, together with the drawing of the honey inside, dried out the staves and set them to leaking at every joint. When we came to team them to the station there they were. To make matters worse, the dripping honey smeared the hoops on the under side so they would not hold when driven.

I got through with that shipment with only a few dollars' loss from leakage; but it was a lesson to cooper carefully every barrel before filling. The hoops should be again driven just before shipping. Empties should be stored in a dry place several months, if possible, then coopered well and waxed. On no account should barrels intended for honey get wet. The ends of the staves swell, and because the hoops prevent expansion, their fibre is crushed so they gape open on drying in a manner which no hoop driving will close. They can be caulked with rushes and waxed so as to hold; but it is a lot of work and the result is not so satisfactory as though they had been kept under cover. Liquid honey can be shipped quite safely in barrels, although, of course, the risk of leakage is entirely removed by granulation.

To liquefy honey which has granulated in barrels, the hoops and staves may be knocked off and the honey cut up with a piece of steel wire having a handle on each end. Some remove only the head of the barrel, dig out the honey with a clean spade and return the head for future use. It is possible to reassemble the knocked-down barrel, if one has a cooper's skill and tools. One would need to compare methods here in view of labor, cost of barrels, and the fuel value of the staves and head.

Honey in barrels can be sold only to such manufacturing and re-filling concerns as have facilities for handling them. Necessary changes in equipment used for handling 60-pound tins can easily be made, and a patriotic service would be rendered by

such firms using barreled honey instead of tinued.

Tin Packages for Selling

The standard tin packages for honey are: 60-lb., 30-lb., 10-lb., 5-lb., and 2½-lb.

Sixty-pound tins may be square and crated singly, or boxed singly or doubly, or they may be round and jacketed. Crates or boxes for square tins can be made or repaired at home, and square packages pack more closely for shipping. On the other hand, they jam more readily and leak in transit, and the first cost is slightly higher. They are seldom retailed and the Ontario experience is that in years of large production they are the hardest package to sell, probably because Ontario beekeepers use them too freely.

Thirty-pound lard pails, bucket-shaped, with a slip cover, japanned with a stencilled honey label, are sold to a limited extent. They are a good family size, and make useful pails when empty; but they can be shipped only granulated and are awkward to crate or box. I have seen small grocers in Montreal dig granulated buckwheat honey from them for retail in wrapping paper.

Ten-pound, five-pound and two and a half pound pails are made both slip cover and lever cover, both plain and lithographed. For retailing at home the slip cover is a little more convenient; but it is not so satisfactory for shipping. So long as demand exceeds supply, plain tin lever cover pails may be sent direct to the consumer for use at an early date. Pails lithographed with the beekeeper's brand, name and address, sell better, keep free from rust indefinitely, and continue to advertise his honey so long as the pail continues in use, wherever it goes. Plain tin pails of honey stored in unheated rooms in changeable weather fail to warm up quickly with a rising temperature, and their cool surfaces condense moisture; frequent wetting and drying dull and soon rust the tin, and lower the selling value of honey which is otherwise first-class. Furthermore, custom requires that all tin containers of food for retail be covered with an attractive camouflage. In order to compete on the shelves of the high-class grocer with other package goods, honey must be made quite as attractive as they. Uniform crates of 60 pounds capacity for all the smaller sizes are standard for shipping.

By a ruling of the Ontario Beekeepers' Association, ten-pound pails and smaller sizes are filled gross weight and their size, as manufactured in the Province, corresponds. Previous to the adoption of this ruling much confusion prevailed. Some sold gross weight, using pails of the right size; others sold net weight and required larger pails. The manufacturers had to make two sizes of pails so nearly alike that mistakes in ordering and in filling orders were frequent. Beekeepers selling net weight lost the price of the pail, or asked for its return, with indifferent results, or charged extra for it and

made the consumer dissatisfied, or brought it back a second-hand pail later, or lost custom through charging a higher price for their honey than those who sold gross weight.

All this confusion of selling practice resulted in heart-burning and in-cremination, until the decision of the association established a standard which most beekeepers now observe. In selling gross weight the beekeeper does not conceal from the buyer the fact that he is sharing with him the cost of the package, the custom is general and there is no objection. Where the net weight custom is enforced by law, as in the United States, prices become adjusted accordingly. Ultimately the consumer pays—he must if production is to be continued; and it amounts to about the same thing whether we sell net weight or gross weight, so long as all sell the same way.

Sixty-pound tins are always filled net weight. These are sometimes made too large and the novice puts in amounts varying from 62 pounds to 65 pounds, keeping account of them and itemizing the weights in his invoice when selling. He is unfortunately, though not unjustly, disappointed to find that the buyer will only pay for a standard amount in a standard package.

Glass Containers for Honey

Well liquefied honey is sold in a great variety of glass containers, from two-quart jars down to small bottles for individual service. First cost, breakage, boxing and increased freight rates make glass an expensive package; but it puts up an attractive appearance and pleases Madam Fastidious Buyer. The individual service bottle is absolutely necessary if patrons of public eating places are to have honey at all. Honey is too "sticky" to serve in public in the usual way.

Paper Containers for Honey

From time to time different forms of paper honey containers have been advocated. Parafined manilla paper bags, advocated by R. C. Aikin, of Colorado, were among the first. He filled them with alfalfa honey and let them stand open until it granulated, then folded the tops down and sealed them. They were nicely printed in colors with the beekeeper's name and brand, and made an attractive package. I filled all sizes of these from the 10-pound size down, with clover honey, which granulated hard and firm. Some high-class grocers tried them, but they did not sell well. Their customers preferred liquid honey when they could get it. Furthermore, the bags could not be kept long in a warm temperature without becoming soft and sticky. In other words, the honey, of whose keeping qualities beekeepers boast so much, became more perishable and more liable to be a loss to the dealer who did not happen to sell it promptly. Next came cone-shaped paper milk bottles, recommended by W. A. Ponder, of Indianapolis. Their fate was the same as that of the bags.

About that time opening large tins

or barrels of granulated honey in the grocery store and retailing the honey wrapped in paper like bulk butter was tested extensively. In one case a barrel of clover honey, without the barrel, was made the center-piece of a grocer's Christmas window, and created quite a sensation. In another case the manager of a chain of provision stores in Ontario arranged with a beekeeper to purchase clover honey in 60-pound blocks in tin or wood, intending to strip and use them for window displays before cutting them up to retail by the pound.

These practices were soon discontinued; but we thought the failure was due to prejudice in favor of package goods for retail and cast about for a convenient and inexpensive package for granulated honey. We still believed that Mrs. Fastidious Buyer would like granulated honey if we got it to her in the right way. So "honey bricks" were introduced. That is, the block of honey was cut up with wires into bricks of uniform size, a butter-cutter being used for the purpose. Each brick was wrapped in thin waxed paper and placed in a carton, which was then covered with a lithographed label, fastened at both ends with tasty seals.

In the Pettit aparies honey bricks were tested most thoroughly. They sold well at first, but repeat orders came slowly, the preparation of them was slow, disagreeable and expensive, and the second season we did not think the matter worth following up. Even the firm who advertised them most widely does not seem to have any more to say about them, and I do not know of any style of paper package being marketed extensively at the present time.

So the pendulum of the paper package has swung with the years and the reasons for its failure to stay may be summed up as follows:

When the two are marketed side by side, honey which has been carefully liquefied sells more freely than granulated honey. Even the best honey we are able to secure does not always granulate with a smooth, dry grain, suitable for a paper package. If left exposed to the air honey generally loses aroma, flavor and specific gravity, yet such exposure is practically necessary when paper bags are filled for granulation. All granulated honey becomes soft in time, so that the paper package would not be safe for honey stored beyond the winter months. Yet this is likely to occur at any time, and thus one of the chief arguments for honey is lost.

The chief arguments in favor of the paper package are its cheapness and lightness; but for shipping, it would require stronger and more expensive crates. For those who like granulated honey they open up very nicely for serving, provided the honey has granulated well and has not gone soft. If the time should come that we cannot get tin at any reasonable price, paper seems the best substitute in sight. Until then

I cannot see that tin is any more expensive in proportion to the price of honey, or of paper than it has ever been. Prices of all three have advanced. Dollars are cheaper than they were. It takes more of them to buy the necessities of business and of life, so we stand about where we did in that respect.

—Georgetown, Ont.

Being Sweet Without Sugar

By Mary G. Phillips

NOW that the canning season is upon us, every woman's thoughts turn toward sugar. Will there be enough for all of us to do the canning and preserving that is necessary in order to save the fruit in our gardens? We are assured by the Food Administration that what sugar there is will be fairly and equally distributed, but of course that means with the co-operation of every housewife. In a democracy like ours, the success of any plan of dividing food stores depends upon the willingness, sincerity, earnestness and common sense of the consumers, and that is what Mr. Hoover is banking on in his plan for the fair division of sugar.

We all know that there is not enough sugar now in the world to allow us the annual 81.6 pounds per person that we are accustomed to. But we also know that that is too much sugar for our own good. England is the only other nation to use such large quantities of sweetening, for her usual sugar ration used to be even larger than ours—86.3 pounds. People who live very active lives where muscular exertion is constantly necessary, need a great amount of sugar, because it is rapidly assimilated and its energy becomes immediately available to the body, but the ordinary person needs very little. The only defense that most of us have for the amount of sweets that we eat is that sugar improves the taste of many foods, and we like it. Before the war, Germany and France were using just about half as much sugar per person as we were, and Greece and Italy were eating only about 7 pounds a year per person. Can you imagine the average American cutting down his ration to that? It would undoubtedly mean going without soda water and ice cream between meals, tabooping cake and candy, eating unsweetened cereal and all sorts of "sugar sacrifices," but it can be done, and if we can taste the sweet fruits of victory by now eating unsweetened foods, I move that we do it. It is carried unanimously, and so there will be larger quantities of sugar released for the preservation of this season's fruit crop. Dr. Alonzo Taylor says:

"Everything that we do, plan, eat, wear, must be analyzed and measured from one single point of view—will it contribute to the carrying on of the war, or will it contribute to its prolongation? There is no other thing in the world for us but to de-

fine everything in our lives as acts of military necessity or policy."

Although women are eager to conserve sugar, they are asking somewhat impatiently, "Why is there a sugar shortage?" and "Where is the sugar?" and the reply is the usual one, "C'est la guerre!" If you will look at a map of the world showing the regions where sugar cane and sugar beet (our only two sources of granulated sugar) are grown, you will see immediately why there is less sugar for us today. The largest producer of sugar cane is India, but with her enormous population she has no sugar for export. Second in production is Cuba, and most of the sugar for us and for Europe comes from that island and the other West Indies. The Barbadoes have had over sixty per cent of the surface cultivated for cane for two hundred years. But sometimes the crop fails in Cuba, and nowadays the ships to carry a crop are few and far between. It also happens occasionally that a submarine interferes with our obtaining the sugar we expect. Here at home we find cane growing only in Louisiana along the lower delta of the Mississippi.

However, within the last half century we have had a new industry arise—the manufacture of granulated sugar from the sugar beet, so that we no longer depend wholly upon sugar cane. The sugar beet grows in the north in regions where the summer temperature is around 73 degrees, and where there is considerable summer rainfall. In America it is produced principally in Michigan, Wisconsin, Minnesota, Colorado, Utah, Idaho and California. In Europe, unfortunately for the world, the areas devoted to sugar beet cultivation are the parts of northern France and Belgium now occupied by Germans, so that any sugar produced there goes for German consumption. Germany is the only other European country to raise sugar beets to any great extent, with the exception of a small area in southern Russia, also of no use to us. So it is that our allies must depend upon us for sugar. When we remember, too, that soldiers need more sugar to provide fuel for their bodies than when they were leading civilian lives, we will see how necessary it is for us to use as little as possible. Have you not heard stories of soldiers so starved for sugar that they would trade almost anything they owned or undergo any hardship for the sake of getting a tiny piece of chocolate?

I find that the easiest way to conserve sugar is to ration the family. I buy only so much each week, and if it does not stretch to the end of the week, we do without and eat honey. We generally find that it does stretch to the week following. Our great grandmothers had no granulated sugar, nor did the old Greeks and Romans, who were famous for their sweets, and indeed until a little over a century ago, everyone was dependent upon honey, maple syrup, sorghum or corn syrup. Honey is the

most concentrated as well as the most ancient of these natural sweets. Beekeepers' wives are particularly fortunate in knowing this good food, and in having the opportunity of feeding it to their growing children. There are so many who do not use it at all, that beekeepers' wives might do missionary work in teaching its value, as well as in advertising their husbands' business, by talking for honey as a food. Granulated sugar is so refined in its manufacture that there is nothing in it but pure sucrose, while honey, manufactured only by the bees, contains not only predigested sugar, but also small quantities of valuable mineral salts, gums, and one of the two recently discovered mysterious chemical substances which are necessary to growth, called "water-soluble-B." There is an added value in honey to me, and that is its romantic quality. In its limpid beauty I see the myriads of flashing wings carrying into the dark hive the watery nectar, which by some strange alchemy known only to the bees, is transformed into this wonderful aromatic sweet. I think of the millions of generations of workers who have faithfully carried out the life of the hive as it was thousands of years ago. Probably back as far as the Stone Age, our forefathers searched the woods for beebtrees, in order to carry home to their caves the precious stores of honey. Can't you see the naked brown babies standing at the mouth of the cave, brushing their hair from their eyes in order to see better when their father might appear down the leafy vista? Can't you imagine their joy when he comes bearing a sticky, dripping mass of broken comb on a grape leaf, and hear them murmur "Ugh! Ugh!" as they cram honey, pollen and brood into their mouths, all at once? That is Stone Age talk which means "Thank you, kind father, for this fine honey. It is too bad you cannot find bee-trees oftener."

It is for us who know honey not only to spread the knowledge of its value as a food, but now, we may well give up the use of sugar almost entirely, using honey instead.

Children are especially fond of honey, and there are many ways in which it may be used for them. Try making cocoa with honey and you will find there is a smoothness of texture and delicate flavor that is delicious. A pinch of cinnamon makes a pleasing variation. Then very often for school sandwiches. I mix honey and peanut butter, a combination much enjoyed. If you do not already own the Bulletin on "Honey and Its Uses in the Home," (Farmers' Bulletin 653), send to the U. S. Department of Agriculture, Washington, D. C., for it, for it contains many good recipes and suggestions.

I suppose that every beekeeper's wife has experimented with honey in canning. It gives satisfactory results, although the flavor of the fruit is generally a little changed, particularly if a strong honey is used. Apples canned in honey taste almost like quince, and they make a specially

good pie. This year I shall preserve my currants in honey, making the famous Bar-le-Duc preserve, but I do not believe I shall pick out the currant seeds one by one with a needle.

Currants in Honey. (Bar-le-Duc.)

Take equal weights of honey and currants. Bring the honey to boiling point, add the currants and boil gently until the fruit is tender. If the currants are so juicy that they make the honey watery, remove the fruit and boil the liquid down until a rather thick syrup is obtained.

I believe that the patriotic thing to do this year with regard to fruit is not to make jelly if the fruit can be used in any other way. Canning requires least sugar, but if you have fruit which you wish to preserve, by all means make jam. Any housekeeper who has rows of shining glasses of clear jelly, cannot show them with pride to her friends this year. Instead, she would need to hide them with shame—but surely no American woman will let it be said of her that she is not strong enough to forego the pleasure of making and eating jelly when she has the strength to send her men to the battlefield with a smile. The brave women of England who have been getting along on the meagre ration of 8 ounces a week per person for many months, have succeeded in saving from that little bit enough to help preserve the large fruit crop. Now they are to be allowed an extra supply of as much as ten pounds for each member of the family. Any sugar over that amount necessary to save the fruit of their own gardens will be granted, provided that the jam made be sold to the government for the use of gardenless folk.

Many fruits may be dried for winter use, particularly apples, cherries and peaches. Others may be canned with no sugar or honey, as green gooseberries, or with thin syrup. Then, when they are to be used, more sweetening may be added if desired. In all my canning and preserving, I keep at my elbow all the government bulletins I can get on the subject. Those that were almost worn threadbare last season, and which I shall follow closely again this year, are Farmers' Bulletin 841, Drying Fruits and Vegetables in the Home; Farmers' Bulletin 853, Home Canning of Fruits and Vegetables (especially recommended for housewives in the south), and Farmers' Bulletin 839, Home Canning by the One-Period Cold-Pack Method (recommended for housekeepers living in the northern and western States). All of these may be obtained by writing to the U. S. Department of Agriculture, Washington, D. C. We cannot afford to have fruit spoil before or after canning this year, and so we must make ourselves as efficient as possible when it comes to preserving the fruit. We hear so much of German efficiency that I scarcely like to use the term, but if we can beat the German at his own game, we will surely win the war!

Changing from Comb to Extracted Honey

By C. P. Dadant

MR. EDITOR: I am contemplating changing from comb honey to extracted. My frames are all alike for brood-nests. They are the standard Langstroth and the hives are 8-frame size. My comb-honey supers are half depth and, if fastened two together, would make one full depth extracting super, which would enable me to change very easily from one to the other. What I wish to know is whether you would advise to use half depth frames in those comb-honey supers and extract from them. I know that you have had much experience right along this line. I had thought that the shallow frames might be preferable, as one stroke of the honey knife would clean one side, in uncapping. I would appreciate any suggestions that you may offer.

Very truly,

Delmar, Iowa.

In order to give me reasons for the ideas that I am about to develop, I have thought it best to relate my experience in comparative tests of both full stories and half stories.

We began successful beekeeping with the 8-frame Quinby hive, which may be properly compared to an 8-frame Jumbo hive. The Jumbo hive takes frames of Quinby depth and Langstroth length, and the Roots put them upon the market and gave them that name at the suggestion of A. N. Draper, who had seen our large hives in use and thought them just right. But our hives and the Jumbo hives are all made now of 10-frame size, because we noticed that the 10-frame colonies filled just as many supers as the 8-frame colonies, and they were 25 per cent larger, therefore yielding 25 per cent more honey on an average. That is to say, a colony in a 10-frame hive filled the 10-frame super as quickly as the colony in 8-frames filled its own narrower super.

For the information of those who may not know the difference between our Quinby frame and the Langstroth and Jumbo, we will say that the Dadant-Quinby frame is $2\frac{3}{8}$ inches deeper and $1\frac{1}{2}$ inches longer than the Langstroth or Hoffman frame. The Jumbo is of Langstroth length and Quinby depth. If we were beginning over, we would probably adopt that frame.

That the greater result with the larger hives is due to a greater breeding room for the queens was proven to us in the following manner:

About 1876, we took over 105 10-frame Langstroth hives of bees to manage for an old beekeeper who could no longer take care of them. He had worked for comb honey, but we preferred the production of extracted honey, so we prepared to run this apiary by our methods. We tried both full stories and half stories. The half stories (so-called) that we used on these 10-frame Langstroth hives

just filled the requirements of the prolific queens. In many cases, supers out on the hive early were filled with brood, which gave us an increased amount of field workers when the heavy crop came.

Our own hives of 10-frame capacity usually had sufficient room below for the most prolific queens. This convinced us that the 10-frame hives of Langstroth size are too small to accommodate prolific queens. A story and a half Langstroth proved just right for handling. Of course, when we placed a second half story over the first, we secured honey in it.

At the same time we tried full-sized upper stories. We did not like them because the bees bred in the center of the upper stories or in the lower edge of their combs. So we often had both honey and brood in the supers. Someone will, perhaps, say: "Why did you not use a queen excluder?" Someone in the December number asked how the Dadants kept the queens out of the upper story if they did not use queen excluders. The answer to both is that the Langstroth 10-frame hive is too small and that we want all the brood the queen can produce in the spring. So we could not keep the queen out of the upper story if we used a 10-frame Langstroth hive without excluder, and yet we want all the brood that may be produced. With the larger hives the queens usually have enough room below and rarely go in the supers.

We have never used the 8-frame Langstroth hives. But if we had them now, I believe we would consider it necessary to use two full stories for breeding and more full stories when the crop came. A shallow half story of just the depth of the pound sections is too small for prompt extracting. Our own so-called half stories are deeper than half a story of Langstroth size. The side bar of their frames is 6 inches and the case itself is 6 $\frac{1}{2}$ inches deep. This makes the combs of the right width for the use of the uncapping knife and an expert uncapper gives just two strokes of the knife, one downward on one side of the comb, the other upwards on the other side. So there is no motion lost, and that is how my son-in-law, Leon Saugier, in a red-letter day, uncapped 5,500 pounds of honey in 8 hours, in the bounteous season of 1916.

In our extracting supers we use one comb less than in the lower story. In an 8-frame hive we would use only 7 frames in the extracting super. If you use 8 frames in the upper story of the standard size hive, the combs will be too thin for profitable work. With 7 frames the combs will be thicker and the result will be less labor and less expense, with the same yield. In a 10-frame hive we use 9 frames in the super.

An advantage of the half-story super is in giving accommodation to an undersized colony. A colony may do fairly well and yet not be powerful enough to occupy a full additional story all at once. This is most in evidence with large hives. As the 8-

frame hive is practically an undersize, the additional space provided by another full story would not look so vast as with our large hives. But in any case when you add another full story you positively double the size of your hive at one operation. This is a good move sometimes, but it often proves unsatisfactory. We prefer to do it more slowly.

The advantage of the full upper story system lies in having but one size of frames. This looms up big to many people, but it does not tempt us.

From the above experiences, you will probably conclude that, with the 8-frame hive, it is best to follow your suggestion and double your comb-honey stories and use full size frames. Very likely, after weighing all the arguments, that will be the best course to pursue. At any rate, by all means avoid using half stories as shallow as the pound section comb-honey super. They are altogether too shallow for profitable work and there is too much handling.

Introducing Queens by Smearing With Honey

By F. M. Baldwin

WHEN the editor of the American Bee Journal offered a prize of \$10 for a description of the best simple device in use in an apiary, I said "That's my money; I'll make my wife a present of it." Then at once I proceeded to write about it in my mind. But, alas! Like many other things I do, it was purely mental and never saw the light of day. The months have gone by; I have slept on my rights and have lost my day in court. The device is not costly. It calls for no extra investment; the article is already in use in every household. It is easily accessible, found in every kitchen. A coffee cup or a drinking glass is the thing in mind. If one of these is not convenient an old tin dipper or even an empty can will serve. So much for the simplicity of the device. Now, as to its usefulness.

While living in Florida I persuaded my friend, Rev. P. H. Hensley, Jr., of Brooksville, to go into the bee business, giving him such instructions as I could from time to time. He got a few black bees and I sent him Italian queens as frequently as he could use them. It was his first year with bees and he had never tried to introduce a queen by any method. I showed him how and he succeeded in getting all I sent him safely into the hives. Other novices have found the method a success. Prof. E. G. Baldwin, of DeLand, Fla., and Henry S. Bohon, of Roanoke, Va., are experts of many years' experience. They have found it safe, easy and time-saving. They are recommending it in their writings as well as using it among their bees. That it works with the novice and the expert unfailingly is enough to prove the practicability of the device and entitle it to consideration in

any contest for a prize, but having led the opportunity go by unimproved, I cannot now claim the reward. He who fails to enter can lay no claim to a crown in a race.

First, find and remove the old queen, then pour about three or four ounces of honey into the cup. Put the queen to be introduced into this honey and roll her around a number of times with your finger until she is thoroughly smeared. Don't be afraid of drowning her. Just immerse her again and again until it looks like she is dead. Then turn the honey and the queen over the tops of the frames and let the mess run down between the combs, carrying her with it. Shut up the hive, being careful to provide against robbing, and leave it alone for at least three days. Don't open the hive to see how your experiment is coming along. To do so might cause trouble. Be patient, and when you examine after several days you will find the lady perfectly at home, and she will have laid a fine lot of eggs if she is a good breeder.

place. Desiring to mate them I carried four virgins when they were four days old to the yard of Mr. Henry S. Bohon, five miles north of Roanoke, and introduced them by the honey route into three-frame nuclei. The fourth day, wanting to know how well my attempt to get them fertilized had succeeded, I opened the nuclei. Three of them had mated and were at once caged, returned to the Hartman yard and re-introduced by the method under consideration.

The fourth virgin was missing. It is my belief that she was lost on her wedding flight. But of course there is a possibility that the bees balled her. If they did, it is the first and only case of the kind that I have known. In a published article over his own name, Mr. Bohon says that he believes this method will work in more than 95 per cent of the cases in which it is used. Hope you can get some of the experts to give it a full test and report. If it is as safe as some of us believe, it is time the fraternity were fully advised about it.

Mt. Vernon, Ga.

My Neighbor's Garden

By C. D. Stuart

WHEN the honeymoon is over, then the humdrum life begins.

After two blissful months I went back to my neglected bees, and the Magic Girl started on a conventional calling expedition. Already she had made friends of my neighbors and came and went among them like the bees, except that she gathered seeds, slips and whole plants where the bees took only nectar. Our own strip of yard was beginning to look like Joseph's "coat of many colors." One neighbor called it a "Vaudeville Garden."

The idea amused me greatly. Where had that sombre mite heard of ragtime and footlights? Her dresses were black, her eyes large, solemn and black, and she lived behind a dense funeral hedge of cypress in which black shadows lurked

even on the sunniest days. Once I had thought to penetrate the recesses of that mysterious garden of hers, but a great spotted dog barred my way. I wished the Magic Girl would not return that call; but she only laughed knowingly and invited me to go along and ward off the spoons.

Inside the hedge a sun-flecked path beckoned through a lane of bloom to a secluded verandah; but we chose a by-path that careened gaily round a corner, through another cypress hedge straight into the oddest bit of landscape gardening—so colorful, its flowers totally unrelated, yet so harmonious in ensemble! Here was vaudeville, drama and grand opera all rolled into one. It was like a huge airdome stage set for the performance. Even the strip of lawn just beyond waited for the spectators to stretch themselves, and everywhere the hum of bees like the expectant buzz of an audience before the curtain rises.

Sage—An old-fashioned flower for an old-fashioned virtue
(Photograph by John R. Douglas)

I have found eggs in abundance and also hatching larvae the fourth day after introducing by this method, showing that no time was lost after the hive was closed up. The bees at once licked the honey off the queen and she was as much at home as if she had always been a part of that colony. It is my practice to let the hive alone until the fourth day. But Mr. Bohon, being of a more inquiring turn of mind, reports that he has found the queen at work laying eggs an hour after he poured her down between the combs.

Confessedly it is more difficult to introduce a virgin that is several days old than any other queen. Last summer I visited at Roanoke, Va. In August I raised some Italian queens in the yard of Mr. P. B. Hartman about five miles southwest of that

The Devoted Heliotrope
(Photograph by A. B. Coldwell)

End men of the minstrels
(Photograph by A. B. Coldwell)

"Stay right where you are!" a voice called, and our mite of a neighbor emerged from the wings, her snowy hair, divested of its widow's cap, gleaming 'gainst the background of dark-green cypress. "I want you to know my actor friends."

"That's why we came by the stage entrance," replied the Magic Girl, advancing to meet our hostess, while I, marooned on a cunningly devised rustic seat at rear center of the stage, with groups of hollyhocks and sunflowers to the right and to the left of me, felt like the interlocutor in a minstrel show. Women are all like that. They get together and talk and leave a fellow sidetracked in some conspicuous position. Luckily I had the bees for company. They had followed us and were busy stripping off and carrying away on their legs in large quantities the make-up of those selfsame "actor friends," the cheerful coreopsis, a few faithful wallflowers and stocks still blooming, and rows of presumptuous snapdragons. Judging from the noisiness of

their wardrobes, the mimes had just acquired speaking parts. They were stationed in front of the minstrels, and the small black-garbed figure walked among them—a very stage manager. "These remind me of actors in a stock company," she was saying, "ready for any place assigned, and enduring. Think of stocks in June!" "It's a game she plays," whispered the Magic Girl in passing. "They're real people to her."

"Asters are the housemaids of the flower theatre, the bachelor buttons are butlers—English butlers that say 'beggin' your leave' before every remark—and the candytuft, dear little children left to the care of servants," continued the pathetic wavering voice, like a phonographic announcement of *dramatis personae*; "but," indicating sections of blue and purple, between which lay a rainbow patch of color, "these represent the fine and true of the stage—the plays we heard when I was a girl; heliotrope, devotion; sage, domestic virtue; and verbena, family life and prayer—unity against evil. All that actors think of now-a-days, is 'putting something over,' no matter what."

The bees evidently agreed with her as to the standby qualities of old-fashioned flowers, and numbers of them flew regularly to extract their sweets.

My thoughts wandered from such out-of-date melodrama to the tufts of red clover that had industriously wedged themselves into corners—supers and stage hands, perhaps—and to watching the bees extricate themselves from the silken skirts of the chorus girls, I'd call 'em. Did you ever see a bee entangled in the gossamer threads of a poppy? A submarine in a net has nothing on it. It backs and turns, rolls over, gets dust in its eyes, and, finally, flies away with a Zip! Bang! that is alarming to encounter. And there were so many in that chorus—and so many daring bees.

"They're the ballet," explained our Theatre Fan. (So then I had guessed

it nearly right.) "They're performing the dance d'heures. The red poppies are for the long, consoling hours of morning; purple, the fantastic extravagance of full day, and white, peace of evening and slumber. One can almost hear the music, slower and fainter—"

She stood in a listening attitude as though to catch the strain of some well-remembered air. I shook off an uncanny feeling. I preferred the orchestra stationed in front of the flower-actors and spreading out to the reserved lawn-space, the orthodox position for orchestras—a solid mass of pink *mesembryanthemum floribundum*, that took to its maternal heart all the cares and petty jealousies of the actors, and absorbed their small voices in its blare of dazzling color. That's the sort of music for me! That and the hilari-

ous applause of the bees buzzing round each performer.

Suddenly I realized the orchestra had been playing all the time. It continued to play. It played us out of the yard and up the street to our door, with the precision and dispatch of Alexander's Ragtime Band. That's my style of theatricals, especially the getting-back-home feature. But I could see that the Magic Girl loved the ballet best.

"Was she ever an actress, or just wanted to be?" I asked.

"Her husband was a noted English actor," she returned, absently, for in the eyes of the Magic Girl still lay the shadow of the hour dance that must end alike for all.

Chico, Calif.

Propolis Poisoning

By Dr. A. F. Bonney

IN the American Bee Journal for May Dr. Miller discusses poisoning by propolis, and calls for a remedy.

There are many plants the pollen from which cause disorders in the human, as rag weed, which is accused of producing hay fever; poison ivy, which does cause serious irritation, and "Missouri," to whom Dr. Miller replies, has symptoms very like those produced by this plant. In the deserts of Arizona I formerly encountered a plant called locally "The Sneeze Weed," the invisible pollen from which, even at the distance of a mile or more, if there was the slightest breeze, would irritate the nasal passages to such an extent that violent sneezing followed and persisted, but there was no further trouble.

There are other plants the pollen from which causes an irritation similar to what the ivy does, but they are so rare that I am inclined to

Mesembryanthemum Floribundum, a bee on every flower

My neighbor's path in June. (Photograph by A. B. Coldwell)

think that "Missouri" had a case of ivy poisoning through propolis gathered by the bees; however, it is very seldom that this can occur, and we may never hear of another case. As to a remedy, my experience with ivy poisoning has been rather liberal, and one of the very best remedies is a mixture of camphor and alcohol with an addition of 5 per cent of glycerine. The new U. S. P. formula for spirits of camphor must be used, made of full strength alcohol. The old formula contained 50 per cent water.

As an ounce of prevention is bet-

ter than a ton of cure, in cases like this, I have prevented the Rhus poisoning (my patients were wood-choppers and others who were obliged to be in the woods) by having them smear the skin with a two and a half per cent carbolic acid (phenol) ointment. This serves a double purpose. The phenol is a powerful antiseptic, the vaseline of the ointment protects the skin.

If the camphor fails to give relief, "Missouri" might try a weak solution of sugar of lead.

Buck Grove, Ia.

any sort of dress, with elastics, closing around high shoes, and buttoning at the wrists and neck after slipping on the veil.

The accompanying photograph will illustrate better than an explanation how to make the bee-woman's apron-dress, which has given the desired services. The idea of it was due to Miss Berliet, a French lady apiarist. It is drawn on like trousers and is buttoned up and down the front like a clown's suit. A belt around the waist keeps it in place; it is practical in preventing the indiscreet invasions of the bees and also protects positively the clothes against soiling from the wood tar or ashes of the smoker, or from honey, wax or propolis. It may be made sufficiently becoming and attractive to suit the most fastidious taste.

Firm unbleached linen of good strength is considered the best for this purpose. If it is objected that the spots made upon it by the smoker or by propolis will show readily, on the other hand, a light-colored fabric is less apt to be objectionable to the bees, who attack dark clothes more readily. A light fabric is also cooler in the sun, and this is worthy of consideration.

When a lady beekeeper has but two or three colonies to care for, she may consider a plain kitchen apron as sufficient, but one cannot be too careful. "Prevention is better than cure."

Women's Help in Beekeeping
Apropos of Women's Help in Bee-

BEE-KEEPING FOR WOMEN

Conducted by Miss EMMA M. WILSON, Marengo, Ill.

Honey Cake Without Eggs

1 cup of honey.
1 cup of sour milk.
1 teaspoon of soda.
1 teaspoon baking powder
2 tablespoons of shortening.
2 cups of flour.
Salt and seasoning.
Take shortening and soda, stir together thoroughly, then add milk. Add baking powder to flour. This makes a good, large cake or a fruit cake by adding fruit and spices. It fits in well in conserving food these war times.

ALMERON S. EASTMAN,
Memphis, N. Y.

Dummy Hive

A 12-frame dummy hive made in a few minutes out of two 5-frame shipping cases.

The screened covers of the cases had, of course, been taken off when the bees were transferred into their regular hives, and all that remains to be done to make the dummy hive is to take off the screened bottoms also, knock off one side of each case, with the inside center cleat of each, and fasten the two cases together side by side by means of these same cleats, nailed on the outside of the case ends across the middles, so as to form handles as well as hold the cases together. The slotted cleats on the inside of the end boards, which served to hold the bottoms of the frames in place during shipment, are to be pried off, as they take up the room of two extra frames, besides time when using the dummy. The bottom boards, with the screen removed, can be nailed on again if desired, thus completing a very light, handy holder for extra combs in the honey-house, or for use while looking over the hives in the apiary. Other sizes of shipping cases can, of course, be put together in the same manner.

MARGARET ULLMAN,
Highland Park, Ill.

Ladies' Bee Apron and Dress Combined

It is unnecessary to get stung when we can provide against it.

One of the inconveniences for bee-keeping ladies is that bees climb up into their clothes and not only give them a disagreeable feeling of insecurity, but often expose them needlessly to stings. In order to be sure of one's self one must not be under the fear of having the bees crawl up under one's clothes.

Mrs. Odier, of near Geneva, Switzerland, who helps her husband in his apiarian operations, is very sensitive to bee stings, which cause her great pains and swellings, with fever for several days. It became necessary for her to devise a practical suit which could be readily drawn over

Bee dress used by a Swiss woman, Mrs. Pierre Odier, of Geneva, Switzerland

keeping. If only the personal pronoun of the successful beekeeper on the convention floor were all. But HIS honey, HIS business, and the way HE works the bees, are only symptoms. The disease itself is prevalent among beekeepers and common to other pursuits as well.

A woman is eager to help. A man takes that help as a matter of course, tolerantly if somewhat inefficient, and with hostility if she should be indiscreet enough to show too much intelligence, or if, perchance on some occasion she neglect to ask HIS advice on some minor point.

If she works too slow, she is lazy; if too rapidly, then she is trying to drive HIM; if she does her work with exquisite care, she is old-maidish, and if she puts it through in a hurry, she automatically acquires the title of a "slouch."

But woe to the woman who discovers anything whatsoever, either right or wrong, with HIS bees. Also woe to the bees. Whole colonies can

perish (by starvation or disease) while waiting for HIM to make the discovery. Similarly the woman may close the entrances to weak colonies, only the next day to find them robbed out, because HE thought the bees needed more air, and that women were something of a nuisance monkeying around HIS bees.

Why should women work either for love or praise from their husbands? Why not work for the wage that is justly theirs? Or, better yet, the rich relative failing to depart this life at the psychological moment, why not appropriate a portion of the capital which (theoretically only) belongs to her by virtue of having helped HIM in its accumulation, and be an apiarist in her own right?

Perhaps (?) he would lend a helping hand occasionally, and perhaps she would be kind and well-bred, or, to sum it up in one word, JUST, and say "OUR bees."

A HELPER.

has made some mistakes. Because it stands for education and extension work in beekeeping, some will not support it—selfish motives. This retards the growth of the National little compared to the indifference of the majority of the rank and file of beekeepers who overlook what might be accomplished by a strong organization.

In these times it is not necessary to mention the benefits of organization; we see it on every hand, trade, industrial, fraternal. Even the beekeepers are waking up, owing to Government extension work, and are forming County and State associations better than before. This seems the best way to make a solid foundation for a National organization and I expect in time to see all these affiliated with the National Association.

The National has no publicity department, it is only through the courtesy of the bee journals that it is possible to reach the beekeepers. To each of you that reads this, I say: Why throw the expense and responsibility of the National work on a few when your support would make an organization that would be able to do what even the most optimistic have thought possible? Forget the past, think of the future if you wish, but remember nothing is certain but the present and the present need of the National is members. Officers of local and State associations, you could help greatly. Some State Secretaries are sending in lists of new members each week, why not you? The annual dues to the National Beekeepers' Association are \$1.50 per year. To become a member it is only necessary to send this amount to the Secretary-Treasurer or pay it to your local or State Secretary, who will send it on. You will get a receipt by return mail. You will NOT get a year's subscription to the "Domestic Beekeeper, or any other magazine,

MISCELLANEOUS NEWS ITEMS

The Northeast Kansas Beekeepers' Association held a very profitable field meet at the apiary of O. A. Keene, Topeka, on the afternoon of April 18, 1918. Mr. E. W. Atkins, of the Entomological Department of the Extension Department, Washington, D. C., was present and gave demonstrations in handling bees, transferring, etc., and gave an interesting talk on general management of bees. A large and enthusiastic crowd attended the meeting, showing increased interest in beekeeping.

A. R. HOCKENSMITH, Pres.

Beekeeping at the University of Missouri.—The Department of Entomology of the University of Missouri has been offering courses in beekeeping for the regular University students for the past five years, and during the past two years special courses have been offered for agricultural students in the short winter course. The courses have been well attended and have attracted many men and women who have had years of practical experience in handling bees. Women, as well as men, select the course in beekeeping and a number of students on completing their university course have been pushing beekeeping in their respective communities.

Missouri was one of the first States of the middle west to recognize the possibilities in beekeeping and the importance of offering fundamental instruction in beekeeping along with other agricultural courses. Missouri, with more bees than any other State in the Union except Texas, offers some unusual opportunities in beekeeping. However, the big bee problems, wintering, pasturage, etc., have as yet been scarcely touched. With

an army of men and women with scientific training in beekeeping distributed over the State to co-operate with this Department, the Missouri Apicultural Society and State and Federal Extension workers, the solution of many of Missouri's bee problems will be simplified. Every Missourian who keeps bees must be reached with fundamental information on up-to-date beekeeping.

The National.—The National Beekeepers' Association has in the past done much for the beekeeping fraternity. In the opinion of some it

Fig. 1.—Class of agricultural short course students assembling hives and hive equipment in the insectary of the Department of Entomology, University of Missouri

included, as formerly. The National is not financially interested in any bee journal, but National members can secure, through the Secretary-Treasurer, any or all of the bee journals at 75c each per year. This offer is good for the rest of this year only. If you wish the Market News Service on honey, issued by the Bureau of Markets, direct from Washington, mention it when you send in your dues.

FLOYD MARKHAM.

Beemen to Encourage Increased Production.—Beekeepers are quietly insuring to Wisconsin a source of sugar other than that secured from beets and sorghum cane by their encouragement of the beekeeping movement in many of the towns of Wisconsin. To further the development of the industry the following bee meetings are scheduled for June:

Wausau, June 1; Stevens Point, June 3; Grand Rapids, June 4; Marsh-town, June 5; Owen, June 6; Lady-smith, June 7; Baron, June 8; Chip-pewa Falls, June 10; Eau Claire, June 11; Menomonie, June 12; Baldwin, June 13; Ellsworth, June 14.

G. H. Cale, a beekeeping extension agent from the United States Department of Agriculture, will attend each meeting, and will speak to Wisconsin beekeepers on the patriotic value of the industry and the latest methods of furthering the production of honey.

H. F. Wilson, of the Department of Economic Entomology of the College of Agriculture, will attend many of the meetings to lead the discussion on experiments in beekeeping out at the experiment station.

Fermenting Honey—A Practical Result

In our number for April, 1917, page 121, the editor told of a visit at the apiary of Mr. Irving Kenyon, of Camillus, N. Y., and of the peculiar trouble experienced by this practical and wideawake beekeeper. Mr. Ken-

yon's honey crops were subjected to a peculiar trouble. The honey fermented in the cells and often burst the cappings, being decidedly sour. We suggested that it might be due to some peculiar blossom. But Mr. Kenyon thought it due to a microbe within the hives, perpetuating itself from year to year. The trouble was so annoying that our friend resorted to the extreme remedy of transferring all his bees to sheets of foundation, in the spring, and melting all the old combs into wax. He now writes:

"You will remember our talk about honey souring. Well, I promised to report my success this season with the shake plan as used to cure American foulbrood. I don't pretend to know the cause of this trouble, but after 15 years' experience with it I am well satisfied that it is contagious and is spread by robbing. Not having a single colony that did not not show it in 1916, this year (1917), after shaking, I saw it in less than one-fourth of one per cent of the honey. I expect to shake again this season, and think that will clean it out entirely. I believe more of this trouble is getting a foothold than beekeepers are aware of.

"IRVING KENYON,
"Camillus, N. Y."

Preserving with Honey Instead of Sugar.—A lecture-demonstration will be delivered in various cities of Massachusetts during May and June. (If the demand for further lectures is warranted, it may be possible to engage Mrs. Hutchinson after July 1. Requests should be made to the undersigned.)

Mrs. Mary E. Hutchinson, of Wakefield, Mass., has been engaged to speak in various cities of Massachusetts on Saturday afternoons, on methods of preserving with honey; even 100 per cent honey can be used. It is generally believed that honey

will not serve in jellies, but Mrs. Hutchinson demonstrates that 100 per cent in these is practical.

The first lecture was given in Worcester on May 18, at Horticultural Hall, at 2:30 p. m. At this time, also, there was a regular monthly meeting of the Worcester County Beekeepers' Association, and the regularly announced meeting of the Federated Massachusetts Beekeepers' Association, Inc., as guest.

In Springfield, Mass., it is arranged for Mrs. Hutchinson to speak on June 15, in the Mahogany room of the Municipal Auditorium. This meeting will be under the auspices of the Hampshire, Hampden, Franklin Beekeepers' Association, which will convene at 2 p. m.

Mrs. Hutchinson's future engagements are subject to arrangement. Inquiry concerning them should be made to the undersigned.

Mrs. Hutchinson is not only a beekeeper, but a most practical user of honey, in preserves and in many other ways. Her suggestions, which are plain, every-day and practical, are very helpful. Since sugar is not plentiful, nor is it immediately expected to be, honey can well be substituted in preserves. It is anticipated that Mrs. Hutchinson will be found most beneficial to her audiences. These lectures are entirely free and held by arrangement of the Massachusetts Agricultural College. All interested are urged to attend.

B. N. GATES,
Amherst, Mass.

Bee Literature in Our Local Libraries.—Many of the public libraries of our State and nation are fully aroused to the seriousness of the food situation, and with this in mind they are making every effort possible to provide literature on all phases of the subject of Food Conservation and Food Production.

One of the food articles we are urged most earnestly by the Federal Food Administration to conserve is sugar. The best way to save sugar is to increase both the production and the consumption of honey as a substitute for sugar.

The librarians of our State have been provided with a very excellent list of the best books and pamphlets on the subject of Bees and Honey, and they have been urged to secure all of the literature included in this list. In this effort the librarians would be greatly aided and encouraged if every keeper of bees would get in touch with his local library and would aid the librarian to select and secure the best literature suitable to the community, and would then take steps to advertise the bee literature which is in the library.

A practical illustration of the excellent co-operation that can be given by beekeepers was shown at a recent Food and Garden Show in the Public Library at Dixon. At this Food Show, Mr. C. O. Engel gave a talk on the subject of sugar and honeybees. He also contributed some excellent pamphlets which he had

Class of short course students at the University of Missouri getting practical experience in handling bees

gathered on bees and honey and made several excellent posters on the subject. This co-operation was greatly appreciated by the librarian, Miss Mary F. Wynn, and did much to arouse local interest in the literature which she had gathered in her library.

It is most earnestly hoped that those interested in this important

subject will make an effort within the near future to get in touch with their local librarian and manifest by this interest an appreciation of the librarian's effort, and willingness to co-operate with the librarian in advertising this literature.

Library Publicity Director,
Urbana, Ill.

LEGAL SERVICE DEPARTMENT

Are Bees Taxable?

I am writing to enquire whether bees are taxable. They tell me they can tax my bees, as they are personal property. LOUISIANA.

In most States bees are taxable, the same as any other personal property. The exceptions are States where a specific provision of law exempts them. In Iowa the law exempts ten colonies from taxation. The Iowa Beekeepers' Association has asked that this provision be repealed, since the specialist must pay taxes on his bees while the careless man with only ten colonies does not pay any taxes. There is no apparent reason why the man who invests his money in bees should not pay taxes on the same basis as though he owned cattle instead. The same rule applies generally.

Forcing Move of Bees

One of my neighbors has complained to the county attorney about one of my bees stinging her. They are trying to force me to move my bees. Only two swarms have clustered outside my yard in the three years I have kept them in the present location. There is no other convenient location to which I can move them. Can you tell me what to do about it? MINNESOTA.

A man has the same right to keep

bees that he has with any other property. However, the public has some rights which he is bound to respect. If the bees are so situated that they are a source of danger and annoyance to the neighbors, they should be moved, otherwise not. The fact that one of the neighbors received a chance sting would probably not be sufficient cause to compel you to move, for it is very possible that there are other bees in the neighborhood, and one might get a sting even though your bees were moved away. You should build a high fence or other protection to turn the line of flight away from the highway so as to endanger those passing by as little as possible.

An occasional gift of honey to near neighbors will do much to insure the friendship of those near by and insure friends who will support you in case complaint is filed.

The beekeeper who lives in a city or town should take every possible precaution to so place his bees that they are as far as possible from walks and streets and so placed that the line of flight is above the heads of passersby.

This subject is fully discussed in chapter 10 of Productive Beekeeping.

DR. MILLER'S

ANSWERS

Send Questions either to the office of the American Bee Journal or direct to
DR. C. C. MILLER, MARENGO, ILL.
He does not answer bee-keeping questions by mail.

European Foulbrood

I am running for extracted honey. I have been keeping bees for twenty odd years, and have never had any trouble with bee diseases up to the present season. I now have the European type of foulbrood, and have about 50 colonies diseased. Last fall (September) I prepared the bees for this season, leaving approximately 40 pounds of stores on each hive, so now there is much honey with the bees. We have some nectar coming in, but our flow will not come until later. Now, Doctor, I have heard that you know how to handle this type of brood disease, and save the combs. Will

you please write me how it can be done, and at the same time not spread the disease. There are plenty of stores in the brood-chambers. I do not know what to do with these combs of honey and dead brood. CALIFORNIA.

ANSWER.—It is quite possible to save the combs affected by European foulbrood, but if the disease is American foulbrood, the combs cannot be saved. The first thing in the treatment is one of very great importance, and that is to see that the colonies to be treated are strong. Generally they are weak, and must

be made strong by the addition of brood or bees, or both, even if it requires doubling up several colonies to make one strong one.

The next step is to stop the laying of eggs for a period of ten days. If the case is a severe one, the queen is practically certain to be poor, and should be killed. Even if the case is a mild one, and the queen is poor, kill her, and plan to have another queen laying in her place ten days later. You can do this by giving a ripe queen-cell or a virgin just hatched, giving it at the time you kill the queen; or you may give a young laying queen ten days after killing the old one.

In any case, the cell, virgin, or laying queen should be of best Italian stock, for it is generally agreed that such stock is better to combat the disease than blacks or hybrids.

If the case is a mild one, with a good queen, merely cage her in the hive for ten days, and then free her.

The old combs of honey and brood are to be used just as if they were not affected, for the chances are not great that the disease will re-appear, but I should not want to use such combs in perfectly healthy colonies, for there is a chance they might introduce the disease.

To sum up, make your colonies strong, stop egg-laying for ten days, and see that at the end of the ten days each colony has a laying queen of best Italian stock. You may count pretty safely on the success of such treatment, simply treat it over again.

Swarm Prevention

How will the following do for swarming colonies? I am working for comb honey.

Set a hive filled with sheets of foundation and one comb of brood on the old stand, shake most of the bees and the queen into this, leave only enough bees to care for the brood in the old hive. Now put the comb-honey supers on the new hive, on top of the supers put a frame with mosquito netting, in the center of which is a Porter bee-escape; on top of this the old hive with brood and bees, the cells being cut out as fast as the brood hatches. The bees trying to get out cannot go back, so the swarm will get all the young bees, and it will be in almost as good a condition as if it had not swarmed, except the building of combs. I don't know if it has been tried, most likely so, but I never saw it in the papers. INDIANA.

ANSWER.—The bees will make short work of tearing out the netting, and even if they didn't they would carry down black bits of comb from above to darken the cappings of the sections.

Foulbrood

From what I read, the foulbrood is not in the new nectar coming in, so it must lie between the queen and the nurses, presumably the queen.

Now, Doctor, is this disease caused by inbreeding? If so, would it not be a good plan to requeen every two years with Italian queens?

The black or native bees seem to have the disease the worst, so I have about convinced myself that it is caused by too close breeding. CALIFORNIA.

ANSWER.—No, the disease is not in the nectar. If you should change the queen of a diseased colony without for a minute stopping the egg-laying, the disease would continue. So you can hardly lay it to the queen. If you give a comb of diseased brood to a set of the best nurse-bees in the world, you may confidently expect the disease to spread itself cheerfully through the hive. So it would hardly be just to say that the fault was due to the wrong kind of nurses. No, the real culprit is a measly little beast of a microbe that is fed to the larva.

The worst case of inbreeding in the world will not result in foulbrood, unless that fatal microbe be fed to the babies; so changing the

queen would not be the thing unless it should be that the change should bring more vigorous and resistant stock; and in that respect a change of queen might be important.

Drone-Cells—Brood -

1. I understand that drone-cells are preferred by bees for storing honey, for the reason, as I suppose, that such cells permit easier ingress and egress and require less wax and labor to produce for a given area. Why, then, should not we use drone-comb for storage purposes for extracting?

2. Is the spreading of brood to be recommended in building up a colony? If not, why?

CANADA.

ANSWERS.—1. I'm not so sure about bees preferring drone-cells for storing honey. I know they prefer them at times for rearing drone-brood, and I've known them sometimes to go a little outside the brood-nest for the sake of rearing drone-brood. I don't think I ever knew them to go out of their way to store honey in drone-cells. I don't know, however, that there's any objection to having drone-comb in the extracting chamber, unless it be that sometimes bees are a little slow about filling honey in drone-cells, perhaps holding them open with the idea of having the queen lay in them.

(We much prefer worker comb to drone comb in the contracting super, as the queen sometimes gets into the super and might produce a large number of drones.—Editor.)

2. Some advocate and practice it. I haven't practiced it for many years, because there's too much danger of chilling brood. Besides, I'm not sure I gain anything by it, since of their own accord the bees start all the brood they can cover, and why should you want any more?

Swarming—Kinds of Queens

1. Is it better to let the first swarm come out, or to brush them by the brushed swarm plan?

2. Will there be any other natural swarms come out after the first natural swarm? If so, should it be prevented?

3. Why can more honey be produced by extracting than by running for comb honey? What is the usual price of pure extracted honey?

4. What is the difference between tested and untested queens? Is it that tested queens are mated and untested ones are not?

KANSAS.

ANSWERS.—1. If it be convenient for you to watch for the swarm, especially if you have not much experience, it is better to let the bees swarm naturally.

2. One or more afterswarms are likely to issue, and this should be prevented. When the prime swarm issues, hive it and set it in place of the old hive, setting the old hive close beside it, facing the same way. A week later move the old hive to a new stand 10 feet or more distant. There should be no more swarming.

3. The bees don't have to build fresh comb every time they store extracted honey. The usual price for extracted honey has been somewhere about 10 or 12 cents; now it is nearer 20 cents.

4. Tested and untested queens are both mated; untested are those which are sold before their young bees have hatched out, and it cannot be told whether they are purely mated or not; tested are those whose young workers show by their markings that they are purely mated.

European Foulbrood

1. Will zero weather kill germs of European foulbrood?

2. Will it be safe to seal sealed frames of honey taken out of foulbrood hive, although these frames have had no foulbrood in them?

3. Is there danger of foulbrood appearing in spring if all brood has been removed from hives in fall and sealed frames of honey put in their place?

4. Will it be necessary to boil chaff cushions and cloths used on foulbrood hives?

VERMONT.

ANSWERS.—1. No.

2. I think there is no danger in feeding frames of honey that have had no brood in them, if the foulbrood is European, but would hardly want to risk it in case of American.

3. That treatment was recommended for American foulbrood by the late W. E. McEvoy, and so far as I know, the treatment is reliable. Just take away all combs after brood-rearing has ceased in the fall, and give combs of sealed honey from healthy colonies.

4. I think not.

Failure in Wintering

In May, 1917, I bought two hives of Italian bees (Nos. 1 and 2), Langstroth 10-frames, to begin with. Everything went well. July 14 I caught a swarm (No. 3) out of hive No. 1; July 16 a swarm left hive No. 2, but I could not get it, having entered into a hollow of an oak tree about 40 feet above ground, and it is not advisable for one 65 years old to get the high of that sort of air. A second swarm out of hive No. 1 followed those absconders on July 18, however. I had the chance to catch another swarm out of hive No. 2 on the same date. That gave me four hives (old) No. 1 and 2 (new) No. 3 and 4, and I thought to be on the way to success. My good friends seemed to be happy and I did not disturb them except during the flow, when I took out some filled frames from hives Nos. 1 and 2 for storage. October 25 I opened hives again; found Nos. 1 and 2 in very good condition—plenty of bees and honey for winter food. Hive No. 3, plenty of bees but apparently not enough honey; so I gave them two full frames of honey out of above stores. Hive No. 4, not so many bees and honey; so I also gave them two full frames of honey. November 16 I placed all four hives in a shed with hinged roof, located on a terrace of a hill sloping south. I placed one foot of marsh hay on the wooden floor, then boards over that, and the four hives on this, close together. The bees kept flying until cold weather came. I then placed cushions filled with chaff around the sides and backs of hives, Alexander feeder under hives 3 and 4 and some hay over the hives. Before this I had put on top of each hive a queen-excluding board, then a piece of woolen carpet and thereon the cover, also contracted hive No. 4 with division board and placed some woolen carpet between the walls of the hive. The entrances of hives 1 closed with wire netting, 3 meshes to one inch, and then I placed three entrance blocks in front of this, leaving an opening of $\frac{3}{4}$ inch. When the thermometer dropped to 12 and 20 below. I covered the hive with marsh hay on north and west sides. Then nature put two feet of snow on all this protection. I kept the entrance clear of snow by placing a slanting platform in front of each hive.

February 24, as the thermometer showed 65 degrees above at noon, I opened the entrances of the hive, taking away the blocks, and a few bees came out of hives Nos. 1, 2 and 3; they also carried a good many dead bees. Hive No. 4 didn't move up, in spite of my knocking. I then closed the entrances again with the blocks as before.

March 18, noon 68 degrees, I opened the roof of shed, took off the covers from the hives and I found that bees in all four hives were dead.

The bees were in clusters between the frames; also in hive No. 2, on top of the frames. There was plenty of food in hives 1, 2 and 3, and even a little left in hive No. 4.

Can you tell me what the trouble was? Did I close entrances too tight, or should I have placed a super on top of the hives?

What would you advise to do to restock my hives? Buy bees by the pound, with queen, or nuclei? would you place bees into hives just like new swarms, or must you place queen separately into hive, and where, on top, or under frames?

WISCONSIN.

ANSWER.—It is not a very safe thing to make a guess about bees in all cases, but I don't believe I can be far out of the way in

saying that the fatal thing in your program was reducing the entrance to three-eighths of an inch square. At the very least the opening should have been eight times as large.

If you cannot buy bees near home, and have to send south, it will probably be better for you to get combless bees by the pound, say in 2-pound packages with a queen in each package. A good way is to put the package of bees inside the hive beside the combs, allowing the bees to go upon the combs gradually, keeping the queen caged for a day or so.

(Bees by the pound are hard to get now. Better buy some swarms in your vicinity if you can.—Editor.)

Swarm Prevention

1. In destroying queen-cells to prevent swarming, how are we to determine whether the cell in question is to produce a queen to take charge of the hive, when the old queen goes out with a swarm, or whether it is a case of superseding?

2. How successful is the entrance guards as a preventive of swarming? Have you any objections to it?

IDAHO.

ANSWERS.—1. No one can tell by looking at a queen-cell whether it is intended for swarming or superseding. Moreover, so far as we can judge the mind of a colony of bees, it sometimes changes its mind, and what was in the first place intended for swarming turns out to be superseding, and vice versa. We can, however, make a pretty fair guess at the intention of the bees by attending circumstances. If swarming is intended, there will be a larger number of cells started than for superseding. There is no positive certainty as to the number for either, but if only 2 or 3, or even 5 or 6 are present, superseding is likely to be the program; whereas, for swarming there are seldom less than ten or a dozen, and it may run away beyond that. If cells are found at what is usually swarming time, or when other colonies are swarming, the probabilities are in favor of swarming; whereas, before and after swarming time, and at any time when little or no nectar is coming in, then it's a fair guess that superseding is intended.

2. A queen-excluder at the entrance does not in the least prevent swarming. The bees are just as sure to swarm with as without one. But it will hold the queen, and when the swarm finds the queen is left behind, it will return, and the beekeeper who is away from home when the swarm issues can do whatever is needed to be done at his convenience in the evening, or in the next few days. But if the colony is left without attention, in the course of a week or ten days, the first young queen will emerge, the bees will continue swarming and returning, and after sufficient time the old queen having been put out of the way, the young queen will begin laying without mating, producing only drones, and the colony is doomed. Except as mentioned, I would not think of trying to prevent swarming by any attachment at the entrance.

Hybrid or Italian Stock

On page 135, American Bee Journal, Kansas says he has a hybrid queen that produces pure Italian drones. I thought that I had learned that according to Dzierzon the drone is without paternal percentage, that a black queen mated with an Italian drone produced pure black drones, but mixed workers and queens. Having recently lost all my bee literature, together with my house and contents, by fire, I have nothing to refer to. But, Doctor, speak low, so P. C. Chadwick doesn't hear, because if I am mistaken I just know he will laugh.

MICHIGAN.

ANSWER.—You are right that a black queen mated with an Italian drone produces pure black drones, also an Italian queen mated with

a black drone produces pure Italian drones. Kansas says his hybrid queen produces pure Italian drones. Possibly you may say that a hybrid queen should produce hybrid drones. So she should if she contains mixed blood herself. But Kansas may say that no matter how pure the Italian blood in a queen, if she meets a black or hybrid drone, she cannot be sold for a pure Italian queen, and a hybrid queen of that sort will produce pure Italian drones. Fight it out yourselves.

Classified Department

Advertisements in this department will be inserted at 16 cents per line, with no discounts of any kind. Notices here cannot be less than two lines. If wanted in this department, you must say so when ordering.

BEEES AND QUEENS

FOR SALE—Colonies of extra fine strain Italian bees, with select tested queens, in new 1-story 8-frame single wall-hives, standard full-depth, self-spaced Hoffman frames, \$10 each, f. o. b. here. The bees are free from disease. Wilmer Clarke, Earville, Madison Co., N.Y.

FOR SALE—Italian queens from best stock; produce gentle, excellent honey gatherers; very prolific and unexcelled winterers; untested, 90¢; 12 for \$10; tested, \$1.30; select tested, \$1.75; extra select tested, \$2.50; breeders, \$5; pound packages, per lb., \$1.50; nuclei, per frame, \$1.50. Add price of queen wanted. Prompt deliveries. Special prices in quantities. Golden Queen Apiaries, R. Kornegay, Jr., Mgr., Mt. Olive, N. C.

OUR BRIGHT ITALIAN QUEENS will be ready to ship after April 15. Untested, 75¢ each, \$8 per doz., or \$65 per 100. Safe arrival guaranteed. Tillery Bros., Georgiana, Ala., Route 6.

BEEES AND QUEENS from my New Jersey apiary. J. H. M. Cook, 147 84 Cortland St., New York City.

TESTED leather-colored queens, \$2.00; after June 1, \$1.50; untested, \$1.00; \$10 per doz. A. W. Yates, 3 Chapman St., Hartford, Conn.

GOLDEN Italian Queens, untested queens, \$1 each; six, \$4.25; \$9.25 per doz., 50, \$32.50; \$60 per 100. Tested queen, \$1.50; one frame nucleus, no queen, \$1.25; 2-frame, \$2.25; 3-frame, \$3; breeders, \$9 and \$10. L. J. Dunn, 54 Broadway Ave., San Jose, Cal.

OUR select bred mated queens winter well. Honeycomb Apiaries, Yakima, Wash.

FOR SALE—Warranted queens from one of Dr. Miller's breeders, \$1 each; \$10 per doz.; tested, \$1.50 each; 2-frame nuclei without queen, \$3; 3-frame \$4.50; add price of queen if desired. Full colonies, 10-frame, \$10; 8-frame, \$9; in Danz. hives \$8 each; tested queens in all colonies. We are sold out of package bees. Our yards are free from disease. Geo. A. Hammer & Son, Prairie Point, Miss.

FOR SALE—3-banded Italian queens, 55¢; ten, \$5. Circular free. O. C. Wandrie, Frazee, Minn.

FOR SALE—Pure Italian queens; goldens that are golden, and Doolittle's choice stock. Select untested (laying queens), 1, \$1; 6, 85¢; write for prices. Pure mating, safe arrival and satisfaction I guarantee. J. E. Wing, 155 Schiele Ave., San Jose, Calif.

FOR SALE—Golden Italian queens that produce good honey gatherers; no foulbrood; select tested, \$1.50; tested, \$1.25; untested, 85¢; 6, \$4.75; 12, \$9. After July 1, select tested, \$1.25; tested, \$1; untested, 75¢; 6, \$4.25; 12, \$8. No bees for sale. D. T. Gaster, R. 2, Randleman, N. C.

FOR SALE—Three-banded Italian queens; untested, one, \$1; six, \$5; twelve, \$9. Tested queens, \$1.50 each. Rob't B. Spieer, Wharton, N. J.

PURE 3-banded Italian queens, as good as you can buy with money; no disease, and every one guaranteed. Write for prices. No more nuclei or colonies for sale this season. J. P. Diemer, Liberty, Mo.

FOR SALE Italian queens; untested, \$1, or \$10 per dozen. No discounts on quantity orders. Satisfaction guaranteed. M. Bates, Greenville, Ala., R. 4.

NORTHERN BRED ITALIAN QUEENS—Ready May 1, each, \$1; six, \$5. Allen R. Simmons, Claverack, N. Y.

GOLDENS that are true to name. Untested queens, \$1; 6, \$5; 12, \$9; 50, \$35; 100, \$67.50. Garden City Apiaries, San Jose, Calif.

THREE-BANDED ITALIANS ONLY—Untested queens, each \$1; 6, \$5; 12, \$9; 50, \$35; 100, \$67.50. H. G. Dunn, The Willows, San Jose, Calif.

QUEENS BY RETURN MAIL—Choice tested queens, reared last fall and wintered in 4-frame nuclei, \$1.25; \$14 per doz. Queens of this season's rearing, untested, \$1; \$9 per doz. We breed the 3-banded Italians only and our strain is known for gentleness and honey gathering qualities. Every queen guaranteed. Never a case of foulbrood in our apiaries. J. W. K. Shaw & Co., Loreauville, La.

FOR SALE—Fine Italian queens at 90¢ each, \$9 per doz. Ready April 16. Safe arrival guaranteed. T. J. Talley, Route 3, Greenville, Ala.

BOTH Italians and hybrid bees at \$2.50 per pound with untested queen; 2 pounds, with queen, at \$4. Mrs. T. H. Carruth, Big Bend, La.

GOLDEN ITALIAN QUEENS—No better honey gatherers anywhere at any price. Untested, \$1; tested, \$2. Wallace R. Beaver, Lincoln, Ill.

THE Sinking Creek Queen introducing Cage; 5 years' test of absolute success; indisputable for introduction of valuable queens; also several queens can be kept in one hive in perfect harmony; small and works on the brood comb; especially adapted for queen breeders. Price 60¢ per doz., 2 doz. for \$1; post paid. Sinking Creek Apiaries, Gimlet, Ky.

SWARTS GOLDEN QUEENS produce golden bees of the highest qualities; satisfaction guaranteed. Mated \$1; 6 for \$5; tested \$2. D. L. Swarts, Lancaster, O., Rt. 2.

FINEST ITALIAN QUEENS, June 1 to November, \$1 each; 6 for \$5. My circular gives safe methods; free. J. W. Romberger, 3113 Locust St., St. Joseph, Mo.

QUEENS—H. D. Murry's strain of 3-banded Italians; reared by the Doolittle method. Prices untested, 1 for \$1, 6 for \$5, 12 for \$9. No disease. Safe arrival and satisfaction guaranteed. Route 4, Honey Grove, Texas.

FOR SALE—3-banded Italians; queens from best honey-gathering obtainable. Untested queens, \$1; 6 for \$5; 12, \$9. Safe arrival and satisfaction guaranteed. O. B. Rix, R. 1, W. T. Purdue, Ft. Deposit, Ala.

GOLDEN QUEENS that produce Golden workers of the brightest kind. I will challenge the world in my Golden and their honey-getting qualities. Price, \$1 each; tested, \$2; breeders, \$5 and \$10. 2Atf J. B. Brockwell, Barnett's, Va.

GOLDEN and 3-banded Italian queens will be our specialty. We can also furnish Carniolans. Tested, \$1; untested 75¢ each. Bees, per pound, \$1.50; nuclei, per frame, \$1.50. Send your orders for bees early. C. B. Bankston & Co., Buffalo Leon Co., Tex.

THREE-Banded and **Golden** Italian Queens and pound packages in spring, from the Sunny Southland. Grant Anderson, Rio Hondo, Texas.

THREE-BANDED Italians; untested queens in April and May, one, \$1; 6, \$5; 12, \$9. Tested, \$1.50 each. One-pound packages of bees, \$1.50 each; two-pound packages, \$2.00 each. Add price of queens if wanted. If you want as many as 50 packages write for prices and discounts on early orders. Safe arrival and satisfaction guaranteed. No disease, and all queens purely mated. Cotton Belt Apiarie, Box 83, Roxton, Texas.

SELECT bred, mated queens, \$1 each, prepaid. Bred from the selected stock of eleven yards total over 1,500 colonies of bees run for commercial honey production. Only one grade of queens—no culls sold, \$10 per dozen, prepaid. Honeycomb Apiaries, 402 N. Fifth Ave., Yakima, Wash.

HONEY AND BEEWAX

Dealer in all kinds of Bee Supplies.

SITUATIONS

WANTED—Reliable, energetic and alert beekeeper, or student helper, in largest series of outapiaries in northwest. Work for extracted honey and all equipment and methods strictly modern. Give age, height, weight, experience, references and wages expected in first letter.
The Hoffman Apiaries, Janesville, Minn.

"Practical Queen-Rearing"

Is the title of the new bee book, cloth bound, 100 pages, which has just been written by Mr. Frank C. Pellett, who is well known to our readers.

For many years there has been a demand for a book which would give in concise form the many different methods of queen rearing, as the Doolittle, Pratt, Dines, Miller, Alley and others with variations as practiced by different large breeders.

You have this in the new book which is just out. Send for your copy now and get informed as to your best method of rearing queens from your best colonies. Good pointer in it also for the large beekeeper and veteran queen breeder.

Price, postpaid, only \$1.

By special arrangement we can offer it and a year's subscription to the American Bee Journal for only \$1.75.

(Canadian orders 15 cents extra.)

QUEENS Hardy, Long Lived and Disease Resisting QUEENS

Twenty-Two Years of Select Breeding Gives Us Queens of Highest Quality--Queens for Honey Production--Queens of Unusual Vitality

"There are few Queens their equal and none better."

WHAT BEES DO, HEADED BY OUR QUEENS

"One swarm made 185 sections of honey and another 296 sections. I am well pleased."—MELVIN WYSONG, Kimmell, Ind.

"Your bees averaged 150 pounds of surplus honey each. I find them not only hustlers, but gentle."—FRED H. MAY, Meredosia, Ill.

"I have tried queens from several different places and like yours best of all."—C. O. BOARD, Alabama, N. Y.

"We are only one mile from Lake Erie and exposed to high, cold winds; in fact, this is the windiest place along the great lakes. Your bees were able to stand the winter with only an insignificant loss, and we would have no others. As for honey, they averaged 175 pounds of extracted surplus, did not swarm, and gave an artificial increase of 30 per cent, which is as fine a record as can be had in this locality, especially when the work is done entirely by amateurs." Name furnished on request. North East, Pa.

Price List of Our Golden and Three-Banded Italian Queens

Untested	\$1.00; 25 or more, \$.90 each	Select untested	\$1.10; 25 or more, \$1.00 each
Tested	1.50; 25 or more, 1.40 each	Select tested	1.75; 25 or more, 1.60 each

We guarantee safe arrival of all Queens, that they are very resistant to European foulbrood, and, in fact, will give complete satisfaction. Wings clipped free of charge. Our capacity is 2,000 Queens monthly.

M. C. BERRY & COMPANY, Hayneville, Alabama, U. S. A.

Crop Report and Market Conditions

In our report for this month we have taken advantage also of the May report of the Department of Agriculture which had to do with the losses, causes, condition of bees and condition of honey plants.

Of our reporters we asked the following questions:

1. Condition of bees?
2. Number of productive colonies as compared to 1917?
3. Condition of honey plants?
4. Outlook for crop compared to 1917.
5. Prices offered for honey?
6. Honey sold and at what price?

Condition of Bees

The Department Report gives the loss of bees as about 19%, which is higher than usual. Our reporters in almost all instances agree that the bees are hardly up to normal for this season of the year, though they are coming along rapidly. In the East they are behind the average, as is also the case in the central and north central States. Minnesota and parts of Michigan and Wisconsin are above the normal, as is most of Kansas.

The whole South is still under extra good conditions, though some reports are that the crop, so far, is not up to 1917. Texas, which has had two very unfavorable seasons, now reports the bees building up fast and that at last there are some prospects that there may be something to offset the small crops of the last two years.

In the whole of the West condition of bees is fair to good.

The summary of the Department is that condition of bees is about 86% of average and a little less than a year ago.

Number of Colonies

In spite of the large increase last year and of the large increase being made this spring, it is doubtful if there will be as many bees for the crop as in 1917, though the non-productive colonies changed into productive ones may bring the average up somewhat.

In all the territory east of the Mississippi and north of the Ohio there was but one report that claimed more bees than a year ago, most reports showing from 60 to 85 per cent as many.

The South shows, roughly, about 25% more bees than a year ago, and in the Rocky Mountain region there are a few more than in 1917 with about normal for California.

Again, the Department report shows 89% as many bees as May 1, a year ago, but the large amount of package increase, etc., since may make up a part of this loss.

Honey Plant Conditions

In the New England States plant conditions are fine, with a regret from some that there will not be the bees to gather the honey there should be.

Ohio and Indiana are average, as are also Michigan and Minnesota, with parts of Wisconsin, Illinois and most of Iowa and Michigan showing poor prospects, on account of the lack of white clover.

In the whole South plant conditions are fine and Texas generally is rejoicing over the prospects as compared with a year ago. The mesquite flow promises to be good. West Texas, however, reports poor prospects as compared to a year ago, and New Mexico may hardly be up to normal.

It is too early yet to judge of conditions in the Rocky

Mountain region, although expectations are that plants will be normal except in Idaho, where it is hardly expected that the extremely favorable season of 1917 will be equalled.

California will do well if the plants range up to 1917, though in some parts they are much better.

Crop Prospects

Practically all regions except parts of Illinois, Wisconsin, most of Missouri and Iowa, West Texas and other scattered sections, claim that there will be a better average than a year ago, if the weather is favorable from now on. Many claims that the crop might be short if the drought were continued have been dispelled by bountiful rains since their reports were sent in.

The Department report shows plant conditions as being 87% as against 82% on the same date last year, but still far from the average of 92% over a series of five years. Conditions should improve, however, before the next Department report comes out.

Honey Offers

A year ago the beekeepers were being flooded with offers for their crop in advance. This year the offers are comparatively scarce, except for honey actually in hand. This is likely due to two causes. In the first place, beekeepers are not so keen to contract, but are waiting to get what price they can when the crop becomes available.

Secondly, the exportations of honey depend largely upon the availability of shipping space. We know of one offer being made by a foreign company for three or four cars of white extracted at around 20 cents f. o. b. steamer. This places the responsibility upon the shipper of finding space for his product before it can be sold.

Even though very little exportation should be made, the price of honey should still rule high, owing to the excessive demand for sweets at home.

Some offers made are as follows:

New York, 17c for white extracted.

Illinois, 15c for white extracted.

Alabama, 17c for extracted, immediate delivery.

Colorado offers from 12 to 15 cents on extracted.

Idaho, one offer of \$3 per case for comb.

California offers on extracted ranging as follows: 12½, 13, 14, 15, 16½, 13, 15 cents.

Another series of offers are being made at a stipulated market price at the time the honey is available for shipment, such price to be governed by prevailing price on same size lots.

Honey Sales

Four cars of Texas honey have been sold at 17 to 17½ cents. One sale has been made ahead in California at 12 cents for all extracted, and many more rumors of reported sales at a like price were sent in. Generally, the beekeepers are less inclined to sell than a year ago, and rightly so.

Nearly all beekeepers think that their honey should be worth at least 17 cents f. o. b. their station for white, and at least \$4.50 per case for comb.

On the basis of past performances and with the expectation that shipping space will be easier to obtain as time goes on, is there any reason to doubt that producers will be able to obtain the prices as suggested above?

An Illinois Field Meet.—On Saturday, June 29, there will be held in the large grove of O. S. Biggs, at San Jose, Ill., a beekeepers' picnic and field meet. It will be held under the auspices of the Illinois River Valley Beekeepers' Association, who have extended an invitation to everyone

possible to be present. Dr. Phillips has consented to attend.

Colorado Meet.—The Colorado Honey Producers' Association will hold a field meet and basket picnic at Longmont, Colo., Saturday, June 15, at 10 a. m. All interested in bee culture are invited to attend.

The New Jersey Beekeepers' Association will hold a Field Day in the apiary of G. Fred Jordy, one mile north of Flemington, on Wednesday, June 12, 1918. The program will consist of demonstrations by experts, such as grafting queen-cells, quick method of transferring, etc. Come; bring your lunch.

E. G. CARR, Sec.-Treas.

Statement of the Ownership, Management, Circulation, Etc., required by the Act of Congress of August 24, 1912, of *American Bee Journal*, published monthly at Hamilton, Illinois, for April, 1918:

STATE OF ILLINOIS, } ss.
COUNTY OF HANCOCK, }

Before me, a Notary Public in, and for the State and county aforesaid, personally appeared M. G. Dadant, who having been duly sworn according to law, deposes and says that he is the Managing Editor of the *American Bee Journal*, and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management, etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in Section 443, Postal Laws and Regulations, printed on the reverse side of this form, to-wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are:

Publisher, *American Bee Journal*, Hamilton, Ill.

Editor, C. P. Dadant, Hamilton, Ill.

Managing Editor, M. G. Dadant, Hamilton, Ill.

Business Manager, V. M. Dadant, Hamilton, Ill.

2. That the owners are:

C. P. Dadant, Hamilton, Ill.

II C. Dadant, Hamilton, Ill.

V M. Dadant, Hamilton, Ill.

Leon Saugier, Hamilton, Ill.

L. C. Dadant, Hamilton, Ill.

M. G. Dadant, Hamilton, Ill.

Jos. Saugier, Hamilton, Ill.

That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of the total amount of bonds, mortgages, or other securities, are: None.

(Signed) M. G. DADANT.

Sworn to and subscribed before me this 4th day of April, 1918.

H. M. CUERDEN.

My commission expires August 25, 1921.

KEEP INFORMED ON TEXAS CONDITIONS

Federal Farm Loan Bonds Supply Funds To Finance Farmers

The First Year's Work

The bond of the Federal Loan System should command the attention of all investors.

The Federal Farm Loan System is the one agency of the United States Government which will bring to America month by month, year by year, and decade by decade through all the future a high grade security, issued for the purpose of carrying out a great national agricultural policy.

The whole world looks for salvation to the American farmer.

The American farmer looks for financial help to the Federal Farm Loan System.

The Federal Farm Loan System seeks to enlist the wise investor in its movement to finance the farmer safely, soundly and conservatively, and thus save the world.

There are twelve regional Federal Land Banks, all operated under the inspection, examination and control of the Federal Farm Loan Board, a bureau of the Treasury Department at Washington.

The first of these banks to be organized received its charter March 1, 1917. Others were chartered immediately afterward. The farmers borrow through national farm loan associations. The first of these associations received its charter on March 27, 1917.

On March 31, 1918, associations had been formed to the number of 2808, or about four associations to every five counties in the United States.

About 56,000 farmers had joined these associations for the purpose of borrowing money on farm mortgages.

Loans amounting to over \$160,000,000 had been approved by the banks and on over 30,000 of these loans money had been paid to the farmers to the amount of about \$80,000,000.

And since March 31st the work has gone on—new associations have been organized; new applications have been made; new bond issues have been authorized.

And it will go on forever. So long

as investors will buy Federal Farm Loan Bonds, and so long as farmers need money and can give security this work will go on. It is a mighty movement to put farming on a better financial basis. You can enlist in it to your own profit and to the good of the Nation by buying Federal Farm Loan Bonds.

Federal Farm Loan Bonds bear 5 per cent interest, payable semiannually, May and November, and in the language of the Federal Farm Loan Act, "shall be deemed and held to be instrumentalities of the Government of the United States, and as such they and the income derived therefrom shall be exempt from Federal, State, Municipal and local taxation." It will be noted that this exemption is complete. Interest on these bonds need not be included in income tax returns.

Such exemption from taxation in a five per cent bond constitutes an advantage hitherto unknown in American investments. These bonds are issued in denominations of \$25, \$50, \$100, \$500 and \$1,000, and in either coupon or registered form. They are due in 20 years and redeemable after 5 years.

Federal Farm Loan Bonds are printed in the Bureau of Engraving and Printing in Washington, and have the same protection against counterfeiting that is enjoyed by the currency in your pocketbook.

In the language of the Farm Loan Act, Federal Farm Loan Bonds "shall be a lawful investment for all fiduciary and trust funds and may be accepted as security for all public deposits." You can offer your banker no better collateral. You can buy Federal Farm Loan Bonds at 101 and accrued interest. Order through any bank, trust company, broker or express agent, or write to any of the twelve Federal Land Banks:

The Domestic Beekeeper

AT HALF PRICE

There are many readers of **American Bee Journal** who have never taken the **Domestic Beekeeper**, consequently, do not know what we are doing for our subscribers. Here is our special offer: The price of the **Domestic Beekeeper** is \$1 per year. Send us 50c for the last half of 1918 and we will mail you the back numbers for the first half of 1918, so you will receive a full year for the 50c—just half price. This offer is good for the first 200 subscriptions received, as we have only 200 full sets to offer.

Buy your 60-lb. cans through us—only 98c per case of two, from Detroit, Mich. Beekeeper supplies bought for our subscribers at a considerable discount from catalog price.

Have your foundation made from your own wax; our proposition is a good one. Any make of foundation or supplies you prefer, shipped direct from the factory to you without the middleman's profit.

Remember that 50c pays for the **Domestic Beekeeper** for all of 1918; also, our large buying experience is at your service.

You will need the **Domestic Beekeeper** to keep in touch with the minimum price-fixing committee, appointed by the Chicago Northwestern Association, of which the editor is one, to be in shape to intelligently place a price on your 1918 crop of honey. This committee saved producers something like \$500,000 on their 1917 crop and expects to do even better this year.

An enterprising honey producer cannot afford to be without the **Domestic Beekeeper** at this especial time. The **Domestic Beekeeper** (successor to the Review) is the producer's own journal, having no interests excepting the producer.

Address, with your 50 Cents

The Domestic Beekeeper

Bee Catalogue now

Big Money? — Yes — Read How

If your banker said to you, "Mr. Brown, buy that piece of land next to you at \$100 per acre; it will be worth \$2,000 per acre this coming summer," would you buy it today, or wait—well, until later on? We are sure you would not delay one moment.

We offer you the same kind of buy—that is, make \$20 on each \$1 invested. Buy your sections and bee-supplies *now*, for the sections cost less than \$1 per hundred, and next summer, when they are filled with honey, they will be worth \$20—think of it, those same sections that you bought for \$1. The same holds good on other supplies. **ORDER NOW** and tell your neighbors the same, or Mr. Railroad Embargo "will buy that piece of land next to you and you'll be left."

OLD COMB

Ship your old comb and cappings to us for rendering. We charge you 5c per lb. for the wax rendered and pay you the highest market price.

WAX AND HONEY

We always buy Comb and Extracted Honey, as well as Beeswax, so when you have the above to offer, write us and you will be well pleased.

THE FLOWER AND THE BEE PLANT LIFE AND POLLINATION

By JOHN H. LOVELL,
Botanical Editor of "The A B C of Bee Culture"

Every beekeeper needs this volume in order to understand the honey flora. Descriptions are given of bee-flowers, humblebee-flowers, butterfly-flowers, hawk-moth flowers, flowers pollinated by the wind, and many others. It will also be of great interest to gardeners, fruit-growers and lovers of nature generally. It is fascinating, not only because of its very great informative value, but because of the sense which it imparts of the beauty of nature as revealed in the subject. Do you know why some bees visit only one kind of flower? Or how many flowers there are of each color in eastern North America? Or whether bees and butterflies prefer certain colors?

Illustrated by 119 photographs taken by the author, chiefly of flowers natural size. \$2 net.

Will be sent postpaid on receipt of price, by JOHN H. LOVELL, Waldoboro, Maine.

Charles Scribner's Sons, Fifth Ave., New York

New Bingham Bee Smoker

NEW BINGHAM BEE SMOKER

In 1878 the original direct draft bee smoker was invented and patented by Mr. T. F. Bingham, of Michigan. Mr. Bingham manufactured the Bingham Smoker and Bingham Honey Knife for nearly thirty-five years, and in 1912, becoming a very old man, we purchased this business and joined it to our established business of beekeepers' supplies and general beware. Those who knew Mr. Bingham will join us in saying that he was one of the finest

men, and it gives us much pleasure to help perpetuate his name in the beekeeping industry.

Bingham Smokers have been improved from time to time, are now the finest on the market, and for nearly forty years have been the standard in this and many foreign countries. For sale by all dealers in bee supplies, or direct from the manufacturers.

Smoke Engine	Size of Stove	Weight	Retail
Doctor	4 x7-inch	2 1/4 lbs.	\$1.25
Two above in copper, extra each	3 1/2 x7-inch	2 lbs.	1.00
Conqueror	3 x7-inch	1 1/2 lbs.	.50
Little Wonder	3 x5 1/2-inch	1 1/4 lbs.	.65

Hinged cover on the two larger sizes. Postage extra.

BINGHAM HONEY UNCAPPING KNIVES

WITH NEW GOLD HANDLE

We are furnishing the same quality steel, best money can buy, thin-bladed knives that Mr. Bingham manufactured years ago. The old-timers all remember these knives and many are writing in, as Mr. Volstad in the following letters. The substitutes offered by others have not given the satisfaction desired.

Lyle, Minn., June 21, 1917.

A. G. Woodman Co.
Gentlemen: Have you the thin, good working uncapping knives we used to get about 20 years ago and that worked to perfection?

K. H. VOLSTAD.

We sent an 8 1/2 and 10-inch knife and received the following letter:

Lyle, Minn., July 5, 1917.

A. G. Woodman Co.
Gentlemen: Knives received; glad you sent them at once. They are just what I want and have been looking for, but did not know where to get them.

K. H. VOLSTAD.

Many of the most extensive honey producers insist on the Genuine Bingham Knives. Mr. N. E. France, of Platteville, Wis., gave us a fine unsolicited testimonial on the steam-heated Bingham Knife, too long for this space.

Blades	Weight	Price
8 1/2-inch blades	12-oz.	\$.90 each
10-inch blades	14-oz.	1.00 each
10-inch blades, steam heated with tubing	20-oz.	3.00 each
Steam Generator, with safety valve	40-oz.	2.00 each
Double Burner Oil Lamp Stove	7 lbs.	2.75

Postage extra

A BOOK FOR BEGINNERS

"First Lessons in Beekeeping," written by the editor of this magazine, is intended primarily for the use of beginners in beekeeping. You should have it. Price, postpaid, \$1, or clubbed with the American Bee Journal, one year for \$1.75.

American Bee Journal, Hamilton, Ill.

?? WHY ??

Why is it that so many beekeepers prefer Dadant's Foundation? Why does it give such good satisfaction and why is it that when tested side by side with many other makes beekeepers have reported that "they take to DADANT' first."

Do We Use Special Sheeting Machinery? No

We use the Weed process of sheeting our beeswax into endless rolls, and it is the same process as used by nearly all manufacturers.

Do We Use Special Foundation Mills? No

We use the same kind of mills as are used by practically every foundation manufacturer in the world.

Do We Use Special Beeswax? No

We use beeswax such as is produced by beekeepers all over the United States.

THEN WHY?

BECAUSE

Our beeswax is cleaned in such a way that all impurities are removed and all the fine qualities are retained.

BECAUSE

Sulphuric and other acids recommended and used by many manufacturers for cleaning beeswax are not used by us.

BECAUSE

Our motto is and always has been "EVERY SHEET PERFECT"—and we live up to it.

BECAUSE

For FORTY YEARS comb foundation has been, and still is, our *specialty*. When you get DADANT'S FOUNDATION you know that you are getting the best that money can buy. When you send your beeswax to us to be worked into foundation you know that you will get perfect work done. When you ship us your old combs and cappings to render you will get the maximum of wax they contain and, if desired, this wax will be worked into the finest quality of foundation made.

IT IS UP TO YOU, therefore, to insist on DADANT'S FOUNDATION when you order your goods from your dealer. If you cannot get it from him, then order from us.

DADANT & SONS
HAMILTON, ILLINOIS

LEWIS SECTIONS

HAVE

INDIVIDUALITY

BECAUSE they are in a class by themselves. They are not like other sections. Very rarely do they break in folding---in fact one of our customers writes us that he has put up (folded) thirty thousand Lewis Sections in a season and has not found *one section* in the whole lot that was not perfect. Beekeepers everywhere, no matter what their preference may be for hives or other bee equipment, agree that, when it comes to sections, the LEWIS SECTIONS are supreme. This is—

Because the material which goes into a **Lewis Section** is of the right kind, especially selected for the purpose. The stock is sorted and re-sorted—the discolored stock thrown out, leaving only the whitest material to go into **Lewis Sections**.

Because the V groove, which is the most important process in the manufacture of a section, is made just right. In the **Lewis Section** it is cut just deep enough so that the section will not break in folding. The **Lewis Section** expert has been supervising the manufacture of **Lewis Sections** for over thirty years.

Because the finishing of the section is given the utmost care. The **Lewis Sections** are polished on both sides in a double-surfacing sanding machine designed in the Lewis plant especially for this purpose. It insures the uniform thickness of each and every section. The dovetailing of the ends is smooth, clean and just right.

Because even after the **Lewis Sections** are completely manufactured, the packing is considered a very important part of the marketing. All **Lewis Sections** are put up in regular standard packages containing a good, full count. A tight wooden box is used, entirely enclosing the contents, so that no discoloration from air can occur, no matter how long the sections are carried in stock. The package is also strongly braced at all corners, insuring delivery in good order.

AT THE SAME PRICE YOU PAY FOR OTHER STANDARD MAKES OF SECTIONS YOU GET ALL OF THE ABOVE WHEN YOU BUY THE LEWIS SECTIONS

MEXICAN BEEKEEPING

Primitive Methods of Beekeeping Practiced by the Mexican Peons in the Lower Rio Grande Valley, as Seen by Frank C. Pellett

THE visitor to the lower Rio Grande Valley finds himself in strange surroundings. Even the man who has lived for years in Central Texas finds conditions unfamiliar. When our party arrived at Brownsville, in February, the wild oranges were hanging on the trees and the roses were in bloom, although there had been some frost. The wild oranges, like the wild crab-apples of the north, are ungathered, because they are so sour as to be unpalatable. Loads of cabbages were going to market and fields of lettuce were ready to harvest. There was little to indicate the zero temperature which had so recently been left behind at our northern home.

Brownsville is a quaint old town with a foreign aspect: Mexican women sit on the sidewalks offering their drawn work for sale, Mexican boys carry papers from door to door, while their dark-skinned daddies drive their funny carts about the streets. More than half the population of the city and surrounding country seems to be Mexican. Not far from the city are to be found villages composed entirely of Mexican population, with perhaps none who understand the English language. The houses in these villages are made of palms or canes, with roofs of similar material. In our last issue was shown a picture of some of the houses in such a village, and figure 1 in connection with this story shows the home of the apiary herein described. This house is made partly of boards, while many of them are built entirely of such palms or grasses as happen to be within reach. In such a climate there is scant provision made for protection from cold. To keep dry is all that is necessary during most of the year.

Now and then, during the winter months, there are damp and chilly days when the weather is extremely disagreeable. Although it seldom frosts, one feels the chill keenly without plenty of clothing or a good fire.

Mention has already been made of the great variety of flora in the valley. About all the thorny species of West Texas are present, with the addition of a great variety of plants similar to those found further north. In the north, the elm is one of the earliest sources of pollen in the spring. The species of elm that is common in the valley blooms in mid-

summer. The willows also are common. They are among our most widely distributed trees, being found from the far north to the Mexican boundary.

The birds are as strange as the plants. Green jays, inca doves and chaparral cocks take the place of the familiar species of the north. The English sparrow is about the only familiar bird to be seen. In east Texas one finds most of the birds which he knew in the north, but in the Brownsville country they are nearly all strangers. The turkey vulture is a common bird everywhere in

Fig. 1. Home of the proprietor of the apiary.

Texas, but no crows are to be seen in the valley.

A whole chapter might be written about the ants of Texas. There are very interesting species to be found there, including the agricultural ants, which cut down every plant about their mounds except what is known as ant rice, thus giving this plant special opportunity to grow.

The cutting ant is even more remarkable in its habits, since it carries bits of leaves to its nest for the purpose of reducing them to pulp and cultivating a fungus. The long files of these insects on the march, each with a piece of leaf over its head, gives them the name of "umbrella ants" in some places. There are so many things of interest that a naturalist gets fussed, because there is not time enough to see them all.

One of the most interesting things is a small yellow insect, which greatly resembles the common yellow jacket of the north. It has some characteristics of the wasps, and some of the bees. The nest is composed of paper like that of the bald-faced hornet, or the yellow jacket. The cells are small, being about the same size as those of the yellow jacket; but the nest is large, one that we saw being nearly three feet through, the long way. The astonishing thing about this insect is the fact that, while its nest is made of paper like that of any other wasp, it stores honey like the honeybee. The honey is not sealed in the combs, however. The Mexicans are fond of the honey, and hunt for these paper nests for the small amount of honey secured. Local beekeepers also assert that it swarms like the honeybee. The question arises whether it is a wasp or a bee. Unfortunately, we were unable to find any nests which were occupied, although several empty ones were shown to us. So many different persons vouched for the above facts concerning the

Fig. 3. Looking in, one sees rude shelters under which are placed the bees.

habits of the species that we could not doubt them. If the insect has been described in our literature, I have so far been unable to find it.

There were four of us in the party, in the journeys about Brownsville. Mr. A. Lynn Stephenson, a local beekeeper, certainly knew where to find interesting things. He knows not only the bees of the valley, but the plants and the people. No stranger would have been able to find the apiary which furnished the photos to illustrate this article. We drove for some distance along a well-traveled highway and then turned into a little by-road that wound around through the cactus and brush for a long way, until it ended at a little Mexican village in a bend of the Rio

Grande river. The village itself was situated on the bluff overlooking the river, while immediately below it was a considerable acreage of cleared land which was being prepared for crop. Mr. Stephenson acted as interpreter, and secured for us the permission to visit the apiary and secure the desired photographs. On another occasion, when the party started out without him, we made slow progress, since no one could talk Spanish, and we were unable to make ourselves understood.

If this was a farm paper instead of a bee journal, some of the Mexican goat ranches that we passed would be worthy of a story.

In all my travels I have never seen anything in the way of an apiary that bore the slightest resemblance to the one we found there. Enough has already been said about the climatic conditions to make it clear that there is much swarming among the bees in the valley. This apiary is conducted primarily for wax, rather than for honey. At one time there were several hundred colonies, although the number had been reduced somewhat at the time of our visit.

The first thing one sees is a high fence made of canes, as shown in figure 2. The purpose of this fence is not entirely clear, since the gateway is open with no provision for closing it. This fence surrounds the apiary on three sides, while the fourth side is the bluff above the river. On coming to the gateway and looking in, one sees rude shelters similar to the Mexican houses, under which are placed the bees. Once inside, one finds several of these huts, and under each are rows of the bee boxes. The purpose of the huts is clear enough, for the midsummer days are hot, and shade is very desirable for protection from the extreme heat.

The hives are nothing more than rough boxes. Unlike the box hive,

Fig. 2. Fence of canes about the apiary.

Fig. 4. Inside, one finds several of these huts in a row and under each are rows of bee-boxes.

one side is left entirely open, or a sheet of burlap or cheesecloth is hung over it. Of the hundred or more hives, perhaps one-third had a cloth hung across the front, the rest were entirely open, as shown in figure 5.

About twice each year the combs are all cut out and the bees thrown back into the empty boxes. There is, of course, much loss from the melting of combs filled with brood, but the peon is indifferent to that. The wax is a saleable commodity and the bees will soon re-establish themselves. The wax is sold, for the most part, to the Catholic priests for the making of wax candles for ceremonial purposes.

This system has one great advantage over the box hive beekeeping of other sections; it automatically eliminates American foulbrood. With all the combs melted up at such frequent intervals, this disease can never get much of a start among the bees, and the nearby beekeeper, following practical methods, needs have but little fear of the harboring of American foulbrood by his Mexican neighbors.

"Honey for Cooking"

By Dr. Burton N. Gates, Associate Professor of Beekeeping, Massachusetts Agricultural College

"HONEY for Cooking" is an expression commonly met with in talking to the public who are eager to supplement and to save the sugar supply, but who at the same time are anxious to make a portion of their usual preserves, jellies and jams and to prepare their household foods. The public is ready to use honey in the various ways but they say "Honey for Cooking" is so expensive. The only remark in reply is, in Yankee fashion, a question, "Are you sure that it is so much more expensive than sugar?"

When purchased in jelly tumblers or less than pound packages, the rate

is high. The consumer pays for the bottle, for the handling, overhead charges, cost of selling, etc. Unfortunately, too, few markets offer honey in more than two-pound packages. It is seldom that a five-pound pail or a ten-pound pail can be procured other than from some bee-keeper. On the other hand, maple syrup is to be had by the gallon. The question may be raised, therefore, are the beekeeper and packer at fault in supplying the small package of honey and not offering a larger package? There is every indication that the jobber and retailer will handle it if it is available. The public is in a receptive mood, ready to learn how to liquefy candied honey, how to properly keep it and use it, if obtainable in bulk. But if sold in large packages it would seem that the prices should be consistent with the

lessened cost of packing and handling.

Since the expression "Honey for Cooking" is so commonly met with, why not use it as a catch word in introducing perhaps, first, the five-pound package, and later the ten-pound? Let the package bear these words and with them a brief explanation of liquefying the candied honey and of properly keeping it after liquefied. Brief suggestions for utilizing honey in the preparation of foods and preserves could also be included.

There is another feature. The eastern producer who is in the midst of large and dense populations finds a ready sale locally for all the honey which he produces; moreover, he finds that the pound package is his best selling size. Probably his best profits are on this size. Therefore, there is little inducement for him to pack in larger containers, thereby reducing the price and his profits. However, low grade honey produced in the commercial apiaries of the west might well be packed and graded ready for eastern retail trade and known on the eastern market as "Honey for Cooking." Perhaps it would help the producer to dispose of his darker honey. The question, therefore, may be raised: is there not an opportunity to wholesale, properly labeled, five, and possibly ten-pound containers, crated in lots of six and shipped in a wholesale way ready to be disposed of directly to the jobbing grocers? It would cost the producer slightly more to prepare his honey for market in this form, rather than in the sixty-pound cans, but it is the writer's opinion that a satisfactory profit could be obtained and yet the honey made available for cooking purposes at a cost attractive to the public.

There would be needed a little educational work among the jobbers. Perhaps, too, the retailers would need to be informed. The public, however, is ready

THE EDITOR'S VIEWPOINT

Foulbrood Kill or Cure

Through carelessness on the part of the printer, 3 lines were dropped out of the editorial in the May number. It made a part of the editorial unintelligible. Alas, that printers are not perfect. Meanwhile we received a very interesting letter on the same subject from an Ohio inspector, Mr. A. C. Ames. The reader will find it in this number. It is worth perusing, for it tells things about inspection which the average beekeeper does not know.

How to Keep Bees

We are in receipt of a second edition of a bulletin with the above title, written by the well-known and experienced apiarist, Arthur C. Miller, and published under the auspices of the Rhode Island State Board of Agriculture. The book contains 50 pages and a number of illustrations. In so short a space one cannot expect a full treatise. But the directions given are certainly the most important for the beginner in beekeeping. The book may be secured from the State Board of Agriculture at Providence, Rhode Island.

Diet and Disease

J. L. Rentoul, in the British Bee Journal, suggests, May 2, that "Isle of Wight" disease, which is quite similar to our "constipation" or "paralysis" or "May disease," is a bowel trouble and that its cause and cure depend a great deal upon the diet. No doubt he is right, as most of the authorities recognize that these diseases begin when the weather is damp and chilly and the pollen or honey harvested is probably of poor quality. But when he suggests that

sugar feeding may be responsible for the disease, we believe he is mistaken, for we have seen the disease where the colonies had never been fed on syrup. We must hunt for the cause elsewhere. However, it is quite probable that sugar is not a desirable food for bees in any event and it should not be used whenever good honey is available.

Wastefulness and the High Cost of Living Versus Foulbrood

An editorial appeal against public and private wastefulness was published in the American Bee Journal for June, 1913, five years ago, when no one foresaw the dreadful destruction of human life and human products which is now taking place. Wastefulness and its connection with the possible spread of foulbrood were pointed out. But the urgent need of economy in all lines was not yet felt. The reprint of this editorial will give an interesting illustration of the progress achieved in this direction during the past 4 years, for much of the reform then suggested has been accomplished.

The writer one day noticed a little cluster of excited bees on the ground in a poultry enclosure. Upon examination, he discovered that they were bent upon gathering a lump of granulated honey, which had been thrown there with the other table waste. The chickens had eaten everything but the wasted honey, butter and bones.

We complain of the high cost of living and seek a remedy in every direction but the right one. The American way is to waste, waste in all directions. We wasted our forests, under the plea that it was more profitable to burn them off than to save them. We waste our coal at the mines, in many places, allowing the slack to consume itself by spontaneous combustion, or by

contact with the air. We waste our land, leaving innumerable spots uncultivated, even in the heart of civilization. We waste our manures, often even contaminating our streams by using them to wash away useful fertilizers. But above all things we waste our food.

This reproof is not intended for the foreigner who has been raised on economical methods in a thickly settled country. In all probability, the foreign-born American who reads this has been taught, in his young days, to consider bread and meat as sacred under the plausible plea that he might starve some day, for want of such food as he proposes to throw away, and also because so many millions in the world do not get as much as they want to eat. But our American education is different. Many a bright, neat, sensible and educated American mother thinks nothing of teaching her children to take a heaping plate-full of all kinds of food, leaving half of it unconsumed, in a disgusting heap, made of a mixture of all the dainty dishes served upon the table. Nay, in many cases, children are taught that it is good manners to accept or take more of one dish than you can possibly use and leave two-thirds of this upon your plate. Thus meat, gravy, bread, potatoes and other vegetables, fish, butter, jellies, pie and honey are carried to the back yard, or thrown into the slop-pail.

When this waste takes place upon the farm, it is but half wasted, for the hogs and chickens consume most of the remnants, so however expensive it may be to feed bread, cakes, jellies or honey to the hogs, the food is not altogether wasted. But what of the cities? How much of this willful and unnecessary waste is made to clog the sewers or sour and rot in the refuse can in the back lot?

What has this to do with bee culture? Why should a bee journal take notice of this bad custom and sound a note of warning? Because, as far as honey is concerned, the waste constitutes a danger. Because if one-fifth, or even only a tenth, of the honey served upon the tables is thrown away, there is a chance in many instances, of the bees getting at this second-hand, and bringing to the hive, with it, undesirable bacteria. The very best honey may contain in it germs which, absolutely harmless to human beings, mean ruin to the brood.

Why are brood diseases almost permanent around many large cities in this country, if it is not owing to the fact that some of the honey shipped from all parts of the country is, to a large extent, exposed where bees can reach it?

One will say that, in most cases, the honey is healthy for the bees and entirely free from germs. True. But we know that in a case of contamination, the microscopic germ which causes brood diseases is so small and so sparingly scattered in the honey that scientific examination has usually proven inadequate to find it. In other words, those germs of

bacilli, which are **entirely harmless to man**, are so infrequent in contaminated honey that a microscopic examination usually fails to detect them. But they are situated in the most favorable condition for development in the stomach of the larva.

Aside from the dangers arising through the wasting of honey and other foods, is it not time for civilization to take notice of the wanton loss which has thus far been considered fashionable and proper?

We dare say that, our country through, from one-tenth to one-fifth of all the food served upon our tables finds its way to the dung heap, untasted. Think of wasting 10 to 20 per cent of your food! How long would this amount support you in your old age?

This habit is not confined to the wealthy and well-to-do, but is noticeable even among the wage-workers, though in less degree. Neither is this any benefit to the housekeeper, for she has to prepare so much more food, and after each meal has an ugly mess to clean up, made of the neatest and finest morsels that she has artistically prepared. Aside from the high cost of living created by such an untidy habit, this alone ought to urge us to stop it.

Death of G. M. Doolittle

Marietta, N. Y., June 10, 1918.

Gilbert M. Doolittle died June 3 of church failure. He was taken ill in church the day before. He was 72 years of age in April last. A widow survives him. No children.

P. G. CLARK.

G. M. Doolittle was one of the most experienced beekeepers in the United States. He was a subscriber of the American Bee Journal as early as 1870, and a contributor, more or less

G. M. DOOLITTLE

regularly, to this magazine and *Gleanings* from that time to this.

The greatest invention of Doolittle was his method of queen-rearing, explained in his book "Scientific Queen-rearing," published originally in 1888, with numerous later editions. We have explained, in this magazine, in May, 1917, how the method was brought about. In October, 1878, a beekeeper, by the name of Boyd, suggested, in *Gleanings*, the possibility of using old queen-cells, taken from almost any hive of bees, and placing in each of these a larva. Then A. I. Root suggested the use of a rounded stick wetted and dipped in beeswax

to make these acorn cups artificially. Doolittle put these suggestions together and also devised the rearing of queens in the upper story of a strong, queenright colony, by using a queen-excluder between the stories. This gave the basis for his system, now used all over the world. In France a description of the Doolittle method was published in 1902, by Giraud-Pabou, who was very successful with it. The Italians also brought it into prominence, and perhaps the most perfect establishment for the rearing of queens by the Doolittle method is that of Enrico Penna, of Bologna.

During the past few years Mr. Doolittle spent his entire time in the care of an invalid wife, who survives him and will miss him still more than the bee fraternity. For several years past Mr. and Mrs. P. G. Clark have been in charge of the Doolittle queen-rearing yards and apiaries.

Bibliography—The Bees and the Honey (Le Api E Il Miele.)

A book of 240 pages with the above title has just been published by Professor Giuseppe Montagano, of Rome. It is a treatise of modern beekeeping, containing useful advice and devoting an entire chapter to the transferring of bees from the old skep to movable frames.

The most interesting point of this book, to us, is the difference it establishes between the Italian bee (*apis ligustica*) and the Sicilian bee (which the author names "*apis sicula*." He asserts that there is a visible difference between the two, the Sicilian worker bee being of more "ashy" color, while the queens are of chestnut color and the drones of a "dark-ashy color (*cenere scuro*.)" He holds that this race is still more peaceable than the Italian, though perhaps a little smaller. He advises the mixing of the two races, by introducing the Italian bee in Sicily.

In the October, 1915, number of the American Bee Journal, we introduced evidence that the only part of Italy where the Italian bee does not exist in its purity is the province of Liguria, south of the Ligurian Alps. So the name "Ligurian" is a misnomer. The name "Sicula" for the bees of Sicily is much better adapted to the race which it represents. It might be advisable to give those bees a trial in this country.

The author of the book does our editor the honor of publishing his photo, describing him as the editor of the "greatest bee periodical in the world." It is very flattering, and we hope to deserve it.

G. M. Doolittle, discussing beekeeping with Mr. and Mrs. Clark in the Doolittle & Clark queen-rearing apiary in 1916.

How to Get 2 Cents More for Honey

By Chilton Gano

IF honey producers could get 2 cents per pound more for their honey than at present, and still not have the consumer price advanced—in other words, if they could lower the cost of distribution that much—they would jump at the chance.

Well—they can do this!

The Texas honey producers did it, and it only took them six weeks. How they did it is no mystery. It was simply (to quote Kipling) "the everlasting teamwork of every bloomin' soul."

Any group of honey producers in a fairly small territory can do the same thing.

The writer told the story of the Texas Honey Producers' first year of co-operative marketing in the May and June issues of the American Bee Journal. Now it is desired to "point the lesson" from their experience—to analyze what they did—get at the gist of it—grasp its principle—as an aid to other beekeepers in doing likewise.

Too often the mistake is made of reading such stories and then forgetting them—in one ear and out the other. This would be a great mistake, in the present case. It is probable that nothing so important and significant to the subject of honey-selling generally has happened in a long time.

Suppose we follow the "Before and After" method of summarizing what was done. The situation in Texas before co-operation will be seen to be exactly like the situation prevailing today in a score of honey-producing communities. The contrast with conditions after co-operation was adopted, will be found striking and will make it clear just how distributing methods were improved and their cost lessened.

Beekeepers who want to secure better prices and realize that better prices must be "earned"—that they won't just come for the wishing—are advised to thoroughly grasp the lesson of this article, then to study the two articles in May and June American Bee Journal, and, finally, to interest the beekeepers of their communities in the new and better method of selling honey.

Remember, that it only took the Texas producers six weeks to permanently advance honey prices 2 cents. That is inducement enough for any man. But here is another inducement: The new plan gave new life and new impetus to the Texas honey industry. Texas honey is now in demand, is paying everybody connected with it, its production is worth while, the producers have every reason to increase production to the utmost. **This is helping to win the war!** Anything that promotes production of a sugar substitute is helping to win the war.

Before Co-operation

Before co-operation in Texas the

situation was just like it is in any community where each farmer is his own salesman. Some of the producers were selling to speculators, some to jobber' buyers, some direct to the wholesalers or retailers in nearby cities; some, perhaps, unsatisfied with prices procurable in these ways, were trying to sell direct to consumers of their community. There was no general understanding regarding what was a fair price for honey. Each producer got the best price he could. If he happened to feel blue or discouraged, or the buyer could make him feel so, he might sell at no profit whatever. Some even sold below cost without knowing it, having no correct idea of what it costs to produce honey.

It is thus seen that producers were inevitably underbidding each other in the markets. Such a condition benefits no one. When prices to the producer are unsatisfactory he has no incentive to put up a quality product, to pack it properly, or to take care of it during distribution. His business, being inadequately financed, is shabbily conducted. This brings honey on the market in an unattractive condition. It doesn't appeal to the trade or to the consumer. It can't compete in "looks" with the handsome products of big packers now featured in every grocery store. Farmers don't realize how many things sell because of their sanitary, clean-cut, appetizing "look."

Under these conditions honey didn't appeal to producers, trade or consumers. It isn't surprising that it was a drug on the market in July, 1916, selling at 5 cents for extracted and 7 cents for comb. These prices were born of ignorance and ruinous competition.

Again, grocers didn't want to handle it, because it was too much of a hit and miss proposition. You can't build up a regular consumer demand for a grocery product that sometimes you can get and sometimes you can't, and that varies in pack, color, price and flavor, every time you buy it. Grocers have been educated by the big manufacturers to where they like businesslike methods and standard products attractively packed.

After Co-operation

Nobody was satisfied. Then the wholesalers and retailers heard that the producers had waked up and were going to get together and mend matters. The trade don't usually welcome the news that producers want better prices, but this time was an exception to the rule. Honey was "N. G." as it was. It wasn't making money for anybody. The trade must have realized that the only way to get a presentable product was to give the producers fair prices.

News of the meetings of the beekeepers and their analysis got around. They believed they must have at least 2 cents a pound more for honey in order to deliver a good product. They agreed that such an advance was only fair—was only a "living wage." Well—the trade didn't "kick." Within six weeks after the producers had determined to organ-

ize, before they could have done very much except "talk" and "plan"—Texas honey was bringing the higher price. It just shows the salutary psychological effect on an industry when "teamwork" becomes the motto.

And the minute it became apparent that honey need no longer be a "beggar" in the markets, but was "worthy of its hire," there began to be an incentive to throw away its old clothes and "dress up." The Association set out at once to remedy all the defects in the old system of marketing honey.

One defect—a big one—had been the absence of standards. Honey grading rules were adopted that should be rigidly followed by all members of the Association. Today the grocer can no longer complain that he is unable to get the kind of honey his customers have been buying from him in the past and prefer. He orders by grade name, and if the honey doesn't meet the grade description, the Producers' Association makes good and penalizes the member who packed it.

Another defect had been absence of a guarantee by the producer to the consumer. Grocery products like Shredded Wheat, Heinz's Beans, Welch's Grape Juice, bear the maker's name and label, and this serves as a guarantee of quality. Somebody stands back of the product and says, "I packed this; if it isn't O. K., I'm ready to make it good." The Association adopted a brand and label, which is its guarantee to the customer that honey so branded is first-class and can be depended on.

Another defect had been too much handling of the product between producer and consumer. And this is highly important. In the case of both extracted and comb honey, re-handling costs money—and in the case of comb honey it also causes unnecessary leakage and breakage. The Association plan doesn't allow the jobber to handle the honey at all. The jobber does all of the other usual things. He gets the retailer's order, extends him credit if desired, and collects for the shipment. But he doesn't deliver the honey. It is shipped direct to the retailer by the producer, who acts under instructions from the Association's general manager, Mr. E. G. LeStourgeon. This one factor of direct shipments, saving leakage, breakage, re-handling charges, bookkeeping and storage, is no doubt alone saving more than the 2 cents per pound which was accorded the producer after six weeks under the new plan.

This article is intended merely to draw the broad, emphatic lesson from the experience of the new Texas organization—not to tell the whole story. As a matter of fact, the 2-cent advance was only the beginning of the savings and benefits secured by this Association, as may be learned by referring to the previous articles.

What the Texans did can be done by any beekeepers. One thing should be noted, however, Texas has

a new law authorizing the co-operative form of corporation. Many States now have such laws. They greatly facilitate the working out of co-operative marketing plans. The writer expects to discuss this subject in detail in his next article.

Chicago, Ill.

A Month in Florida

By the Editor

A month in Florida! Why, many beekeepers go to Florida for the entire winter!

This is true, but there are only a few hundred of them, and beekeepers who never went to Florida, and never will go there, can be counted by the thousands, so perhaps many of our subscribers will enjoy reading the experiences of a winter month spent in the South.

I will not mention our stop in St. Louis, or at Nashville. The winter was just ending there, for it was near the end of February, but there was still ice on the Mississippi, opposite our home, almost thick enough to cross on, while at Chattanooga, when we arrived there, the second day of our trip, the fruit trees were opening their buds. We visited the his-

torical spots celebrated as the headquarters of the Federal and Confederate armies on the hills back of the city, the camp at Chickamauga and Lookout Mountain, from the top of which we looked down 1,700 feet on the city and on the moccasin-shaped Tennessee River making a sharp bend at the foot of the mountain.

The following day, for we traveled only in the day time, we passed through Georgia and began to realize that we were reaching southern countries; the fruit trees were in full bloom, the peach trees being already out of bloom.

On the fourth day of our trip we left Jacksonville, Fla., which, by the way, we do not admire as a city, and traveled in a southwesterly direction. At noon we reached the country of oranges. The trees were in bloom and the odor of orange blossoms pervaded our car. The small saw palmetto that we had seen all the way from Southern Georgia, was now accompanied by the cabbage palmetto, a tall tree, and the landscape assumed a tropical appearance, but—what swamps! How much white sand throughout Georgia and Florida, a plain, flat country, covered mainly with small pines and live oaks, to

which hang the long festoons of southern moss.

In the evening we reached St. Petersburg and realized that we were indeed in a country of perpetual summer, for around the hotel all sorts of flowers were in full bloom. St. Petersburg has fine streets, delightful walks, a beautiful bay—Tampa Bay—good fishing. It is a city of tourists, one of the finest spots in which to spend the winter months. It rains there so little during the winter that the daily paper, the Evening Independent, is given free to its subscribers on every day of absence of sunshine. They say they had 56 such days in seven and a half years.

The white sand is the worst feature in this land of sunshine. Ordinary crops cannot grow. A joint grass stretches its stems, creeping over the ground like the legs of a spider, 30 or 40 feet in all directions, and makes a sort of network over the sand. Then leaves gather in this grass and in the course of time it makes a little soil.

I hunted for beekeepers, as I do wherever I go. W. H. Plunkett, who lives in St. Petersburg, is a native of Florida and owns an apiary eight miles from the city, in one of the rare fertile spots of the country. He took me to it in his automobile. An apiary of some 50 colonies, hidden behind live oaks, cabbage and saw palmettos, and drooping moss on the trees, made a wonderfully wild looking sight. The bees were gathering a little honey, but the crop from palmetto blossoms had not yet begun. That is the main source near St. Petersburg.

Mr. J. J. Wilder, our well-known contributor, who spends his winters in Bradentown, only 30 miles from St. Petersburg by water, came to see us and urged us to visit the city in which he lived. We agreed. A few days later Mr. Wilder met us at the Bradentown landing, accompanied us to the hotel and the next morning brought half a dozen beekeepers with him with two automobiles, to welcome us and take us around. We were already aware of the hospitality of beekeepers in general. This was another evidence of it. Mr. J. R. Notestine, a northerner who has lived in Florida for five years, took us with him, his daughter driving, and together we visited the most interesting plantation in the country, the Atwood Grapefruit Ranch, across the Manatee River, near Palmetto, a farm of 170 acres of fine grapefruit trees about 20 years old, many of them still bending under the weight of fruit up to 5½ inches in diameter. They were picking the grapefruit and packing them in the warehouse, situated on the Manatee River, at the end of a private dock. We saw the washing of the grapefruit and the sorting and boxing. Their largest crop is 100,000 cases, or about 160,000 bushels.

They utilize bees in fertilizing the bloom and Mr. H. L. Christopher, an old and experienced beekeeper, keeps two apiaries there, in different parts of the orchard, at the request of Mr. A. H. Brown, the manager. We sam-

The Cabbage Palmettos make a fine avenue in their native soil.

pled the grapefruit, and Mrs. Dadant, who says that grapefruit is too sour for her taste, found them delicious. They had ripened on the trees, that is the secret. The bees had harvested some honey from grapefruit and orange blossoms and Mr. Christopher was expecting a crop from saw and cabbage palmetto bloom, which were budding and would bloom within a month. Mr. Christopher took out a comb of orange honey which another beekeeper, Mr. E. A. Reddout was kind enough to put up in a tin for us so that we could sample it at leisure.

A new thing to me in the apiary line was the raising of one end of the hive cover by inserting a quarter inch wedge under it. This is practiced by Mr. Christopher in his apiary. It gives ample ventilation during the crop and helps keep down swarming. The bees did not seem to use this opening for in-and-out flight, possibly because the broodnest was below.

The same afternoon we took a trip to Sarasota, with Mr. and Mrs. Wilder, who, by the way, is a charming lady, and their little daughter. Acres and acres of vegetables are grown in spots of fairly rich land along the way between the two cities. There is a great deal of enterprise in that neighborhood. A number of artesian wells are just being bored to irrigate the crops, for water is needed as much as fertilizers. Sarasota is a small place, but with a bright future. We visited the Sarasota Bee & Honey Company, managed by C. N. Biorseth, with his sons and son-in-law. Between them they care for a number of apiaries, some 500 or 600 colonies. Learning that we wanted to taste the honey of the locality, he brought us a 20-ounce jar of orange honey which had taken first premium at the county fair. This honey is fine, indeed.

Back to Bradentown in the evening, we made a call on the celebrated founder of the largest bee supply establishment in the world, Mr. A. I. Root. Mr. Root and his wife spend all their winters in Florida. We found Mr. Root bronzed like a southerner, but as hale and robust as a young man, in spite of his 78 or 79 years. He exhibited to us a much worn hoe and said that this hoe was the secret of his health, for he spent most of his time in the garden. He gave us an introduction to Mrs. Root, a charming old lady, whom I had never met, and made me the compliment of introducing me to her as the head of the strongest competitive firm the A. I. Root Company had ever found in their business. Mr. Root grows potatoes and beans mainly in his garden and said that he had sold \$100 worth of new potatoes by March 23, a feat that surely no one else in the entire United States has done so early.

We had seen tomatoes and corn in bloom in Sarasota, but the only vegetable crops offered on the markets thus far were lettuce, radishes, carrots, cabbage, etc.

We were disappointed in the surroundings of the Root home. That spot seemed to have suffered more from frosts than any other that we

saw. The orange trees, the shrubbery and even some of the shade trees had suffered as if a fire had blown over them. It made a desolate looking sight. It was the same at the Wilder home, a few blocks away. These homes are a mile or so from the business part of Bradentown. The growers of oranges keep off the frosts with smudge on cold nights.

Returning to St. Petersburg, we remained there until the latter part of March, spending a part of our time fishing on the bay. Fish are plentiful and those who are fond of the sport can readily catch more fish than they can eat.

During our stay in Florida we saw many lean cows and very few healthy looking cattle. As milk is high, wife remarked, "Why don't they feed their cows better?" But the answer came, "It is not the lack of food, it is the tick that keeps them thin." Then we were told that to keep cows free from ticks in this warm country, it is necessary to dip them every two weeks in a bug-killing solution. Some large cattle growers keep a tank of medicated water through which the cattle are regularly driven. That is the only way in which they can keep it away. But aside from the ticks there are

other drawbacks to cattle raising. For instance, sandburs (*cenchrus carolinianus*) are everywhere present in the grass, not only in the country but even in the city yards, and one can imagine the difficulty for grass-eating animals.

Inquisitive friends want me to give here my opinion of Florida as a honey-producing State. I do not think that I can add anything or change anything concerning this subject, as it was treated by J. J. Wilder in the April number, page 122. If you wish to try Florida for bees, investigate for yourselves, as there are good and bad locations. Mr. C. C. Cook, located at Tasmania, a new town, close to the famous Lake Okeechobee, on the west of it, in a country that I thought entirely uninhabited, told me of the most wonderful crops and swarming that I had ever heard and sent me some delicious gallberry honey from that vicinity. It is almost as white as clover, but a little strong in flavor.

There are unexpected possibilities in Florida. It was on the east coast that our departed friend, the veteran apiarist O. O. Poppleton harvested his immense crops. But the main attractions of Florida are its wonderful winter sunshine, its wild tropical

The "kiddies" beneath a hibiscus on a Florida lawn in February.

scenery, its immense fishing and boating resources. Between the numerous "keys" and the main shores, the weather is balmy, the air is pure and one can forget there the rest of the world and its troubles.

Treatment of European Foulbrood

By W. S. Pangburn

Read before the students of the Short Course at Ames.

THE subject of European foulbrood is a very important one to the beekeeper. I think I am safe in saying that it is the most important subject with which we have to deal at the present time.

Formerly, the producing of a maximum crop of honey, and disposing of it to the best advantage, were the two subjects that deserved our most careful attention.

Shortly after the European war began, the selling of honey became the least of the beekeeper's troubles, and will be so long as it lasts.

Producing maximum crops is still a vital question, owing to the fact that European foulbrood is ravaging the apiaries in many spots, and maximum crops are not produced in localities where it exists.

It matters not whether you have had the disease, whether you now have it, or whether you have never had it. It is a menace to the industry so long as it exists, for one never knows when or where it will break out, either for the first time, or anew.

I do not know of a man who would make the statement that he knew all about the ways the disease was transmitted, and could give a treatment that would cure it to stay cured.

It is true, there are a number of treatments that will clean up the disease for the season, but no assurance for the next year.

It seems also to be true, that some methods are a success in some localities and a failure in others. Why this is so is not entirely clear.

J. J. Wilder taking recreation at his Florida home

In my own opinion, the disease is not so virulent in some localities as in others, else it would seem that if a treatment had merit in one locality it should work in another, but we know it is not always the case. For instance, about the time the disease broke out in my own yard, Dr. Miller wrote an article for the American Bee Journal, with the head lines "European Foulbrood at Dr. Miller's." In this article he gave three different methods that he had used with success, two of which I tried, with little success.

Mr. Holtermann, of Canada, tried his methods, also Wesley Foster, of Colorado; that is, caging the queen for ten days and then releasing her on the same set of combs.

Mr. Foster came out with an article condemning the plan as not successful with him. His opinion was identical with mine, that the disease reappeared in far too many cases to be relied upon.

I also found that a queen caged in the height of egg-laying for ten days was, in most cases, quite as poor as

a dead one. I have not been the only beekeeper that has found this true.

Mr. Holtermann, in the American Bee Journal, said he could not help but think that Dr. Miller had the disease in a very mild form to yield to this treatment, and I thought so too. Later I learned something that verified that opinion. It was that Dr. Miller had the disease in his yard for three years before he knew that he had it, and I am quite sure that if the disease had been as virulent as it was in my yard, he would have realized before three years that he had something, else he would have had no bees. I am satisfied that two years, without treating, would have put us out of the bee business.

This statement is not given with any intent of belittling Dr. Miller, because I have not the slightest doubt that the methods he described were a success with him. But the idea I wish to convey is that the same treatment will not always work in different localities, and also that the disease seems more virulent in some places than others.

I fully realize that it is a very hard matter to outline a treatment that will suit any and all conditions. We do not always follow the same line ourselves in all cases. There are many things to be considered, such as the man, honey flow, weather conditions, the time of year the disease appears, the condition of the bees, etc. So it is only possible to outline the main points.

First, if you have never reared any queens, you should learn how at once. Any beekeeper should know enough about queen rearing to rear his or her own queens, as a young queen from a good vigorous strain of Italian bees is the "sine qua non" in cleaning up the disease.

When you find a colony in your yard is resisting the disease, naturally you will want to breed from that

The Joint Grass creeps over the white sands of Florida, taking root every two inches, and resembling a spider.

queen, and if you cannot rear your own queens, how are you to do it?

While most any strain of Italians would be better than hybrids, if they were not inbred bees, simply because they are Italians does not spell success in cleaning up foulbrood. That there are strains of Italians that are more immune to the disease than others, there seems to be but little doubt.

When you find a queen that has gone through an epidemic of European foulbrood with no sign of the disease, spot her for your breeding queen. You may get fooled on her the following year, but keep on trying until you do find one, then rear your cells from her. But do not make the mistake I did once and get so struck on a queen as to practice inbreeding and have it to do over again.

N. E. France says inbred bees will succumb to the disease fully as quickly as hybrids, and I found it true. Use at least two strains in your yard to avoid this, and more would be better.

If you will paste these last remarks in your hat, and work along these lines you will be on the road to success.

As soon as you are aware of the presence of foulbrood in your apiary, or in your locality, examine every colony carefully, and at least once a week after. Cage or kill the queen in all diseased colonies **immediately**, not the next week. The longer you leave her free to lay after the first diseased larva appears, the more disease you will have to clean up. You will be surprised, if you have never had any experience with the disease, to know how bad they will get in a week's time if left to themselves.

After going through the yard and marking all colonies diseased, also the strong and the weak ones, unite the weak colonies until they are strong, even if it takes 3 or 4 piled up to make them so. You are cutting down the number of cases to be treated, saving money for queens if you have to buy, and lessening the chance of infection to healthy colonies. You will not need to save any for experimental purposes, for in all probability you will have plenty of them before the season is over.

You should not expect a weak colony to clean up even under the most favorable circumstances. So do not try it, as it will be time worse than wasted. In ten days or two weeks (depending on circumstances) you will be ready for the cells from your breeding queen, if you have one, else young queens from some good breeder, which should have been ordered previously to introduce to these colonies that have had their queens removed.

In our own yard we figure on using ripe cells to graft at this time, as we have better success with them than with queens, and if we have plenty of cells we do not always wait ten days before we graft, because it is some days before the young queen begins to lay.

I might explain more fully as to why we prefer the cells to queens. It

sometimes happens that in stacking up colonies a queen cell is overlooked at the time of cutting, and while a very small per cent of queen cells hatch from a foulbroody colony, it does sometimes happen, and you have a virgin running somewhere in the hive bodies. Even though there is no virgin in the hive, a colony that has been without a queen for ten days or longer is the hardest kind of a colony in which to introduce a queen, as any good beekeeper knows.

If you are paying a dollar apiece for your queens, and this virgin is not found before you introduce your queen, you have lost your dollar, and this might happen often enough with the novice to make a very dear colony of bees.

If you graft a cell and the cell is O. K. after 24 hours, you are safe in thinking they have no queen. If the cell is destroyed, you can thank yourself that it was your cell instead of the dollar queen.

If we are using queens from some breeder, and are ready to introduce them, and the bees have not cleaned out the dead larva, we aim to shake them from the diseased combs onto clean ones, in a clean hive. We have at times in our yard several colonies which we call hospital colonies, and we give the diseased combs to these colonies to be treated later. This lessens the chance of disease breaking out the second time, and the process of cleaning up repeated, which should be avoided if possible, as, if you don't watch out, the summer will be gone, the harvest ended, and your colony not saved.

If the disease appears in your apiary early in the season, before many young bees are hatched, and your colony has had no chance to make up for winter mortality, with perhaps cold, damp weather, and no flow, you have about the worst condition imaginable to fight European foulbrood. The fact is you can't fight it until conditions change. Robbers are bad at these times, making examinations exceedingly difficult, and with these conditions, if you are not a first-class beekeeper, you will probably spread more disease than you stamp out.

When fruit bloom is out and the bees are busy gathering pollen and honey, is the proper time for the average beekeeper to commence operations. But waste no time when the conditions are such that you can work, and remember, you must have a flow, either natural or artificial, to accomplish anything in fighting foulbrood.

If you have followed the outline of treatment I have described as thoroughly as you should, the apiary should be in a fair way to clean up, and by having some swarms at this time, you can boost it in the way that I shall now describe.

You will, in all probability, unite some swarms, which will cut down your number, and to follow this up without any increase, you soon would be out of bees. I think I hear someone saying, I could start nuclei and increase without natural swarm-

ing. I can only say, you might, and you might not. Remember, you now have European foulbrood, and nothing but strong colonies should be tolerated in the yard. You should allow no robbing now. If you do, likely enough your summer's work will come to naught. Personally I do not want any nuclei to bother me as long as I know foulbrood is close by.

When a colony swarms, the queen is picked up at the entrance, as we always clip our queens. The old hive is removed from its stand and the new hive with a clean set of combs in its stead, a queen excluder on top of that, then the supers from the old colony, with the caged queen at the entrance.

The brood from the colony that has swarmed is examined closely for any disease. If it shows no disease, it is put on a stand and left to rear its own queen, and perhaps a bunch of nice cells that can be used to good advantage at this time. If it shows any trace of disease it is stacked over some colony that has been treated previously, and has not yet a queen; never over a colony with a laying queen. In a few days the young bees from the hatching brood will give the colony a boost that it badly needs, and there is nothing like young bees to clean out the diseased combs, as it is in their line of business.

We never aim to allow a queen cell to hatch from a queen that shows disease. This plan is followed as long as we have swarms and colonies that need help. It is no serious setback to the colony that swarms, and it is a decided boost to those colonies that contracted the disease and had their queens removed, and soon puts the whole apiary in condition to gather honey and strengthen up for fall.

In summing up, there are 8 points I would like you to remember:

1st. Learn to rear your own queens.

2nd. Remember that a young queen from a vigorous strain of Italians will come nearer to cleaning up the disease than any other thing.

3d. Do not inbreed your bees.

4th. Italianize with a good resisting strain of bees before you get European foulbrood.

5th. Cage or kill the queen **immediately** after finding the first cell that shows disease.

6th. Examine your bees at least once a week after you are aware the disease is present in your own yard, or in your neighbor's.

7th. Allow no robbing.

8th. Do not treat a weak colony for foulbrood. You will not succeed.

Center Junction, Iowa.

European Foulbrood and Its Treatment

By C. C. Miller

A GOOD friend, who knows a lot about bees, and for whose opinions I have the highest respect, has written me a few words about my theory as to the way in

which European foulbrood is continued and spread in a colony into which the disease has been introduced, and also as its treatment. The theory is this: If you cut or crush bee-larvæ, the workers eagerly devour the juices; when a colony is brought to the point of starvation the bees tear open the larvæ, suck their juices, and throw out the white skins. Similarly, when the miscreant of European foulbrood (*Bacillus plauton*), gets in its work upon a larva, and while the juices of the larva are still palatable, they are consumed by the nurses and fed to healthy larvæ. These become diseased, and in turn their juices are fed to other larvæ, and so the work goes merrily on. But the time is limited in which the juices of an infected larva are sufficiently palatable to be consumed, and as soon as sufficiently offensive they are no longer sucked up by the nurses. So if the laying eggs, and the consequent rearing of brood, be broken in upon for a sufficient time, there will cease to be in the hive the diseased larvæ of the right age to be consumed, larvæ coming into existence subsequently will not be fed infected matter, and a cure will result.

My friend says: "The question which I would like very much to have you or someone else answer is, how in the world does European foulbrood ever appear the next spring if the method of transmittal is through the eating of freshly dead larvæ? There must be some other way, probably through the eating of infected honey, and yet when we know how readily a colony can get along with honey from affected colonies, if the colony getting the honey is good and strong and of vigorous stock, this hardly seems credible."

I can easily see how this objection might seem insurmountable, for one might say, "If cessation of egg-laying for 10 days proves a cure, then after a cessation of months, as in winter, surely there should be no question as to a cure, and yet, we know when spring arrives business opens at the same old stand."

I am not certain that I can give a satisfactory reply to this, yet reply is not utterly lacking. Although nearly all cases of transmittal may be in the way I have indicated, yet that is not the only way, and my friend is quite right in saying, "There must be some other way." That other way may be through the introduction—I think we might say the accidental introduction—of a spore; for in a way the usual introduction is not accidental, but intentional, at least so far intentional that it is the intention of the nurse-bee to feed the infected juices, whereas there is never any intention to feed the dried spores. It is to be remembered that in a colony, or in an apiary, where European foulbrood has existed for even a few weeks, these spores, or dried seeds, abound by the million. They are scattered over the combs and in the cells, on the floor and at the entrance, and all over the ground for a distance of rods. Is it

any wonder that now and again one of these spores, possibly sticking to the toe of one of the nurses, should accidentally fall into some baby's porridge and make a start of the disease? Take a bad case in the fall, where multiplied millions of spores are all through the hive, the bees too discouraged to clean up, and is it at all strange that the following spring a few spores should find their way into the food of the larvæ? In line with this, you will probably find that early in the spring the case is not nearly so bad as it was the previous fall; indeed, you may not detect it at all until June. This accidental swallowing of a spore by some baby may account for the fact that after a cure has seemed complete the disease may turn up again in the future.

Now, my friend, I'm not sure that this answer to your question will satisfy you, and to tell the truth, it doesn't fully satisfy me. By any sort of reasoning I can use, it seems to me it ought to be the rule that the cessation of brood-rearing for the winter should at least generally result in a cure, and it doesn't. To be sure, I suspect that if close watch were kept it would be found that cases of over-winter cure are not altogether wanting. But the explanation I give is the very best I can do, even to accommodate so good a friend as you. If you can offer a better, I'll gladly accept it, or if you'll offer a theory more easily accordant with all the facts, I'll drop mine like a hot potato.

You further say, "You state that you do not find dead larvæ after they have been dead long enough. I am wondering whether three or four days might not be just as good as ten, if the condition of the larva was the determining factor." What a revolutionist you are! Of course, you know that I was trying to follow the Alexander treatment, and by mere blunder made the time of queenlessness shorter than he. His plan was to have the colony without egg-laying 27 days, and he was very emphatic that it should be "not a day less." I was criticised very severely for my presumption in cutting down from 27 days to 16, and now you come suggesting 3 or 4! Well, between you and me, I was never very sure about that 10 days, but 10 is a round number, and I wanted to be on the safe side. As to cutting down still further, suppose we figure a little. The larvæ are fed during a period of 5 days; so if we should stop egg-laying for 5 days it would seem it might stop the continuance of the disease. But is a larva effective as a disease-carrier at any time of its 5 days' existence? I don't know. I doubt. It may be fed infected pap the minute it hatches from the egg, but that doesn't immediately kill it. It may be, for anything I know, 2 or 3 days before it gets to the point where the nurses tear it open and suck its juices. Indeed we know that some do not reach that point before they are sealed over. So it is possible that no larva is torn open until it is 2 or 3

days old; in other words, it is effective as a disease-carrier during only the last 2 or 3 days of its larval existence. In that case it might not be very hard to grant your 3 or 4 days of egglessness.

Here's something that seems to me corroborative. Some have reported the curing of European foulbrood by merely changing queens. At least this treatment was successful in nearly all cases. Now, when a laying queen is removed and a new one is introduced, there is a break in egg-laying, which may be 2 or 3 days. I suspect it was the break in egg-laying rather than the change in queens that made the cure, and if that short break was successful in these cases, why not as short a break in general?

Of course, in so short a treatment the dead larvæ will not all be cleaned out; plenty of black ones more or less dried up will be found in the cells; but the bees will not eat them, and so they will not continue the disease. It's the big yellow fellows that count; if none of them are found present we may say, "It's a cure," no matter how many black larvæ are present. To be sure, there's always the possibility that a spore from some black larva may accidentally get into baby's dinner, but that's exceptional.

Even supposing a treatment of 27 days—or even 10 days—should be always successful, and that not more than 9 out of 10 cases should be successful with 3 or 4 days' treatment, I'm not sure but I should prefer the shorter treatment. For would not the gain in brood more than repay the few cases needing to be treated over again?

Some have reported success by merely putting the brood of a diseased colony, together with adhering bees, in an upper story, leaving the queen upon foundation or empty combs in the lower story, under an excluder. This may be accounted for by saying that nurse-bees are not inclined to travel far on the combs, and so do not go from the upper to the lower story to carry the disease. This may well be true, for when a colony is first attacked by the disease it will be found confined to one comb for some time, perhaps a week.

I've tried to answer as best I could; here's a question I leave you to answer. Once in a while a case will be found, not very bad, and without anything being done for it a later examination will show that the disease will have disappeared. On what sort of theory will you explain that?

Let me give you another item. You may know that during my first experience with European foulbrood I treated it the same as American. I assembled the diseased brood from all over the yard and piled them on top of one of the diseased colonies, several stories high, intending to treat this colony after the brood in the upper stories had emerged. After some three weeks I lifted off the upper stories and opened the brood-chamber with no little interest to see what I should find after an ag-

gregation of so much foulness. To my surprise, I found the disease was gone, not a yellow fellow left, and, so far as I remember, the disease did not show up again in that colony. Why? Did the developing of such an immense force of young bees have anything to do with the case? Marengo, Ill.

After having written the foregoing article, I sent my friend a copy of it. As soon as he could he wrote back telling me that (*bacillus pluton*) doesn't have any spores, intimating an easy way for me to make correction in my article before it got into print, so as not to expose my ignorance. I think, however, that I'll make no correction. Exposure may be good for me, for the fact is that I supposed no bacillus was ever so thoughtless as to be without its spore, and perhaps I ought to be more careful as to writing about things concerning which I know so little. So, instead of making any correction, I'll let you make your own corrections, after reading Dr. Phillips' letter, in which I am sure you will be interested.

C. C. MILLER.

Washington, D. C., May 25, 1918.

Dear Mr. Miller:

Your interesting article, prepared for the American Bee Journal was received while I was on the road. Our Mr. Sturdevant took it with him to Ithaca, N. Y., where he is to work on European foulbrood for a while and where I met him to help arrange some of the details. We went over the article together, and now I have brought it home to acknowledge its receipt. This will explain the delay.

There are one or two comments, one especially important, and which I think you will want to use as the basis of a change in your American Bee Journal copy.

You refer several times to spores, while (*bacillus pluton*) does not form spores. This fact upsets things a bit, for it makes it all the harder to understand how the bacilli live over winter. However, you can simply change the word "spore" to "bacterium" and not materially change the sense. We do not know how the vegetative bacilli can live over winter, and, since they cannot be grown on any bacteriological medium, it is difficult to get light.

You also speak of a "had case in the fall," but such a case is as scarce as hen's teeth. We have had samples here every month in the year, but after July it is usually dried material.

You could be more definite on over-winter cures, for they are not rare. In other words, when the disease disappears in July, if conditions are right for preventing the disease, it frequently never reappears.

I believe I told you that my father's little apiary was 100% European foulbrood in 1915, when I went out in June. I showed my brother how to shake on drawn combs (my second plan of treatment.) He introduced Italians and (most important of all) he built winter cases. No dis-

ease has been seen in the apiary since, but the region is full of it. I examined the apiary one week ago today and the colonies average brood in 15 frames. I have an idea that the folks at home will not experience a sugar shortage this year. A few colonies now have misnamed queens and I hope to get out home and requen these in August.

E. F. PHILLIPS.

Beekeeping in Jerusalem

(Concluded from June)

By Ph. J. Baldensperger

THE garden and thicket near the slopes of Moriah and up to the slaughtering place in the open on Mt. Zion were then a diminutive bee paradise. I found an ample collection of honey-plants all about the fields, in the hedges, on the ruins of crumbling houses, and often the city walls were lined with them on the inside—for seen from the exterior the walls are perfectly clean except near the tower of Hippicus, and the Jaffa gate dating, no doubt, from before the final fall of Jerusalem under Titus.

Broad-beans (*fava*), a favorite plant with orientals for kitchen use, were largely cultivated in early spring and gave plenty of honey and some pollen. The dried stalks and leaves are excellent food for camels and cattle.

Cactus hedges, originally planted to hedge in the fields, had become the principal plants in some fields there. The big yellow and orange flowers give an excellent honey in May, as well as plenty of pollen for rearing brood. Camels feed on the tender leaves, and the impenetrable thickets were shelters of generations of dogs—the hygienic police of ori-

ental towns—where refuse is continually thrown into the streets and hardly ever swept. Hygienic principles have certainly been applied since the Allies under General Allenby have once more delivered Jerusalem from the hands of the Turks.

Dandelions, marigold, mignonettes and one or two borages grow all about the vacant spaces and bees bun on them gaily.

Big mignonette, as well as mustard, seemed at home in the walls, and great shrubs of capers (*Capparis spinosis*) carpeted the walls, and the graceful white flowers invited bees. Some authors thought this plant the hyssop of Scriptures. Henbane (*Hyoscyamus niger*) and Horehound (*Marrubium vulgare*) grew about the wrecks of old buildings and the honey of the latter plant was so agreeable that we called it Rah-el-halome, as resembling in flavor the "Turkish delights," a sugar pastry usually prepared in Damascus.

Select cauliflowers grow all about the dung hills of Zion and Moriah, and the "fellahin" choose the best plants for seed; the immense bushes give much honey in autumn. Except for these last, all above-named honey-plants could be classified as swarm-preparing flowers, according to the prevailing east or west winds. The hives were usually in good shape for the best honey-plants in June and July.

Wherever the bees could reach the luxuriant thyme fields, which throve around the town, they made a splendid harvest. Our Nahale used to say that the thyme gave the best honey to seal the combs and then it was time to take out the crop. It is identical with the renowned Hymettus honey of ancient history. The most progressive of Judean kings, Herod the Great, had apiaries around his private estates, in his paradises of Ain-Rimmon and Herudium (a desolate paradise now), and Jericho. He used to send honey to the Roman court, and since then Jericho honey was greatly demanded by the Roman emperors. Cleopatra received the beautiful estate of Jericho with its select plants and hives and enjoyed them for some time.

The "fellahat" (peasant women) of Siloam and El Tur (Mount of Olives) almost exterminated the magnificent thyme bushes all around the town to use as fuel and for culinary purposes. They prepared their bundles and carried them home on their heads as if they were great wheels higher and broader than themselves. We used to admire their dexterity with their immense load, in perfect equilibrium as they toiled up the hills of Zion towards their villages. They sang in unison or chattered as if they were picnickers. Their assiduity in plucking up the precious bee-plant has rendered beekeeping almost useless between the walls and the road leading all around the town. There was originally a broad and deep ditch sometimes over a hundred feet wide. The ditch has partly disappeared.

From the Jaffa gate to the corner of Tancred's heights on the west, the

Ph. J. Baldensperger, who is writing for us a series of articles on Beekeeping in the Holy Land.

Greeks and Armenians had buildings and olive yards. Around the Jaffa gate and the Tower of Hippicus a deep ditch with a luxurious growth of honey-plants embellished this part, at least from the bees' point of view. From Tancred's Heights (the part whence Jerusalem was stormed in 1099 A. D.) to the Forth of the Storks, the ditch was in good condition and afforded plenty of food for birds and beasts.

As carcasses were thrown in, dogs, ravens and vultures found food by day; jackals and hyenas carried off what they could by night. The land was manured and gave plenty of honey-plants. Skeletons were left to bleach in the sun forever. From Stephen's Gate to the corner of Moriah the ditch was transformed into a Moslem cemetery, where they repose near their sanctuary till Judgment Day. Olive trees grow on the slopes toward the Cedron, and innumerable squills (*Scilla maritima*) grow around the Moslem and Jewish cemeteries beyond Cedron.

Squills begin to bloom about the 15th of August, a sign, our Nahale used to say, that the Nile in far away Egypt was overflowing. The flower stalks are much visited by bees and they carry home quantities of white pollen.

From Moriah to Zion and around to the Tower of Hippicus the ditches have been filled up with city refuse, carried out through ages. Centuries of continued heaping up in the ditches has lowered the road on the south side, and often the road resembles a trench of which the walls are piled rubbish. The big, slanting rampart below the Tower of Hippicus, sometimes called "David's Tower," was full of bee-plants, the bottom of the ditch was overgrown with cactus hedges, which gave plenty of bee forage in spring, and prickly pears at the service of whoever could reach them.

Common marjoram (*Origanum vulgare*), as well as different species of peppermint, grew here and there. Not only the bees found food there,

but the natives used the leaves of the Traatar, the first-named aromatic plant, which they dried in the sun, crushed and ate as a condiment with their bread. The stout shrubs of Pistachio had never time to grow very high, as they were cut down every year, yet the bees found an odoriferous, resinous matter for use in their hives.

How we envied the Tapji (artilleryman) when he was seen in the midst of the tropical flora, cutting down with his sharo sickles big bunches of rose-colored antirrhinum purpureum. I saw later that the big flowers containing honey for more than one bee each were never utilized by the domestic honeybee. The big blue-black giant bees, the wood bee, bit the flower open at the base of the calix and pumped out the nectar in this original way. Bumblebees of different kinds also sucked at the deep-calix flowers.

In Jerusalem, as elsewhere, I found in later years that almost all native beekeepers distinguished two very different kinds of bees, one very gentle, the other furious. In Egypt they called the furious kind Shami, or Syrian bees, and the gentler kind Baladi, or native bees. Egyptians are, as a rule, more submissive than the wilder, indigent Syrians. The same must hold true of their bees.

Nahale, as well as others of his school, assured us that there were two very distinct kinds in Palestine—the Harthi (agricultural or ploughing bee), were the more infuriated, and the Malki (possessing or royal bees). The Fellahin are considered less civilized and are warlike, whilst the upper classes in towns were gentler and submitted to royal laws.

The Harthi build long combs like furrows made by the plow, from the back to the flying hole, while the Malki made beautiful circular combs like full moons, said Nahale. When he examined the latter bees he blew them back with the tiniest whiff of smoke and he could take out the honey without receiving a single sting. Not so with the Harthi; all

their combs ended at the back, and he had all the streets filled with bees. They were managed with great difficulty, as every modern beekeeper understands, and this haphazard building made them a new race. Even here in France, I often heard amateurs talk of a furious and a gentle kind of bees, and they were astonished after having warned me of the fact, to see me manipulate the furies just as easily as the gentle ones. Most such persons cannot understand the secret, which lies wholly in the quality of smoker, or also, very often, in the harsh hands of the beekeeper himself.

Harthi and Malki bees were as busy carrying honey to their hives in spring, when rain did not fall, one as the other; both suffered equally from drought when the drying winds from the east or south left no parcel of moisture in the nectaries, and the odoriferous thyme bushes were almost burned by the fierce sun.

Nahale would usually come out to Zion's school, where he had the bees, on or about the 15th of August, which, according to the Catholic church, is the Ascension Day of the Virgin Mary. But Nahale was a stout Moslem, and I often asked myself if how he adhered to a Christian date.

The overflow of the Nile, at least the springing up of the high stems of the squills; the feast of Paphos in Cyprus, to the feast of the virgin; the worship of the Judaites in the days of Jeremiah, to another regina or queen of heaven; the wax offerings to Ceres in Greece; the offerings of first fruit to Demeter in Sicily, or to Derketo at Jaffa, before Hebrew history—all of them point out to the same origin, with almost the same ceremonies, with products of the honeybee as principal offerings.

No wonder that Nahale, who knew Miriam el Bathul, that Shpeta, an orthodox Greek Christian who knew El Adra Miriam, all respected the same person in the same place at the exact season as it had been practiced for many thousand years, though giving different names.

Harthi and Malki bees were forgotten as well as Ceres, Ashtoreth or Adra, for on the 15th day of August it was honey day, and the beautiful combs, thick with thyme honey, drew out one Masha Allah (What God hath granted) after the other. Sober in words, Nahale did not say much more, but Shpeta in Ramler told me that the image of the Adra, or of her hands were perfectly acknowledged in the honey-combs. A prior of the Greek convent explained how the objects of value were found in the day that she came out of the sea—evidently she was Ceres, but christened Mary.

Our neighbor across Hinnom el Asalli was a wealthy descendant of the honey man who gave his name to a street in Jerusalem.

He had gathered his wealth by selling Asall (honey) taken from the apiaries which were built against the high city walls of Zion.

Jerusalem on the west side. at the left, the valley; in the center, Notre Dame de France, near Tancred's Heights; at the right, the Tower of Hippicus; the town walls in the foreground.

Honey was given to us at breakfast when we were infants in Jerusalem, and we have not yet become tired of it, but take it once or twice daily now, and the grown-up girls enjoy it greatly.

Nice, France.

An Open Letter to F. Dundas Todd

By A. C. Ames

I HAVE carefully read your article in May issue of American Bee Journal. As you used my name, I feel free to reply to you. However, you placed me in Iowa, which is an error. I have been on the apiary inspection force of this State (Ohio) for five years.

I believe, Mr. Todd, if you were on the inspection force of some of our eastern States you would have a different idea in regard to the handling of the bee diseases than you have. One of the few things that are established in bee culture is that different localities require different methods of management.

Your method of treatment, or rather eradication of bee diseases, will be successful if you do not have the following conditions to contend with. In a State the size of Ohio it would take one hundred to one hundred and fifty men working the entire summer to inspect every colony in the State. You will admit that it is necessary to have trained men for this work. Where are we to get the men? We have trouble obtaining satisfactory men with only three on the force. Is there any State in the United States or Province of Canada that will furnish one to two hundred thousand dollars to do this work, and continue it one year after another? No. The beekeeping industry is not important enough to justify such an expenditure. We, of course, do not consider beekeeping of minor importance, but the general public does, and it does not compare with other things agricultural—either in value of output, number of men employed or of capital invested.

Another thing—what are you going to do with bees that cannot be reached? I believe you will admit that there is no difference between our so-called domesticated bees and wild bees. I believe there are as many bees in trees, houses, etc., in Ohio, as there are in hives. I know of one wood lot of 2½ acres that was cleared and contained thirty-five bee trees.

This probably is an exception, but with careful search I feel certain that bee trees can be found in nearly every wood lot in Ohio. Bee trees harbor disease—I have found it there, and have had beekeepers that I have made clean up prove it to me and ask me: "What are you going to do about it?"

Another thing—you have no large cities in your territory, or at least none that receive honey from all

points of the compass. Around all our large cities, such as Cleveland, Cincinnati, Toledo, Columbus, etc., we have continual outbreaks of disease. Why? Because the empty sections and containers are thrown out and bees usually clean them up. That is well and good, but if the honey came from a diseased apiary, what then? You would soon have every beekeeper in or near our cities burned out of business.

We in Ohio do make an honest effort to compel our queen-breeders to keep their yards free from disease, and, what is more, we usually succeed. Our queen-breeders never know when to expect us, and they also know that if we find disease they will be placed under a rigid quarantine. That is not a nice position to be placed in—with orders to be filled and general queen-breeding operations under way. When this happens it usually makes a break that pretty nearly spoils a breeder's whole season. As a result, our breeders are careful. To do them justice, however, I believe they would be careful anyhow from a business point of view. They are a pretty good sort of men.

Now, I want to tell you about my own yards. In 1916 I had the worst attack of adult bee-trouble I ever saw. What it was I do not know. Dr. Phillips, E. R. Root, Mr. Bocoek from England and others visited my apiary. None could offer any real advice. All, however, advised to re-queen, which I did. The disease gradually abated and by late fall very little could be found. It cost me several thousand pounds of honey, but as a result of the re-queening I had all my bees in good condition for 1917. I, however, raised my queens from an Italian strain that was not resistant to European foulbrood. I did not give this disease any thought, because, so far as I knew, there was none of it nearer than fifty miles. Imagine my surprise to find European foulbrood late in May, 1917. This required re-queening again, and a careful watching of the brood-chambers. When I first discovered this disease I found three cases at home and two at the outyard. Over 50 per cent of my bees were diseased at some time or another through the season. I re-queened everything, but I took 100 pounds average extracted honey, although the season was generally considered a failure. You do not state as to your method of handling European foulbrood, but if you handled it as you do the American you would have to inspect the diseased yard every few weeks all summer, and you would make no headway, for it can only be controlled by a resistant strain.

Many of our best beekeepers in both Canada and the States consider it a greater plague than the American.

This spring I have 130 colonies in the best condition I have ever seen bees at this time of the season. My winter loss was about 5 per cent—mostly due to starvation, as the bees

were under 6 to 8 feet of snow for about eight weeks, and while under the snow started brood-rearing, which exhausted their stores. I winter in four-colony cases. This spring I have so far found twenty cases of American foulbrood, but no European foulbrood. I expect it to show up, though. The wonder to me is that none is in evidence yet. It may be due to the fact that I did not allow a single colony to become badly diseased last season, as I examined every brood-nest every seven to ten days throughout the season.

But to return to the American foulbrood I have this season. To treat that by your method of eradication we would burn those colonies. There is not a colony in the lot in which a dozen diseased cells can be found, and the colonies will average seven combs of brood today, with the clover flow thirty days off. The most of those colonies are carrying supers today, or they would swarm out during the fruit bloom, which is now on. To burn those colonies would mean the burning or destroying of—if we have a good season—3,000 pounds of honey and the loss to me of a round \$500, and this at a time when we need every last ounce of food possible to obtain. I should resist the burning of those colonies by every means in my power.

I am not saying that it will not work with you, for under your conditions it probably will. But I do contend that under conditions as they exist in Ohio, your plan will not work, and I do believe you are making a mistake in advocating such a plan for universal use. One of the greatest faults I have to find with our bee journals is the publishing of plans of different sorts that for their success demand a condition that is not universal. It may be permissible to publish these plans, but qualifying statements should be made.

To refer again to my bees. I am certain that my outfit is in far better condition because of my having had the diseases, than it would have been had I not had the diseases. The disease made me do things that I knew ought to have been done that I probably would have neglected. In other words, it made me give my bees close attention and do the things that you and I and other apiary inspectors are advising beekeepers to do, that we do not do ourselves.

I do not believe there is any apiary inspector who can examine a large apiary known to be diseased and discover every case of disease present on one inspection. I have examined my yards three times this spring and each time I have found additional cases, and I expect to find more, and I have had no robbing.

For several years I have held that with us it was too much to hope that we can ever eradicate bee disease. But we can teach our beekeepers how to handle the disease, and that is what we are trying to do.

Weston, Ohio.

Women's Clubs and the War Foods

By Mary G. Phillips

IT used to be that mention of Women's Clubs made men, and many women, smile, and some supposedly intelligent women even prided themselves upon the fact that they did not belong to a club! But that day is past, thank goodness! and the way in which groups of women are begged to help, or to use their influence in all sorts of civic and national problems, is sufficient evidence that clubs justify their existence. Just as important as the aid they render a community, however, is the inspiration and stimulus they give to the individual member, and it is this which we miss if we drop out of our neighborhood clubs in order to give more time to war work. I believe that it is far better to keep your club, but turn it into an instrument for helping win the war.

Of course there are clubs, and clubs. In one small community of my acquaintance, composed of about thirty-five families, there were three flourishing clubs several years ago. One was a sewing club which met at noon, ate a sumptuous lunch, and spent the afternoon either mending or embroidering, according to the size of the family of the individual member, and talking, the discussion ranging not far from kitchen and children. The second club was frankly a card club, composed of women who felt the need of relaxation from the cares and responsibilities of housekeeping. These two clubs flourished side by side for many years, and it was not until three years ago that the growing need for something different crystallized into a new club. The women who formed this last one felt that they did want the stimulus that comes from rubbing up against other minds, and they did want their thoughts turned occasionally into channels other than those which had to do with their everyday tasks, but they wanted the new channels to lead somewhere. So the new club, scoffed at as "high-brow," affiliated immediately with the County Federation, in order to know what lines of helpful work were being carried on and to become a part of the large movement for better schools, better care for sick and needy children, etc.

Now, what has happened to these three clubs since the war changed our whole fabric of daily life? At first, the more thoughtful and earnest workers dropped their club membership to enable them to give the time to Red Cross work in the city. This made the clubs sit up, and it was not long before each made its decision as to its future character. The sewing club dropped its luncheon, each member bringing two sandwiches for herself, and the sewing became Red Cross work. This club is now an active Red Cross Unit, and every woman in the town works there instead of taking the long trip

to the city. I regret that the second club remains a card club, for these poor, overtaxed members, carrying so great a part of the burden of war, feel more than ever the need of relaxation. The third club, after much deliberation, decided to keep its identity and to help the war work in avenues other than the Red Cross. With the insistent needs of the Red Cross ever before us, it is hard to remember that we must not relax our efforts one iota in helping on the usual work which falls to women's lot in a community. So this club is continuing the encouragement of gardening and canning in the colored settlements nearby, is still carrying on the work of the visiting nurse in the county, and other such work. Naturally, the character of its meetings has changed materially since the war began, and that brings me to the point of my story—the connection between clubs and food. Every club should be a center of food conservation today. Is your club doing it? If not, cannot you see that every meeting includes a discussion of the latest news from the Food Administration?

For the June meeting, the Friday Club had a Hoover Day, when each member pledged herself and her family to wheatless meals until harvest. The wheat substitutes, rice and rice flour, cornmeal and corn flour, barley, oatmeal, potato flour and peanut meal formed the basis for the program. Each talk on a substitute was only five minutes long, but in that time much was learned concerning the production and use of each one. Food Administration posters and Hoover costumes added a touch of color to the room, and on the table were all sorts of delicious foods, breads, muffins, cakes and puddings, made entirely from substitutes. Each member had contributed her best recipe and a sample. As these were tasted and discussed, two things became clear—that better results are obtained generally if you mix two substitutes instead of using just one, and that you can use your old favorite recipes if you follow the Food Administration table of substitutions. This table is invaluable if hung on the kitchen wall where it may be consulted conveniently.

Measurements of Substitutes Equal to One Cup of White Wheat Flour

Barley— $1\frac{1}{2}$ cups.
Buckwheat— $\frac{7}{8}$ cup.
Corn flour—1 cup (scant.)
Corn meal (coarse)— $\frac{7}{8}$ cup.
Corn meal (fine)—1 cup (scant.)
Corn starch— $\frac{3}{4}$ cup.
Peanut flour—1 cup (scant.)
Potato flour— $\frac{3}{4}$ cup.
Rice flour— $\frac{7}{8}$ cup.
Rolled oats— $1\frac{1}{2}$ cups.
Rolled oats (ground in meat chopper)— $1\frac{1}{2}$ cups.
Soy bean flour— $\frac{7}{8}$ cup.
Sweet potato flour— $1\frac{1}{2}$ cups.
You see from this that you can use any recipe that you like, the only difference being that instead of using wheat flour you substitute the amount of some other grain or a mixture of two, according to this ta-

ble. The batter often looks too thin or too thick, but you will find that if you have measured accurately (all measurements being level), the result will be good after baking. All substitute mixtures should be baked **more slowly and longer.**

The best cakes made from substitutes at the meeting were the three for which I give recipes below. The sponge cake was especially light and tender, and as corn flour is not very expensive, it does not make an expensive cake, particularly if you have your own eggs:

Corn Flour Sponge Cake

4 eggs.
2 tablespoons lemon juice.
 $\frac{7}{8}$ teaspoon salt.
1 cup sugar
1 cup corn flour

Separate the whites and yolks of eggs; beat yolks until thick and lemon colored, then add the lemon juice and salt. Add sugar and beat until light. Fold in the well-beaten whites of eggs and the sifted flour and bake in a moderate oven.

Spice Cake—Using Barley Flour

$\frac{1}{2}$ cup fat.
 $\frac{3}{4}$ cup sugar.
1 cup syrup or honey.
3 eggs.
 $\frac{3}{4}$ cup milk.
1 teaspoon vanilla.
 $\frac{1}{2}$ teaspoon ginger.
6 teaspoons baking powder.
 $\frac{1}{4}$ teaspoon salt.
1 teaspoon cinnamon.
 $\frac{1}{2}$ teaspoon cloves.
1 teaspoon allspice.
 $3\frac{3}{4}$ cups barley flour.
1 cup raisins.

Cream the fat, sugar and egg yolk. Add the syrup and mix well. Mix or sift the dry ingredients and add alternately with the liquid. Add the flavoring and fold in the well-beaten egg whites. Bake for one hour in a moderate oven, increasing the heat slightly after the first twenty minutes.

Chocolate Cake, Using Buckwheat Flour and Ground Rolled Oats

$\frac{1}{2}$ cup fat.
 $\frac{3}{4}$ cup sugar.
1 cup honey or syrup.
3 eggs.
 $\frac{3}{4}$ cup milk.
1 teaspoon salt.
12-3 cups buckwheat flour.
 $\frac{1}{2}$ cup ground rolled oats.
6 teaspoons baking powder.
1 teaspoon cinnamon.
2 squares chocolate.
1 teaspoon vanilla.

Cream the fat, sugar and egg yolks. Add the honey and mix well. Add the dry and liquid ingredients alternately. Add flavoring and melted chocolate. Fold in well-beaten egg whites. Bake about one hour in a moderate oven, raising the temperature a little after the first twenty minutes.

Going without wheat seems like a little thing to do when we read of the ration our American prisoners are living on in the prison camps of Germany. Here is a sample:

Breakfast—Acorn coffee, two slices of bread made of rye, sawdust and potato flour.

Dinner—Soup with a small piece of tough beef, coarse turnips and no potatoes.

Supper—Soup again, with two slices of bread.

Red Clover as a Honey Plant

By Frank C. Pellett

THESE have been so many conflicting statements regarding the question as to whether or not the honeybee is able to secure honey from red clover (*Trifolium pratense*), that it has seemed worth while to investigate the subject with some care. There have been so many reports of honey from this source, that it is desirable to learn whether the honey did come from red clover, or whether the beekeepers have been mistaken, and some explanation of the confusion is necessary. There is no question but that the plant secretes nectar in abundance, but since the corolla tubes are much longer than the tongues of the bees, they are unable to reach it under ordinary conditions. It is a well-known fact that plants behave very differently under different climatic conditions, so an effort has been made to secure evidence from as many localities as possible, and from a great variety of conditions.

In Iowa the writer has sometimes found bees working freely on red clover in extremely dry seasons. At such times, the bees were apparently getting some nectar, although it could not be detected in the hive. However, one year Mr. C. H. True, of Edgewood, Iowa, had on exhibition at the State Fair a generous quantity of honey which he thought was secured from red clover. It was slightly tinted with red, and had a flavor different from white or alsike clover honey. The explanation often given is that in dry seasons the florets are somewhat dwarfed, and because of the shorter tube the bee is able to reach the honey. Dr. L. H. Pammel, botanist at the Iowa College of Agriculture, has made a special study of bees and red clover under Iowa conditions. After having many measurements made, he has reached the conclusion that the effect on the length of the corolla tube, as a result of drought, is so slight that the bee would not be able to reach the nectar from this cause. He goes on record as follows:

"I have for several years closely observed honeybees and red clover, and from these observations I am still inclined to the opinion, earlier expressed, that honeybees do not get nectar from the flowers of the red clover, notwithstanding the opinion of many beekeepers in Iowa." (Third report Iowa State Bee Inspector.)

At the 1917 convention of the Illinois Beekeepers, Mr. Frank Bishop, of Virden, reported that one season he secured an average of 100 pounds per colony from 150 colonies, from red clover. According to his statement, there was no other bloom within reach at that time. He further stated that he visited the red clover

fields, investigated the matter carefully, and was fully satisfied that red clover was the source of the honey.

So many reports from well-known beekeepers are to be found in our literature, that it seems worth while to quote several of them, together with the place where the reference is to be found. Mr. Wm. McEvoy, of Woodburn, Ontario, wrote to *Gleanings in Bee Culture*, page 486, 1907, as follows:

"In September, 1905, I extracted over 3,000 pounds of pure red clover honey, after giving the bees plenty to winter on. This honey was a light amber color, and good in flavor, and sold for the same price as honey gathered from white clover. My bees, being Italians, worked well on the second crop of red clover, which was not injured by the midge in my locality, in 1905, on account of the first crop being cut early."

Adrian Getaz, of Knoxville, Tenn., makes the following contribution to

Red Clover Blossoms.

the subject in *Gleanings*, page 660, 1909.

"In regard to bees gathering nectar from red clover, several opinions have been advanced. Generally it is supposed that owing to drier weather, the second crop has blossoms with shorter corollas, and that the bees can reach the nectar on that account. Another theory is that the nectar is more abundant, and fills up the corollas better, and thus comes within reach of the bees. A German apiarist a few years ago undertook to settle the matter, and spent a part of the summer lying down in the clover fields to see how it was. He reported that very few insects take the nectar through the corollas; but some kinds cut a hole near the bottom and help themselves through it. The hole once made, a number of insects, including bees, take advantage of it; and if the bees do not work on the first crop, it is because there are few hole-boring insects present."

Here follows a brief report with nothing to indicate whether the bees were seeking nectar or pollen:

"Last year was very dry and there was scarcely any white clover in

blossom here; but the bees went fairly wild on the red clover, and it was the first crop, too." (J. F. Brady, Deerfield, Minn. *Gleanings*, page 149, 1911.)

That the subject is not new will be found by examining the files of the bee magazines of many years ago. Apparently it has been a controverted subject since beekeeping has been followed seriously in America. In the first volume of the *American Bee Journal*, page 228, 1861, we find the following:

"I noticed, in August and the beginning of September, while the bees were gathering honey from buckwheat, that they obtained pollen of a brownish color from some source. On investigating the matter I found that they collected it from red clover. This somewhat surprised me, as I had never seen them gathering honey from the red clover to such an extent, particularly while other forage was plenty. * * * I have also noticed that the bees visited only those heads that were imperfect, the tubes being shorter in consequence."

The principal interest attached to the above is the statement that the bees visited only the imperfect blossoms. On page 9 of the same volume is a statement somewhat similar, reported in one of the German journals, of Italian bees getting honey from red clover, in 1858. It is said that the season was very dry and the blossoms somewhat smaller as a result.

In 1899, page 15, *American Bee Journal*, we find another report of bees working on it in dry weather:

"My bees work more or less on it almost every year during hot and dry weather; but it does not produce as fine honey as white clover; when candied it is coarser grained, and has a water-soaked appearance. I wish that my bees would let it alone, for we have plenty of white clover when the red is in bloom" (Fred Bechle, Poweshiek County, Iowa.)

Again, on page 27 of the same issue, Theo. Rehorst, of Fond du Lac County, Wisconsin, reports:

"The mammoth red clover produces good honey and all our honeybees can reach the nectar, although the corolla is far longer and deeper than the common red clover. I never saw any honey from common red clover; only thin, red stuff, thin as water."

In 1903, E. E. Hasty, of Ohio, wrote, in the *American Bee Journal*, that while he admitted that bees worked freely on red clover at times, he was extremely doubtful about their ability to get much honey from it. The same doubt has been expressed by numerous observers from time to time, the usual explanation being that the bees are gathering pollen, rather than nectar.

On page 491 of the 1903 volume of the *American Bee Journal* is reported an interesting case of honeydew from red clover. Since it is the only case of the kind found in all the literature consulted it is quoted quite fully:

"For about ten days my bees have been bringing in honey from the

second crop of red clover. Now this is nothing remarkable, for I have seen them doing so for more than twenty years past; but recently, passing through a field of red clover in bloom, I stopped to watch them, and, to my surprise, found them working, not on the blossoms, **but on the leaves.** This, I confess, I had never seen before. On closer examination I found the clover leaves covered with small plant lice, and the under leaves covered with honeydew, very similar to that frequently found on the leaves of the hickory, oak and other trees, though the honey is not so dark-colored as from leaves of trees."

On page 839 of the American Bee Journal for 1906 is found a rather convincing discussion of the subject of honey from red clover. It was at a convention of the National Association, and several men of wide reputation took part in the discussion, and testified to the fact that they had secured surplus from red clover. Hutchinson stated that he had secured 500 pounds from red clover at a time when there was nothing else in bloom, and that it was a light amber or dark white color. Messrs. Townsend, Stone, Davenport and others agreed that they had secured red clover honey, Townsend reporting as much as 2,000 pounds stored in two weeks' time.

The subject is discussed at length in Bulletin No. 46 of the New Zealand Department of Agriculture, by Isaac Hopkins, whose experience in this connection is interesting. We quote him in part:

"In my early days of beekeeping it was a moot point whether Italian bees worked on red clover or not. At this time I had a unique opportunity of testing the matter thoroughly, an opportunity which would rarely occur; therefore, I feel myself on safe ground when dealing with Italian bees and red clover.

"For five years (1882-87), I was located on the late J. C. Firth's estate at Matamata, where I started large bee farms. My bees, which were chiefly Italians, were near to thousands of acres of red clover. * * * Now and again we saw a few here and there gathering pollen from the blossoms, and sometimes a good deal of pollen from red clover was brought in when, no doubt, it was scarce elsewhere.

"In order to make a thorough test, I shifted, on one occasion, a number of strong two-story colonies to the center of a 700-acre paddock of red clover. The first crop had been cut for hay, and the second crop flowers were just opening. There was no ordinary bee forage anywhere near. After the fourth day, I examined the hives and found from the odor that came from them on removing the covers that some nectar had been gathered from the surrounding clover. I also observed that some clover pollen had been stored.

"There were two seasons out of the five when my bees worked more freely on the red clover than in others. In those seasons it was noticeable that

myriads of small slate colored moths flitted about the clover, while they were rarely seen at other times. I was much interested, and in casting about for the reason, I became satisfied after very many tests that the red clover was secreting at times much more nectar than usual, and it may have been that it reached a higher level in the tubes on these occasions, and so came within reach of the tongues of the bees. Be that as it may, some red clover nectar was gathered from second crop flowers in these seasons."

While the different observers are by no means agreed as to the reason why the bees are able to get nectar from red clover on occasion, the testimony is very closely agreed upon the fact that it is only from the second crop, and in hot and dry seasons, that the bees are able to store honey from this source. So many widely-known men come forward with the positive statement that they have been able to secure surplus honey from red clover, that we can hardly question the fact that honey is sometimes stored from this plant. Whether the corollas are punctured by other insects, the tubes are shortened by drought or the nectar rises higher in the tube, remains to be proven.

How I Won My Bee Honors

By D. M. MacDonald

MY apicultural training began in my boyhood, over 50 years ago, in the dear home garden, with its multitude of perennial flowers, its abundant fruit bushes and its miniature orchard of apple, plum and other nectar-bearing trees. The small valley was an ideal honey-producing one. In the summer every meadow field was like a garden bed, the white clover covering it as with a mantle of white, and in autumn the sloping hills on either side, for leagues and leagues, were one mass of purple heather, smelling on the glorious days of August and September sweet as a honeycomb.

Over forty years ago, in my own apiary, working among the bees was an unmeasured delight, and when the bee fever caught on, the pursuit became a fascination, and the study of the indefatigable workers became a charm. That the hobby proved a paying one increased the zest and added to the interest. My day's work only occupied from 10 a. m. till 4 p. m., with Saturday an off day, and Sunday, of course, a day of rest. So there was ample time for prosecuting the pursuit.

Fortunately, too, I was early introduced to bee literature of the best, those ancient tomes which breathe the true spirit of the Bee Master. For pure, unmitigated enjoyment, commend me to an old, old beebook. Its perusal opens up a new and untainted pleasure. As a counterpoise I was made familiar with the masterpieces of the New World—with Langstroth's inimitable treatise, with Quinby's "Mysteries," with Root's admirable compendium, with Glean-

ings, and the Old Reliable. My own library was being steadily added to, and every beebook known was open to me.

About thirty years ago I made attempts to add to bee literature, and finding every article submitted accepted, I broadened out, sending contributions to America. There was in all this a fair foundation for presuming to aspire to adding the title of "Bee Expert" to my name. Urged by some members of the Council of the British Beekeepers' Association, who desired me to act as an examiner for the Third Class north of the Tweed, I resolved to make the plunge, in August, 1909.

Almost under the shades of Carlisle Ha. in the sweet valley of the River Eden, and looking out in the distance on the Cumbrian Mountains, clothed at the time in a rich dress of purple heather, I underwent a rigorous examination in all the branches of practical beekeeping. The examiner was thoroughly conscientious and occupied the full time specified. The dusk of evening being well advanced made the queens hard to find, and the day being rather unfavorable, handling bees and frames was a trying ordeal. However, in due course, there came down from headquarters the intelligence that I could write myself down a "Third Class Expert."

The Association has wisely decreed that no man shall proceed further unless he proves that he can handle bees and show that he has a good general knowledge of the whole art and practice of beekeeping on modern lines.

My ambitions, however, aspired higher, so, after a holiday in the South of England, visiting some of the leading apiaries there, I had a hard grind preparatory to sittings for the higher pass. This examination was all in writing, held near home, with a Major approved by the Council of the British Beekeepers' Association, to supervise the proceedings. The time allotted was five hours, the first half being taken up with the practical side of the subject and the other half with the scientific, five questions being given in each section, and every minute of it was taken up with busy writing. The test was a fairly severe one, as each question not only required several pages of foolscap to answer, but several of them had to be supplemented by drawings and sketches illustrating the subject treated, such as various organs of the bee.

At the close, the Superintendent sealed up the papers and posted them directly to the Secretary of the British Beekeepers' Association. The examiner receives only the numbers assigned to each candidate, no names being sent to him. In due course notice came down that a pass had been secured and later a "Second Class Certificate."

The first pass was merely a preliminary skirmish, in fact it is now described as the "Preliminary" examination. The second was to test the examinee's mettle. The crux of the

matter had yet to come. Towards the end of May in the following year the final examination was held. It somewhat resembled the former one, but candidates have to show evidence of a superior education. It covers a wider field, too, and embraces a knowledge of the bee literature of the Continent and America. The questions on the anatomy and physiology of the honeybee, in my case, were distinctively stiff and searching. No superficial knowledge would suffice to obtain a decent pass.

It may be well here to give a brief summary of the field covered in the three examinations. The lowest consists of two parts. The first is taken up with a series of manipulations of hives, piecing together sections, frames, inserting the foundation in these, handling bees, spotting queens and handling frames. Few candidates fail in this branch. The second which consists in oral questions, may be made a severe test, covering, as it does, the whole field of elementary knowledge of bees and beekeeping.

To pass the second, candidates must show evidence of a fair education, and the knowledge demanded includes the following: 1. The natural history of the honeybee, with its anatomy and physiology. 2. Products of bees. 3. All about swarming. 4. The apiary as a whole. 5. Handling frames and manipulating stocks. 6. Wintering bees. 7. Difficulties of beekeeping, including diseases. 8. The work of each month of the year. 9. Honey and wax extractors. 10. Smokers and other appliances for subduing bees. 11. Comb foundation, fitting in, etc. 12. Our bee flora. The most common nectar-bearing flowers and trees.

For the final pass evidence of a good education has to be certified, and at least three years' practical experience of beekeeping is requisite. Candidates will be subjected to somewhat severe tests in any or all of the subjects given above and they will be required to show a satisfactory acquaintance with the best literature on bees and beekeeping.

Even then the ordeal is not over for them. If they pass the paper test they must deliver a short lecture on some beekeeping topic before the Board of Examiners in London. The subject is given out to the candidate only five minutes before he is called on, and that time is given him for thinking over the topic selected. At the option of the Board, he may be subjected to a further oral examination as well as to practical tests of his abilities. In my own case I had to deal with "The Pitfalls That Beset the Footsteps of a Novice, and the Advice You Would Give in Order to Save Disaster." The title is somewhat paraphrased, as the Council may consider they have an "all rights reserved" claim on the original for future use. In course of time the "Final Certificate" reached me and I became a full-fledged "Expert."

These certificates are highly valued, and many of their possessors, by their holding the Final, have been

able to secure good situations as lecturers, experts and instructors in beekeeping to many of our County Councils and to some of our agricultural colleges. Amongst these certified experts are several ladies. They make excellent candidates at all the three stages, and in the final of those who secure 90 per cent and upward, generally half are of the fair sex.

My position as examiner of the paper work of the intermediate and final, enables me to conclude that excellent results follow the close study of the whole field of beekeeping ne-

cessitated by the preparation for a pass in these stages. It is almost impossible but that these young men and women must turn out better apiarists as a consequence of the efforts made.

The recently re-constituted Scottish Beekeepers' Association, through their Council, are making an earnest endeavor to organize somewhat similar examinations, with power to grant certificates—but on a rather wider basis. The Irish Beekeepers have been issuing expert certificates for a good many years.

Banffs, Scotland.

Bees in the City

Would the action of the council mentioned in the following clipping be legal, and would it stand?

Pennsylvania.

"By unanimous vote the Council passed on first and second reading an ordinance forbidding the keeping of bees anywhere in Franklin within 500 feet of a dwelling house. It was conceded that there are very few places left where bees may lawfully be kept in Franklin when this ordinance passes. A fine of \$25 is imposed, with jail for 30 days if fine and costs are not paid. Mayor Emery stated that only two or three citizens will be deprived of their bees by the ordinance. He said the keeping of bees is a menace to the neighborhood, and instanced a case where he said children dare not play in their yard because of the bees kept by a neighbor. 'A bee is a useful ar-

ticle,' said the Mayor, 'but the city is not the proper place for it.'"

Answer—This is only another example of arbitrary action on the part of a town council. It would be no more unreasonable for them to pass an ordinance prohibiting the keeping of dogs within the city limits because somebody had been bitten, or horses because someone had been kicked. There is little chance that such an ordinance would stand the test in court. However, the beekeeper with only a few colonies kept for pleasure would find it too expensive to fight such a case. This is one more good example of the imperative need of an organization to look after such matters for beekeepers everywhere. With 5,000 members, a membership fee of a dollar each would pay for fighting such farcical ordinances, as well as providing other needed legal service for the beekeepers.

Conducted by MISS EMMA M. WILSON, Marengo, Ill.

Honey and Good Health

I notice very frequent objections to use of cane sugar. What can you say of the use of honey as a substitute?

A. Cane sugar requires digestion. When taken in concentrated form and in considerable quantity, it is irritating to the stomach in highly objectionable and various ways. Honey has the advantage that it requires no digestion, but is ready for immediate absorption. Honey contains various flavoring matters derived from flowers, some of which are harmful to some people. In fact, most people are able to take honey only in moderate quantities. A large amount produces discomforts, often headache. Some people are made ill by eating honey. Such persons are usually individuals who have been sensitized to the pollen of the plant from which the honey is gathered. The bee in the process of gathering honey collects considerable quantities of pollen and other foreign bodies. It is said that bees introduce into the honey minute quantities of a substance from a poison bag for the purpose of preserving the honey, which is accomplished by the formic acid which it contains. This is highly irritating, and in certain hypersensitive persons seems to produce unpleasant effects.

The foregoing is taken from that excellent monthly, Good Health. One is somewhat at a loss to know what will be the effect of its teaching upon the consumption of honey. The government is making urgent appeals to beekeepers to produce the largest amount of honey possible, advising the production of extracted honey rather than comb honey, because a colony of bees will produce a larger amount of honey in the extracted form; we are to Hooverize on sugar so that our allies may not suffer for want of it, and it is not strange that a seeker after good health, should turn to that most popular and reliable dispenser of information regarding matters of diet, and inquire what is to be said of the use of honey as a substitute for sugar.

In the reply certain things are said

The beekeeper of the South is modernizing his methods fast.

about the effects of honey and of sugar and each one is left to judge for himself whether it is advisable or not to eat less sugar and more honey. And it is not very hard to suppose that some might think somewhat after the following fashion: "Honey has flavoring matter, harmful to some people; most people are able to take honey only in moderate quantities; some people are made ill by eating honey; a large amount produces discomforts, often headache; and there's some sort of trouble about a poison bag. Doesn't look like a very safe thing to eat honey. Sugar seems to be a bad thing, too, but only when taken in concentrated form and in considerable quantity. So the only danger with sugar seems to be in having it in concentrated form. Well, I don't need to take it in concentrated form; it's easy to dilute it so as to make it perfectly safe; but there are several things wrong with honey that I don't know how to remedy; so it's sugar for me." Now, it is not at all likely that Good Health thinks the average person is in any more danger from eating honey than from eating sugar. What a pity it didn't say so. In fact it has said in previous issues in effect that honey is the safer of the two, and why not now? To be sure, there's that one sentence, "Honey has the advantage that it requires no digestion but is ready for immediate absorption," but that sentence contains so few words in its favor as compared with the many against it, and the number of words is likely to have undue weight with the not too careful reader. As a matter of fact, however, that matter of "immediate absorption" is a thing of so much importance that it overbalances by far any real objections that may be made against honey.

It would be interesting to be told what flavoring matters in honey are harmful to some people, and just how many people in a thousand have been thus harmed.

Most people are able to take honey only in small quantities, a large amount producing discomforts, often headache, we are told by Good Health. Will it tell us whether honey is any worse in this respect than sugar?

There is an intimation that there is something unwholesome in the pollen gathered by bees. It is true that many pounds of pollen are gathered, but nearly all of it is stored separately, and does Good Health really know of any harm coming

from the minute quantity of pollen that is found floating in honey?

"It is said that bees introduce into the honey minute quantities of a substance from a poison bag." That seems to be a resurrection of a silly notion that had some currency a good many years ago, but was supposed to have found its final resting-place years ago; the whole of it being that the bee uses its sting as a trowel to manipulate its wax, and just before sealing up a cell of honey it drops a tiny drop of poison from its sting. Has Good Health any proof that anything, good or bad, ever passes from the poison bag or sting into the honey? And does it know that any real harm has come from the minute quantity of formic acid that honey contains?

It is not believed that so reliable a journal has any desire to give honey anything but a fair show, and it may not be unreasonable to ask it to tell beside the advantage of immediate absorption, whether honey contains vitamins and minerals not at all contained in sugar, and if so, what is the importance of them.

Transferring an apiary in the South—F. M. Baldwin.

MISCELLANEOUS NEWS ITEMS

Keep Bees Better—Keep More Bees—A bulletin on bee culture has recently been put out by the Department of Agriculture at Washington, D. C., headed as above. It is an urgent appeal to beekeepers not only to run their own bees for the most honey, but to rent or lease unproductive bees and get the maximum amount from them.

The bulletin says:

"There are in the United States about 800,000 persons who own bees, but there are not enough who keep bees efficiently and with the greatest possible profit to themselves. The war has created a need for abundant production of all food supplies

and honey is a non-perishable, concentrated food. Efficiency in honey production comes only from study of the best practices perfected and recorded by others. The study of the bees themselves must not be neglected, for all beekeeping practice depends on a knowledge of bee activities. California beekeepers will do well to study the literature on eastern methods. Local differences are often unduly magnified.

"This circular is compiled to make easily available certain material which cannot well be presented in bulletin form. If your beekeeping questions are not answered here or in the Bureau bulletins, please indi-

cate your needs. Every beekeeper should join the nearest beekeepers' association, should subscribe for a least one bee-journal, should own and study at least one book on beekeeping and should know what aid in beekeeping is obtainable from State offices or from the Agricultural College."

A California Bulletin—"Beekeeping for the Fruit Grower and Small Rancher, or Amateur," is the title of a 12-page bulletin written by Geo. A. Coleman and gotten out under the direction of the College of Agriculture at Berkeley, Calif. It is, as its name indicates, a bulletin of information to the small beginner. Subjects dealt with are Kind of Bees to Keep, Where to Obtain Them, Equipment Necessary; How to Handle Bees, What You will Find in the Hive and What to Do, Cleaning Hives and Frames, Preparing for the Honey-flow, Beekeepers' Library, etc.

Missouri Apiary Superintendent.—Our good friend, R. A. Holekamp, of R. F. D. 1, Hillsboro, Mo., has been appointed superintendent of the Apiary Department at the Missouri State Fair, which is to be held at Sedalia, August 10 to 17. Friend Holekamp believes in getting things properly advertised, and he is sending a circular letter to beekeepers soliciting their co-operation for the apiary exhibit. Write to him for information.

Isle of Wight Disease.—We are in receipt of Bulletin No. 85 of the West of Scotland Agricultural College, by Joseph Tinsley, B. B. K. A. Mr. Tinsley makes a preliminary report on his experiments concerning this disease. He evidences the fact that the remedies recommended during the past years, izar, bacterol, dioxygen, phenol, formalin, sulphur and other drugs, have given negative results. But he makes a rather encouraging suggestion concerning a culture recommended by the famous Professor Metchnikoff, *Bacillus Bulgarius*, which would appear to have cured at least one case on which experiments were made.

With so many learned experimenters at work on Isle of Wight disease, we may hope to have, some day, a cure which will also cure the similar disease, the so-called paralysis.

The Ames Meeting.—The second annual Short Course in Beekeeping at the Iowa Experimental Station at Ames, Iowa, was a decided success, as it was well attended by beekeepers and students.

Some of the notable addresses were by C. P. Dadant, of the American Bee Journal, Hamilton, Ill.; Mr. D. A. Davis, of Washington, D. C.; Professor F. Eric Millen, Mr. W. S. Pangburn, of Center Junction, Iowa; Professor Pammel, and others of the faculty, and Mr. Edward Brown, of Sioux City. Mr. Fred Hall's address regarding swarm prevention was a striking one, and attracted much attention. Dr. Bonney, of Buck Grove,

showed models of some of his new ideas, a feeder, hive entrance, combined decoy hive and swarm catcher, electric comb patcher and others.

While at Ames the writer was shown the last word in aluminum honeycombs, the invention of an Iowa man, and there seems to remain not a particle of doubt but that it is a decided success. The samples I saw were pieces inserted in regular combs, and the bees had not only accepted and used them, but where they were shallow had built them up as though working on wax combs. As such combs would be moth-proof, as well as mouse-proof, they could be stored anywhere without fear of loss. When aluminum is again available at a moderate price they can be made to sell at about 25 cents, I am informed by the inventor.

A. F. BONNEY.

Bibliography—The Flower and the Bee

"The Flower and the Bee—Plant Life and Pollination" is the title of a magnificent work, by our well-known correspondent John H. Lovell, whose articles on honey plants and on pollen-gathering insects have been much appreciated, not only in the American Bee Journal, but in other special publications.

The book presents the function of bees, beetles, flies and other insects in the pollination of flowers. It contains 119 illustrations of flowers and insects in the skilled manner for which the author is well known. It is a monumental work and deserves a place on the book-shelf of every student of entomology or botany.

The New York State Beekeepers' Association will hold a Field meet at Hayt Corners, N. Y., August 2, at the summer home of C. B. Howard. Dr. E. F. Phillips will probably attend.

Loss of Bees by Flood.—Mr. J. W. Tinsley, of Ames, Iowa, lost an en-

tire apiary by a cloudburst. Nine and a half inches of water fell at that spot that evening.

Palmetto Honey.—Good honey can be produced right by the side of Lake Okeechobee, in southern Florida. We have just received a fine sample of scrub palmetto honey from C. C. Cook, Tasmania. This town is to be found only on the latest maps. It is a new place, west of that big lake, in the wildest of Florida.

Idaho Meeting.—The Annual Field Meeting of the Idaho-Oregon Honey Producers' Association will be held on the premises of Gottfried Lohrli, Parma Idaho, Wednesday, July 10. All honey producers of southwestern Idaho are cordially invited to attend.

P. S. FARRELL, Sec'y.

UNITED STATES DEPARTMENT OF AGRICULTURE

Bureau of Markets

Honey arrivals since May 15:
Medina, Ohio—220 pounds Kentucky, 4,005 pounds Nebraska, 7,638 pounds Florida, 757 pounds Pennsylvania, 1,080 pounds Colorado.

Shipping point information Friday, May 31:

San Francisco, Calif.—Demand light, fair for export, movement slow, growers holding for higher prices. Prices to growers: Orange blossom, 18-22c, mostly 20c; sage, 20-22c; light amber, 16.2-3 to 20c. Unofficial estimate orange blossom crop, 1918, 300 to 400 tons; expect lighter crop of sage than last year, on account of cold weather and rains.

Los Angeles, Calif.—Demand and movement good, market strong. Cash to producer on farm: White orange, strained, per pound, 20-21c, mostly 20c.

Kansas City—Receipts very light. Supplies insufficient to meet demand. Demand limited, market strong, few sales, all sales in small lots. Missouri, first native honey on market, quality and condition good; 24-section flat cases, No. 1 light, \$7.50. Beeswax: approximately 500 pounds ar-

Group present at the Short Course at Ames, Iowa.

rived. Buyers paying 40c per pound.

Minneapolis—Receipts very light. Supplies very light. Demand and movement good, market firm. All sales in small lots. Comb honey: Minnesota, Wisconsin and Iowa, white, 24-section cases, \$6.50; special brands, \$7.00-7.20. Extracted: Minnesota white, fancy, 60-lb. pails, 21-22c per pound. Beeswax: no sales reported.

St. Paul—Receipts light. Supplies light. Demand good, market firm, all sales in small lots. Comb honey: Minnesota and Iowa white, fancy, 24-section cases, \$6.50. Extracted: Minnesota, supplies exhausted. Beeswax: no sales reported.

Denver—No fresh arrivals. No comb honey on market; extracted honey supplies practically exhausted. Demand good, movement slow, market very strong. Sales direct to retailers: white to amber, 19-20c per pound. Beeswax: receipts very light. Supplies very light. Demand good, movement slow. Price to producers, 37½-40c per pound.

Chicago—Supplies negligible. No sales reported.

Philadelphia—6 kegs and 1 barrel Florida arrived. Supplies extremely light. Demand far exceeds supply, market strong. Extracted: domestic and southern in barrels, 24c per

pound. Comb honey, no supplies, no sales.

Cincinnati—3 Cuba, 150 lbs. Tennessee, 4,293 lbs. Alabama, 945 lbs. Kentucky, 2,724 lbs. Florida arrived; imports via New York City, 695 lbs. extracted. Comb honey, no arrivals reported. Extracted: supplies very light, demand good, market firm, few sales, account of high prices; Cuban, last sales about 10 days ago; dark amber, 22c per pound. No later sales reported.

St. Louis—Practically no supplies; no sales.

New York—Arrivals, 265 barrels Porto Rivo, 8 cases Mexico, incomplete. Receipts light. Movement slow, demand moderate. Since April 15 no reports arrived from Cuba, Santo Domingo or Haiti, only arrivals now from Porto Rico, Texas, Florida and Mexico. Extracted honey: Porto Rican, also some Cuban that arrived previous to above mentioned ruling, \$2.07-2.52 per gallon; Florida, few sales; light amber, \$2.60-2.65; white, \$2.80-2.90 per gallon. Beeswax: arrivals, 160 bags West Indies, 10 cases India, 30 bags Haiti, 164 bags Cuba, 80 bags Porto Rico, 46 bags and 15 cases South America, 38 packages Portugal. Market steady, demand and movement good. Yellow, 41-43c; dark, 38-41c per pound.

expecting to feed candy soon. What was unusual with me was the frequent occurrence of pretty well soaked chaff above the brood-chamber. There was one colony that exteriorly showed no sign of life, so I let it go almost to the last. Upon removal of chaff tray I saw the bees quite lively, stores almost gone. By giving them frames of honey I saved them. When the bottom-board became revealed there came in sight a thick layer of dead bees, enough to block up the entrances (7-16 inch). So, of course, they could not get out. There was some wetness about the frames. What was the cause of all this? Next to this colony was another in exactly the same kind of hive, and all was O. K.

4. What is your way of fixing up preparatory to outside wintering? Please state exactly what to place over brood-chamber, style of board over same, etc.

PENNSYLVANIA.

ANSWERS—1. I'm not sure there's anything to criticize, unless it be that with so shallow an entrance close down on the floor there might be danger of clogging with dead bees.

2. I don't know what is best. Good results should be obtained with a strong colony having an entrance 2¼x¾, or an entrance at each end made by turning your entrance-block upside down.

3. I don't know why this should have been so. It's an old saying that bees never do anything invariably, and it often happens that under what appear to be exactly the same conditions there are quite different results, which no one can account for. With fuller knowledge of all particulars I might be able to tell why, but most likely not.

4. I have had no experience for many years in outdoor wintering, and so can only refer to the experience of others as found in the books and bee journals.

Drumming

Here is a little experience I had drumming bees to prevent swarming.

The swarm came off and clustered in the usual way. I shook them in a swarming box and left it in the grass until about 5 o'clock p. m., then put them back in the same hive they came out of. The next day about 10 a. m., I took one super off and put three empty supers on next to the brood-chamber, put the partly filled one on top and stopped the entrance of the hive, drumming the bees up in the supers to give them to understand they had lots of room. I let them out, and in less than two hours they were working and made no further attempt to swarm. They made 92 full combs and seven partly filled combs of honey.

Was it the drumming that did the good?

NEW YORK.

ANSWER—It is hard to say positively, but it seems certain your treatment was instrumental in preventing further swarming. But one cannot be sure just how or why. It is possible that the bees had been delayed in swarming, perhaps by bad weather, and at the time the swarm issued one or more virgins were ready to emerge, which they did as soon as the old queen went out with the swarm, and then while the old queen was out all that had not emerged were massacred in their cradles, so that no cells were left for further swarming. There are other possibilities in the case, but I doubt that you would find it a reliable line of treatment in general. At least I would expect more failures than successes.

Sting

Having never read or heard of anyone being stung by a queen bee, I would like to know the effects of same; is it worse than the sting of a common bee?

ILLINOIS.

ANSWER—I don't know what the effect of a queen's sting would be, but would not expect it to be different from that of a worker. I've been handling queens for more than half a century, and I've never been stung by one, and should not expect one to sting me if I should handle them a century longer.

DR. MILLER'S

ANSWERS

Send Questions either to the office of the American Bee Journal or direct to
DR. C. C. MILLER, MARENGO, ILL.
He does NOT answer bee-keeping questions by mail.

Swarm Prevention

I was reading the experience of one Fred W. Hall, of Iowa, on non-swarming. He says on or about the first of June he de-queens all of his colonies except where he wants an increase, then he takes the queen from the most populous colony and places her in a new hive, together with two or three frames of honey, and sets the new hive on the old stand, then in nine days he goes over all colonies and destroys all queen-cells except one good one. Then by the time they get straightened around it is too late to swarm. What do you think of the idea, and what effect, if any, would it have on the honey crop? INDIANA.

ANSWER—Mr. Hall is a good beekeeper, and with him the plan results in good crops. In the hands of a careless man, there is danger that more than one queen-cell would be left, making swarming practically certain.

Comb Honey

1. When running for comb honey, what is the best plan to use to hive on, full sheets of foundation or old combs?

2. Is honey ripe as soon as sealed?

3. How many supers do you use on each hive for comb honey? If you take it off as soon as the most of it is sealed, as you say in your book of "A Thousand Answers to Beekeeping Questions" two supers would be enough. The most beekeepers say tier up as long as the honey is coming in, and that is the way I have always done, but my honey is not as nice and white as I would like to have it. I have had as many as seven comb-honey supers on at one time.

4. I use the 8-frame hive. Which do you think is the best for comb honey, 8 or 10-frame? INDIANA.

ANSWERS—1. Old combs, if you have them; if you haven't, then full sheets, but never starters unless you want to raise drones.

2. Yes, with occasional exceptions.

3. In a big flow two would be very unnecessary. Five would generally be all right, and occasionally a colony would need 7 or 8.

4. As a rule the larger hive is probably better.

Pound Packages—Hives—Extracted Honey

1. Will the bees from the south that are sold in pound and larger packages go through the winter all right here?

2. What hive would you advise me to buy, the Dadant hive or the Lewis hive?

3. What is the Dadant method for producing extracted honey? ILLINOIS.

ANSWERS—1. Yes.

2. I don't know enough to answer.

3. Oh, my! It would take a book to answer that. Fortunately, there is such a book as Dadant's Langstroth. Yet in the main I suppose the methods of the Dadants are not very different from those of other good beekeepers.

Wintering

1. Will you be so kind as to criticize from your standpoint, bee-entrance for winter as afforded by blocks which fill up a space 1¼ by ¾ in. The openings at each end are 2¼ by 7-16 in., making a total opening of 2 square inches.

2. What is or would be, your ideal of an opening to have during winter, when the total space available is 1¼ by ¾ inches?

3. About March 20 there was unusually mild weather, after a winter during which I think the bees did not fly out at all. I took advantage of it to examine every one of my 62 colonies. Conditions then were about exactly the same as appeared May 7 last year, as to stores. I equalized stores, fixed up things generally,

May Swarm Returning to Hive

1. One of my swarms swarmed on the first day of May. I hived them on the old stand in a new hive with full drawn combs. They seemed all right and they made some honey. But finally they came out and went back into the old hive. What was the cause? Did they supersede their queen? I saw a few eggs in the new hive, some cells had two eggs. They swarmed last year, so the queen could not be very old.

2. Last winter one of my swarms died. In the spring, when I opened up the hive, I found about 50 pounds of honey. What was the cause. The honey was good. IOWA.

ANSWERS.—1. I don't know. You are above latitude 41 degrees and it would hardly seem that a normal swarm should come out the first day of May. The plurality of eggs in a cell after the swarm was hived looks as if the bees had no proper queen, but laying workers. These two points taken together look as if it might have been some sort of a freak swarm, which found itself no better off in the new hive and then returned. But this guess may be wrong.

2. It is possible that the colony perished out because it had a poor queen, or none.

Sealed Honey for a Swarm

Should a new swarm be put in a hive that has sealed honey in it—about 10 pounds?

IOWA.

ANSWER.—There will be no harm in using such a hive for a swarm, provided there has been nothing like foulbrood in it, and in some cases the honey may be a help.

Making Frames to Exclude Queen

Up to the present time I haven't used a queen-excluder, as I run for bulk comb honey. But my bees increase so fast and get so crowded that the queen is forced up into the supers and nearly all the brood is drone. Couldn't the top bars of the brood-frames be made or spaced so as to exclude the queen, which would do away with the patented excluders, thus saving the beekeeper at least 20 cents on each hive? GEORGINA.

ANSWER.—The apertures in a queen-excluder must be very exact. If just a little too small neither queen nor worker can pass, and it takes an exceedingly small increase in size to allow a queen to pass. It would need very fine workmanship to have the spaces between top-bars thus exact. Even supposing you had them made thus perfect, the bees would crowd in bee-glue, and in only a short time you would find some of the spaces large enough to allow the passage of a queen. I don't believe the thing is worth trying.

Bees Deserting Hive

I had a swarm desert the hive this spring, leaving several patches of brood in combs, but no honey. I had noticed it was weak and looked for the queen a few days before they absconded, but could find none. They seemed all right, but weak. Why did they leave? MISSOURI.

ANSWER.—It was likely what is called a hunger swarm; that is, the bees deserted the hive because they ran out of stores.

Care of Hives—Clover—Kind of Hives

1. I have 50 10-frame hives and four 8 frame hives, all painted. I want to know how to take care of my hives. Had I better set each one on a brick? Had I better arrange 2x16 scantling to set the hives on, and how far apart should they be? How high?

2. Is wild clover or white clover a good pasture for bees?

3. When and how should I sow it?

4. Would one and a half acres be much help to my little apiary?

5. What advantage has the hive on page 153, American Bee Journal, over hives like the ones on page 121?

6. Which side of bottom-board would you use, shallow side or deep side? TEXAS.

ANSWERS.—1. Putting hives on scantling 16

feet long would have the rather important advantage that it would be easy to level them. (They would be level from side to side, and the back end should be about an inch higher than the front end.) It has the disadvantage that jarring one hive would jar the whole lot. It has the further disadvantage that where the bottom-board rests on the scantling the water collects at each shower, tending to rot the bottom. On the whole, perhaps it is better to have the hive on bricks. Let the hives stand in pairs, the two hives of each pair as close as they can be without touching. The distance between each pair and the adjoining pair may be as little as 30 inches if you are badly crowded for room; but 4 feet is better if there is room. No need to have the hives very high; unless there be some special reason for it, four inches between the ground and the bottom-board will do.

2. Where white clover succeeds it makes splendid bee-pasture. But have an impression that it does not succeed well in all parts of Texas.

3. Sow it spring or fall, perhaps preferably with grain.

4. Yes, an acre and a half well set with white clover should yield quite a bit of nectar.

5. The hives on page 153 are supposed to allow freer examination of combs without danger of killing bees.

6. The deep side, allowing large entrance.

Kind of Hive

1. Would you advise a young man working in an office who wishes to keep from 10 to 20 colonies of bees to use Jumbo hives, or Standard 10-frame hives? I cannot be on hand to take care of swarming and want to obviate or check swarming as much as possible. I intend to run for extracted honey.

2. I have read in your "Forty Years Among the Bees," page 190, your experience with Jumbo hives. Do you conclude that the Jumbo hive is of little value in curbing swarming?

3. How do the Dadant and Jumbo brood-chambers compare in capacity? Mr. Dadant claims that his hive is practically non-swarming. MINNESOTA.

ANSWERS.—I hardly know what to say. One objection to the Jumbo hive is that being unusual, in case you should want to sell out you might not find so ready a sale as for something more nearly standard. With either hive you may be practically safe from swarming by using the Demaree plan. When you find the bees have started cells, put all but one frame of brood in an upper story over an excluder, leaving the queen in the lower story with one frame of brood (preferably one not very well filled with brood) and the hive filled out with drawn combs or frames filled with foundation. Some think it better to have empty extracting combs in the second story and the story of brood over this. Kill all sealed cells at time of putting up the brood, and again 7 or 8 days later.

2. While it is a fact that the colony in the Jumbo hive was the first in the apiary to swarm, it is hardly likely that such would be the rule.

3. I don't think there is much difference in the capacity of the two. The freedom from swarming with the Dadant hive may be not only because of the large size of the hive, but also because the frames are spaced 1½ inches from center to center, instead of the usual 1½.

Space Over the Bees in the Hive

How much space is allowable over the bees in the hive? I think of making boxes an inch deep and the size of a hive, into which I will put hard candy and invert said boxes over the bees, for additional feed. Would the inch over the space already there do harm or good? Will bees cluster above the frames if there is room for feed? IOWA.

ANSWER.—It is generally understood that at

a time when bees are busily at work building and storing, if more than a certain space, called bee-space, be allowed, the bees will build in it comb, and perhaps store honey therein; and if less than a bee-space be allowed, it will be filled with bee-glue. Exactly what bee-space is is none too well known, but it is somewhere in the neighborhood of one-fourth of an inch. So, in the busy season it is advisable to have neither more nor less than a bee-space above the frames or at their sides, although as large as three-fourths of an inch may be allowed under the bottom-bars.

But your proposal is to have an inch space over the top-bars to hold candy for food, and as you would hardly be feeding at a time of storing, the larger space could hardly do any harm other than to oblige the bees to keep warm the additional space, and this disadvantage may easily be overcome by the advantage of giving food when needed. The bees will readily go above to get the candy.

While it is a good plan to provide thus for the needs of the bees, there is a still better plan. It is to give the needy bees frames of sealed honey. You say you have no such frames. Well, then, feed the candy, but make your preparations so you will not need to do so again. Make it part of your plans this year to have two frames of sealed honey saved over winter for each colony you expect to have next spring. Good honey is better than sugar to feed babies, whether they be bee babies or household babies. If you don't need to feed the bees next spring to prevent starvation, you will need to fill up the vacancy in the brood-chamber, and thus allow the bees to begin just so much sooner to store in the supers.

Wintering

I am thinking of wintering my bees in two 10-frame hives, as a permanent brood-chamber with all the stores they contain. What, in your opinion, do you consider the worst drawbacks to this way of management, and would there be any need of manipulating the supers or combs before swarming time? MISSOURI.

ANSWER.—I'm not sure that I can tell exactly why, but there seems to be a limit to the amount of room that can be profitably used in the brood-chamber, and before deciding that you will run all the colonies in the way mentioned it would be well for you to try a minority of them in that way. It would hardly seem that any manipulation of supers would be needed before swarming time; yet you can't 'most always tell.

Moving Bees—Distance From Apiary

1. The weather being unfavorable last spring, and not knowing just when to move my bees, I waited a little too long. They had come through the winter strong, had plenty of stores, and I finally moved them from winter quarters on the southeast of the house, to the orchards. I did this at evening (nightfall). All seemed well, but next morning a large swarm of bees hovered over the old spot and they became chilled and settled on the base of the weatherboards of the house. I then picked them up and got a berry box full, and shook them before the hive and they all entered, but when they had warmed up, it seemed, they returned to the old spot and hovered over it until a rain set in and killed them. Was this a swarm which had lost its queen, do you think?

2. I moved the hive after dark and all seemed O. K. If so, what could I have done to save the bees? Would they have returned to the hive if I had replaced it in the old position?

3. Notwithstanding that bad luck, the hive thrived and I got a super of extracting honey at the end of the season. The honey was very dark. We have much sweet clover, some white clover, wild flowers of all kinds, and thickets of buckbrush. Several persons, on eating the honey claimed it made them dizzy.

Could it be some plant which causes this, or does all honey bring this on when eaten in quantities, or is this just a coincidence?

4. I have black bees and find them none too gentle, and want to re-queen. Would an apiary of about 30 hives, distant about one and a half miles, mix and make hybrids if something should happen and the bees raised a virgin?

MISSOURI.

ANSWERS.—1. I don't think there was any swarm in the case. It was merely the bees returning from their flight to the place they had marked as their proper locality.

2. Yes, if you had returned the hive to its old position the bees would have joined it all right; only there would be some trouble with any of the younger bees that had never flown before the change, and had marked the new location, for they would want to stick to the new location upon returning from the fields. If you had fastened the bees in the hive for a day or so, putting them on the new stand, and then in the middle of the day opening the entrance after pounding on the hive so as to frighten the bees, very likely you would have had no trouble. In such a case, however, if some of the bees should persist in going to the old location, put there a brood-comb for the bees to settle upon, and at night shake these bees in front of the hive on the new location, repeating this each day, you would find that in a few days they would give up their old location.

3. It is possible there was something in the character of the honey to cause dizziness, but it is hardly likely.

4. There would be a considerable chance that one of your virgins might meet a drone from an apiary a mile and a half away.

Melted Combs—Using Old Combs

1. Last season I removed about 60 pounds of honey from a swarm that I had just purchased, and on melting up the combs was surprised that the wax did not set regularly, but was in a crumbled form, resembling cornmeal. The honey had a peculiar flavor and seemed a little sour or fermented. From two other hives in the same lot I noticed a peculiar odor, but could not find any indications of foulbrood similar to symptoms of disease as shown in government reports.

2. Is there any harm in using combs from old hives from which bees died this winter, where a few of the combs on places are moldy and filled with dead bees? NEW YORK.

ANSWERS.—1. I don't remember that I ever had any experience with wax in this granular form, although I know it sometimes happens,

and I doubt whether the honey or disease had anything to do in the case. If you please I'll step down off the rostrum and give the boss a chance to talk; he knows a whole lot more than I do about wax.

(Usually the granular form of wax is due to the melting wax being beaten by the steam or boiling water. In many cases granules at the bottom of cakes are caused by this trouble. We have seen wax so beaten that it looked like cornmeal and contained 50 per cent of water. Dry heat is the remedy.—Editor.)

2. It will be all right to use them if there has been no disease in them

Requeening

Please give me advice through the American Bee Journal on the following: I have eight

hives of mixed bees that are very cross, so I want to re-queen. I want to take a hive with full frames of foundation, put in an Italian queen and set one of the hives of the hybrid bees on top of this hive, putting a queen-excluder between the two hives. After the Italian queen gets to laying and young are coming out, lift up the top hive and put a board with bee-escape, so bees can come down from old hive but cannot go back to the hybrid queen. After all bees are out, then remove old hive and kill hybrid queen. What do you think are my chances of success? I have already arranged one hive. VIRGINIA.

ANSWER.—I think the chances are ten to one that your new queen will be killed.

Foulbrood

1. I would like to know the different conditions existing between American and European foulbrood. I have eight or ten colonies that have some kind of a disease.

2. Is the McEvoy treatment safe for any kind of diseased brood?

3. Is it necessary to use queen-excluders under extracting supers. The supers are two half stories fastened together with full depth frames in them. The hives are eight-frame size. KANSAS.

ANSWERS.—1. In American foulbrood if you thrust a toothpick into a diseased cell and draw it out the dead matter will string out in a thread an inch or more long. In European foulbrood the diseased larvae nearly large enough to seal over will have a distinctly yellowish color. The thing for you to do is to send a sample of the diseased brood to Dr. E. F. Phillips, U. S. Dept. of Agriculture, Washington, D. C., and he will tell you what the trouble is, and also send you information as to treatment. If you write in advance he will send you a box in which you can send the sample to him, and also a frank to pay postage.

2. It is generally used only for American foulbrood.

3. Excluders are nearly always used, as otherwise you are likely to have brood in your extracting-combs.

Bees of a drafted man, Walter Hagler, of Gibson, Miss., has just been called and had to dispose of this well-kept apiary

Home yard of R. A. Shults, at Cosby Tenn.

“Practical Queen-Rearing”

Is the title of the new bee book, cloth bound, 100 pages, which has just been written by Mr. Frank C. Pellett, who is well known to our readers.

For many years there has been a demand for a book which would give in concise form the many different methods of queen rearing, as the Doolittle, Pratt, Dines, Miller, Alley and others with variations as practiced by different large breeders.

You have this in the new book which is just out. Send for your copy now and get informed as to your best method of rearing queens from your best colonies. Good pointers in it also for the large beekeeper and veteran queen breeder.

Price, postpaid, only \$1.

By special arrangement we can offer it and a year's subscription to the *American Bee Journal* for only \$1.75.
(Canadian orders 15 cents extra.)

Buyers of EXTRACTED and COMB HONEY
Shippers and Exporters of HONEY

[The WORLD is Our Market]

Crop Report and Market Conditions

For our July number we asked the following questions with regard to conditions:

1. Condition of honey plants compared to last year?
2. How is the honey-flow?
3. Honey movements and prices. What is being offered by the buyers for honey?
4. What do you expect to realize for your honey?

HONEY PLANT CONDITIONS

Conditions are extremely spotted this year with regard to honey plants. In some localities the conditions are favorable, while in others the reverse is true. All in all, it seems that in the whole eastern half of the country the plant prospects will hardly be up to last year. Reports by States follow:

Massachusetts reports 100% as good as last year; Connecticut is fair, with New York sending in conflicting reports, the average of which would hardly warrant expecting as good a stand of honey plants as last year.

The South is about normal, with Kentucky showing a decided improvement over 1917, as does Alabama and Mississippi.

Pennsylvania only shows a fair prospect, while Ohio seems to be about 135% as good as 1917. Michigan is about normal, while prospects in Wisconsin are very poor.

Illinois has much more clover than last year, and Iowa very much less. In fact, the only parts of Iowa where much honey will be harvested are where there is basswood and sweet clover. Missouri again has very poor prospects; Nebraska claims 50%, while Kansas is about normal, as is South Dakota. Minnesota's honey plants are only 50% as abundant as in 1917.

Texas reports very much better conditions than last year. It is to be hoped so, as conditions last year over a majority of the State were about as bad as could be.

In the whole of the West conditions are at least as good as in 1917, with the exception of Idaho, which had such a splendid crop last year that it doubtless will not be completely duplicated in 1918. In California plant conditions range from 60 to 100% of 1917.

THE HONEY FLOW

The New England States expect a very good flow. New York claims she will have 75% of 1917.

In the South there should be as much honey produced as in 1917, even though Georgia claims less. Alabama and some of the other sweet clover regions, should help bring up the average.

Pennsylvania expects only a fair crop, while Ohio's hopes are still high. Wisconsin will have a partial failure, with Michigan producing probably 60 to 80% of what she did in 1917. One large producer in Minnesota expects a failure on account of drought. Other reports would indicate half a crop.

Indiana and Illinois may have some honey, while Iowa and Missouri will approach a crop failure, unless the weather should be extremely favorable towards honey secretion the latter half of the summer.

There is little or no flow in Texas now, but prospects are good for later flows.

It is yet a little early to predict for the West, as their flow does not begin in earnest till July. New Mexico al-

ready reports honey coming in fairly well. The whole West should average slightly better than in 1917, and with at least as many bees to gather the crop.

The orange honey flow in California has been very satisfactory, with that from sage not so good. The total crop cannot excel that of last year very much.

HONEY PRICES

Some buyers are still offering as low as 13½ cents for honey on contract. The bulk of offers are in the neighborhood of 15, 16 and 17 cents. Several cars of orange have been bought of producers at 21 cents, while some of the producers are holding their orange crop for 25 cents. One commission firm on the coast offered a car of orange a few days ago for 21½ cents f. o. b. coast.

One or two beekeepers have sold their crop at 17 cents, while one car of Imperial Valley honey was sold recently at 17½ cents f. o. b. shipping point.

With very few exceptions, all old honey is cleaned up, and at prices ranging at 20 cents or better.

The demand for honey is exceedingly good, in fact better even than it was at this period last year. Foreign buyers are appearing in the field, some making arrangements through their home consulates to get ocean transportation as soon as the crop is available.

The stringent regulations on sugar will no doubt help the sale of honey at home, even at the higher price.

HONEY PRICES EXPECTED

There is the greatest contrast between conditions among beekeepers this year and last. Last year it seemed that the beekeepers were anxious to sell, and at the prices offered by the buyers. This year very few forward contracts have been made. The majority of producers are willing to wait and take what the market will be at the time they are ready to sell their crop.

The bulk of suggestions as to price expected ranged around 20 cents for extracted, wholesale, and \$5 per case for comb. Some state that they are going to hold for 25 cents wholesale in car lots.

With present prospects not too flattering for a honey flow total in excess of last year, and with the demand as strong as it is already, it seems that a price of 20 cents for white extracted, wholesale, should not be out of the way. How much higher the price may go is hard to conjecture.

Push your Home Market,
even though prices
are high.

The time may come again
when Home Markets
will be useful.

KEEP INFORMED ON TEXAS CONDITIONS

The *Beekeepers' Item*, a monthly paper edited by Mr. Louis H. Scholl, well known to our older readers, and an authority, has many interesting items which should interest beekeepers, not only in the Southwest, but throughout our country.

In order to allow you to become acquainted with this paper, we offer a special combination of *Beekeepers' Item* one year with *American Bee Journal* for only \$1.25.

Or, if you desire, we can send you your choice of *First Lessons in Beekeeping*, or *Practical Queen Rearing* with the *Item* one year for only \$1.25.

QUEENS Hardy, Long Lived and Disease Resisting QUEENS

Twenty-Two Years of Select Breeding Gives Us Queens of Highest Quality--Queens for Honey Production--Queens of Unusual Vitality

"There are few Queens their equal and none better."

WHAT BEES DO, HEADED BY OUR QUEENS

"One swarm made 185 sections of honey and another 296 sections. I am well pleased."—MELVIN WYSONG, Kimmell, Ind.

"Your bees averaged 150 pounds of surplus honey each. I find them not only hustlers, but gentle."—FRED H. MAY, Meredosia, Ill.

"I have tried queens from several different places and like yours best of all."—C. O. BOARD, Alabama, N. Y.

"We are only one mile from Lake Erie and exposed to high, cold winds; in fact, this is the windiest place along the great lakes. Your bees were able to stand the winter with only an insignificant loss, and we would have no others. As for honey, they averaged 175 pounds of extracted surplus, did not swarm, and gave an artificial increase of 20 per cent, which is as fine a record as can be had in this locality, especially when the work is done entirely by amateurs." Name furnished on request. North East, Pa.

Ready Money for Your Honey

SHIP IT NOW

If you have honey for sale, we want to buy it. Ten thousand producers in all parts of the world witness to the reliability of this house. No purchase too large or too small. We handle many carloads a year. Send us a sample and name your most reasonable price. We buy every time your price justifies.

PROMPT REMITTANCE

Remittance sent by return mail for every shipment we receive. Honesty and integrity during the many years in the honey business have won for us the good will and confidence of thousands.

OLD COMBS and CAPPINGS

Send them to us for rendering. We pay you the highest market price for beeswax, and charge you but 5c per pound for the wax rendered. It pays to send us your old combs and cappings.

WANTED---COMB HONEY

Comb and Extracted Honey find ready sales here. Tell us what you have. We buy Beeswax at high prices. Always glad to reply to inquiries.

Our New Home

We are now located at
Pearl and Walnut Sts.,
and have the largest
Honey House in the
country. When you are
in Cincinnati don't for-
get to call on us, for it
will be a pleasure for us
to show you our won-
derful new home.

We Sell Lewis' Beeware

"Lewis" stands for the highest quality Beeware known. It is safe and reliable. "Made like furniture." We are glad to fulfill your needs.

BREEDERS.—The cream selected from our entire stock of outyards; nothing better. These breeders, \$5 each.

Can furnish bees on Danzenbaker and L. or Hoffman frames.

Above prices on bees by pound, nuclei, and colonies do not include queen. You are to select such queen as you wish with the bees, and add the price.

No bees by pound sent out till first of June. Breeders, select tested, and tested queens can be sent out as early as weather will permit.

Send for testimonials. Orders booked now. Reference: Any large supply dealer or any bank having Dun's reference book.

H. G. Quirin, Bellevue, Ohio.

THE FLOWER AND THE BEE PLANT LIFE AND POLLINATION

By JOHN H. LOVELL,
Botanical Editor of "The A B C of Bee Culture"

Every beekeeper needs this volume in order to understand the honey flora. Descriptions are given of bee-flowers, bumblebee-flowers, butterfly-flowers, hawk-moth flowers, flowers pollinated by the wind, and many others. It will also be of great interest to gardeners, fruit-growers and lovers of nature generally. It is fascinating, not only because of its very great informative value, but because of the sense which it imparts of the beauty of nature as revealed in the subject. Do you know why some bees visit only one kind of flower? Or how many flowers there are of each color in eastern North America? Or whether bees and butterflies prefer certain colors?

Illustrated by 119 photographs taken by the author, chiefly of flowers natural size. \$2 net. Will be sent postpaid on receipt of price, by JOHN H. LOVELL, Waldboro, Maine.

Charles Scribner's Sons, Fifth Ave., New York

MOTT'S NORTHERN-BRED ITALIAN QUEENS

that resist disease well. Those that resist disease must be hardy, prolific, and hustlers; they are gentle. Bees per pound. Plans on "How to Introduce Queens and Increase," 25 cents. List free. Untested \$1 each.

New Bingham Bee Smoker

NEW BINGHAM BEE SMOKER

In 1878 the original direct draft bee smoker was invented and patented by Mr. T. F. Bingham, of Michigan. Mr. Bingham manufactured the Bingham Smoker and Bingham Honey Knife for nearly thirty-five years, and in 1912, becoming a very old man, we purchased this business and joined it to our established business of beekeepers' supplies and general beeware. Those who knew Mr Bingham will join us in saying that he was one of the finest

of men, and it gives us much pleasure to help perpetuate his name in the beekeeping industry.

Bingham Smokers have been improved from time to time, are now the finest on the market, and for nearly forty years have been the standard in this and many foreign countries. For sale by all dealers in bee supplies, or direct from the manufacturers.

	Size of Stove	Weight	Retail
Smoke Engine	4 x7-inch	2 1/2 lbs.	\$1.25
Doctor	3 1/2 x7-inch	2 lbs.	1.00
Two above in copper, extra each50
Conqueror	3 x7-inch	1 3/4 lbs	.85
Little Wonder	3 x5 1/2-inch	1 1/4 lbs.	.65

Hinged cover on the two larger sizes. Postage extra.

BINGHAM HONEY UNCAPPING KNIVES

WITH NEW COLD HANDLE

We are furnishing the same quality steel, best money can buy, thin-bladed knives that Mr. Bingham manufactured years ago. The old-timers all remember these knives and many are writing in, as Mr. Volstad in the following letters. The substitutes offered by others have not given the satisfaction desired.

Lyle, Minn., June 21, 1917.

A. G. Woodman Co.
Gentlemen: Have you the thin, good working uncapping knives we used to get about 20 years ago and that worked to perfection?

K. H. VOLSTAD.

We sent an 8 1/2 and 10-inch knife and received the following letter:

Lyle, Minn., July 5, 1917.

A. G. Woodman Co.
Gentlemen: Knives received; glad you sent them at once. They are just what I want and have been looking for, but did not know where to get them.

K. H. VOLSTAD.

Many of the most extensive honey producers insist on the Genuine Bingham Knives. Mr. N. E. France, of Platteville, Wis., gave us a fine unsolicited testimonial on the steam-heated Bingham Knife, too long for this space.

	Weight	Price
8 1/2 inch blades	12-oz.	\$.90 each
10-inch blades	14-oz.	24.00 per crate
10-inch blades, steam heated with tubing	20-oz.	3.00 each

10 lb. Friction Top Pails in crates of 113	12.50 per crate

For a limited time we offer the above packages at these special low prices, shipment to be made from Chicago. Write for prices on 60-lb. cans, giving quantity wanted.

A. G. WOODMAN CO., Grand Rapids, Michigan

"Falcon"

THINGS THAT ARE NECESSARY FOR YOUR APIARY

1. There must be a good location for the apiary.
2. Queens must be healthy and vigorous to put life into the hives. (Our queens are the best to be had and at reasonable prices.)
3. Your bees cannot do the work they should if you do not give them the best with which to work. If they have ample storage space, if they can work all the time without slack motion, they will be more contented and swarms. To accomplish this, you must give them ample storage space, that is, the **RIGHT HIVES AND SUPPLIES. "Falcon"**

Beekeepers should be placing their orders early for their early needs. He who waits is apt to suffer. These late beekeepers who want their goods in such a hurry at the last minute will lose some of the honey crop by not furnishing their bees with ample storing space. Railroad embargoes and rush business make deliveries slow.

Our famous "Falcon" supplies will please you. Do not wait. Order now and strike while the iron is hot. "Falcon" means the best, the standard of perfection. Red Catalog and Simplified Beekeeping upon request. Dealers everywhere.

W. T. FALCONER MANUFACTURING CO., Falconer, New York
 Where the Good Beehives Come From

HONEY WANTED

We are in the market at all times for unlimited quantities of Honey, both comb and extracted. Before selling your crop let us hear from you, quoting your lowest price, either f. o. b. your station or delivered Cincinnati. If extracted, mail sample and state how it is put up. If comb honey, state grade and how packed.

A BOOK FOR BEGINNERS

"First Lessons in Beekeeping," written by the editor of this magazine, is intended primarily for the use of beginners in beekeeping. You should have it. Price, postpaid, \$1, or clubbed with the American Bee Journal, one year for \$1.75.

American Bee Journal, Hamilton, Ill.

?? WHY ??

Why is it that so many beekeepers prefer Dadant's Foundation? Why does it give such good satisfaction and why is it that when tested side by side with many other makes beekeepers have reported that "they take to DADANT'S first?"

Do We Use Special Sheeting Machinery? No

We use the Weed process of sheeting our beeswax into endless rolls, and it is the same process as used by nearly all manufacturers.

Do We Use Special Foundation Mills? No

We use the same kind of mills as are used by practically every foundation manufacturer in the world.

Do We Use Special Beeswax? No

We use beeswax such as is produced by beekeepers all over the United States.

THEN WHY?

BECAUSE

Our beeswax is cleaned in such a way that all impurities are removed and all the fine qualities are retained.

BECAUSE

Sulphuric and other acids recommended and used by many manufacturers for cleaning beeswax are not used by us.

BECAUSE

Our motto is and always has been "EVERY SHEET PERFECT"—and we live up to it.

BECAUSE

For FORTY YEARS comb foundation has been, and still is, our *specialty*. When you get DADANT'S FOUNDATION you know that you are getting the best that money can buy. When you send your beeswax to us to be worked into foundation you know that you will get perfect work done. When you ship us your old combs and cappings to render you will get the maximum of wax they contain and, if desired, this wax will be worked into the finest quality of foundation made.

IT IS UP TO YOU, therefore, to insist on DADANT'S FOUNDATION when you order your goods from your dealer. If you cannot get it from him, then order from us.

DADANT & SONS
HAMILTON, ILLINOIS

LEWIS SECTIONS

HAVE

INDIVIDUALITY

BECAUSE they are in a class by themselves. They are not like other sections. Very rarely do they break in folding---in fact one of our customers writes us that he has put up (folded) thirty thousand Lewis Sections in a season and has not found *one section* in the whole lot that was not perfect. Beekeepers everywhere, no matter what their preference may be for hives or other bee equipment, agree that, when it comes to sections, the LEWIS SECTIONS are supreme. This is—

Because the material which goes into a **Lewis Section** is of the right kind, especially selected for the purpose. The stock is sorted and re-sorted—the discolored stock thrown out, leaving only the whitest material to go into **Lewis Sections**.

Because the V groove, which is the most important process in the manufacture of a section, is made just right. In the **Lewis Section** it is cut just deep enough so that the section will not break in folding. The **Lewis Section** expert has been supervising the manufacture of **Lewis Sections** for over thirty years.

Because the finishing of the section is given the utmost care. The **Lewis Sections** are polished on both sides in a double-surfacing sanding machine designed in the Lewis plant especially for this purpose. It insures the uniform thickness of each and every section. The dovetailing of the ends is smooth, clean and just right.

Because even after the **Lewis Sections** are completely manufactured, the packing is considered a very important part of the marketing. All **Lewis Sections** are put up in regular standard packages containing a good, full count. A tight wooden box is used, entirely enclosing the contents, so that no discoloration from air can occur, no matter how long the sections are carried in stock. The package is also strongly braced at all corners, insuring delivery in good order.

AT THE SAME PRICE YOU PAY FOR OTHER STANDARD MAKES OF SECTIONS YOU GET ALL OF THE ABOVE WHEN YOU BUY THE LEWIS SECTIONS

A TRIP IN SOUTHERN GEORGIA

The Editor Visits the Georgia Apiaries of J. J. Wilder, Tramping Through the Swampy Underbrush to Get Close-hand Information

RETURNING home in the last days of March, I left wife behind with our children, and was advised by Mr. Wilder to stop at his southern Georgia apiaries, in charge of Mr. W. B. Bradley, with headquarters at Fargo, Ga., on the head waters of the Suwanee River. My wife, in her girlhood days, had often sung of the "Suwanee River, Far, Far Away," but had never known where it was located, and was almost tempted to go with me on that account.

Many people have read of Wilder's numerous apiaries, some rather incredulously, for he numbers them by the hundreds and his colonies by the thousands, shipping 10 or 15 carloads of honey annually. Glints of disbelief have been emitted occasionally by a reader. This was an excellent opportunity to find out how much his statements were worth.

Mr. Bradley, a bright, wide-awake young fellow, was at the station at

Fargo when I arrived there in company with Mr. and Mrs. Wilder, who were going home to Cordele and continued on the way. Bradley was going to an apiary 20 miles north, where he had left his automobile, so I got on the train again and we stopped at Thelma. The apiary was in sight of the station, right in the middle of the woods. Imagine a flat country of very straight, slim pines, from which all the large trees have been removed, leaving only the stumps and a thick growth of underbrush composed of saw palmetto, seven or eight different kinds of huckleberry brush, a large amount

of gallberry brush (*Ilex globra*), and an occasional cypress swamp with shallow water where different water bushes grow, among which the tupelo gum, *nyssa capitata* or ogeechee lime, furnishes abundance of honey-producing flowers in April and May.

There, near an apiary of some 80 colonies, two men were working, preparing supers and frames for the harvest. The bee-house, measuring about 20x36 feet, was full of extracting half-story supers, with empty combs in them, and a large lot of barrels which had very evidently contained honey the previous year. It was a business-looking place.

Wilderness of Saw Palmetto and slender Pines in Southern Georgia

Wilder's Apiary at Fruitland, Ga.

While they were cooking the noon meal, I loafed about the swamp, after taking my bearings, for a man readily gets lost in that immensity of flat, sandy, pine land. It was then that I found out why they call by the name of "saw" palmetto the dwari palmetto, *sabal serrolata*. Its stem is armed with sharp teeth like those of a saw. The cabbage palmetto, so rich looking in the heart of Florida, is not to be found at this point. The climate is too cool.

The bees were making honey and I noticed them sucking from some huckleberry blossoms, although I was told that these plants produced no honey. Dinner over, Bradley and I started in the auto truck through the swamp, following a winding trail northward, occasionally passing a darkey's cabin, one room with a door, and windows without sash, only wooden shutters. What do they live on in this wilderness? Corn pones and a little bacon. No chickens; rarely a garden spot; only a few razor-back hogs running at large about the swamp. Here and there a white man has settled. He tries to grow crops, but his principal business, if he is not a beekeeper (and beekeepers are few and far between) is to harvest the sap of the pines,

which is distilled and made into turpentine. Here and there a northern man has grubbed out a fine farm, built a good home with fences, and has left. The house is empty. Why? He was only a northern sucker! He thought he would show the southern people how to till the land, but the white sand has gotten the best of him.

We traveled some 50 miles that afternoon and visited five apiaries. We stopped at one of them a couple of hours and put on supers, for we had a lot of extracting supers with us in the truck. Mr. Bradley is only one of the numerous men Mr. Wilder employs in his business. He is certainly a capable man. His crop of 1917 was 125 barrels. A mute testimonial of an extensive crop is to be seen in the pile of empty combs and supers and the empty barrels in rough sheds at the apiaries, getting ready for the next crop. The hives are all 8-frame Langstroth, with Hoffman frames, the supers half-story. Occasionally a colony is given two full stories, if the queen is sufficiently prolific. Here I learned how one can spread the brood in a hurry with the Hoffman frame; as four or five frames may be shifted at one motion of the hive tool and an out-

side frame inserted in the center. No danger of chilling the brood in southern Georgia in March, and Mr. Bradley was spreading brood and inserting empty combs in the center, everywhere.

The Wilder apiaries contain a number of colonies of Caucasian bees. These are great "propolizers," as has

Chincapin in the Suwanee swamps

been shown to us before by Mr. Atwater. At the Bradley apiaries I saw colonies that had almost entirely closed their wide entrance with propolis, leaving but a small hole for the workers to go back and forth, and giving clear evidence of the correctness of the name given by the ancients to this substance "pro polis," two Greek words meaning "before the city." A similar condition is brought about by the bees in the Holy Land, as mentioned by Mr. Baldensperger in our June number. The endless fight against death-head moths induces them to strengthen and narrow down the "gates of the city" with "pro polis."

The apiaries are in the brush, away from houses, close to the barely visible auto trail. In nearly every case they are protected only by a posted notice offering a reward of \$50 for the conviction of thieves. Mr. Bradley has 15 apiaries under his charge. He said that they lost several hundred pounds of honey by thieves every year. But what to do? The Georgia "cracker," "poor white trash" the negro calls him, is, like the negro, of the opinion that whatever he finds in the woods is his property, or ought to be. Hence an occasional theft from the thrifty apiarist, who must figure that in the profit and loss; for to seek the thief and have him punished would probably not be safe. Things burn easily in the pine wilderness. Southern Georgia was ablaze with forest fires in every direction as I traveled through it, and when Mr. Wilder asked Mr. Bradley what the prospect was for honey, the answer was, "It is good if they don't burn us out." Miles and miles of good bee-pasture are devastated by the carelessness of the inhabitants, who seem to delight in burning the woods. At each apiary, the pine needles which cover the ground must be regularly raked away and destroyed, for fear of fire.

The afternoon trip over, we re-

The Chincapin of Georgia and Florida

turned to the city of Fargo, late in the evening, through the swamps, the brush and the sand.

The next morning I had the pleasure of visiting the Suwanee River, a wilderness stream, looking like a creek, there, only a few miles from its head, but which I am told widens into an immense river near its mouth, traveling through swamps most of the way. Along this stream, besides the tupelo gum is found the chincapin, *castanea pumila*, whose flowers produce very dark, inferior honey, but Mr. Wilder, who has a number of apiaries on the lower Suwanee, uses this honey for feeding.

In all these southern, flat, pine timber lands, the principal business of a town is turpentine and lumber. The sawmill is the life of Fargo, for Fargo is no exception to the rule. On the day I was there the town was in a flurry, for the Mill Company had gone into bankruptcy two months before and on that day the mill was sold at auction, with all that belonged to it. This included three-fourths of the houses and the hotel. It was sold in a lump to one party, and the old lady who kept the hotel wondered whether they would close the mill and turn her out of the hotel, which she had kept for a number of years. She was very talkative, and said to me: "I hope they will keep the business going until the war is over, for if they do not, I will starve."

The next day I went to Cordele, where more apiaries were to be visited by me. Beekeepers in the north who have wondered whether Mr. Wilder did not overstate when he wrote of his hundreds of apiaries, need not be in doubt, for he has apiaries all over the south, with reliable men in charge. Mr. F. T. Branch, the man with whom I visited the bees around Cordele, has charge of 20 apiaries, some 1,200 colonies, and these are, like the ones in southern Georgia, located in the brush.

Is the South, therefore a reliable country for beekeepers, and would it be profitable for a northern beekeeper to move there? My answer is in the negative. The Wilder method is certainly good. Many apiaries, scattered over immense spaces, in charge of reliable men who know the resources of the country and can make a profitable season out of a small per-colony yield, bring results. But the drawbacks are numerous. Difficulties of travel, swamps, white sand, unimproved soil. The negroes seem to delight in building forest fires, without any very plain purpose, for after the land is cleared it is probably less valuable than when it had still a growth of young pitch pines. It looked very much as if they only wished to see the big blaze during the cool spring nights. These fires are very damaging to the apiarists, for they not only endanger the hives, but also destroy the immediate expectation of a crop from palmetto or gallberry or other low shrubbery. The only safe honey-producing trees after a forest fire are the tupelo gums, which grow with

The Tupelo Gum of the South

their foot in the water like the cypress.

Each country has its special resources, its methods, and it is delightful to go from one region to another and see the different crops, from different soils and entirely different sources. But if you have a good location, do not seek a change. Wherever you go you will find difficulties to overcome and you must remember that "a rolling stone gathers no moss."

How Far Bees Will Go for Honey

By L. B. Smith

IF I am not mistaken (I haven't time to look up the files of the American Bee Journal that I have) I subscribed for this journal in the fall of 1881, while the late Thomas G. Newman was editor. I have been a constant reader of it ever since, with the exception of one year. I have read, and written more or less about bees in nearly all the newspapers published in the United States

and some that were published in other countries. I have been a close student of apiculture all my life. With this introduction to the readers of the American Bee Journal, I shall take up my subject of the distance bees will travel, or fly, for honey.

In the spring of 1882 I purchased my first yellow-banded bees—Italians and Cyprians. People came for miles to see those bees, as they were quite a novelty then. At that time I lived in what was known as the "cross timbers" of Johnson County. Not many bees were kept, and my yellow bees were the first of that color that had been brought into the country. The location was a poor one; all other bees in the community were either black or brown in color, and were as much alike as two black-eyed peas, as the expression is sometimes used. But to get to my point, it was not infrequently that I saw those yellow bees of mine four and five miles out from home, busily engaged in gathering nectar from horse-mint, wild marigold and other plants in season. At that time I was

a novice myself, and gave little thought to the subject, supposing that bees traveled that far or farther, if necessary. Sometime later, however, from reading my beebooks and journals, I noticed that several authors stated that one and one-half to two miles was supposed to be the limit that bees traveled for stores. This set me to thinking, and to investigate further.

In the spring of 1883, an old-time box-hive beekeeper came to my home and said: "Smith, I want you to come down and help me to find a bee-tree." He went ahead to say that some very beautiful yellow bees were working on the blossoms in his orchard. Being a great lover of such pastimes, I agreed upon a date to make the hunt. When the date arrived we met, fully prepared with our equipment to make the search. Sure enough, when we reached his home, there were the yellow bees on the blossoms in great numbers. We proceeded to catch and bait some of them. We soon had a line started that went directly toward my home. We baited and lined those bees for

hours, until we had traced them to within a mile of my apiary. We were then convinced that they were my bees. By air line it was fully five miles from my yard to the home of my neighbor.

The two years, 1886 and 1887, were extremely dry in Texas, being remembered by many people as extensive droughts. The first of these years was a total failure for bees; but the second was better. A few local showers of rain fell in different parts of the county. Some parts of the State had fair rains; but in my own immediate vicinity we had practically no rain. Some seven miles away from my home was the black land belt; in favorable years the horse-mint grew to perfection there. It was the chief dependency for a honey crop nearly all years. In this year, several local rains happened to fall there. There was a good bloom in a short time, and my Italian and Cyprian bees averaged a surplus of sixty-eight pounds of honey per colony. The distance from my apiary could not have been less than six or seven miles. While dealing with this

point, let me quote a few lines written at that time for *Gleanings in Bee Culture*, for 1888, March issue, page 206. "To further prove that they (bees) will go six or eight miles, I remember that this year (1887) has been noted for drought, and what rain came has only been partial showers. In June, when the mint blooms, everything here was burned up, but six or eight miles out on the prairie, there was plenty of rain in time to make the mint crop splendid; the result of it is, I got sixty-eight pounds of extracted honey to the colony." Does this look to you, my reader, that bees fly not more than two miles for stores? Don't tell me that I was mistaken, and that the bees gathered this honey from some other source. I was familiar with all the surrounding country for miles; furthermore, I am sure that this plant was not growing any nearer my apiary.

At another time, in this same locality, I got a surplus of twenty pounds of comb honey to the hive from the wild marigold, when not a plant of it grew nearer than four miles of my apiary. That year the crop was plentiful about six miles away.

Some three years ago, during the "kinnikinic" bloom—one of the sumac families—a friend of mine was attracted by the loud humming of bees passing over him. This man, Mr. D. H. Stribbling, is a beeman himself, and, being interested, he stopped to investigate. He soon discovered bees by thousands passing over him. From the direction they were coming, and from the color of several, he was persuaded that they were from my own apiary. At that time, he tells me, he was fully three miles from my home yard, and the bees had to go at least one mile further. My home apiary here in Llano County, is situated approximately two and one-half miles from any mesquite timber; yet during a fair blossom this apiary stores surplus honey from this tree about as fast as my outapiaries that are in the midst of the bloom.

Now, in conclusion, it is unnecessary for me to take up more space. I am sure that bees do fly this far here in the South, and that they do gather surplus honey a great deal farther than two and one-half miles from home. Instances are too numerous to the contrary; and too many have reached the same conclusion that I have. Now, gentle reader, understand that I have no long-distance or long-tongued bees for sale. I am merely interested in knowing more about the honeybee.

Llano, Texas.

Entrances

By Arthur C. Miller.

RECENTLY the location of the hive entrance in relation to the position of the combs has again attracted attention, but this time in connection with comb conditions and not with temperature within the hive.

Some years ago beekeepers had a

The Comb-Entrance and Great Propagator

long and earnest discussion as to whether the hive entrance should be at the side or end of the hive, or, more properly, whether the sides of the combs should be toward the entrance or the ends towards it. The arguments had wholly to do with temperatures, the side entrance being called the "warm" and the end the "cold." Then some gentle and sympathetic soul put a spoke in the wheel by saying that the bees could reach any desired part of the hive easier and quicker with the ends of frames to entrance than the other way, as if time or labor was of consequence to bees. So the supply men settled on the end way. But not so all beekeepers, some wise ones stuck to the side way. Some who were wise or otherwise used two entrances, the second one being an inch hole bored half way up the front of the hive.

To avoid raising the issue of relative warmth, let me say right here that my present remarks have to do with the condition of the combs and position of stores as affected by location of entrance. Size of entrance also enters into consideration of the case, as does the space below the frames. For sundry reasons a space of about one inch below frames is pretty generally considered to be as little as desirable. It is what I use and the conditions I shall describe are with such space.

With a full entrance it is the habit of bees in the fall to cut away the lower part of the combs adjacent to the entrance, the wax secured being used in capping and re-enforcing combs elsewhere in the hive. After the combs get old and leathery this cutting is not so apparent, but the mischief to the combs occurs long before they get tough and black.

Where the combs are end to the entrance the lower front corners are cut away, often for two or three inches back and up. The following spring that space is filled with drone comb.

If combs get turned end for end the other corner gets cut away, and it is not unusual to find both corners filled with drone comb or 9 square inches in each comb, which is 90 square inches of drone comb in a 10-frame hive. This is equal to four-fifths of an L-comb, and when we add the drone cells found in other places we get altogether too much drone comb, often more than a whole L-comb.

Now, drones are not only costly to raise and maintain, but they are also an excitant towards swarming. Besides the expense of the drones we have the loss of foundation. We buy it and put it in the frames and then the bees cut it out. Not a very profitable procedure. So much for the comb condition.

Position of the stores is affected by entrance location. Regularly we hear the complaint that bees died in winter with plenty of food on the opposite side of the hive. They store their food around the brood-nest or cluster, usually forcing the cluster down close to the entrance if fall supplies are abundant. As they eat back it may be towards one side or

the other as well as upwards, and it is not unusual to hear the remark that the bees were found on the sunny or sheltered or warm side of the hive. Now, why permit conditions which favor such misfortunes?

When the combs are side to the entrance, stores are still around the cluster, but as they work back, it is away from the side where the stores are being, or have been, consumed, and toward more stores. Where the side entrance is used it is rare to find dead bees on emptied combs with plenty of food on the opposite side of the hive.

Then, when we are working over the hives it is so much nicer to work at the back of the hives, but if the frames run from front to rear it is awkward to handle them from the back, so we stand at the side, where we can, and we cannot do so on the long row plan so often used and pictured. Furthermore, on the end entrance plan we cannot move a comb without disturbing the entrance guard, and if there is a scarcity of nectar and robbers are about we are not helping matters for either ourselves or the bees. With the side entrance, however, the guards are not disturbed until the front comb is removed, the last one we touch if we are going through the hive as when hunting for the queen. This may sound a small matter, but just work with both styles for awhile and it will be found far from small.

In harvest time and hot weather all sorts of plans are resorted to for increasing the size of the entrance, such as putting a rim or blocks between floor and hive-body, but with the side entrance and one inch space below frames we have an entrance 1x18 inches instead of 1x14 inches, as with the end entrance, an increase of no small amount.

To return to the matter of drone-comb. With the side entrance the only comb with drone-cells is kept next to the entrance, where it is used last by the queen and deserted first.

Incidentally, at the beginning that frame has only two-thirds of a sheet of foundation put in it. The bees fill the lower part with drone-comb, and cut and refill to their hearts' content and the beekeepers' satisfaction. The top of such frame is painted a distinguishing color, so that it is not misplaced in manipulation.

Consider these factors, but for the present ignore the "warm" and "cold" notions. These have their value, but are as nothing compared to the others.

Providence, R. I.

Price Recommendations—The Chicago Northwestern Beekeepers' Association will send out price recommendations again this season the same as last year. These price letters are free to all members of the above association, and to any beekeeper in the States of Michigan, Indiana and Wisconsin who has ten or more colonies of bees. The Secretary would like to have the names and addresses of every beekeeper in the above States to put on the mailing list. We are depending on membership fees to cover the expense of getting out these letters and would like to enroll as members at least 500 of the leading beekeepers in the above and surrounding States. The beekeepers who received these price recommendations last year profited many thousands of dollars by following the advice given. The first letter will be sent out about July 20. Other letters will follow every eight weeks or so. The idea is not to boost prices but to try and establish a more uniform price for honey. The dues to the above association are \$1.50 per year, which also includes membership in the State Association, and a cloth-bound copy of their annual report which also contains the proceedings of the Chicago Northwestern annual meetings.

THE EDITOR'S VIEWPOINT

Bees in Packages by Mail

At last we have a ruling whereby bees in packages, as well as queens and attendants may be sent through the mails.

It is now up to the shippers of bees to make their containers for bees so strong and unbreakable, as well as unbreakable, that there will not be any question of this ruling being viewed for the good of the service.

Following is an extract of the ruling:

Office of Postmaster General,
Washington, June 18, 1918.

Order No. 1577.

Amend Paragraph 1, Section 476, Postal Laws and Regulations of 1913, by adding thereto the following as sub-paragraph (a).

(a). Honeybees in quantities may be sent in the mails, without insurance or C. O. D. privileges, under the same conditions as are prescribed for queen bees and their attendant bees when delivery can be made to the addresses within a period of five days. If the cages are wooden the material of which they are constructed shall not be less than three-eighths of an inch thick and the saw cuts therein or space between slats shall not be over one-eighth of an inch wide; if wire screen is used for the sides of the cages there shall be two thicknesses of screen separated by slats at least three-eighths of an inch in thickness. The container shall be provided with a suitable handle and no water or liquid food shall be placed therein. Such parcels shall be transported outside of mail bags.

A. S. BURLESON,
Postmaster General.

Transferring Bees

by Temporary Anesthesia

In "L'Apicoltura Italiana" Engineer A. Capponi, of San Remo, gives his method of transferring and uniting colonies by putting the bees to sleep with a dose of about 10 grammes of sulphuric ether. The hives or

skeps to be transferred are taken early in the morning, before they have begun their flight, placed upon a cloth and the edges of the cloth raised up and tied around the box or skep so the bees may not be able to escape. They are then carried to the house, bottom side up, when they begin to roar from excitement. The liquid is then applied with an atomizer, by cutting a small hole in the cloth. In a minute the hum of the bees lessens. A second and a third hive are then operated upon and by that time the first colony has become completely still. The bees may then be shaken into movable-frame hives. In a little while, if the operation has been well conducted, they come to life again. Bees from different hives may be united in this way without the least fighting on their part.

The claims of Mr. Capponi concerning this method are the following:

1. He kills or injures but a very small number of bees.
2. He avoids stings to himself or others.
3. The work is done in the shortest possible time.
4. He makes colonies of any strength he chooses by mixing together the bees of as many colonies as he desires.

It is necessary to add that this method is employed upon common skeps, or "bugni," as they are called in Italy, that are intended to be killed for their honey by the ignorant owner. Engineer Capponi, who is a progressive beekeeper, saves a large number of bees which are gladly given him by their owners in this way. He relates the astonishment of the "contadini" when they

see the bees revive, after a few minutes, in modern frame hives with combs. It gives them an object lesson and causes them to desire to follow the modern ways.

The temporary anesthesia of bees is not without danger. It is quite easy to give them an overdose from which they would never recover. But we live in a time when numerous operations upon human beings would not be possible without chloroform or ether. So, if human beings may be put to sleep temporarily, for an operation, why not bees? However, I can see a number of our old veterans shake their heads with disapproval. They prefer taking the chances of the stings, and so would I.

This is not the first suggestion of anesthesia in the handling of bees. The "Cours D'Apiculture," of Hamet, published some 60 years ago, contains a chapter devoted to this subject. The ingredients recommended by him were puffballs or lycoperdon fungi, nitrate of potash (saltpeter), chloroform, ether, etc.

One of the greatest advantages claimed by him for this anesthesia is the ease with which bees may be united or given strange queens.

The Chicago Northwestern

We call the attention of our readers to the notice of the Chicago Northwestern Association in another column. Both this Association and the Illinois State Association are useful to Illinois beekeepers. Mr. James A. Stone, of Farmingdale, Ill., is Secretary of the State Association, and a remittance to either him or Mr. Bull will secure membership in both.

Observation Hives

"I want to put bees in an 8-frame observation hive. Is this the proper time to do it, and what is the best way?"
TEXAS.

Similar questions are repeatedly asked concerning observation hives. Many people imagine that an ordinary 8 or 10-frame hive with glass on sides and ends is the proper kind of observation live, so much so that dealers have found it necessary to keep them for sale. But the only observation—or observing—hive worthy of the name is a hive containing only one comb, with glass on both sides, or several combs one above the other, but all supplied with glass on both sides, so that neither the queen nor the bees can escape from observation. In an 8-frame hive the outside combs only, and perhaps the

ends, may be seen, but those outside combs are the least interesting and the queen only occasionally may be seen upon them. She usually seeks to hide herself as soon as the combs are uncovered and gone to the inside.

With a single-comb observation hive, we can witness the laying of eggs, the nursing of the brood, the building of combs, the rearing of queens and in fact all the performances of the bees and of the queen. If it is arranged so that a little of the comb is built crosswise, so as to have cells attached to the glass, we can watch bees while they are in this comb. In fact, such a hive is an endless source of amusement and all the information about the natural history of the bee is secured there at first hand and the teachings of the naturalist confirmed.

An observation hive may be stocked with bees at any time during the season when bees breed. An 8-frame observation hive, on the other hand, should be stocked with bees only at the time of making divisions or natural swarms.

The single-frame observation hive is supplied with a comb of brood, bees and honey, from some populous colony, usually from a choice queen, so that if we rear queens in it, they may be of some value. If not sufficiently strong in bees, after it has been stocked, it may be made as strong as desired by shaking at its entrance, on a cloth, a number of young workers who have never yet taken flight; they will adopt it as their own, since they have no knowledge of any other place. Young bees are secured from the brood-combs of a populous colony while the old bees are in the field, in the middle of the day.

Even a neglected, hopelessly queenless observation hive may be the source of information, as it often contains drone-laying workers, who will give us the spectacle of an occurrence which some noted beekeepers have doubted. There is no end to the pleasure which may be derived from such a hive, even for visitors who are not in the least informed about the bees. The cost is small and when the summer is ended the comb and its occupants may be united to some other colony.

The Export Market

The American beekeeper owes much of the present favorable market to the foreign demand which cannot be met. According to the "Australasian Beekeeper" there are

more than fourteen hundred tons of honey being held in storage at Sydney for shipment abroad. In that far country sufficient shipping space is not available and the honey must wait a favorable opportunity. Australia also has a large supply of wheat which would do much to relieve the present world shortage, if ships were available to transport it to the European markets. Ships and more ships, is the crying need to meet the losses caused by the submarines, and to transport the food necessary to meet the constantly growing demand from overseas. It is apparent that high prices for honey will continue for some time, even though the war should close. However, in Australia, where lack of shipping facilities prevents the beekeepers from making the most of the foreign demand, honey is quoted at from 9 to 12 cents per pound. With the termination of the war and the consequent release of shipping, the prices in different places can be expected to equalize, on a basis of normal freight charges.

Foreign Notes

The Italian editors file away and probably bind their exchanges. Once in a while we read in their magazines something taken out of Gleanings or out of the American Bee Journal of 6 or 8 years ago and it reads to us like new matter and we wonder whether it was really published so long ago. Try to save and bind your bee magazines, and read them over, in a few years. In many cases you will find something useful or interesting which you had forgotten.

The April number of "L'Apicoltore" of Milan celebrates the 80th anniversary of the President of the Italian association, Count Visconti Di Saliceto. We believe the Count is the only representative of an ancient ruling family deeply interested in beekeeping. Beekeepers, as a rule, belong to the middle class, like you and me. We wish Count Visconti many more years of life. We know him to be a true democrat, even though he be a descendant of the rulers of Lombardy.

The same number of "L'Apicoltore" publishes the death knell of the old German Berlepsch system of hives. This system was represented in Italy by the "Sartori" hive. It is being fast replaced with hives of the Langstroth system, under the name of "Dadant-Blatt" hives.

The "Bulletin D'Apiculture" of

Switzerland publishes in its April number some studies upon bee paralysis by Dr. G. E. Turesson taken from the Swedish "Bootanisk Tidskrift," translated by Dr. Rotschy. Turesson attributes the invasion of paralysis to the fungi of mold. Without doubt, cool weather, accompanied with dampness is most dangerous for paralysis, May disease, vertigo, or Isle-of-Wight disease.

Now is the time to Requeen

If you are a careful beekeeper, you will have kept record of the amount of honey produced by each colony in your apiary.

Now that the crop is nearly over, you can devote your attention to increasing the prolificness of your queens by breeding new queens from your best colonies and introducing them in the colonies from which mediocre queens have been removed.

The time was, when a beekeeper could breed for honey-producing qualities alone and come nearly hitting it right, but with the prevalence of European foulbrood it is also very important to have a strain of bees which are in part or entirely resistant, and the common black bee, or its cross, will not usually measure up to the pure Italian race. Unfortunately, the Carniolans and Caucasians have not been given thorough enough trial to determine their resistance.

Possibly you do not want to bother with rearing your own queens, but would rather leave it to the experienced breeder to give you queens from a good honey-producing stock. In any case, it will pay you to requeen wherever your stock is impure or where the queen has a colony very much below the average of your yard.

Leave Enough Honey for Winter

Many beekeepers will be inclined, with the high price of honey, to extract very closely from their bees, either in the hopes that all colonies can gather enough to winter on during the late summer or fall, or in expectation of feeding later on a lot of sugar syrup for winter stores.

It is bad practice at any time to replace good white honey by sugar for wintering. It is doubly bad practice now, since the department has made a ruling whereby beekeepers are only to get half of the sugar they require, and care is to be taken that such beekeepers are not extracting honey and feeding sugar to take its place.

On the Supply Maker's Trail No. 3--The Making of Comb Foundation

By Frank C. Pellett.

IT is an interesting journey to visit the various factories engaged in making bee supplies, for the purpose of getting a glimpse of the operations necessary to supply us with equipment. Most interesting of all is the making of foundation, for in foundation we give the bee something only partly done, which she must finish for herself. In nature, the honeybee never builds her own hive, but she always builds her own combs. She simply takes possession of any suitable shelter, whether it be a hollow tree or a vacant space under the roof or between the walls of a dwelling. Any place where her combs can be built in safety, will do. The making of hives is, then, rather a problem of providing for our own convenience in manipulation, than of saving of labor for the bees. Extractors, containers, smokers—everything else in the way of supplies, are made for the convenience of the beekeeper; foundation alone for lightening the labor of the bees.

In reviewing the wonderful development of beekeeping during the past half century, one is led to wonder whether any great improvement still remains to be brought forward. With the possible exception of the movable frame hive, no single invention has done as much for the beekeeper as foundation. Even yet, many beekeepers fail to appreciate fully the possibilities of its use. It is only after visiting the hundreds of apiaries where the bees are lived on empty frames, and permitted to build combs to suit their fancy, and comparing the results obtained with those secured by the expert beekeeper, as an inspector is compelled to do, that one comes fully to realize what foundation is worth to the

honey producer. If the millions of neglected colonies of bees in America could be supplied with full sheets of foundation on which to build their combs, and with plenty of super room—even though no other attention was given aside from what they now receive—this one thing, alone, would add millions of pounds of honey to our product, and go a long way toward relieving the present acute shortage of sugar.

In reading the literature of a half century ago, one is impressed with the great care exercised to save every small piece of good worker comb. There was much cutting and fitting of combs in order to cut out patches of drone cells, and replace them with worker comb. It was a laborious process to secure a large number of good combs in those days and, at best, they bore small resemblance to the perfect combs which we find in a well regulated apiary of the present time. While there are a great variety of uses to which beeswax is put in the manufacture of various commercial products, the beekeeper is his own best customer. It is probable that more wax is now purchased for the manufacture of comb foundation than for any other purpose.

It was a happy thought that suggested the impression of the cell base on a thin sheet of wax, but many years of experience were necessary to develop to perfection a machine which made the production of foundation, on a commercial scale, a possibility. In the May (1917) number of the American Bee Journal the editor told something of the history of this enterprise, so it is not necessary to repeat it here. However, we note that it was not until 1875 that the first printed wax was offered for sale in New York. It was several years later that a uniform product of good quality appeared in the market, and then began the slow process of educating the mass of beekeepers to the advantages of it. The well-informed beekeepers were quick to

see the possibilities of its use, even at the high price for which it sold at the first. Like any new invention, its value had to be demonstrated before coming into general use. Now we rarely find a beekeeper of experience who would allow the bees to draw new combs without full sheets of foundation. The extra honey cost to the bees in building the combs amounts to more than the cost of the foundation, to say nothing of the advantage of the straight combs composed of worker cells, which are so important to the success of the beekeeper.

For a time it was common practice among beekeepers to buy a small mill and make their foundation at home. While it is quite possible to make a fairly good grade of foundation on these hand mills, it is slow and tedious work, and there are many imperfect sheets. The big mills now make it at so low a price that few beekeepers care to bother with a hand mill. Usually they ship their wax to a commercial establishment and have it made into foundation, at a low cost.

When foundation is made on a hand mill, it is necessary to dip a board or sheet of metal in the melted wax, then run the sheet of wax which is peeled from its surface between the rollers bearing the impression. At the foundation factories the wax is first sheeted by machinery, and made into rolls which are later run through the mills. The different operations are thus necessary to make the finished article, and each of these processes requires a different machine.

Sheeting the wax so that it can be fed through the mill in a long belt-like roll, is an ingenious operation. A large quantity of beeswax is melted, for nothing but pure beeswax enters into the manufacture of comb-foundation. This melted wax is held in a large trough, in connection with the sheeting machine. A water-cooled metal roll turns in the hot wax. Since it is cooler than the wax, it is instantly coated with it. It turns against a knife that peels off the coat of wax and forces it through a narrow slot. By the time it has passed through the slot it is cool enough to work nicely, like the taffy which we delighted to pull in our childhood days. Beeswax is very flexible at blood heat. The slot through which it is forced is long and narrow, thus bringing the wax through in the shape of a thin sheet, which is fastened to a wood roll that turns slowly and winds up the wax much like thread is wound on a spool. When about 30 pounds of the wax has been thus wound it is cut off and laid aside and a new spool started. The width of the sheet is adjusted to the size of finished foundation desired.

Our second picture shows the stockroom where a large quantity of sheeted wax is ready to go to the mill to receive the impression. The first picture shows the sheeting machines winding up the wax. Large quantities of wax are sheeted in advance of needs of the mill, since it can be easily stored and cared for in this form.

Sheeting the wax—The first stage of making foundation

The final process is rather simple. The roll of wax is threaded, so that it runs between two metal rolls as it unwinds. The rolls are cut to reproduce the impression of the base of the cells the size and shape of worker comb. As it leaves the rolls it is automatically cut into the proper lengths which the trade demands. As fast as the sheets are cut they are sorted and packed by young ladies, who become very expert. Paper is placed between the sheets of foundation to prevent them from sticking together or being otherwise damaged.

Beeswax is sensitive to changes in temperature. When the wax becomes warm it gets soft and the impression might easily be lost. In extreme cold it becomes so brittle that the sheets are easily broken. When packed in paper boxes with paper between the sheets of foundation, it is safe from all extremes of weather, is free from dust, and may be kept for years without damage.

Glimpses of Southern Beekeeping--Boneset

By Jos. S. Scott

EVERYBODY knows about a surplus flow from alfalfa, clover, orange, basswood, etc., but does anyone know of a surplus flow from something unusual? Let's have something out of the ordinary ruts. I'll start the ball rolling with a flow from boneset.

I have been a beekeeper for seven or eight years and during that time there was boneset here, but I never noticed that the bees worked on it; why? Well, I think that the main reason was that my crop of saleable honey is over with by the 15th of May, when there is no more for that year except a light flow in July from summer titi and honeydew. This is left for them to winter on. As the bees can fly most any day and every day in the year, it is seldom that they have to stay in the hive over four days in the winter. So they winter well on the honeydew mixture.

This year there was a lot of velvet beans planted near my bees and I knew that they would get some-

thing in August from them, so I prepared to make some increase and requeen all of them during this flow. The flow was heavier and longer than I expected and these young queens went to laying like it was spring, and I never saw a larger lot of bees just right for gathering honey when the boneset began to bloom. I thought at the time that it was goldenrod, but was doubtful, as I have never seen any honey from goldenrod here; so after they had been on it for several days I followed them to the woods, and they were on boneset. They worked furiously for about ten days and gave me a surplus of at least 20 pounds from this, when we had a terrible wind and rain storm that kept up for at least ten days, at the end of which the boneset had been washed and beaten to pieces. I think that with a week's more flow they would have given me at least a super full of pure boneset honey.

I think the velvet bean flow, together with the young queens, put them in a position to gather this surplus. Heretofore they had dwindled down after July so that they were in no condition to gather a surplus, if there had been any. Was it that, or was it that this was a year that the

boneset yielded? I am waiting anxiously for this fall to come to try it again.

The honey is of good body, a light amber color, with a very strong flavor. The honey when first sealed is so strong that one cannot eat it. After a time most of this strong taste disappears.

The picture in the September, 1917, issue of the American Bee Journal is a beautiful picture of the species of boneset that yielded me this honey.

Mt. Pleasant, Ala.

The Maintenance of Colonies From the Close of the Honey Flow One Year Until Its Beginning the Next

By Geo. S. Demuth, Apicultural Assistant, Bureau of Entomology

THE business of honey production seemingly consists of caring for innumerable details, each of which, to be effective, must receive attention at exactly the right time. The beginner is always overwhelmed by this great mass of details, and even some who are more advanced in

Thirty Thousand pounds of Sheeted Wax in stock-room ready for the mill

Girls sorting and packing the foundation as it comes from the mill

the work may occasionally lose their way temporarily in the struggle with many little things that make up beekeeping.

It is well, when struggling through a maze of details, to look up occasionally to get a more definite idea of the purpose of each of the details of our season's work, in order that we may weigh them and thus find their respective value as bearing upon the ultimate purpose of all our manipulations. When we can see each of these details in its relation to all the others and can trace out just what part each one plays toward the ultimate purpose of the beekeeper, we shall probably revise our conception of the relative importance of the many things we attempt to do in the apiary.

Two phases of the work—When examined with this in view, we find

that each and every one of the multitude of things which we attempt to do during the year's work among the bees falls under one or the other of two great groups of activities. First we have one group of manipulations scattered throughout the greater portion of the year, each of which bears directly or indirectly upon a single purpose—to have, at the beginning of the main honey-flow, all colonies strong in energetic workers of a good strain.

Strong colonies at just the right time, however, do not alone insure the best results in honey that the location and season may afford, since strong colonies may divide themselves by swarming into two or more medium or weak colonies, thus defeating to a great extent the purpose toward which the beekeeper has directed his efforts during almost a year of preparation. Even if a division of the working force is prevented during this critical period—the honey-flow—other conditions, such as lack of suitable storage space for incoming nectar, crowded brood-chamber or insufficient ventilation, may cause the workers to loaf during the height of the honey-flow and in this way defeat the purpose of the beekeeper. The second great group of manipulations of the apiary, therefore, includes all those having for their purpose the providing of conditions tending to hold the gathering and storing instinct of the bees dominant and the prevention of a division of the working force of the colonies during the main honey-flow.

With a given equipment in a given locality during a given season, the resulting honey crop is determined by the degree of thoroughness and promptness with which these two things are done. Any manipulation which does not bear directly or remotely upon one or the other of these two purposes is something aside from honey-production, while those manipulations affecting to the greatest degree these two purposes are obviously of greatest importance.

Briefly stated, then, honey-production consists of doing two things—1st, providing workers of a good strain for the harvest, and, 2nd, using these workers to advantage during the harvest. The dividing line between these two phases is most clearly defined in localities having a single short honey-flow from which all, or practically all, the surplus honey is secured.

The Preparation Period—It is my purpose to confine my remarks to the first of these two grand divisions of the work of honey-production—providing conditions which result in strong colonies at the beginning of the honey-flow. In doing so, I am not unmindful of the more tempting array of material in the other group which has to do with the greatest activity of the season, around which is centered the greater portion of our enthusiasm in beekeeping. Neither would I have you infer that these more interesting things are of secondary importance in honey-production. They form, in fact, the super-

structure, and to most of us are the very essence of beekeeping. But the first group is the foundation, without which the superstructure cannot exist.

The tendency to neglect details of the lowly foundation while enjoying the structure above is a sufficient reason for a careful consideration of those factors which constitute the foundation of the honey crop.

Interest—You are well aware of the fact that our interest in the activities of the honeybee, especially during this one happy and busy month—the honey-flow—is the chief stimulus that impels us to do our part of the work and that the promptness and thoroughness with which we do it is largely determined by the intensity of this interest. The beekeeper, during a good honey-flow, when the bees are crowding him mercilessly, works from early morning until far into the night and knows no fatigue until he relaxes for his night's rest. Even then the night, instead of appealing to him as a time for rest, seems only to be another obstacle thrown in the way to prevent the doing of the many things in which he is so tremendously interested. At such times the beekeeper needs no other stimulation to better effort, for his intoxication is then complete. It is fortunate for the industry that beekeeping furnishes, at least at long intervals, such a tremendous stimulus, but as is the case with other powerful stimulants, the relapse between times is the dangerous corollary. At the close of the honey-flow, bees and beekeeper slow down at the same time and the intensity of interest at other seasons seems to be inversely as the square of the distance (in time units) from the honey-flow or peak of the season. This slump of interest in the bees that comes with the cessation of the honey-flow and the radical transfer of activities from the apiary to the honey-house and to the market, often works greatly to the disadvantage of the beekeeper. It sometimes even results in many colonies being permitted to approach the verge of starvation after the honey crop has been removed from the hives. In such colonies brood-rearing is suspended during the time when eggs should be laid to produce bees that make up the winter colony.

In addition to the seasonal fluctuation of the intensity of interest, there is the sagging of interest during poor seasons. After a series of poor and indifferent seasons, the beekeeper's interest may sag so low that when a good season occurs he is not prepared to take advantage of the opportunity. This is the basis for the saying among beekeepers that the best seasons usually "catch" them with the poorest preparation in number and strength of colonies.

Beekeeping is a peculiar industry in that the real business of the apiary, actual honey production, is confined to but a few weeks of the entire year, while the preparation for this supreme effort is scattered throughout the remaining ten or eleven months. In much of this prep-

aration there is considerable latitude as to the time for any particular manipulation and the limit of time beyond which the manipulation is no longer effective is not always clearly defined. In addition to this, there is an annual shifting of these limits and some seasons are so favorable that the colonies need but little if any help from the beekeeper from the close of the main honey-flow of one season to the beginning of the next. In other words, the bees are so nearly able to take care of themselves during the entire non-producing portion of the year that there is danger that the beekeeper will depend too much upon their ability to do so.

The difference between the highly successful and the less successful beekeeper is probably not so much in the greater skill of the one as in the greater degree of interest sustained during the ten or eleven months of non-production for, if the interest is sustained, skill will be developed. The intense interest and enthusiasm of the beekeeper during the honey-flow cannot retrieve a situation lost during the period of preparation. If bees to gather and store the crop are not present in great numbers and ready for business when the honey-flow comes, no highly refined methods or complex apparatus can take their place. One of the great needs of the industry is, therefore, some stimulus to sustain the beekeeper's interest and thus induce him to systematize and simplify his manipulations during the eleven months of preparation.

Three Periods in the Preparation

It is my purpose to call attention to the few essential things to be done during the ten or eleven months of preparation for the honey-flow and to suggest the advisability of working out some system by which none of them shall be omitted. An analysis of the requirements of a colony of bees from the close of the honey-flow of one year until the beginning of the honey-flow of the next, on the basis of purpose on the part of the beekeeper, reveals three well defined periods.

1st. Production of Bees for the Winter Colony.—There is a date some time during the latter part of summer which marks the dividing line in brood-rearing between that brood, the resulting bees of which die before or early in winter, and that which results in bees that make up the winter colony. This date, of course, varies in various localities and with different seasons in the same locality, and is greatly influenced by conditions governing the amount of energy that the bees expend before winter begins. In order to have a colony for winter, therefore, there must be some brood-rearing after this date. Thousands of colonies are lost annually because brood-rearing was not sufficient to replace the wastage of bee-life during late summer and early fall. Since we cannot lose in winter colonies which we did not have the previous fall, it is an error to charge such losses to wintering. The workers

that make up the colony at the beginning of the broodless period must be young and vigorous either in the sense of their age in days or in the amount of energy they have already expended, or in both.

The central idea, therefore, of this first course in the construction of the foundation for next season's honey crop is the production of bees whose lives are to span the winter broodless period.

2nd. Conservation of Energy — During the broodless period, the length of life of the worker bees must be greatly prolonged if the colony survives. Instead of the accepted six weeks' normal span of life under active conditions, the energy of the bees must be conserved that they will live six months or more. The existence of the colony during the winter in the North, therefore, is dependent upon conditions enabling the bees to live slowly enough to last until more favorable weather conditions permit their replacement with young. The so-called spring loss or spring dwindling is usually, properly speaking, a winter loss, and the weakened condition in the spring of colonies that were normal in strength the previous fall must be charged to winter loss. The central idea in that which we call wintering is the conservation of the energy of the bees.

3d. Increase in Population—Some time in the spring, while still anxious that bee energy shall not be wasted, the beekeeper desires that it shall be spent judiciously in brood-rearing. Here, as during the previous period, the instincts of the bees are in harmony with the desire of the beekeeper. From this time until the beginning of the honey-flow, the primary purpose of the beekeeper is a tremendous increase in the population of each colony, so that it shall reach the possible maximum about the time the honey-flow begins. If there is sufficient time previous to the honey-flow, as in localities where buckwheat furnishes the main crop, he may even increase the number of colonies, thus producing more workers for the harvest. This being the final lap in the preparation for the honey-flow, failures here are more noticeable, but not less destructive to profits, than are the failures during the other two periods.

Three Fundamental Requirements

During each of these periods numerous environmental factors, such as weather conditions or presence or absence of minor honey-flows, exert influences favorable or unfavorable to the ultimate purpose of the beekeeper. In their battle against the many unfavorable conditions, there are but three fundamental requirements on the part of the bees—food, protection and room for expansion during periods of greater activity. In other words, if a normal colony of bees is never permitted to run short of stores, if it is at all times well protected, especially against extremes of temperature, and if brood-rearing is not at any time checked (when brood is desirable) by a lack of room, such a colony, barring accidents, will be

prepared for the honey-flow in time to take advantage of it. Aside from providing and improving his equipment or controlling disease, the work of the beekeeper consists only in supplying any deficiency that may occur in food, protection and room. These are but primitive facts in beekeeping, but they are basic and are exactly the factors to the neglect of which may be traced most of the failure to have colonies at the beginning of instead at the close of the honey-flow. All the details of work, not concerned with equipment or disease, during this entire period, are concerned only with stores, protection or room for expansion of colony activity.

During the three periods into which the entire period of preparation is naturally divided, the emphasis on these fundamental requirements changes. Food, of course, is prominent as a requirement during each of the periods, with additional emphasis on quality during the winter; protection has its greatest emphasis during the winter and early spring, and room for the expansion of the brood-nest is primarily a spring requirement.

(To be concluded in September number)

Small Helps to Canning Efficiency

By Mary G. Phillips

DOES your back ache, and are you tired all over after canning today? Then sit down in the most comfortable chair on the porch and cool off, while you review the situation, and reflect on the numbers of tired women, more than ever before in our history, who, like you, sit down at the end of the day with a sigh of relief that one more batch of jars is filled and put away. Everywhere, north, east, south, west, they pull the shoes from their weary feet at night and drop into bed spent, but happy. The wives of farmers have the longest and hardest days, probably, for in addition to doing the regular housework, they generally have several extra men to feed, help with the milking or feeding of chickens and stock, and are frequently handicapped by inconveniences like having to pump all the water, keep fire going in a wood stove, and in addition—the canning.

But it is not only the farmers' wives whose daily strength used in canning is adding to the military strength of our cause. There are the women of suburban towns who have been used to having a man for the heavier part of gardening, and a maid for the heavier housework. Now that men for day's work at gardening have virtually disappeared, and husbands are too busy with their part of the war work to be available, these women have spaded and planted the gardens themselves. With the kitchen help problem likewise acute, they are also doing their own housework and laundering. To women unused to these tasks the burden is heavy, but with the same grit as the

farmers' wives are showing, and with the determination not to be undone by the noble French and English women, they have made themselves equal to the task, and besides, add canning to the day's work. As for the women of the city, most of them who can leave home for even part of the day, are engaged in filling the vacant places left by men in business. But when their day at the office is done and the apartment is cleaned, and meals are over, these business women, like the rest of us, can!

Now, nine out of ten of the canning army have plunged into the extra work eagerly and willingly, but without first planning for it adequately. The cherries were ripe before you knew it, so, although you meant to have every bit of equipment necessary this year, when time is such a precious commodity, you did expect to finish housecleaning first, and get winter clothes packed away, and make yourself a couple of new morning dresses, but—the cherries hung red upon the trees and you dropped everything else in order not to lose one of them to the robins. It was nip and tuck, but with the children's help in picking and pitting (you did mean to buy a stoner this year), and by keeping at it day after day, you managed to salvage fifty quarts of potential pies, now safely placed on your top shelf. Then you turned again to finish the cleaning and the half-made dress, but—peas came on, and then you knew you were in for it, and the rest of the summer would see you with some canning to be done every day.

Well, it is too late now to go back to the beginning of the season, but there are still many vegetables and fruits to be preserved for winter, so let me ask you as you rest for a few minutes, to think of your equipment and the arrangement of your kitchen. "Disorganization is the main difficulty with housework," says one observing man, and he is partly right. We do not plan, systematize and simplify sufficiently. It is too late to reorganize your entire kitchen this season, but there may be many little steps toward kitchen efficiency which you could make tomorrow morning which will make your day's work shorter and lighter.

For instance, while canning, one is constantly washing her hands. Where does your hand towel hang—close beside the sink, or behind the door at the other side of the kitchen, so that you have to take a dozen steps to wipe your hands, and a dozen steps back to your work?

Have you but one sharp paring knife, generally referred to as "the" knife, which Johnny persists in borrowing to cut string, so that when you miss the knife just as you are about to prepare your vegetables, you have first to find Johnny in order to locate it? Two or three such small knives, involving an outlay of about 75 cents, save much wear and tear.

Again—have you a lifter for hot jars, or do you burn your fingers and lose your temper trying to lift the jars from scalding water with a spoon or cloth or what not? Such a

lifter looks like two forks arranged scissors-fashion and costs 25 cents.

Once more—have you a wide-mouth funnel for filling jars (cost, 10 cents), or do you waste material and make work for yourself by attempting to fill jars without?

Do you follow the government bulletin advice and blanch your vegetables in cheese-cloth? If you have thought it too much bother to hunt up the cheese-cloth, or thought it "just as easy" some other way, try the cloth, just to see how great a time saver it is. Following the government bulletin is one sure way to succeed, and the woman who thinks she will save time by skipping what to her mind seems a trifling operation need not be surprised when she "has bad luck" with her canned peas or corn.

Have you a kitchen table on casters that you can easily pull close to the stove? If you have you know what a comfort it is to lift filled jars directly from the stove to the table with no steps between.

Have you thought carefully of your kitchen arrangements, or is the refrigerator, sink, stove, table shelves arrangement hit-or-miss? It is not a difficult matter to have the furniture so placed that you do not weave backward and forward over your kitchen floor a hundred times during one operation.

Do these seem like little things? So are minutes, and yet they are of great importance in this time of crisis. Some super-efficient housekeepers may say, "Why, of course I have all those time-savers, and do all those things!" but the majority of housekeepers skimp on kitchen utensils and do not think sufficiently to save themselves. We need the utmost strength of every woman of the nation and not an ounce of it should be wasted any more than food should be wasted.

Washington, D. C.

Parthenogenesis Among the Solitary Bees

By John H. Lovell.

IN the May number of the American Bee Journal the editor gives a very interesting criticism of Fabre's views on parthenogenesis in the honeybee. It is the more surprising that Fabre should so positively deny Dzierzon's theory, since he himself has described parthenogenesis in *Halictus*, a genus of solitary bees. As among the bumblebees, the sexes mate in the fall, the males soon die, but the impregnated females hibernate during the winter. With the return of warm weather in the spring these prospective mothers dig burrows in the ground which are 5 or 6 inches in depth and have several short lateral branches, in each of which and in the lower end of the tunnel a cell is built. In each cell a ball of bee-bread, about the size of a pea or smaller, is stored and an egg is laid on this little mass of food. The composition of the bee-bread is essentially the same as that of the honeybee. From these eggs come

only females; there are no males in the first generation. In like manner the queen bumblebee's eggs produce only workers in the spring. Each burrow of *Halictus* thus contains 8 or 10 females, sisters, since they are progeny of one mother. Beginning with the cell in which she was born, each female digs a new group of cells, connected with the main tunnel. Although there are then no males in existence, each of these virgin sisters provides her cell with a ball of bee-bread, and lays eggs, which by parthenogenesis give birth to both males and females—the second generation.

"To sum up," says Fabre, "judging by the three species that form the subject of my investigations, the *Halicti* have two generations a year, one in the spring, issuing from the mothers who have lived through the winter after being fecundated in the autumn, the other in the summer, the fruit of parthenogenesis, that is to say, of reproduction by the powers of the mother alone. Of the union of the two sexes, females alone are born; parthenogenesis gives birth at the same time to females and males."

If in *Halictus* unimpregnated females can lay eggs which give birth to both males and females, it is less surprising to learn that in some instances there are laying workers of the honeybee which can also produce both drones and females. There was a time in the history of the honeybee when there were no workers, but only males and females. The virgins of this period, as in *Halictus*, may have been able to lay eggs, which gave birth to both sexes. With the evolution of the worker the egg-laying power has been largely lost by this caste. The ability to produce females may have disappeared more completely than that of producing drones; but still manifest itself under special circumstances.

Since Fabre admits parthenogenesis in *Halictus*, why should he so unhesitatingly deny it in the case of the honeybee? As the editor of the American Bee Journal has shown, this was partly due to his natural dislike of the Germans, partly to his neglect to study the honeybee, which is a cause for some surprise, and partly, perhaps, to the fact that he himself discovered parthenogenesis in *Halictus*.

It is usually the egg, which develops into a new individual without fertilization, since it is larger and contains more food material; but theoretically there is no reason why the sperms may not also do so, and it is said that in certain of the brown sea-weeds (*Ectocarpus*) the sperms, which are unusually large, do develop into new plants of small size. Parthenogenesis can excite little surprise, indeed it might well be more common. The egg and the sperm are only specialized spores, and parthenogenesis seems to be the retention of the primitive power to multiply sexually by means of spores. A spore is a single cell which can produce a new individual. Many of the lower plants, as among the sea-weeds and fungi, multiply wholly by spores. The union of two spores is a sexual act.

There are algae in which the larger spores grow directly into new plants, while the smaller unite, or conjugate, before developing into new individuals. There are also algae in which spores of the same size may produce new plants sometimes independently and sometimes by conjugation. The writer fully agrees with the editor of the Journal that parthenogenesis in the honeybee is a well-established fact.

Waldboro, Maine.

"A Mountain of Honey"

By Luc Sites.

TOGETHER with an old prospector named Jabe Gates, I was running a tunnel into the side of the mountain above Hell Hole, upon the head waters of the American River, in Eldorado County, California, hunting for copper, as my partner had found copper floating down the mountain and had traced it up to an almost perpendicular ledge of rock about midway between the river and the peak of the mountain. We were about three thousand feet above the river and at least that far from the Red Cliffs, which were jagged rocks and cliffs at the summit of the mountain. So we concluded to run a tunnel straight into the heart of the hill and see if we could tap the copper vein, which Gates said must be deposited there. We worked three summers and had run the tunnel in about eight hundred feet (we could not work in the winter, for this is in the high Sierras, about seven or eight thousand feet elevation, and the snow piles mighty high), and blasting a good deal of the way, as the rock was hard in places, but soft in others.

About 1 o'clock one day we came back into the tunnel and the shots had burst down the whole face of the drift, and as we commenced shoveling it away we could see a sticky mass that looked like molasses. As we shoveled and cleared out the mass we could see great slathers of comb. We took a bar and broke down the rock the full width of the tunnel and there we were with a solid mass of honey in the comb full width of our tunnel. It was as black as any black strap molasses you ever saw, and we could see that it was a regular cavern, as the wall was well defined.

We took a candle box and a mining pan full of the stuff to the cabin, and as we were low on sugar and didn't have any syrup on hand, we concluded to try some on pancakes for supper. We tried it out, and if you ever heard of two sick miners, we were the ones, for in less than half an hour later we were writhing in pretty hard pains, and it wasn't until nearly morning that we concluded to live.

Of course, it made us sore at the discovery we'd made. But in a few days we tackled the job again and ran an upper cut about fifty feet alongside the mass, intending to run ahead again over the lower tunnel, but this mass of honey and comb was

just the same above as below. We cross-cut in two directions, but ran right into this cavern full of honey in both cross-cuts; besides, the work was getting on our nerves, being all sticky, and the smell wasn't the most pleasant. As I said, it was getting on in the fall and we were short of grub, so we determined to go out and get venison, as we needed meat, so we went up to the top of the mountain, and near the cliffs we got a four-pronger. We were right there at the Red Cliffs, so we concluded to explore a little. Strapping our guns to us, we climbed up through the cliffs. It was tedious climbing, as the rocks were sharp and jagged. Finally we got up, say about a hundred feet from the top of the main cliff, and all of a sudden we could see the bees flying around a sort of opening, and although it was well along in the afternoon, thousands of bees were flying in and out of this hole in the rock.

As we stood there watching, Jabe tossed a rock up toward the opening. It was the most foolish thing he could have done. Immediately the bees came for us, and in our haste to get down we ran right onto a couple of rattlesnakes, and while the rattlers didn't get us the bees did. When we finally got down to the ground again we both were a sorry mess, and the blooming bees were still after us.

I should judge from the top of those cliffs to the mouth of our tunnel the distance was easy half a mile, and it was almost straight down. We figured it out that the bees had gone into that hole in the rock maybe a few hundred years before and went to the very bottom and built up from there, and, as near as Jabe could figure it, there must have been at least a million tons of honey deposited in the big cavern.

That winter a big snow slide came down and boulders bigger than a three-story house covered up the

tunnel, cabin and all. Jabe died that winter, down in the city, and I was discouraged and broke. I went back the following summer to see about the claim, but finding the whole thing covered up, abandoned it for good.

San Francisco, Calif.

Vouched for by Mr. E. F. Lane.

Mr. Sites is evidently trying to get ahead of the stories told by our friend Mr. Baldensperger in a previous issue. Let us not stop at that, since honey has been recognized as the "ambrosia" or food of the gods, and since there is also a "milky way," is it not quite probable that some of the stars which we see in the heavens are entirely composed of honey? They say that there are no lawyers in heaven, but beekeepers are surely found there.—Editor.

The Evolution of the Beehive

By the Editor.

"Editor Dadant: An extract from the diary of John Evelyn, who lived, during the times of King Charles I, O. Cromwell, Charles II and James II, at Sayes Court, near London, may interest your many readers, who have read articles on 'The Evolution of the Beehive.' Evelyn wrote, July 13, 1654:

"We all dined at that most obliging and universally curious Dr. Wilkins's, at Wadham College, Oxford. He was the first who showed me the transparent apiaries, which he built like castles and palaces, and so ordered them one upon another as to take the honey without destroying the bees. These were adorned with a variety of dials, little statues, vases, etc., and he was so abundantly civil, finding me pleased with them, to present me with one of the hives which he had empty, and which I afterwards had in my garden at Sayes Court, where it continued many years, and which his Majesty came on purpose to see and contemplate with much satisfaction."

"From this brief account, we are justified in assuming there were movable frames in this observation hive. Evelyn throughout his life kept bees and took more than a passing interest in their work, and the pasture needed for their upkeep. It is interesting to note that Charles II, with other people of 'quality' could find sufficient interest in the bees to contemplate with much satisfaction their habits, on more than one occasion. WILLIAMS HUGH,

"Victoria B. C."

The reading of old bee books is fascinating, but above all things it shows us how circumspect one must be, not to make assertions which later may prove fallacious if not even ridiculous.

In order to discuss "the evolution of the beehive" it is necessary to search the old masters' works, read their arguments in favor of such or such a system and study their descriptions.

After reading Della Rocca (1790)

and Huber (1814), I took up Huish (1815), a well posted English author and beekeeper. He was a great critic and took particular pains to ridicule the discoveries and teachings of Huber, denying Huber's assertion that the large number of drones which bees rear is intended to enable the queen to find one more readily in her wedding flight. Huber discovered that the queen went out to mate and mated "on the wing." He showed that a single mating was sufficient to fecundate her "for 2 years, at least." Huish wrote:

"How inconsistent with reason is such a system! and how contradictory to the daily experience of the attentive apiarian! It is an acknowledged fact that the queen never leaves the hive on any account whatsoever."

Huish also denied Huber's discovery that comb was made by digesting honey. He wrote:

"Mr. Huber's experiments appeared conclusive to the majority of foreign apiarians. * * * These discoveries can only excite a smile on the countenance of the chemist and the naturalist. * * *"

As Huish also criticises Della Rocca, one would hardly expect him to borrow from him. So my astonishment was great when I found passages of several pages translated, verbatim, from the latter's work without giving him credit. For instance, Della Rocca, speaking of the sting of the queen writes:

"The sting of the mother bee is bent, and it penetrates deeply, writes M. Ducarne. It is true that they rarely use it, but they do sometimes, and it makes a wound in proportion to its size. La Grenée says that he has held very active queens in his hands, for a long time without the honor of being stung. As to myself, I have experienced that honor, while holding a queen in my hand, after pressing her a little: in truth the sting was slight and not very painful."

This entire passage, as well as a page before and after was inserted by Huish, in his book, page 30, without giving even a hint that it was Della Rocca and not himself who had managed to be stung by a queen. For shame, Mr. Huish, was this ever noticed by some of your readers be-

The Huish Hive and Stand

The Huish Hive had only top-bars for the combs, and was called a movable-comb hive. The combs had to be cut loose from the walls at every inspection.

fore now? It is a little over 100 years since you wrote it.

I am not writing this just for the pleasure of putting on the witness stand a man who has probably been dead 50 years. It is the Huish hive which I propose to describe. It was in the shape of an inverted straw skep, but with "bars" on which the bees built their combs. The flaring shape of the hive enabled the apiarist to remove the combs readily after they had been cut away from the side walls. This was not Huish's original invention, for the Greek beekeepers were at that time using a similar hive.

My readers, accustomed as they are to our modern hives, will wonder at the possibility of doing any work with such top-bar hives. Yet the great Dzierzon, who was so very accurate, never used anything but top-bars, and at each visit had to separate the combs from the hive walls. Neither were his hives built flaring, but perpendicular, so the work of removing the combs for examination was undoubtedly a great task.

It was only after Dzierzon's discoveries that several apiarists devised movable frames. Neither were they as practical as the present hives. Debeauvoys made his frames to fit snugly in the hive, at first, and the bees glued them fast, so they were practically immovable. Berlepsch used spaces around them but did not make an open ceiling to the hive, so that the combs had to be drawn out from the rear, where a door permitted the removal. Hives of this kind are still in use in many parts of Germany.

All this ancient history enables us to see what a great step forward was made when Langstroth invented the

movable frame with the bee space all around, below and above, with a removable top, so that the combs could be taken out without the use of doors, hinges, drawers, and other complicated contrivances.

The time had evidently come for the complete evolution of the bee hive, for very shortly after the Langstroth invention, similar hives were devised by different apiarists. In this country, A. F. Moon of Rome, Ga., made a claim to having devised a similar hive without having seen the Langstroth invention. In France, L'Abbe Sagot, a most excellent apiarist and a modest man, made an almost exact duplicate of the Langstroth hive without having even seen it.

A Fuzz-Bearing Plant

I see in the May number, page 170 "Poisoned with Propolis," by "Missouri."

I think that his bees have gathered nectar, pollen or propolis from poisonous plants such as poison ivy, poison oak or fuzz-bearing plants such as goldenrod and fireweed, which grow in some years abundantly, are very irritable to the throat and nose and make one feel like having a cold or catarrh.

There are many other fuzz-bearing plants which are irritable and from which bees gather pollen and propolis. Enclosed is a so-called fireweed which grows abundantly this year and annoyed my throat.

B. SCHUNCHEL.

The specimen enclosed, a very hairy, slim stem, with orange-colored flowers on a spike, was referred to Dr. Pammel, who reports as follows:

The plant is *Amsinckia intermedia*. I might say that this plant has been identified for me by W. A. Setchell of the University of California. The note from your correspondent is of interest. Many of the plants of the Borage family are excellent honey plants, for instance the common Borage (*Borago officinalis*); some of the plants of this family do not, however, furnish nectar. Toxic substances are found in some members of this family, for instance, the European heliotrope, which has a volatile poisonous alkaloid, and another Borage, hound's tongue, contains a poisonous alkaloid.

I doubt very much whether the symptoms described by Mr. Schunchel can be attributed to pollen from this plant. I am inclined to think the irritation is caused by the peculiar hairs on the plant, as quite a number of the plants of this family are irritant and in some cases the symptoms are similar to those described by your correspondent.

Ames, Iowa.

Liquefying and Packing Honey

By G. M. Ranum.

Read at Wisconsin State Beekeepers' Convention, 1917.

THE apparatus I am about to describe is the outgrowth of a need felt for some convenient way of heating honey, not only for liquefying purposes but for rapidity in bottling and also for prevention of granulation.

We had long since concluded that the only proper way to sell extracted honey was in the liquid state, and had been making a practice of taking back from the stores any of our honey that had granulated, and replacing it with liquid honey. In fact, we insisted on this change, believing that a uniform appearing product would sell better and satisfy better than one that looks different each time you see it, as will honey when in various stages of granulation. Besides, we were tired of explaining the why and wherefore of honey getting white and hard, and never did quite fancy using a label with an apology attached.

This thing of keeping the stores supplied with liquid honey in nice condition made us no small amount of trouble. We tried various ways of heating the jars, and soon decided that dry heat was better than placing the jars in water, as by the latter plan one or more of the jars might crack and the contents leak out, making a bad mess of the whole thing. And the labels would always be damaged so as to necessitate relabeling. We used to place the jars on the back of the kitchen stove, or in the oven, with the door partly open.

This plan worked all right for heating small quantities, but as the business grew the women folks began to grumble and complain.

My outfit now consists of a brick arch or fireplace built on the principle of a cookstove or kitchen range, with a flat, open top for supporting the honey tank directly over the fire

HONEY HEATING OUTFIT OF G. M. RANUM, MT. HOREB, WIS.

The tank behind the extractor can is a combined uncapping box, capping melter and comb heater for warming combs when otherwise too cool for extracting. It sets on a brick fireplace and has water-jacket like honey-tank. Pipe leading to lower room, which is partly underground, has faucet to draw hot water into sink and for washing jars. Faucet 3 draws cold water from reservoir, represented by opening cut in stone wall. Reservoir contains soft water caught from roof of building, and a pitcher-spout pump in upper room draws from same for filling jacket in either tank. We want soft water for washing jars, and they are dried by sun heat in large windows. Pipe leading to honey-tank connects with strainer under faucet of extractor.

and an oven made of heavy sheet iron, built in, with a flue running all around it.

This oven is used for heating honey in jars or cans at the same time that the honey in tank above is being heated.

The tank is double, i. e., one tank inside of another, with water between. The outer tank is of galvanized iron—an ordinary stock watering tank—while the inner one is made of vat tin, and costs considerably more.

The inner tank holds about 1,200 pounds of honey and the heating and bottling of this quantity makes a nice day's work, including rinsing of jars, putting on covers after filling, etc.

Of course, I have in mind two or three children or a couple of women to help with the job.

We use wood for fuel and each heating when tank is full requires less than a wheelbarrow load of wood. If the fire is started quite early in the morning we can begin filling about the middle of the afternoon.

The jars are rinsed in the morning, or a day or two previously, and dried by sun heat, using large windows for the purpose. We use soft water for washing and have it as hot as can be borne. This makes the jars clear and bright. The honey is heated to a temperature of 150 to 160 degrees and kept there for at least 3 or 4 hours. A longer time is still better, especially if the honey was granulated, and in this none should be drawn until the whole body is liquid.

The honey runs directly from extractor into tank and we do not worry about getting it out if it granulates while there. We expect to heat all of it anyway, whether granulated or not.

The oven holds about 8 dozen quart jars, in two tiers, or four 60-pound cans. The covers are loosened before heating and screwed down again when finished. Temperature of oven

is regulated by leaving door partly open. We used second-hand fire brick for building the arch, but ordinary chimney brick would answer the purpose excepting, possibly, for the parts nearest the fire.

The rubber hose with cut-off can be swung around to fill a number of jars set in place on the table, but is not so convenient as we anticipated. Next season we expect to use a stationary pipe instead of the hose, with the jars placed on a small revolving table. As the table revolves the jars will pass under the cut-off, which the operator works with one hand while pushing the table along with the other. A second person will place the empty jars on the table and remove the filled ones as they come around. Other help can be used for putting on covers and labels.

Mt. Horeb, Wis.

The Acacias

By W. A. Pryal.

IF you have never lived in California, or in the native home of the golden-flowered acacias, you have no conception of what a beautiful sight one of these trees is when in full bloom during the winter months, especially in that portion of California about the bay of San Francisco. The fragrance of the flowers is delicious; there is hardly anything in the perfume line as genteelly sweet—and the pleasant odor permeates the atmosphere for quite a distance surrounding the trees. If delicious perfume is evidence of an abundance of nectar, then the acacias should be great nectar-secreting trees. But I am not prepared to give them such credit; in fact, my belief, based on a study of these trees extending over a quarter of a century, impels me to state that they are not rich in nectar, but I know that they are wonderful pollen-producers.

The acacia is a clean tree and

fairly thrifty, though not a hardy tree in all portions of California. I have read that in the Eastern States they have to be treated as green-house plants, for the cold winters are too severe for them in the open. With us, many varieties grow to be tall trees, growing as high as 40 feet or more. Most of the varieties make stately trees, though some sorts are not symmetrical.

In and around Oakland *Acacia mollissima* has been planted for many years, as it is liked on account of its beautiful golden-yellow flowers, which are borne in great clusters or masses, and when the tree is in full inflorescence it has the appearance of being a gigantic plume or bouquet of feathery-like gold. The flowers are very fragrant and are much used for decorative purposes. Bees work in the feathery bloom the live-long day during all bright days in January and February. Sometimes it blooms here as early as the middle of December, and I have seen it in blossom in Santa Rosa, this State, as late as the end of March. In the same year here it had finished its season of inflorescence fully a month sooner, and Santa Rosa is but 50 miles northwest of here.

The variety above mentioned is also styled *Acacia decurrens*, or black wattle, and is rated as one of the very best yielders of tanning bark known. From tests made by the University of California in 1898 it was ascertained that the California-grown bark yielded 13.5 per cent more tannin than did the Australian-grown bark. As there will always be a demand for high-quality tanning barks, and as the tree mentioned is of very easy culture and a rapid grower, it is probable that it has a great future before it in California. If planted extensively it will assure a valuable supply of pollen and, possibly, some nectar, for early breeding.

The wood is also of value to the cabinet-maker and the interior finisher. It is hard and works up with a fine grain and finish. The leaves of the tree have a fern-like appearance, as may be noticed by reference to the half-tone herewith presented.

Acacia melanoxylon is another tree much prized in Central California and, I believe, also to some extent in the southern portion of the State. It is largely planted as a street shade tree, and upon lawns upon large estates. It is more symmetrical than the variety first mentioned; it also grows more rapidly. In its report for 1897-8 the Agricultural Experiment Station of the aforesaid university says: "*Acacia melanoxylon*, the blackwood acacia, is a neat, straight-stemmed, symmetrical tree, of regular pyramidal outline; foliage very dense, dull green; flowers pale yellow, in the usual small globular heads. A desirable tree for sidewalk planting where compact growth and formal effect are desired. The tree is highly valued for many purposes. It is hard, finely grained, and takes a high polish. Even in the young state it makes an excellent firewood, about equal to oak."

This tree blooms later than *Acacia mollissima* and on that account is not

Acacia Mollissima

so valuable for the apiarist, for by this time there are many other flowers yielding nectar and pollen.

I have noticed that poultry, especially chickens, are partial to the seeds of the last-mentioned variety; they hunt the seeds among the dead and fallen leaves and litter under the trees. I should judge that the trees yield large quantities of seed, as they are loaded with seed pods.

Besides these two acacias, there are several other varieties planted in this State, some of low growth and some fairly tall. The varieties here described and illustrated are the tallest we have—some specimens have already attained 60 or more feet in height.

Oakland, Calif.

Virgil, the Poet of Beedom

By D. M. McDonald.

THIS "silver tongued" poet devoted his "Georgics" to affairs of husbandry and his fourth was devoted wholly to bees and beekeeping. He pictures an old man, possessed of a few acres of land and devoting himself to its culture and that of his bees equalling in his contentment of mind the wealth of kings. There, surrounded by his beehives, he attained perfect happiness, and led an ideal life. Placed, as his apiary was, on a gentle slope overlooking the Bay of Naples, he had on every side all that the heart of a beekeeper could desire. The site, the poet says, must be a well sheltered one where strong winds cannot gain access. A ledge was planted at the adjoining boundary, where willow blossoms were fed on by the busy bees; and, under the welcome shade the beeman often dreamed the midday hours away, lulled by murmuring music of the honey-gathering throng. It was considered important that the bee garden should not be open to the disturbing incursions of

sheep or frisky kids, or heifers rudely brushing the "dew" away, or bruising the springing flowers. "Aerial honey," it must be remembered, was believed to be gathered mainly from the dews of heaven. The flowers were not forgotten—"Let gardens fragrant with saffron flowers invite the bees. Bring thyme, and let fruit-bearing trees and bushes be abundant. Plant lime trees and apple trees to yield their luxurious bloom in spring; also elms, black-thorns and planes. The soft osier, the hoary willow and the tough broom all count, as well as arbutus, grey willow, cassia, the golden-hued crocus, and the deep-colored hyacinth." For coolness near the hives he advises that a palm or stately wild olive should be planted to over-shade the entrance.

Good beekeeper that he was, he had an eye to the comfort of his industrious workers. "Have clear springs and green, damp moss or shallow rivulets coursing through the adjoining meadow. If the water is deep throw willow branches crosswise into the stream that the bees may drink in safety on the frequent bridges." When in spring the bees roam through the lawns and woods to reap the harvest of the bright-hued flowers, and to feast on green cassia, fragrant wild thyme and strong-scented savory, as well as countless other flowers, it was no less necessary that they should lightly sip the surface of the streams, hence these carefully prepared drinking fountains. The hives in this model apiary were of the simplest kind, he tells us, made of hollow bark or woven with pliant osier. "They should have narrow inlets to prevent the heat of summer to cause the honey to run and hinder the colds of winter to cause it to congeal. To keep out the cold the bees smear with wax (propolis) the small crevices in their 'caps.' This glue is more

tenacious than birdlime or the pitch of Phrygian Ida." Bees often made a comfortable home underground in hollow pumice stones, and in the cavity of some hollow tree. Bees still, in the nearer east, inhabit such hives as the clefts of the rocks, some warm cave or the heart of some rotting tree.

He calls the colony inhabiting each of these hives a marvelous miniature republic. Each unit has a large mind in a little body. "They have high-spirited chiefs, and, of course, a king. Their allegiance to this sovereign is matched by no human race of men in the fealty they display toward their chief. The king gone, the bond of union is severed. He safeguards their labors and they look on him with respect and awe, while all attend him in crowds."

"Bees at the same time have home rights. They pass their lives under inviolable laws, they know the true meaning of native country and settled household goods. They toil in summer that they may have stores in winter. All work in summer, all feast alike in winter. So powerful is their love of flowers and so strong their ambition to collect honey that they voluntarily yield up their lives for the good of the community as a whole. When battling against adverse winds they pick little stones to act as ballast, and with these they steady themselves through the unsubstantial vapor."

Their internal government is a marvel of perfection. All is arranged for the greater good of the greater number. Some have charge of the food, some busy themselves in the fields, some store the honey, some collect "gum" from the bark of the trees, some build downwards the viscid wax, others lead out swarms, "the hope of the race." Others pack up and seal the honey-cells, some guard the outer entrance, taking it by turns, some receive the loads of those who return, others in marshalled bands drive away the drones, "an inactive horde." All have one rest from work, all have one common labor.

Wise bees, they are genuine weather prophets, and do not go far from their hives, when rain is impending or trust the sky when east winds approach. They are models in precision, in morality and in conduct. They neither indulge in conjugal intercourse nor relax and effeminate their bodies in love, nor bring forth their young with throes of travail. But they themselves gather their progeny with their mouths from leaves and fragrant herbs. They themselves provide a sovereign and tiny subjects, and repair and replenish their palaces and waxen realms.

Virgil went so far as to say that many thought that bees possessed Divine intelligence; that they had portions of "etherial thought," and moreover, that at the end each bee soared, still alive and conscious, each to count a star, and mount to lofty heaven. Several of the gods of ancient times were supposed to have been bees in some former state of being. At that early period the life of a bee was believed by some to last

Acacia Mellifera

twenty or thirty years; our poet considered "The term of a short life awaits individual bees, yet the race remains imperishable—not more than seven years is passed by them." He distinguished two different kinds of bees, and showed his preference for the one he characterized as the "better breed," because it was the race from whose combs you will press the most of sweet honey, and that of a better quality. As there were two kinds of bees, so he held there were two kinds of king. One is distinguished by his mien and conspicuous appearance. One king is disgustingly squalid, the other shines and sparkles with brightness, ablaze with gold.

The time of swarming was a joyful one. When swarms issue they float through the serene summer sky. Then, to attract them, sprinkle the juices prescribed, bruised balm and the herb of honey wort. Ring bells and beat around the cymbals of Mother Cybele (the Mother of the Gods), and they will settle themselves in the seats prepared. This seems to be a kind of self-hiving. A cure for undue swarming is given: "Just disable the wings of their chief and while they stay no bee will dare to leave the hive." Here is the origin of clipping the queen's wing. At swarming time, or at other periods, ancient bees were fond of engaging in mortal combat. Violent animosity and excitement arises between rival chiefs. Then hearts are panting for war. Sounds are heard like the trumpet and the bugle. Then they sharpen their stings on their proboscis. They meet in shock of battle, mingle in a whirling mass and fall headlong. Their chiefs wield mighty souls in their tiny bosoms. Then sprinkle over them a little dust and put the inferior leader to death, he being a superfluity.

Bees had many enemies in addition to rival bees. Keep the speckled lizard with scaly backs from the well-stocked hives. Of birds, the woodpecker is a determined enemy, and so is the swallow, for they devastate all around and in their mouths they bear away the bees while on the wing to be a sweet morsel to their merciless young. Cockroaches that shun the light, the firee hornet, or the moths, a horrid crew, the spider with its nets around the doorway, are all noted enemies of bees. Above all, however, "fell disease," as in our day, entailed misfortune on bees and beekeepers. He gives elaborate directions for curing, but seems to rely on Schirach's remedy of first killing the bees, and, to cure, cleaning out and thoroughly disinfecting the hives.

In Virgil's time beekeepers appropriated the surplus honey twice a year—after the early and the latter flow. In carrying out this operation everything must be scrupulously clean. First wash your body, foment your mouth with draughts of water, and then with your hand thrust forward the persecuting smoke. If the stores are scant, or a severe winter is anticipated, he advises that they should be denuded of little honey, in order that their lives may be spared

for another season of work and increase. This honey they looked on as the gift of the gods, which came down from the skies as a dew. The flowers gave glue, wax and "animable matter" from which bees were bred. The other means used for resurrecting bees and peopling hives where they died is told in the mythological tale of the shepherd, Aristaeus, but the legend is much older and was horrified by Virgil from Egyptian literature.

The faultless poetry of the Fourth George suffers both from translation and from being presented in prose, but as far as possible, the above has been given in the author's words.

Baniffs, Scotland.

The Metal Honeycomb

By Dr. A. F. Bonney.

THE writer lately received a set (10) of the aluminum honeycombs advertised by a California party, and put them to use. They were put singly into brood-chambers filled with brood and honey, and in "Demareeing" I put four in the center and filled out with drawn combs, as I much prefer to put my foundation above an excluder, for it is drawn out closer to the frames.

After an interval of six days I examined all of the nine I had put in, and in every case the bees had gone to work in them the same as in the wax combs. I could not see that they had discriminated at all.

These metal combs are made of very thin aluminum, almost a foil, and are as deep as the average finished comb. They will, of course, be moth-larva proof, and as they are

strengthened with three wires of about 20-gauge, English, running from top to bottom bars, they should resist the centrifugal action of the extractor nicely. However, there is I think, one very serious objection; the metal is so thin and soft that the slightest blow spoils the opening of the cells, when it is necessary to spend time to restore the size, if not the shape of the opening.

This defect might be remedied by using a thicker metal, but this, at the present price of aluminum, would make the cost prohibitive. The present price, 55 cents at the factory, is almost too high to allow their use on a large scale.

My remedy would be to make the cells about one-fourth of an inch deep, of a reasonable heavy metal, dip them in wax when they are mounted in the frames, and allow the bees to draw them out, as they will, as I know from experiments made recently.

I am now working on some square, round and triangular cells, merely to see what the little animals will do with them.

Buck Grove, Iowa.

There is another possible objection to this metal in combs. It is the effect of temperature in our changeable climate. Beeswax is a non-conductor of heat and it stands the differences between the coldest and hottest weather without bad effect. Metals are good conductors of heat and cold, and metal in the hive combs may be the cause of still greater troubles than we now have in wintering.—Editor.

BEE-KEEPING FOR WOMEN

Conducted by MISS EMMA M. WILSON, Marengo, Ill.

Swarm Prevention in War Time

Never before has it occurred—and let us hope that it may never occur again—that so many women have been obliged to take up the care of bees because the husband, brother, or son, the beekeeper of the family, has been called to become a soldier in this war for righteousness. In many cases, it would be a thing greatly desired if the bees could be allowed to stand still, just as they are, until the return of the beekeeper, so that he might again take up the work just where he left off. That may not be; but it might be to some extent approximated if it were not for that troublesome thing—swarming. Left to themselves the bees will swarm and swarm, the swarms going off and being lost, and the summer's harvest being lost with them.

Fortunately, we are not entirely helpless, and there is no reason why a woman, as well as a man, may not be able to overcome the swarm-devil and end the season with a maximum crop of honey.

All queens should be clipped, the two wings on one side being cut away. Not that a colony with a clipped queen will not swarm; it will swarm just as promptly as if the queen's wings were whole. But she cannot go off with the swarm, and the swarm, finding it has no queen, will return. The worst thing that can happen will be that the queen will be lost; and it is better to lose the queen than to lose both swarm and queen. And then there will be a week or so to provide against a swarm going off with the young queen that will emerge.

Even while having all queens clipped, we must proceed so as to reduce swarming to a negligible quantity, if not to prevent it altogether, without reference to whether the queen is clipped or not. One of the important things is to provide ventilation. Not merely what might be considered plenty, but abundance of it. Unless there is a deep bottom-board with a large entrance, it is not a bad plan to raise the hive perhaps

three-fourths of an inch by putting a block under each corner. But no amount of ventilation under the hive will suffice, we must have ventilation above as well. Let the first super be slid forward so as to leave at the back end a crack of one-fourth to one-half an inch. Then if the supers be extracting-supers—and it is better they should be—let the second super be slid back upon the first, so as to make a ventilating space in front; the remaining supers being slid alternately back and forth, so as to "stagger" the pile, as it is called. For years we have had one or more piles thus staggered each year, no excluder being used, the queen generally occupying more or less of two stories, and in no case has a swarm issued.

Of late years it is coming to be considered that there is less swarming if the frames are spaced $1\frac{1}{2}$ inches from center to center than where the usual $1\frac{3}{8}$ spacing is used. The Dadants use that spacing, and it is thought that it may be an important factor in their being so remarkably free from swarming.

It is doubtful, however, that any advice can be more important than the advice to use the Demaree plan to prevent swarming. In a nutshell, the plan is to have one frame of brood with the queen in the lower story under an excluder, and the rest of the brood above the excluder. The lower story may be filled out with frames filled with foundation, or better still, with fully drawn combs. At the time the brood is put up, all queen-cells found on the combs should be killed, and in eight days all cells above the excluder should be killed, if any are started there.

Enough supers of extracting-combs may be put on at the start to make sure there shall be room enough for all the white-clover harvest, and this should be taken off and extracted as soon as there is any danger that the darker fall honey might be mixed with it.

In an exceptionally fine article by Miss Iona Fowls, in June Gleanings she tells just what the practice has

been in the Fowls apiary for the past five years, giving the following diagram, which makes the matter very clear:

This she gives as the best plan for outapiaries, but there is no reason why it may not be used equally well in a home apiary. It has had a five-years' trial in the Fowls management. Miss Fowls says in explanation:

"This plan is: As soon as danger of swarming arises, every seven or eight days carefully examine the colonies, keep them always supplied with plenty of room, and destroying whatever queen-cells are found, providing they contain only eggs or young larvae. When more advanced cells are found, place on the old stand a hive of drawn combs, one of which contains the queen, a few bees, and a few young larvae. (If no combs are available, most of the frames may contain foundation; but there should always be at least three drawn combs, and a whole set, if possible). Above this place the queen-excluder; then two or three empty supers; and at the very top the hive of brood,

tearing down only the capped queen-cells. At the end of seven or eight days, if no increase is desired, tear down all queen-cells again. If increase is wanted, simply place the upper story on a new stand and leave them to raise their own queen, or introduce a good queen or choice cell in a protector. It is not even necessary to remove any queen-cells; for when the new queen hatches, either she or the bees will attend to that. If one desires no increase, then the queen-cells may be destroyed and the brood distributed to other colonies or left to increase the original colony. That is the entire plan, and it has for years been used by many of the best beekeepers."

It may not be advisable in all cases to give as much super-room as the Fowls give; indeed, in some cases all that may be necessary is to have only the one-story of brood above the excluder, for that will allow for a harvest of one story of extracting-combs. In case, however, that increase is desired, and it is desired that cells may be started above the excluder, the higher the story of brood is raised above the queen, the more sure the bees will be to start queen-cells.

Denmark Beekeeping

In spite of the slow postage—it now takes two months—I have received every number of the American Bee Journal sent except the February one, which went down with the steamer.

I will send you a picture of my place and bees, it was taken last year during a bee course. The course lasted four days and was attended by 26. The man holding the frame is the teacher, beside him is an open hive (we usually have the roof hinged on; it is held in place by a roof-holder, so it does not tip over.) Behind the next hive you find me. I am holding a queen-excluder, of the kind we use between the frames. Our hives are long, holding 18 frames; when the time comes, the excluder is put down between the 10th and 11th frames and those behind it are used to store honey in. My experience is that the bees prefer to carry the honey up rather than behind; but it gives plenty of room. Last year's honey harvest was quite fair, in spite of everything drying out, as no rain fell from May to August.

I enjoyed to read, in the November issue of the Journal, about those three successful women beekeepers. I am sure I am the only one on our island keeping bees for a living, and I don't know of any other in Denmark, either.

It may surprise you that I can make a living on 1,000 pounds surplus; but the prices of honey have just doubled. The price in the fall of 1914 was 20 to 22 cents; in the fall of 1917 it was 40 to 44 cents. All my honey was sold on the local market, and had I had 1,000 pounds more it would have been sold right here on the island. No honey is used for cooking—it is too dear;—it is used

Denmark beekeepers in attendance at a short course in the apiary of Anna Sommer

in place of butter on bread, or sugar or for health. Just now beekeepers are sending in their wants for sugar for the bees. Each beekeeper sends his request to the President of the Beekeepers' Association, of Bornholm (there are about 400), who sends them to the Board of the National Beekeepers' Association, of Denmark, who, in turn, hands them to the Sugar Department at Copenhagen. No beekeeper, whether he is a member of the Association or not, can get sugar for his bees in any other way.

In March, 1917, the National Beekeepers' Association of Denmark arranged a course for teachers in beekeeping at the Agricultural High School at Copenhagen. The course lasted 11 days, and was attended by 26, of which I was one. There was a lecture on beekeeping (special bac-

teria pertaining to bee-diseases), entomology and botany.

I will send you a copy of the Danish Beekeepers' Times containing a picture from the course. The paper used to be issued twice a month, but will this year have only 14 numbers, on account of scarcity of paper. It has about 10,000 subscribers, which is almost equal to the number of members in the National Association, as every member gets the paper.

Wishing you prosperity, I hope and pray that God may speed the time when these fearful conditions that at present prevail in Europe may cease, thanking Him with full heart that our dear little Denmark has been saved from the direct sorrows and cruelties of the war.

ANNA SOMMER,
Lobbeck, Bornholm, Denmark.

brood, let it stay a few days, then remove to a new location?

I am trying it out, but thinking that other amateurs may be as anxious for more colonies of bees as I am, I wish to get to the attention of beekeepers while yet there is time to start new colonies. A. F. BONNEY.

(This, of course, would have to be over a queen-excluder, if there is a queen in the hive. If there is no queen, the introduced queen or cell will be as safe below.—Editor.)

Honey Vinegar—I sent you under separate cover a sample of honey vinegar. This was made about a year ago, following directions from the A. B. C Bee-book, and also from the articles in the American Bee Journal, by Mr. C. P. Dadant. It is stored on the second floor. Please state how I can make it more sour. Or, in other words, how can I improve it?

WISCONSIN.

Either of two things is the cause for the failure of fermentation. The liquid may be too sweet. In that case it would require more water.

However, I am under the impression that the trouble lies in lack of fermentation. Put your vinegar into a boiler and bring it to the boiling point. This will kill noxious germs which may have developed and might prevent fermentation and cause the vinegar to become ropy. Then let it cool; add about as much water as you may have evaporated in the boiling and put in about a gallon of fruit juice. Keep the bung off and put it in a warm place. If you have no fruit juice, wait till the grapes are ripe and use unboiled grape juice. To keep insects out of the keg, use a small sand-bag on the bung. But be sure and keep the keg where it will be warm.—Editor.

Texas Inspector to Kansas—W. E. Jackson, until recently in charge of bee inspection work for the State of Texas, under F. B. Paddock, the State Entomologist, has recently been called to the colors. Mr. Jackson reported for duty on May 31, and has been assigned to the medical laboratory at Ft. Leavenworth, Kans., for work in bacteriology. Mr. Jackson's place under Mr. Paddock has not yet been filled.

Nebraska Meeting—The Nebraska Beekeepers' Association will hold a meeting at the Nebraska State Fair for the purpose of changing and adding rules to the by-laws of the association.

The meeting will start at 9 o'clock in the morning of Thursday of the fair week, which is the first week in September.

Frank C. Pellett is expected to be present at this meeting and also several more good authorities. Some very important matters will come up and it is the business of every Nebraska beekeeper to be present.

O. E. TIMM, Secy.,
Bennington, Nebr.

MISCELLANEOUS NEWS ITEMS

Bee Statistics in the U. S.—Bulletin No. 685, of the United States Department of Agriculture, gives all sorts of statistics on beekeeping, distribution of colonies in the different States, increase, wintering, yields, quality of honey, sources of honey and pollen, conditions and prospects.

We judge that this Bulletin is indispensable to the beekeeper. Like all statistics, it is probably incomplete, but, like all statistics, it will supply some information worth having and will lead to further efforts and greater accuracy. It can be obtained in the usual manner, by writing to the Bureau of Crop Estimates.

West Virginia Beekeeping—This is the title of a 52-page Bulletin, profusely illustrated, and published by the State Commissioner of Agriculture. The author is Charles A. Reese, Assistant Entomologist and Apiarist. The bulletin contains the most indispensable information for modern beekeeping. Every West Virginia beekeeper should secure it. It is published at Charleston by the Department of Agriculture.

Wisconsin Association—The Wisconsin beekeepers who are not members of their State Association should send their names to Mr. Edward Hassinger, of Greenville, Wis., so that they may see what their State is doing for the good of beekeeping. In fact, every beekeeper who cares to succeed should belong to his State Association. Wisconsin has arranged to send its members at regular intervals suggestions on the prices to be secured for honey. They base their information on crop reports and markets.

The State Association has voted \$50 to make a display at the State Fair showing the uses of honey. Premiums to the amount of \$49 are offered at the State Fair in addition to this.

Meetings are organized all over the State and the prospects for beekeeping are fine. But if you want your share of the information and of the success, you should put your shoulder to the wheel. Every State needs to do its share for the general success of the industry.

Do Not Contract Too Closely—I should like to refer you to the Official Bulletin of June 24, a copy of which can be consulted at your post-office if you do not happen to have a copy. In this are given the regulations and restrictions for the use of sugar which are put in force for July 1. You will notice that under the less essential uses they class "Honey Manufacture." By this they undoubtedly mean the use of sugar for feeding bees. In view of these regulations it might be desirable to recommend that they do not extract too closely, so that they will be able to get their colonies through the winter with very little or no feeding of sugar syrup. It is impossible at this time to learn how much sugar will be available next fall, and these regulations and restrictions are changed from time to time so that it must not be assumed that the present regulations will apply next fall. In any event we must see to it that there is no tendency on the part of beekeepers to extract all of their honey to sell at high prices and then expect the Government to furnish them with sugar at a low price to take the place of honey which they have sold.

E. F. PHILLIPS,
Washington, D. C.

Will It Work?—If putting a valuable queen in a hive above a strong colony, for heat, with emerging brood is a good plan, and there is, of course, no safer way of introduction, will it not be equally good to put a ripe cell in the same location with, say five or more frames of emerging

**UNITED STATES DEPARTMENT
OF AGRICULTURE
Bureau of Markets**

Honey arrivals since last report:

Medina, O.—177,007 pounds from California, 120 pounds from Ohio, 2,160 pounds from Arizona, 45,915 pounds from Texas.

Shipping point information, Saturday, June 29:

Los Angeles, Calif.—Very light shipments. Demand slow, on account of exporters having difficulty in securing ship space and delivery at terminals; steady feeling. Few large growers holding for higher prices, dealers buying to fill orders only. Cash to producer on farm: Extracted white orange, 20-21c per pound, mostly 20c; light amber, few sales at 16-18c per pound; alfalfa amber, supplies very light, but increasing, mostly 15-16c per pound. White comb, too few sales to establish market; few sales reported at \$4.50-6.00 per 24-section case. Beeswax, demand slow, weaker tendency, mostly 34c per pound.

San Francisco, Calif.—Demand and movement moderate. Growers holding for higher prices, eastern buyers holding off on account of high prices. Demand good for export, but uncertainty of securing steamer space and British Government Food Regulations retarding movement. Prices to growers f. o. b. shipping point: Extracted orange 20-20½c, sage white 18-19c, light amber 16-18c, alfalfa 15½-17c. Beeswax, 33-38c per pound.

Telegraphic Reports from Today's Markets

(In many markets in the honey trade the term "jobber" is commonly applied to the original receiver who buys direct from the grower in carlot quantities. However, in these reports we use the term "wholesale carlot receiver" to designate the carlot purchaser, while the term "jobber" refers to the dealer who buys in less than carlot quantities from the carlot receiver and who sells direct to retailers. The prices quoted in this report represent the prices at which the "wholesale carlot receivers" sell to the "jobbers.")

Note.—Arrivals include receipts during preceding two weeks. Prices represent current quotations.

Chicago.—Supplies insufficient to quote.

Cincinnati.—3,869 pounds Florida extracted arrived. Supplies light. Demand light. No sales reported. Beeswax: Demand moderate. Average, yellow, 35-38c per pound.

Denver.—No carlot arrivals. Comb and extracted, supplies exhausted. Beeswax: Receipts and supplies very light, steady feeling. Price to producers, 35-37½c per pound.

Kansas City.—Receipts very light. Demand light, movement moderate, firm feeling, few sales. All sales in small lots. Sales to jobbers: Native Missouri, quality and condition generally good; 24-comb flat cases, No. 1, light, \$7.50. Beeswax: No arrivals. No sales reported.

Minneapolis.—No arrivals. Supplies very light. Demand slow, weaker tendency. Minnesota and Wisconsin: Comb, white fancy, 24-section cases,

The late C. Becker

old supplies cleaning up \$4.75-5.50. Extracted, white fancy 60-lb. pails, 20-21c per pound.

St. Paul.—No arrivals. Supplies very light. Demand slow, market fair. Minnesota and Wisconsin: Comb, white fancy, 24-section cases, few sales; all sales in small lots, mostly \$6; special brands, cartons, \$6.75; ex-

tracted supplies exhausted. Beeswax: No sales reported.

New York.—Arrivals: 108 barrels West Indies, 82 barrels, Porto Rico, 10 tierces Porto Rico, 130 barrels Florida, 1 car from Cincinnati. Receipts moderate. Demand and movement moderate; market quiet. Extracted, per gallon, Porto Rican \$2.25-2.50; Floridas, \$2.16-3.00, according to quality, mostly \$2.25-2.40. Beeswax: Arrivals, 28 barrels West Indies, 345 bags Cuba, 37 bags South America, 90 bags Porto Rico. Receipts increasing. Demand moderate, market steady. Yellow, 40-42c per pound; dark, 39-41c per pound.

St. Louis.—No arrivals. Supplies very light. No sales.

Philadelphia.—Approximately 120 barrels domestic southern arrived. Demand good; strong feeling; very few sales. Buckwheat, old crop, 23c per pound; southern domestic, amber 25c per pound.

Death of Chas. Becker.—We regret to announce the death of Mr. Chas. Becker, of Pleasant Plain, Ill., one of Illinois' best-known beekeepers, and for many years Treasurer of the Illinois State Beekeepers' Association.

Mr. Becker has also been an exhibitor at the Illinois State Fair for many years and never failed to take his portion, at least, of the premiums offered.

The sympathy of all Illinois beekeepers and others who knew him goes to his family.

Bottom Starters for Extracting Frames

Beekeepers have found a great advantage in the use of bottom starters in sections. There are more advantages in using bottom starters in frames. With frames containing foundation placed over the brood-nest, I find that the bees begin to build from the bottom rather than from the top, expanding the cluster instead of starting a new one. By the use of bottom starters one gets better combs with the frames almost perfectly filled. With the combs attached firmly to the bottom bar the queen is easier to find, as there are not so many convenient hiding places. I have found that nine and a half supers of combs built with bottom starters hold as much honey as ten supers built in the usual way. It is equally desirable to use bottom starters in brood frames or extracting frames to insure good combs.

C. E. FOWLER,
Hammonont, N. J.

**Transferring From Box Hives
To transfer bees from a box-hive,**

take a large box that can be turned over the box-hive, cut a hole through the bottom 4x5 inches. Nail strips on the outside of the bottom to serve as a bottom for a regular hive. Make an opening in the top of the box-hive to be transferred, then turn the transfer box over the box-hive and have the 4x5 opening over the hole in the top of the box-hive. Shovel dirt around the bottom and stop all cracks or knot holes, so that all bees must come up through the top of the box-hive. Now set a regular hive with a frame of brood and empty combs on the strips nailed on the transfer box. This box now becomes the bottom board for your regular hive. The bees will move up into the frame hive, and I have had them carry up every drop of honey, making the melting of the combs in the box-hive an easy job.

F. A. DUNHAM,
Walla Walla, Wash.

Weights for Hive Covers

For preventing covers from being blown off by the wind it is much more convenient to have weights

that can be lifted by one hand. I take a square box three or four inches deep, without top or bottom, or a fish kit without top or bottom, and fill with cement, same as is used for sidewalks. Before filling, place the receptacle on a loose board. For

handles use any old piece of iron that is long enough to bend in shape. Imbed handle in cement as soon as mould is filled. These are very handy and beat a brick or flat rock a mile.

DR. E. W. PARKER,
Sutherland, Iowa.

Cement Weights for Hive-cover in the apiary of Dr. and Mrs. E. W. Parker at Sutherland, Iowa

DR. MILLER'S

ANSWERS

Send Questions either to the office of the American Bee Journal or direct to
DR. C. C. MILLER, MARENGO, ILL.
He does NOT answer bee-keeping questions by mail.

Breeding

1. Why is it that I can't get an Italian queen to stay with me? I have ordered about a dozen queens and have not had any of them to stay; they would stay from a month to six weeks and disappear. I do not know where they go; do you? I guess they are hurt in the mail.

2. Can you tell me the name and address of a reliable queen-breeder in or close to my state?

3. Does an Italian queen raise pure Italian drones when her bees are crossed?

4. How do you get the queen to lay in drone cells that you want to rear drones from?

5. Does sweet clover bloom every year after it commences blooming?

6. Don't you think it would pay to order untested queens and select a breeder.

ARKANSAS.

ANSWERS.—1. I don't know, and have little data to base a guess upon. A queen might be injured in the mail, but in that case she would hardly continue on duty a month or more. If it were in swarming time I should say she might abscond with a swarm. Bees sometimes have queer streaks, and it is possible that it just happened that a number of queens went wrong with you, and that the very next will go all right.

2. Those who advertise in this journal are considered reliable, and among them you ought to be able to find one not very far away. For that matter, distance does not make much difference, and queens from any part of the country ought to reach you safely.

3. Yes, if a queen of pure stock meets a black drone, her drones will be pure Italian, and her workers hybrid.

4. Let them have some drone-comb near the center of the brood-nest.

5. No, it blooms but once. The first year it grows without blooming, the next year it blooms, and then dies, root and branch.

5. Yes.

Queen Introduction

I wonder how you cage your queens when treating for foulbrood or otherwise.

This spring I brought in a couple of my best colonies to feed up and treat early for foulbrood by caging the queen 10 days or more so as to have something free to work with in rearing cells that I might need. I caged them in an ordinary mailing cage with no attendants or candy, and placed them under the quilt and put on a slow feeder. In 8 days I pulled out all the cells and in a few more days I killed everything that looked like a cell, and then I made sure of releasing them safe.

The queens were well taken care of during confinement. I waited until after dark, when all was quiet, and to make matters doubly safe I poured them on in thick honey. Results: In one case the queen was rolled out the next morning, in the other it was a few days, and she, too, came out at the front dead.

I have since caged some with excluder zinc over the cage and released with better luck, in fact found them laying the next day.

I find a good per cent of queens caged 21 day in the way I mention are let starve by the bees. I notice some if caged with zinc do not start cells.

KANSAS.

ANSWER.—I am puzzled to know why you should have had such misfortune, and the only clue I can see toward even a guess lies in your statement, "I find a good per cent of queens caged 21 days in the way I mention are let starve by the bees." That "good per cent"

makes it seem possible that you are in the habit of caging queens something like 21 days, and that that was the trouble in the cases you mention. I don't know just how long bees will endure a queen that is a slacker, but if she fails to supply the cells with eggs at a proper season I am pretty certain they will cease to have patience with her after a certain time. That time may have elapsed, and then as soon as you let the queen out of the cage they attacked her.

As to the way I have caged, I have had no particular way, and have taken no special precaution. In a few cases I have caged them in the way you describe, in a mailing cage, but generally in the simplest kind of a cage made of wire-cloth, putting the cage between the combs or thrusting it into the entrance of the hive. I have thus caged them hundreds of times, and do not recall a single failure. But if I should allow a queen to be caged much more than ten days (and I'm not sure that even ten days' time is needed in treating European foulbrood), I should hardly look for such constant success.

That's the only guess I can make, and if that guess is right, of course the remedy lies in shorter caging.

Adel and Caucasian Bees

Where does the Caucasian bee come from? Where does the Adel bee come from? I asked another bee journal and they said from Caucasia. In Dr. Miller's "Thousand Answers" it says they were a strain of Italians, and the queen breeder from whom I purchased some said they were a strain of Carniolans. The bees are different in color from the Italians; they vary from black to 5-banded. The queens are either black or golden. Some colonies are good and others are very poor.

ANSWER.—The word "Adel" is a German word meaning nobility, and was used by an American beekeeper as a sort of fancy name for his strain of bees, just as you might entitle your bees "best-of-all" bees.

No doubt Caucasian bees come from Caucasia, as indicated by the name. Please say where in Dr. Miller's "Thousand Answers" you find it said that Caucasians are a strain of Italians. I find nothing of the kind at page 39, where Caucasians are considered.

Reports vary as to the character of Caucasians, but I don't remember that anyone heretofore has reported such a variation in color. Are you sure yours are pure?

Cell Protectors

1. I am having this season quite a number of colonies that look prosperous, but get just one or two queen-cells, especially one I examined yesterday was in appearance equal to the best; but brood and eggs, not a single egg in cup did I notice; but there was one well-developed capped queen-cell. How would you have treated the colony?

2. I noticed in one of the bee journals lately that someone gave queen-cells in protectors. I have a few of them, but have been unable to see that they amounted to anything, at least in this way. I practice considerably to give queen-cells, but rarely otherwise than giving the colony apparently needing one the whole frame as it is, with the queen-cell on it. If it has over one, leave the best one only. What, then, is the use of a protector? Or, do you think that colonies do not take well to queen-cells as just stated, if they come from other colonies—do such need protection?

3. One of my very best colonies I found yesterday with a big lot of eggs in cups in two frames of the upper body, but none at all in the lower body. I hope to keep this colony from swarming until queens ordered arrive, whereupon I expect to divide. What do you do under that circumstance—that is, when there are a number of cups with eggs, but nothing further, and you would like to have swarming deferred with the purpose of thwarting it later on? What is the significance to you of eggs in cups?

ANSWERS.—1. Likely I would have left it to its own devices, in the belief that the bees were superseding their queen. Even when a

queen seems all right, the bees appear to know that she will soon fail, and that single cell points plainly to superseding.

2. I hardly think bees discriminate against a cell from another colony. It is unnecessary to use a protector where not needed; but if you dequeen a colony and at the same time give it a cell, a protector is needed.

3. I would kill the eggs, and again destroy all cells a week later. Cells with eggs may signify either swarming or superseding.

Raising Queens—Bee-Tree

1. If I take a couple of frames of brood containing eggs three days old or younger and some bees without a queen and put them in another hive without a queen or even a queen-cell, will the bees make a queen-cell out of a worker-cell and rear themselves a queen?

2. What do the bees get to make the comb off?

3. If I find a bee-tree on another man's land have I a right to cut it without his authority or knowledge. What would be the best thing to do?

ANSWERS.—1. They might rear a queen, but hardly one of great value. To get a good queen your cells should be reared in a strong colony and left there till sealed, or, still better, until within a day of hatching.

2. Honey and pollen.

3. The best thing, indeed the only thing, is to obtain permission of the owner of the tree.

Queen-Cells—Increase

1. Can I make queen-cell bases myself? If so, how should I proceed?

2. How long can a queen be kept in a nursery in the hive before mating?

3. One of my colonies is making two queen-cells on the combs. Now I have a plan of making increase something like this: When the swarm issues I intend to take the brood out, divide it in two parts, 3 combs and 1 comb with queen-cell, put each part in an 8-frame hive, then put the swarm back on the old stand on two of the combs of brood still left. It is a 10-frame hive. I would fill the rest of the space in each of the three hives with full sheet of foundation, and the supers of the parent colony on the swarm. The swarm would probably be due about the last part of June. That would give each of the three a chance to build up for the gathering of fireweed, which comes here in August. That would give me 66 per cent increase and some surplus. Now, do you think this will work? I think that one of the queens might emerge before the swarm issues, that is, 2 queens, less but queen-cell parts upon the mating of the emerged queen swarm out with her.

What is your opinion about this? I expect them to build up on clover. We have practically no rain in July; that would help in pushing them along. Adverse weather conditions retarded brood-rearing in latter May.

ANSWERS.—1. Yes; any straight bar may be fastened in the frame toward the upper part, and to this the cells may be attached.

2. I don't know; but I don't believe it is well to keep her more than a week or so; in fact, the shorter the time the better.

3. Your scheme seems all right in the main, but aren't you a little astray in counting that an increase of two from one would be 66 per cent increase? If you start with one colony and have an increase of one, that would be 100 per cent increase; if you have an increase of two wouldn't that be 200 per cent increase? In the hive with the queen on the old stand you will do well to have only one frame of brood instead of two.

Normally, neither of the young queens will emerge before the swarm issues, but it is not unusual for some of the bees to swarm out with the virgin on her mating trip.

Super Ventilation

1. After having a swarm of bees, where should the supers be placed on the new hives?

2. Please state the best method for ventilating hives in hot weather. ILLINOIS.

ANSWERS.—1. If you have a queen-excluder on the hive the supers can be put on at once; if not, you should wait until a brood nest has become established in the brood-chamber, for

fear the queen will go up and start a brood-nest above. You will generally be safe if you wait about 3 days.

2. The best way to ventilate depends somewhat on the construction of the hive. If the bottom is not fastened to the hive, it may be raised by a block under each corner. Some have a bottom-board 2 inches deep, and to prevent the bees building down into it there is a bottom-rack which allows free ventilation. There may also be ventilation above the brood-chamber. The first super may be shoved forward so as to leave at the back end a space of a fourth inch or a half inch between the hive and super. If extracting-supers are used they may be staggered, the second super shoved back so as to make ventilation in front, the third shoved forward to make ventilation at the back end. The first section-super may be shoved forward as already mentioned, but there can be no ventilation between any two section-supers. There may, however, be ventilation at the top by means of a cover so constructed as to allow the air to pass up through the center of the super.

Splints or Extra Wires

Would the No. 30 wire used as you use your wooden splints and imbedded by electricity be of much advantage in a frame already wired with four wires? We have some trouble with foundation buckling between the wires, and the combs sometimes break when new when we extract them. If the wires will be of advantage, how many would you use? will they do as well as the wooden splints? COLORADO.

ANSWER.—Yes; I've used five wires vertically, and it works well. I like the splints better, but you may not.

Miscellaneous

1. Is early spring or late fall the best time to unite bees in modern hives?

2. Are hybrids more cross than blacks or Italians?

3. Which are best in your climate, the standard 8 or 10-frame hive?

4. Was last winter very severe in your apiary?

5. What do you use to pack your hives with for winter?

6. How many colonies have you?

7. Do you advocate the use of full sheets of foundation in hives?

8. Do you use a veil while handling bees?

9. In the way of removing queen-cells to prevent swarming, should it be every 8 or 10 days?

10. What do you consider the best method of preventing bees from swarming?

11. How is the honey flow in your location this spring?

12. From what plant in the first harvest does your main honey flow come from? OHIO.

ANSWERS.—1. Generally it is better to unite in the fall. The united colony will winter better than a weak colony left without uniting. But early fall is better than late fall.

2. Yes.

3. 10 frame.

4. No; the winter doesn't make any difference with my bees, because they are kept in cellar.

5. In the cellar they need no packing.

6. Have had up to 400. At present only a tenth of that.

7. Yes; you lose money by using less.

8. Always have one on my hat, and generally pulled down.

9. Ten days will do all right, and even longer; but for fear of bad weather or some other hindrance some prefer to make the time 8 or 9 days.

10. I doubt if there's anything better than the Demaree plan.

11. Not very good; too much cool weather.

12. White clover.

Flax a Good Honey Plant

1. Is flax considered a good honey plant? There will be quite a little flax raised around here this year. A few years ago we saw a

2. What do you consider the best months for honey in northwest Iowa? IOWA.

ANSWERS.—1. I have never heard of flax being much of a honey plant, but if you saw a field of flax just alive with bees you may count that it is some importance, for bees don't fool away their time where they can get nothing.

2. Probably June some years, and July others.

Swarm Prevention With Queen Excluder

On May 20 I found one No. 23 colony building 7 queen-cells sealed. I found and caged the queen, destroyed all queen-cells, removed the hive from its stand and put in its place a hive containing four frames of foundation. Upon this hive was put a queen-excluder and over the excluder the old hive with its brood and bees, and over this two supers, and over the supers the cover. Then the queen was run in at the entrance of the lower hive and the colony was left for seven and one-half days. There was no ventilation at top and the entrance was measured 7x12 1/2. On June 7 I took away the lower story with its excluder and put back the queen in the old hive, which was left on the stand. I found two frames were occupied by the queen. On June 14 the same colony swarmed and the swarm was lost.

so I was surprised. After the swarming I opened the hive and found a new queen hatched out and no queen cells. I think the virgin was born on June 14 or 15. The colony was located in a good shade, where trees stand. One super was half full. Can you tell me what caused the swarm? Do you clip the queen's wings before using excluder plans?

INDIANA.

ANSWER.—When you put up that brood, you killed the queen-cells, but there was brood in all stages, from which, no doubt, the bees started cells. When you gave back the brood to the queen you probably destroyed cells, but one might easily escape you, and that one would be enough to cause the swarming.

You returned the brood in 7½ days. Sometimes that's all right, and sometimes it isn't. Ten days is safer.

Swarming—8-Frame Hives Vs. 10-Frame Hives

1. What, in your opinion, was the matter with my bees? One evening about 6 o'clock what seemed to be a small swarm issued and, after circling around my few stands, they tried to settle on the limb of a peach tree. Just then a rain storm came and the bees tried to enter into several of my hives, but were killed off. Yesterday morning about 7 o'clock the same thing happened again, only this time only one of my hives was attacked and lots of bees killed. As I thought the bees were robbing, I piled grass in front of this hive and sprinkled water on it. Do you think the bees swarmed, or was it a case of robbing? It certainly was an unusual time of day for them to swarm.

2. I am running for extracted honey and am using the shallow extracting super 5½ in deep, and a week ago I noticed drone brood in the lower edge of the frame in the supers next to the hive body. But now I also find worker-brood in supers. Would you advise me to use queen-excluders?

3. I am using 8-frame hives of my own make, but will buy the factory-made hives from now on. Would you advise the 8 or the 10-frame hives? We have no important honey plants here in East Texas, and our honey comes in rather slow. Although my bees have plenty of super room, they are laying out at nights in big clusters in front of the entrance and in front and back of supers. Only one of my colonies has swarmed. I use full sheets of foundation. TEXAS.

ANSWERS.—1. It is hard to be certain, but it looks like an afterswarm trying to enter different hives and being attacked by the bees of the hive they tried to enter. I say after-swarm, because these little swarms with virgin queens are more likely to do such unreasonable things.

2. If there is much trouble in the way of brood in supers, you will do well to use excluders, although you will find less trouble if you change from 8 to 10 frames.

3. You will most likely be better pleased with the larger hive.

New Jersey Beekeepers' Association will hold a field meet at Branchville, Sussex County, at Mr. O. M. Whitaker's apiary, on August 9. Program will start at 10 o'clock. Everyone is invited. E. G. CARR, Secretary-Treasurer.

Binding for Beekeepers

We do all kinds of book binding, such as magazines like the "American Bee Journal," or any other publication. Also make any style blank book, either printed or unprinted heading. Send us your order for blank books and let us bind your magazines.

We also do all kinds of printing, such as Letterheads, Envelopes, Statements or Billheads, Price Lists, Advertising Booklets. No order too large or too small. We print the "American Bee Journal."

LUTZ & STAHL, Keokuk, Iowa

That Good Queen

in your colony that is two years old. Are you going to try her another year? Are you going to gamble on your next spring's crop? Probably she has kept your colony booming for two years. If she hasn't you don't want her. If she has **Don't** keep her. **Why?** Because she has "exhausted herself." She is no longer a young queen. Next spring she will fail you. Your colony will be weak. And in the spring rush the flow will be over before you can get another. Don't risk your 1919 crop for the sake of 75c. Why not request this fall with

Forehand's Three-Bands

THE THRIFTY KIND

and be sure of your next spring crop. Over a quarter of a century of select breeding brings them up to a standard **Surpassed by None but Superior to Many**. We guarantee pure mating, safe arrival, and perfect satisfaction.

"Practical Queen-Rearing"

Is the title of the new bee book, cloth bound, 100 pages, which has just been written by Mr. Frank C. Pellett, who is well known to our readers.

For many years there has been a demand for a book which would give in concise form the many different methods of queen rearing, as the Doolittle, Pratt, Dines, Miller, Alley and others with variations as practiced by different large breeders.

You have this in the new book which is just out. Send for your copy now and get informed as to your best method of rearing queens from your best colonies. Good pointers in it also for the large beekeeper and veteran queen breeder.

Price, postpaid, only \$1.

By special arrangement we can offer it and a year's subscription to the **American Bee Journal** for only \$1.75.

(Canadian orders 15 cents extra.)

**Buyers of EXTRACTED and COMB HONEY
Shippers and Exporters of HONEY**

[The WORLD is Our Market]

Crop Report and Market Conditions

For our August issue we asked the following questions of reporters:

1. How large is the honey crop, compared to last year?
2. What are the prospects for the rest of the year, compared to last year?
3. Has the increase made been sufficient to balance all last winter's losses and bring the total of the bees above what it has ever been before?
4. Is honey in good demand? Is it being sold as fast as harvested?
5. What prices are being obtained, wholesale and retail, for both comb and extracted? What do you expect to get for your own crop, and how much have you?

THE HONEY CROP

Maine reports a crop about equal to 1917, with Vermont and New Hampshire reporting about 80 per cent as much. Massachusetts claims 125 per cent of 1917.

New York claims to be better generally than last year, with conditions still in doubt, owing to the lateness of the crop.

All of the South shows an increase in honey over 1917, with the exception of Louisiana, where the crop is poor. Georgia reports 75 per cent of 1917, but Florida claims 175 per cent, Alabama and Mississippi 200 per cent, Tennessee 150 per cent, with Kentucky below last year's average.

Texas will probably average from 25 to 40 per cent better than in 1917, with far from a good crop yet. Some localities are still short, though not as short as in 1917.

In the Central States, Ohio is about 25 per cent better than it was, Illinois and Indiana are better, because they had a crop failure in 1917. Conditions have improved greatly in these sections and some surplus will be stored, though far from anything like a moderate crop. Over most of Iowa there will be a little honey, but this does not include the sweet clover regions of the extreme west, where the crop is above last year, one reporter claiming 125,000 pounds from his 950 colonies.

Michigan will probably have from 25 to 50 per cent as much honey as in 1917, partly owing to a lack of bees. Wisconsin has had a crop failure, two or three reporting less honey than ever before remembered. Minnesota is the same. South Dakota has fared better, owing to the sweet clover, and will be slightly better than in 1917. Kansas and Nebraska are both slightly better than last year, while Missouri will have a very short crop.

In New Mexico there will be 150 per cent as much as in 1917, while Colorado claims about what they had last season, which is in the neighborhood of two-thirds of a crop. Montana will average well up to last year, as will Idaho. Wyoming may have a little more honey than it did in 1917.

In California reports are conflicting. Most reports are that there will be from 40 to 70 per cent as much honey as last year. The Imperial Valley will range well up to last year, as will Riverside County. One reporter in Acton states that he will get three times as much as in 1917, but the bulk of the reports are as above stated.

FALL REPORTS

Prospects for the balance of the crop rank generally about up to 1917, except that conditions seem to be unfavorable in Tennessee, Minnesota and Wisconsin.

The following States expect more honey from now on than they got in 1917: New York, Western Iowa, Nebraska, Kansas, Wyoming.

INCREASE

Great efforts have been made by beekeepers to retrieve previous losses and bring the number of bees above what it has been in the past year or two. Most localities report all losses made up and possibly some increase. Those States making the most increase seem to be Florida, Ohio, Western Iowa, South Dakota, Nebraska, Kansas, New Mexico, Montana and Wyoming.

Texas claims that it will take a year or two yet to make up past losses, and California claims bees not up to past numbers yet. Missouri, with successive poor crops, is very short of bees.

On the whole, there are hardly more bees than in 1917, and very likely less, especially if the smaller farmer beekeeper is taken into consideration, and this, too, in spite of the efforts of most beekeepers to follow the urging of the authorities to boost honey production.

HONEY DEMAND

In most instances the honey is still on the hives. Local demand is very good and there is no difficulty in disposing of the crop, if the beekeeper is satisfied with the prices being offered him. Bottlers are buying, but not like they did in 1917.

It has been suggested that honey should hardly hold its present high mark, owing to the difficulty of shipping abroad. It is certain that shipping agents and forwarders have difficulty in getting space on boats. In spite of this, however, honey is moving to England, and brokers on the job in New York do not hesitate to offer on all honey offered them. Shipping conditions, too, should improve as the time goes on.

HONEY PRICES

In our last report we suggested a minimum price of 20 cents for white extracted honey. We see no reason to change this, unless it should be slightly. We know of two cars of sweet clover honey from Mississippi being sold for 20 cents per pound f. o. b. shipping station. This is for new crop.

One Georgia producer sold 200 barrels extracted at 18 cents, while his comb went for \$4.50 per case. He states that he will take no less for the balance of his crop.

Some of the offers are being made to producers as follows: Kentucky white, 22c; Texas, 18c; Colorado, 18c and \$5.50 for comb; California amber, 18½c; white, 20c; water white, 22c.

Members of the Montana Association had a meeting recently and recommended the following as the minimum which should be obtained: White extracted, 20c, and comb \$6 per case.

Several producers, some of them having as high as 100,000 to 200,000 pounds, are expecting to hold for a price of 25 cents for white extracted, while one of Colorado's largest comb honey producers is asking \$6 per case for No. 1 comb honey.

One New York broker has suggested that he can get 22 cents for amber and 24 cents for white in cans f. o. b. New York, his brokerage to be deducted. Depending on the freight rate, this would net from 19 to 20 cents for amber and 20 to 22 cents for white.

We see no reason for changing our idea of relative prices. Prices as recommended by the Montana Association should be obtained. Possibly the market will advance, but information at hand now would hardly warrant our suggesting it to subscribers, though it hardly seems that prices as above will see much shrinkage, unless something unforeseen should occur.

KEEP INFORMED ON TEXAS CONDITIONS

The **Beekeepers' Item**, a monthly paper edited by Mr. Louis H. Scholl, well known to our older readers, and an authority, has many interesting items which should interest beekeepers, not only in the Southwest, but throughout our country.

In order to allow you to become acquainted with this paper, we offer a special combination of **Beekeepers' Item** one year with **American Bee Journal** for only \$1.25.

Or, if you desire, we can send you your choice of **First Lessons in Beekeeping**, or **Practical Queen Rearing** with the **Item** one year for only \$1.25.

Send all orders to

Golden Italian Queens

RUSTBURG, VA., R. No. 3, March 18, 1918.

Mr. Ben G. Davis:
Dear Sir—Please find enclosed \$5, for which please send me the very best Golden Queen you can for the money. If you can't ship her at once, please notify me. I ordered one from you 3 years ago last fall that was the best I ever saw. Her bees stored 320 pounds of comb honey the first year. I have several of her daughters that are fine.

Hoping to get a good one again, I am yours truly,
J. W. LAWRENCE.

QUEENS Hardy, Long Lived and Disease Resisting QUEENS

Twenty-Two Years of Select Breeding Gives Us Queens of Highest Quality--Queens for Honey Production--Queens of Unusual Vitality

"There are few Queens their equal and none better."

WHAT BEES DO, HEADED BY OUR QUEENS

"One swarm made 185 sections of honey and another 296 sections. I am well pleased."—MELVIN WYSONG, Kimmell, Ind.

"Your bees averaged 150 pounds of surplus honey each. I find them not only hustlers, but gentle."—FRED H. MAY, Mercedosa, Ill.

"I have tried queens from several different places and like yours best of all."—C. O. BOARD, Alabama, N. Y.

"We are only one mile from Lake Erie and exposed to high, cold winds; in fact, this is the windiest place along the great lakes. Your bees were able to stand the winter with only an insignificant loss, and we would have no others. As for honey, they averaged 175 pounds of extracted surplus, did not swarm, and gave an artificial increase of 30 per cent, which is as fine a record as can be had in this locality, especially when the work is done entirely by amateurs." Name furnished on request. North East, Pa.

Four Bee Books

YOU SHOULD HAVE
IN YOUR LIBRARY

First Lessons in Beekeeping

By C. P. DADANT

A 175-page beginner's book, well illustrated and cloth bound.

Price Postpaid \$1

A Thousand Answers to Beekeeping Questions

By C. C. MILLER

Supplements other books by answering questions not usually taken up. Cloth bound; 290 pages.

Price Postpaid \$1.25

Practical Queen-Rearing

By FRANK C. PELLETT

Gives all the modern queen-rearing methods, simply. A good book for both the scientific queen-breeder and the amateur. Cloth bound; 110 pages; illustrated.

Price Postpaid \$1

Langstroth on the Honey Bee

Revised by
C. P. DADANT

"The Classic in Bee Culture"

A full treatise on beekeeping. Cloth; 575 pages.

Price Postpaid \$1.50

WINTER PROBLEM SOLVED

BY

Woodman's Improved Protection Hive

"THE HIVE WITH AN INNER OVERCOAT"

100% Perfect Protection by Tests, Winters of 1916-17-18

The Inner Overcoats did it Without any special preparation, bees wintered without loss in these hives. There were no dead bees on the hive bottoms, and it was a joy to see the condition they were in as compared with other styles of hives. The Corrugated Paper Bottomless Box, Inner Overcoat, is telescoped down in between the outer and inner hive walls when preparing them for winter. It is removed in the spring and stored away in the K. D. flat. Not more than two minutes are required to insulate a hive for winter or to remove it in the spring by this method. It is the simplest and most efficient method and does away with a great amount of labor. You have no packing cases or packing material, such as shavings, sawdust, chaff or leaves to house and bother with. Try out a quantity of these hives the coming winter, as hundreds of others are doing. Bees are valuable these war times and you cannot afford to lose them. Send for a special circular showing ten large illustrations.

TIN HONEY PACKAGES

2 lb. Friction Top Cans	in cases of 24	\$ 1.15 per case
2 lb. Friction Top Cans	in crates of 612	24.00 per crate
2½-lb. Friction Top Cans	in cases of 24	1.35 per case
2½-lb. Friction Top Cans	in crates of 450	20.00 per crate
5 lb. Friction Top Pails	in cases of 12	1.10 per case
5 lb. Friction Top Pails	in crates of 100	7.50 per crate
5 lb. Friction Top Pails	in crates of 203	14.50 per crate
10 lb. Friction Top Pails	in cases of 6	.90 per case
10 lb. Friction Top Pails	in crates of 113	12.50 per crate

For a limited time we offer the above packages at these special low prices, shipment to be made from Cbicago. Write for prices on 60-lb. cans, giving quantity wanted.

A. G. WOODMAN CO., Grand Rapids, Mich.

"falcon"

THINGS THAT ARE NECESSARY FOR YOUR APIARY

1. There must be a good location for the apiary.
2. Queens must be healthy and vigorous to put life into the hives. (Our queens are the best to be had and at reasonable prices.)
3. Your bees cannot do the work they should if you do not give them the best with which to work. If they have ample storage space, if they can work all the time without slack motion, they will be more contented and swarmless. To accomplish this, you must give them ample storage space, that is, the **RIGHT HIVES AND SUPPLIES. "falcon"**

Beekeepers should be placing their orders early for their early needs. He who waits is apt to suffer. These late beekeepers who want their goods in such a hurry at the last minute will lose some of the honey crop by not furnishing their bees with ample storing space. Railroad embargoes and rush business make deliveries slow.

Our famous "falcon" supplies will please you. Do not wait. Order now and strike while the iron is hot. "falcon" means the best, the standard of perfection. Red Catalog and Simplified Beekeeping upon request. Dealers everywhere.

W. T. FALCONER MANUFACTURING CO., Falconer, New York
Where the Good Beehives Come From

HONEY WANTED

We are in the market at all times for unlimited quantities of Honey, both comb and extracted. Before selling your crop let us hear from you, quoting your lowest price, either f. o. b. your station or delivered Cincinnati. If extracted, mail sample and state how it is put up. If comb honey, state grade and how packed.

A BOOK FOR BEGINNERS

"First Lessons in Beekeeping," written by the editor of this magazine, is intended primarily for the use of beginners in beekeeping. You should have it. Price, postpaid, \$1, or clubbed with the American Bee Journal, one year for \$1.75.

American Bee Journal, Hamilton, Ill.

?? WHY ??

Why is it that so many beekeepers prefer Dadant's Foundation? Why does it give such good satisfaction and why is it that when tested side by side with many other makes beekeepers have reported that "they take to DADANT'S first?"

Do We Use Special Sheeting Machinery? No

We use the Weed process of sheeting our beeswax into endless rolls, and it is the same process as used by nearly all manufacturers.

Do We Use Special Foundation Mills? No

We use the same kind of mills as are used by practically every foundation manufacturer in the world.

Do We Use Special Beeswax? No

We use beeswax such as is produced by beekeepers all over the United States.

THEN WHY?

BECAUSE

Our beeswax is cleaned in such a way that all impurities are removed and all the fine qualities are retained.

BECAUSE

Sulphuric and other acids recommended and used by many manufacturers for cleaning beeswax are not used by us.

BECAUSE

Our motto is and always has been "EVERY SHEET PERFECT"—and we live up to it.

BECAUSE

For FORTY YEARS comb foundation has been, and still is, our *specialty*. When you get DADANT'S FOUNDATION you know that you are getting the best that money can buy. When you send your beeswax to us to be worked into foundation you know that you will get perfect work done. When you ship us your old combs and cappings to render you will get the maximum of wax they contain and, if desired, this wax will be worked into the finest quality of foundation made.

IT IS UP TO YOU, therefore, to insist on DADANT'S FOUNDATION when you order your goods from your dealer. If you cannot get it from him, then order from us.

DADANT & SONS

HAMILTON, ILLINOIS

LEWIS SECTIONS

HAVE

INDIVIDUALITY

BECAUSE they are in a class by themselves. They are not like other sections. Very rarely do they break in folding---in fact one of our customers writes us that he has put up (folded) thirty thousand Lewis Sections in a season and has not found *one section* in the whole lot that was not perfect. Beekeepers everywhere, no matter what their preference may be for hives or other bee equipment, agree that, when it comes to sections, the LEWIS SECTIONS are supreme. This is—

Because the material which goes into a **Lewis Section** is of the right kind, especially selected for the purpose. The stock is sorted and re-sorted—the discolored stock thrown out, leaving only the whitest material to go into **Lewis Sections**.

Because the V groove, which is the most important process in the manufacture of a section, is made just right. In the **Lewis Section** it is cut just deep enough so that the section will not break in folding. The **Lewis Section** expert has been supervising the manufacture of **Lewis Sections** for over thirty years.

Because the finishing of the section is given the utmost care. The **Lewis Sections** are polished on both sides in a double-surfacing sanding machine designed in the Lewis plant especially for this purpose. It insures the uniform thickness of each and every section. The dovetailing of the ends is smooth, clean and just right.

Because even after the **Lewis Sections** are completely manufactured, the packing is considered a very important part of the marketing. All **Lewis Sections** are put up in regular standard packages containing a good, full count. A tight wooden box is used, entirely enclosing the contents, so that no discoloration from air can occur, no matter how long the sections are carried in stock. The package is also strongly braced at all corners, insuring delivery in good order.

AT THE SAME PRICE YOU PAY FOR OTHER STANDARD MAKES OF SECTIONS YOU GET ALL OF THE ABOVE WHEN YOU BUY THE LEWIS SECTIONS

GLIMPSES OF SOUTHWEST TEXAS

Beekeeping Conditions in the Semi-Arid Region Where Every Bush has a Thorn,
as seen by Frank C. Pellett.

TEXAS seems to be divided into several natural regions, from the standpoint of the beekeeper, as already mentioned in a previous article. San Antonio is near the northeastern border of the mesquite region. Mesquite is plentiful for a long distance north of that city, but near the northern boundary of Bexar county is the line where cotton begins to yield honey in surplus quantities. Accordingly that territory must be regarded as in the natural division where cotton is the predominant honey plant. A line drawn in a southeasterly direction from San Antonio, through Cuero

and Victoria to the gulf, would probably mark the approximate eastern boundary of the mesquite region. Figure 1 shows a characteristic group of the southwestern honey plants at Goliad. Here are seen agarita, mesquite, hackberry, Mexican persimmon, brazilwood, anaqua, prickly pear and huisatche; all good honey plants, growing together in one group. At Victoria, in the next county and only about thirty miles away, we find a very different flora. Agarita is common at Goliad, but is absent at Victoria. Victoria is about the eastern limit of mesquite at that point. Anaqua is still to be

found in limited quantity, but the flora is, for the most part, the same as common to other parts of east Texas. It is surprising what a change one finds in the flora in such a short distance. After finding the thorny flora of the southwest for a continuous stretch of about two hundred miles, one is not prepared for such a sudden change. The natural boundary of this region is not difficult to find. The escarpment between San Antonio and New Braunfels distinctly marks the northern boundary, while the river at Victoria is almost as clearly the eastern boundary. The Rio Grande valley marks the south and west boundaries.

It is in this region that commercial beekeeping has reached the highest development in Texas. In some counties one finds more commercial beekeepers than in whole States in other sections of the country. Instead of getting honey from cultivated crops like cotton or clover, the beekeeper is dependent almost wholly on the wild flora for surplus. Beekeepers report that wherever the land is cleared they find it necessary to move their apiaries, as none of the cultivated crops common to this section yield honey in surplus quantity. Even cotton is of little value on the light soils of this part of Texas.

Most of the honey comes from thorny shrubs, such as catclaw, huajillo (pronounced wahyaya) and mesquite. The soapbush has the appearance of an evergreen shrub, and is able to withstand the most severe drought. It is reported as yielding from ten to fifteen days during its period of bloom.

One marked peculiarity of the plants of the southwest is the uncertainty of the time of blooming. In

Fig. 1 A clump of southwestern honey-plants at Goliad, Texas. Aganta, mesquite, hackberry, brazilwood, anaqua, prickly pear and huisatche; all good honey-plants growing together

the northern States the beekeeper can anticipate approximately the time of his honeyflows and prepare accordingly. In the southwest, the blooming periods are likely to occur at almost any time, depending upon the weather. The soapbush blooms after the rains in both spring and fall, and the time of the rains will thus determine its time of bloom. Whitebrush is an important source of honey over much of this part of Texas, and it is said to bloom several times during the year, in favorable seasons, always following the rains. Should the season be dry throughout, it will yield no honey, while in seasons when there are frequent rains it will yield several times in the same year.

At Goliad, the Collier brothers have about a thousand colonies of bees. They report that brazilwood is the

Southern Kansas. It is not dependable every year, but is abundant following wet winters. The moisture serves to germinate a new crop of seed. In the Rio Grande valley it is reported as sometimes yielding as much as 20 pounds surplus per colony, average. The importance of the plant seems to increase as one moves northward. The time of bloom is reported as varying in different parts of the State. Several beekeepers mentioned horsemint honey as having a tendency to ferment in wet seasons. Unless great care is used in ripening, the beekeeper has trouble after the honey is in the cans. A few cases were reported where it even soured in the combs.

This part of the southwest is deficient in rainfall. Most of the plants on which the beekeeper depends yield with but little rain. A light

shower is all that is necessary to bring some of them into bloom. It sometimes happens, as was the case last year, that the flora remains dormant to the extent that little bloom is open. Then bees suffer severely. In 1917-18 the losses were from 25 to 75 per cent in many counties in southwest Texas. The losses were most severe at a distance from the streams, where the upland flora furnished the entire dependence. The most serious feature at such times is the shortage of pollen. At some points in the western portion of the mesquite region, the bees were unable to continue brood-rearing when fed with sugar syrup, and swarmed out and left the hives in large numbers. Along the streams where some pollen was available, the losses were much lighter, and in some cases there were none.

At some points along the Nueces river, there was a secretion from live oak balls which saved the bees in 1917. George Schmidt, at Crystal City, reports this as occurring in dry seasons. He thinks his bees gathered an average of 25 pounds per colony from this source in 1917, most of which was used to carry them through. He took off ten cases of this live oak honeydew. It was amber in color, very thick, and tasted strongly like molasses.

There is a great variation in the yield of honey in different parts of the mesquite region. In some localities the beekeepers are unable to secure more than twenty-five pounds as an average surplus, one year with another. In other places, they report that in a normal season they get 100 pounds per colony. The estimates of yield differ with different localities, from 25 to 100 pounds.

A few miles often make a great difference in the yield, depending upon the local showers of the season. At Sabinal one man, J. A. Simmons, has eleven yards. The extremes are

Fig. 2. The soapbush is able to withstand severe drought

best all-round source of honey in their locality. It blooms sometimes in spring, sometimes in fall. Some years it blooms several times and yields at irregular periods. Mesquite also blooms at two or more periods during summer. The cactus or prickly pear, which is so common everywhere in the southwest, is valued especially for pollen. Its period of blooming is reported as more regular. Beginning in July, it blossoms for four to six weeks. About one year in four it yields some surplus honey, but the flow is usually very short, continuing but four or five days. The honey is peculiar in appearance, granulating in large crystals in clear liquid. It is often spoken of as buttermilk honey, because of this peculiarity. E. G. Le Sturgeon reports one year an average yield of 87 pounds per colony from prickly pear in Atascosa county.

Horsemint is found in every part of Texas which I visited. It is regarded as an important source of nectar from the Rio Grande valley to

Fig. 3. A typical native flora where the cactus and mesquite grow in abundance

only thirteen miles apart, yet he never gets a full crop in all of the yards in the same year. Every year some locations will get showers which do not occur in others, with the result that the yield will be much increased. In the rare seasons when the rainfall is well distributed throughout the year, the honey-flows in this region are wonderful.

In 1900, at Mathis, there was a flow from catclaw in March, followed by huajillo. In May there was a good flow from mesquite, and in June and July a very unusual flow from cotton. There was a further flow from plants that rarely are of value.

For several years following this favorable season commercial beekeeping was an important industry about Mathis. The past two years, with no honey, have proved so disastrous that nearly all the beekeepers who depend exclusively upon the business have moved out. It is very probable, however, that seasons of great abundance will follow the lean years, and thus equalize things, after all. Wm. Atchley was the last of the extensive honey producers remaining at Mathis, but he was preparing to go shortly unless conditions changed. The bees were finding it so hard to maintain themselves, even with enormous amounts of sugar, that it seemed impossible to continue safely.

There are few places in America where beekeeping has attained the importance that it holds in southwest Texas. In towns like Beeville and Uvalde they talk about bees and honey as they do corn and hogs in Iowa or Illinois. Under normal conditions a good many cars of honey will be shipped from a single town. The public has a proper appreciation of the commodity that brings in the cash for conducting the business of the community. In Alabama it is cotton, in Iowa it is corn. California oranges and raisins are exchanged for perfectly good money in east-

ern markets. In southwest Texas honey is one of the leading cash crops. The two years drought has hit the beekeepers and the country generally pretty hard, but other sections and other industries hit the bottom at times. Beekeeping is on too firm a footing to suffer permanently from a bad season. There are a good many men who have upwards of a thousand colonies of bees under normal conditions and who consider less than a carload of honey a short crop.

Apicultural Don'ts

By D. M. Macdonald

DON'T tinker with Inferior Bees. Most cheap articles are dear in the end. Poor, mongrel bees cost as much to house as those which may be called first class. They

are as costly to start when furnishing the new home. Frames, brood foundation, the wire, the process of inserting, fixing and wiring, cost the same. The result of the first season's work in the one case is generally all that could be desired, in the other, comb construction is poor in quality and frequently proves defective, then and for all time. Poor bees often prozopize over much, thus causing the workers needless labor and imposing on their keeper worry which proves a heavy tax on his temper when manipulating, and not conducive to good temper in the bees. Mongrels are almost invariably cross-tempered. At the end of the season with the good bees, bumper crops of well-finished, shallow frames or sections are all but a certainty. The poor bees, in nine cases out of ten, at least, give poor returns, and that of poor quality and defective

Fig. 4. Group of beemen at Beeville

Fig. 6. A group of beemen in the Edwards apiary at Sabinal

finish. The first will give several crates, the others will lag far behind. Packing for winter is a pleasure with the best bees. Every colony has strong forces, ample stores, and many newly-hatched bees. In the other case few bees, a poor cupboard, and too many aged workers make wintering a doubtful asset. Keep the best bees, in the best way, packed with the best winter packing—bees.

Don't Keep Low Grade Queens.—This point is not quite on all fours with the previous don'ts. The same, or somewhat similar results, may occur here again, but there are added drawbacks. A queen guaranteed to lay 50,000 eggs in the time a weakling takes to lay less than half that number gives the population an enormous pull over the inferior one. The results are not in proportion to mere numbers alone. The strong one will not only have double the population, but will present its owner with at least four times the surplus, a point well worth considering. Its work, too, will be more highly finished, be

completed in far less time, and approach nearer to perfection. On account of the larger numbers the strong colony will forage earlier in the forenoon and keep up work later in the afternoon than the laggard. They will go farther afield, thus frequently obtaining richer forage grounds, and they will make flights to the bee pastures on days when the other remains indoors. They will manufacture wax quicker, build comb more expeditiously, and seal stores with less trouble and greater speed. The weakling will worry carrying propolis to glue up every corner in case of draught, the powerful can sustain internal heat without any trouble. Then, as a matter of fact, the strong actually consumes less stores relatively, or at times actually, than the small number. The cause is patent.

Don't Manipulate Out of Season.—Bees are best left alone for about half the months in each year. Winter is a season of repose in the hive interior. Bees exist then in a state of semi-hibernation. Every ounce of calorie-generating food consumed as a result of disturbance is not only needlessly wasted but it acts injuriously, for the agitation begot in the cluster tends to weaken and prejudicially affect the digestive system. To restore the temperature of the disrupted cluster, food must be consumed, and the bees may be forced to take untimely flights to void their feces. In general, the caution applies to too late examinations in autumn and too early inspections in spring. Any attempt at late feeding to remedy defective stores or early stimulation to start untimely breeding, works evil and not good. "Jumping" the frames, your equivalent of our phrase "spreading the brood," in early spring, causes mischief. Opening hives when weather is cold or when a chill wind is blowing, is a blunder which may destroy brood and drive workers from the supers.

Don't Buy Cheap Articles.—Cheap

and nasty are often synonymous terms. A cheap second-hand hive may ultimately turn out a dear one. A novice should never be beguiled into investing in colonies offered "at an old song," because an odd sized hive may be dear at any price, as none of its parts are interchangeable with other hives in your apiary. No worse investment can be made by the beginner in apiculture. Even a parson may be guilty of thus beguiling the unwary. Purchase your bees, if possible, from a near neighbor, a man of probity, on whom you can rely, or treat with an appliance dealer of repute. Such men have to obtain and sustain a good name. Be prepared to give a good price for a good article, the regular market price being a safe guide.

Don't Forget the Profits.—The laborer is worthy of his hire. Some of my hives gave me profits of from 24 to 45 last season, and certainly the pleasures and joys of beekeeping were not lessened by the total drawings being relatively high. Honey has been in abnormal demand. Profits are considerably enhanced when careful saving is practiced. Purchase only what appliances are actually necessary to run your apiary. Be economical without being parsimonious. Encourage no waste. Collect and preserve every particle of wax, and at a convenient season melt it into cakes. Discard no frame that is not really defective, and don't throw away pieces of comb, especially if they are constructed of worker cells. Special care should be taken of all shallow surplus combs from year to year, and of all brood frames not covered by the bees during the winter. In countless ways similar care may be given to tools and appliances, thus doubling, it may be their total existence, thereby raising the balance on the credit side at the conclusion of each honey season.

Don't Value Apiculture for Profits Alone.—M. Maeterlinck practically but graphically strikes the right key-

note in regard to the pleasures of beekeeping: "For one who has known, studied and loved bees, a summer without them would be like one without birds and flowers." The writer felt the force of this the season when disease wiped out his apiary. At last a happy thought dawned on him, that if the mountain could not come to Mahomet, he could go to it. Performe, as if drawn by a lodestone, he was drawn to the bees, and in no other season were so many outside apiaries visited. The study of the bee itself, its customs, habits, government, prescience, wisdom; its anatomy and physiology, form a most delightful pastime, and is well worth the interest and devotion of even the heeman to whom honey getting means bread and butter. The joys of beekeeping are manifold. What can be more delightful than watching the wild gambols of a first flight in spring, the brilliant evolutions of a swarm, the observation of multitudes of bees carrying in all colors of pollen, the steady stream of workers bringing home heavy loads of the nectar which later is converted into sweet, luscious honey?

Don't Keep Bees Without the Journal.—It should be a guide, philosopher and friend to everyone who wants to keep up with all that is latest and best in apiculture. Indeed, I feel the veteran reads it as diligently as the novice, and derives even more pleasure from its perusal. In countless ways it helps lame dogs over stiles. Its news of beedom must be invaluable to all. Dr. Miller's Answers alone are worth the actual cost of each issue. The editor's reviews, summaries, criticisms and articles, short or long, are all of great excellence. Many years ago it was known as the "Old Reliable," and this descriptive sub-title is as appropriate today as ever it was. Each successive year it renews its youth. Outside it is a thing of beauty; inside it is a joy forever. To the novice I would advise that he should make a thorough study of the articles named in the index every December, and devote any spare winter evenings to a re-perusal of those most interesting to him. The results must make him a better beekeeper. Let him read, meditate and inwardly digest; then his labor in future should prove lighter and his results more profitable, because of the acquired knowledge gleaned from wiser heads than his own.

Don't Forget a Good Text Book.—Even before investing in hives or bees the man meditating a start in apiculture should purchase one or more good bee books. The writer, after reading almost every work on bees, ancient or modern, is inclined to place "Langstroth on the Honey-bee," Twentieth Century edition, and Root's latest issue of the "A B C and X Y Z" amongst the first half dozen. From the time of Virgil and Aristotle, that is before the Christian era, men have studied bees and written bee books. From then on there has been a long succession of more or less brilliant writers, and we of this

Fig. 6. The Spanish bayonet is a showy plant of tropical appearance

century reap the benefits of their labors. Authors of our time, while discarding the myths and errors of the past, the chaff, have conserved the good grain, and have added to that the marvelous discoveries of more recent years from Huber's and Langstroth's time until now. Remember the best beebooks of today contain the essence of the wisdom of many generations of "live" beekeepers and the discoveries of more than 2,000 years of patient toil.

Bauff, Scotland.

Legalizing Co-operative Marketing

By Chilton Gano

CO-OPERATIVE marketing, in its best sense, means more than the mere banding of farmers together as an ordinary corporation. The ordinary corporation is financed by the sale of stock and must pay dividends on its capital. Its earnings thus go to members in proportion to their stock holdings, regardless of whether they actually do any business with the organization or not. Such a marketing company is apt to get along without any friction only when members actually hold amounts of stock which correspond in relative size to the business they do with the association. That is, if Farmer Smith's honey represents one-tenth of the entire amount sold by the association in a season, his stock in the corporation should represent one-tenth of its total capitalization.

But this is highly impracticable in practice, for his output this year may be one-tenth of the whole, and next year it may be one-twentieth. Yet next year he pockets one-tenth of the profits, just the same.

In ideal co-operative organizations man-power, not money-power, is what counts. That is why many States have passed co-operative laws authorizing the incorporation of new kinds of corporations which either have no capital stock whatever, or if they do have capital stock pay only a fixed annual interest on such stock instead of regular dividends. The earnings of such co-operative corporations are then apportioned back to the members in proportion to the amount of business transacted with them in the season. In other words, such organizations operate at cost, and all profits go back to the members.

The California laws permit of co-operative associations without any capital stock whatever, and most of the orange and lemon growers' associations are non-capital-stock in form. This form of organization is probably the broadest possible in principle. Members are allowed to make their own by-laws covering financing, voting power, conditions of membership, transfer of membership, etc., yet their association ranks as a corporation.

The big problem where there is no

capital stock is how to get the money to start up. In California the banks know such organizations are good risks, and they usually start on money borrowed on a corporation note, which is gradually repaid from the earnings of the organization.

Where the banks are not favorable, money to build a packing plant can be secured from the members by assessment, according to their acreage or expected crop or average annual crop.

Such associations usually charge a membership fee, either of a fixed amount or graduated according to the acreage or crop of the applicant.

Another Type

The California laws also permit another form of farmers' organization, which sells capital stock but pays earnings in part back to the members according to business transacted. This form of co-operative organization is that most often apprehended by the term. They either pay a fixed interest on capital stock annually, or they pay an initial fixed price to the growers on their crops or product, then devote a fixed amount per crop unit above this to operating expenses and dividends on stock, and then pay back any surplus above this which may be obtained to the farmers according to business transacted. The California Associated Raisin Company is of this type, paying 3 and a fraction cents to the growers on delivery of raisins, taking so many cents per pound from the selling price as their operating margin, and refunding any further surplus to the growers.

Nebraska, Wisconsin and several other States have co-operative laws authorizing this form of co-operation, but have no non-capital-stock associations.

Some of these States very rigidly define how profits shall be divided, whether the members shall have one vote each or vote according to acreage or other standards, etc.

The Texas co-operative law is of particular interest to honey producers just now because of the recent success of the Texas Honey Producers' Association. The Texas law is just a little more than a year old. In simplicity and latitude given to the associations for managing their own affairs, it compares favorably with the California law. Its principal provisions are:

That co-operative associations shall be purely local in character, in no event to extend beyond a reasonable area surrounding a town, but that they may federate with other similar associations of other towns.

That such associations shall be non-profit, passing their profits to a surplus fund or dividing their profits among members in proportion to the respective cash contributions to working capital and patronage.

That associations shall have property of not less than \$500 value, which may be cash, property or notes.

That the association shall have the

right to act as the co-operative selling and purchasing agents of their members only, and may, for their members, sell any and all agricultural crops, and buy machinery, supplies, insurance, and other needs.

That the members shall not be liable to the corporation or its creditors in excess of the membership shares subscribed by them, unless in the by-laws the members are made responsible for an additional amount equal to 100 per cent of membership shares owned.

Look to the Law

Farmers planning to sell co-operatively should by all means take steps to secure proper State legislation, unless it already exists or unless they can incorporate under the co-operative law of another State and then enter their own State as a foreign corporation. Such a round-about procedure is often resorted to by regular business corporations, and would no doubt be practicable in some instances for co-operative associations. However, legal technicalities might make it impossible, in some States, and expert legal advice should, of course, be had in every case.

The simplest way, however, in the long run, would, no doubt, be to select the form of co-operative law desired and assure its passage in the State legislature. The growing list of States which are adopting such laws indicates in general that they are good laws to have, and farmers would ordinarily, just as a matter of pride, prefer to be incorporated under the laws of their own State.

The writer would suggest that the California law is excellent in every way and a good one to copy after, when in doubt. It has proved adequate to the needs of the world's greatest co-operative marketing associations, those of the Sunkist Orange Growers and Sun-Maid Raisin Growers—indeed, has helped to foster the growth of these great federations of farmers, with hardly a question, because of its broad scope and the freedom it permits them in minor matters.

Chicago, Ill.

Bee Laboratory at Ames.—The Iowa State College at Ames, has recently appropriated \$1,200 for fitting up a beekeeping laboratory in the basement of the new science building. There will be ample floor space for the bee work and all modern conveniences, including hot and cold water. Gas and electricity will be installed. There will be four rooms in all. The largest room will be used for the usual laboratory purposes. One will be fitted up for a wintering cellar, one for a honey and wax room, and the fourth will be utilized as an exhibit room. Professor F. Eric Millen, who has charge of the work at the Iowa College, is rapidly extending the work of his department, and new quarters are necessary.

PUBLISHED MONTHLY AT

First Nat'l Bank Bldg., Hamilton, Ill.

Entered as second-class matter at the
Hamilton, Illinois, Postoffice.

C. P. DADANT, Editor.
DR. C. C. MILLER, Associate Editor.
FRANK C. PELLETT, Staff Correspondent.

IMPORTANT NOTICE

THE SUBSCRIPTION PRICE of this Journal is \$1.00 per year in the United States of America and Mexico; 3 years, \$2.50; 5 years, \$4.00; in Canada, 16c extra, and in all other countries in the Postal Union, 25 cents a year extra for postage. Sample copy free.

THE WRAPPER LABEL DATE indicates the end of the month to which subscription is paid. For instance, "dec15" on your label shows that it is paid to the end of December, 1918.

SUBSCRIPTION RECEIPTS—We do not send a receipt for money sent us to pay subscription, but change the date on your address, which shows that the money has been received and credited. In case of errors, please write us.

THE EDITOR'S VIEWPOINT

Transferring From Box-Hives

Bulletin 961 of the U. S. Department of Agriculture on the above subject is at hand. This is one of the most useful publications ever issued by the Department, for the reason that there has been more waste in this matter of transferring than in any other question concerning beginners. This Bulletin is most important in instructing beekeepers who are not yet using the modern methods, but who have kept bees in boxes or gums. This Bulletin should be distributed freely among them.

The different methods of transferring are also very necessary where bees have been in modern hives without the necessary guides to secure straight combs in the frames. A hive with movable frames in which the combs are crooked and run from one frame to another is much worse than a box hive for any manipulation, and is also more difficult to transfer. Let all those who are troubled with crooked combs or have bees in box hives send for this Bulletin.

European Foulbrood

"The Control of European Foulbrood" is the title of Bulletin 975 of the United States Department of Agriculture. This is by Dr. E. F. Phillips, and, like everything that comes from his pen, is practical and to the point. European foulbrood was denominated "bacillus pluton" by Dr. White, the bacteriologist whose studies of bee diseases are now accepted as authoritative and conclusive by scientists the world over. The name "European" was given only to differentiate it from the rosy foulbrood which was called "Ameri-

can," but both diseases undoubtedly exist on both continents.

By securing this Bulletin, together with Bulletin 442, "The Treatment of Bee Diseases," by the same author, Dr. Phillips, 1911, the beekeeper will have the benefit of all the knowledge of the subject acquired in the past 15 years through experiments and the gathering together of information at our Capital.

Another Bulletin, No. 671, just now appearing, has been delayed by an error in the transposition of two cuts, illustrating the appearance of combs containing larvæ dead of European and American foulbrood. This Bulletin is entitled "Diagnosis of Bee Diseases by Laboratory Methods." It is by A. H. McCray and G. F. White. It will interest the bee inspectors and the better informed class of beekeepers. It gives short and pointed statements on the characters of European and American foulbrood, on sacbrood and on Nosema apis. The reputation of the authors vouches for the correctness of the statements.

International Fraternity of Beekeepers

It is out of the province of a bee magazine to touch the present burning question which is constantly in the thoughts of every human being. But the flood of enthusiasm which reaches us in the shape of numerous private letters from across the seas needs public acknowledgement. For this reason, we give place in our columns to a short, typical letter, not written for publication, but so expressive of the popular sentiment among our allies that we feel sure its author will pardon us for giving it

publicity. It is from no less a man than the editor of the oldest existing bee periodical in the world:

"Mr. C. P. Dadant:

"Dear Sir.—At the time when your brothers and your sons are with us, mingling their valiant blood with that of the French, for the defense of right and liberty, I, who have had already terrible trials, cannot help thinking of the American fathers, mothers and wives who have dear ones every day exposed to death or wounds. I feel how much my anxiety would be attenuated if, in a similar situation, I knew that there were near the loved ones some tender-hearted friends who would bring them, whether wounded or healthy, a little enjoyment. Near a friend, they would recover a touch of the family life.

"For this reason, permit me to say to you, dear sir, that if you have a relative, a friend, in this war, write him that he will find in my home a family who will try to help him forget for a few moments the remoteness from his own people, so painful to the one who is fond of family life.

"Please accept, my dear sir, my heartiest good wishes.

"M. SEVALLE,

"Editor of L'Apiculteur,

"Paris, France, July 7, 1918."

Hundreds of similar letters have come to us across the seas, from heroic, bleeding France, from unrelenting Great Britain, from warm-hearted Italy, as well as from smaller allies and neutral countries like Switzerland. But none of them express their hearty good-will any better, or in more concise words, than the above.

Our hearty thanks are extended, in the name of American beekeepers who have sons at the front, for those numerous friendly offers as well as for the warmth and enthusiasm expressed towards our Nation.

Fellow-Americans, whether you are beekeepers, farmers, mechanics, professional men or merchants, you are building, perhaps better than you realize, a wonderful brotherhood with the rest of the human race. The lavish manner in which the Star-Spangled Banner is pouring into the conflict her money, her food, her blood, for the defense of an ideal and the crushing of the most ruthless militarism since the days of Attila, will remain to her credit for centuries to come. Neither should we forget that, aside from a few traitors, there are among us thousands of descendants of the Central Powers who are doing their duty to the country of their adoption with as much patriotism as any of us.

When ruthlessness is crushed and peace again comes, let us hope that

we may see international compacts between all the nations! May I live long enough to attend an international congress of beekeepers, in which all ill-feelings will be forgotten and the countrymen of Huber and Bertrand, of Cheshire and Cowan, of Girard and Bonnier, of Maeterlinck and Wathelet, of Barbo and Visconti, of Kandratieff and Zoubareff, of Berlepsch and Dzierzon, of Langstroth and Quinby, will meet to discuss their interests, their discoveries and their methods, establishing a "Sainte Alliance" of honey-producers.—C. P. D.

Honey in New South Wales

A. Shallard, in the Australasian Beekeeper for June, page 230, writes: "The speculators are holding 1,300 tons of honey in Sydney, and the beekeepers are crowded out of the ships by them. We should have precedence. Fight for it."

The inability to ship honey across seas is helping enhance the price in Europe. When transportation is released, after the end of the war struggle, there will be a great readjustment of prices in all sorts of produce. Keep it in mind.

Iowa State Apiarist Report

The printed report of F. Eric Millen, State Apiarist of Iowa, for 1917, is before us. It is a book of 89 pages, containing a short statement by Professor Millen, as to the work accomplished during the year under his supervision, a copy of the State law on beekeeping and diseases, and copies of the different addresses delivered at the State Beekeepers' Convention held in Des Moines December 4 and 5, 1917.

Professor Millen gives great praise to his predecessor in the State Apiary work, Mr. Pellett. We can assure the beekeepers that Mr. Millen himself is also a worthy worker, and that Iowa was fortunate in securing his services. Iowa beekeepers can secure this work by joining the State Association. Address Professor Millen at Ames.

"Queen" or "Mother Bee"

By Robert Sparks Walker
Editor of the Southern Fruit Grower

SINCE we have been engaged in the world war we have discovered in our own midst many things un-American and undemocratic. In addition to the task of the Americans at home to back up our gallant men at the front, we must

also work faithfully to thoroughly Americanize America.

It is not believed by the best thinkers today that democratic nations would go to war. But from history we have learned that countries ruled by kings, queens, dictators, emperors, sultans, etc., have brought many bloody wars, until the world has, almost as a unit, condemned such forms of government, and it is a great day for the world that such has been the case. To Americans the names "King," "Queen," "Emperor," etc., will ever be held in contempt. Henceforth, no fruit, or any product, can be named or designated by these words and carry with it the suggestion of a high quality. So every name that is un-American and which will bring contemptible utterances should be forever stricken from our vocabulary.

For this reason, I am in favor of immediately changing the name of the "Queen" bee to that of the "Mother Bee." In fact, I move the beekeepers of America today that the change be made.

This bee now merits a better name, and the sweetest and best name in the English language is "mother." There is no other name to equal it, and it is thoroughly American and will strengthen our democracy; whereas, on the other hand, the frequent or rare use of the word "queen" suggests autocracy, the very thing that America and the allies are giving their all to crush. Chattanooga, Tenn.

This suggestion is quite proper, but there are two obstacles in the way. The first is the long established habit, even in our kingless republic, of calling the only fully developed female of the beehive "queen." The first name given her was "king," because they did not know her sex, and because they noticed the great love of the bees for this large bee and the care with which it was surrounded. It was only in 1609 that Butler, an English naturalist, discovered that she was really a female. But long after that, some authors persisted in teaching the existence of a "king" in the hive. We have before our eyes a book by M. J. Simon, dated Paris, 1758, entitled "La Republique des Abeilles," in which the existence is asserted of both a king and a queen in the insect republic.

Hamet, the founder of the now oldest existing bee periodical, L'Apiculteur, tried ineffectually to change the term of "queen" to that of "mother bee." In his book, "Cours D'Apiculture," he carefully avoided the use of the word "queen." Hamet was an ultra-progressive politician, even though he was a very conservative beekeeper, and after the fall of Na-

poleon III, during the Franco-Prussian war of 1870, he again launched a campaign against the use of the word "queen." But, nevertheless, his magazine, now, many years after his death, is still using the term "queen" promiscuously with that of "mother bee."

The second difficulty in the use of the term "mother" is met when we speak of a virgin queen. We cannot say "virgin mother," for the two words are contradictory. We must then follow Hamet and speak of the unfertilized queens as "virgin females," or "young females." For these two reasons we believe that the word "queen" will remain in popular use.

Human beings are fond of pomp, dignity and ostentation.

That is probably why our Canadian neighbors, who are practically living in a republic, affect a great love and excessive respect for a reigning family which has less political power than our President. Is it not probable that constitutional kings and queens will continue to reign, with constantly decreasing power, but with much respect from their so-called subjects, as long as they live decently and behave in a democratic bourgeois-nobility way, an expensive but ancient institution? If so, we can tolerate the "queen" among bees, for she is certainly a constitutional sovereign, with no power whatever, but with a great deal more usefulness to her people than any king or queen that ever existed, for she is indeed the "mother," and the love with which her bees surround her shows that they appreciate her usefulness.—Editor.

Sugar for Feeding

In response to numerous inquiries, we wrote to Washington to find out just how much sugar the beekeeper would be allowed for feeding his bees.

According to their ruling a full allowance is made for feeding bees. In order to obtain this sugar, you should apply to your local food administrator for a certificate, or in case he lacks it, write to your State Food Administrator.

A peculiar part of this ruling of the department is that it stipulates an allowance of 50 per cent of the amount used during the corresponding period of last year by the **manufacturer of honey**. Why add insult to injury, when the beekeepers for years have been trying to convince everyone that there is no such thing as manufactured honey. The pure food law does not allow it, anyway.

SCIENTIFIC HONEY MARKETING

Facts Which Are Important in Evolving a Plan for Practical Honey Selling

BY NELSON W. PECK

THE first important problem which looms up before most beekeepers is generally that of production. In the solving of this and in the attendant details, so much time and energy are usually consumed that little if any intelligent effort is ever made, except in exceptional cases, toward scientific selling.

Taking for granted that the product in question is of its kind as good as any, whether white clover or buckwheat, raspberry, fireweed, alfalfa, sweet clover, sage, orange or aster, let us turn our attention, while there is yet plenty of time for reflection, to this subject of scientific marketing.

Whenever anyone has any more of anything than he can use himself, whether it is doughnuts or cobblestones, someone, somewhere, always exists who could use it if it can be delivered to him at the right price. The price depends largely upon the quality of the stuff, how much of it there is, and how greatly the consumer needs it, or thinks he needs it. The primary object in scientific marketing is to find this necessary someone, tell him that you have just what he needs and at what price he can obtain it. This process is called advertising. It may be accomplished by flaring notices in conspicuous places, which vex the mind and are read and forgotten and which are expensive and hideous. Or it may be accomplished by vendors or mongers yelling at the top of their lungs, "Extra! Extra!! All about the Blank Murder!!! Or by quiet solicitation from shop to shop and house to house. But no matter how we choose to go about it, some form of this advertising is absolutely necessary and must be accomplished as effectively and cheaply and unobjectionably as possible. Most long-lived business firms have found out that a thoroughly satisfied and enthusiastic customer is the cheapest and best advertisement obtainable. So be it, it's very, very necessary to obtain this first customer and his comrades.

Let us consider profoundly this subject of advertising, one of the oldest arts of Mother Nature herself. Have you ever walked beneath an apple tree at blossom time and smelled the dewy fragrance of the bursting flowers and looked above you into the busy market place among the showy pink and white petals? 'Twas Mother Nature's advertising that reached you; but it was meant for the bees, and the chances are, unless you got out before them, that they were there in numbers long before you. Yes Nature has something for sale, both pollen and nectar, and she proclaims in a quiet but effective manner that the nectar is sweet and plentiful; can't you smell it, and see the great

mass of bloom? Yes, all this is for sale, there is plenty of it, it's good and the price is but a few grains of pollen, which is generally well paid. We can always look to Nature for guidance. She is always before us and about us and her activities are numerous and complex enough to furnish us an inexhaustible source of examples and ideas. Like Nature, we have something for sale, and we should both show its abundant beauty and proclaim its useful attractiveness. We may show it in shop windows and proclaim it by labels and well-worded cards in those windows, or we may show or display it at some house door and proclaim its virtues and usefulness by word of mouth alone. Or, better yet, by both display and word of mouth and sample. The idea of samples is very agreeable and effective and though seemingly expensive often produces results warranting all expense. Is your honey unusually good? What need, then, to blare or bawl it out? Let the good housewife, or, better, the husband, or better yet the children, try it. Their tastes will soon tell them if it is to their liking, and they'll want more. Oh, yes! the label on the bottle tells where they can get it—at So-and-so's grocery.

And just here is the grain of wheat in all this bushel of chaff. Most producers of honey begin their selling efforts at the nearest corner grocery. This is an absurd blunder, which works injustice to the poor grocer, injury to the apiculturist and unfairness to the prospective consumer. Scientific marketing directs its first efforts at the consumer. Find those ones who are looking for just what you have for sale, and don't know it. They will find the grocer all right, don't worry about that, and he will find you. But cultivate the love and kindly respect of the consumer first of all. Then will the grocers, and finally our ever necessary and useful friend, the middleman hunt us up and do our bidding, and that with right good will. Bear this in mind, you do not merely sell honey to the grocer in pint jars or jelly glasses or five or ten-pound pails; you sell this honey to the great mass of someones scattered among the people. For this reason always put your name on the label and then, though your customers all move to the North Pole, some grocer will beg the privilege of selling to them for you the honey which you will produce.

Among the best methods of obtaining customers are the following:

1st. For the rural districts and small villages. Start out some afternoon about 3 o'clock with a few dozen ten-pound pails filled as full as you can get them, so there will be a few "tastes" in each pail more than

the net weight. Be sure **not** to take along anything smaller than five-pound pails, and preferably only the larger size. Now, the matter of price must be settled in your mind before you approach your first customer. This is affected somewhat by the competition you have, the demand for the honey and the amount available. We shall suppose that at this time when you are starting out to sell your honey that you could get 15 cents per pound for it in 60-pound cans is about 14 cents per pound, road station. Then let us figure. Fifteen cents per pound in 60-pound cans, cased, at the present price of cans is about 14 cents per pound, net. So the ten pounds of honey without the pail is worth \$1.40, and the pail is worth at present 15 cents, which makes the cost to us of the pail and honey \$1.55, and to this we must add 10 per cent for ourselves, 15 per cent for the jobber and 20 per cent for the grocer, which brings the price of the honey, freight included, up to around \$2.40 to the consumer. But, you say, "why charge the grocer's and jobber's profit when grocer and jobber never handled the honey?" Yes, but my dear friend, **you can never eliminate the jobber and grocer**, for if you do sell direct to the consumer, which you cannot do if you are in any way a large producer, you are then both jobber and grocer yourself, and will in time find that **you cannot do their work without their pay**. So, for pity's sake, right at the start, don't fiddle your crop away and fool yourself, but sell at a scientific price; and, if you can't do that, either buy up your unscientific competitors or get into some better territory, or else some business where there are more scientific people. So, my advice to you is, "sell your honey in the scientific way at the scientific price." You'll be thought more of in the end, and you'll get to Heaven just as quickly as though you half way give your stuff away. Better go give it away scott free with no strings to it, if you feel inclined, but don't half way give it away. Don't half way do anything.

So let's go up to the first house we come to (don't skip any) with a smiling, good-natured, patient face, a 10-pound pail of honey neatly labeled and a price scientifically premeditated. We'll shut the gate behind us, step up to the door, knock gently but briskly and say to the one who comes, "Does anyone here eat honey?" at the same time holding up the pail.

"No, we don't care for any."

"All right, thank you; sorry to have bothered." Don't argue; it doesn't make friends and it doesn't pay.

But if he is interested at all and

makes no move away from you, then quickly pry off the lid and show him how thick it is. Um! Just extracted and still warm. Fresh honey just from the clean combs; all honey, nothing but honey, with only the indigestible wax removed. Explain to him (or her) that honey is only 30 cents per pound and wax is 40 cents, and that is one reason why extracted honey is cheaper than comb honey. And what good is the wax in comb honey? It is indigestible and perhaps irritating to the intestines. Don't we get enough coarse stuff now with our war bread and all? Be sure to give him a taste; a good big taste, on a clean spoon. He will furnish the spoon all right, or perchance one of the children might be glad to taste it and he will get the spoon.

In general women don't like honey and won't use it. They buy it only for children or husband. So, remembering this, if wife comes to the door and husband comes in sight, get his attention or the children's first of all, for they always like honey and, if they once taste it, and mamma has the money, your pail is just about sold. It's the little things that count, and especially children where honey is on hand. When the honey is sold the remark can often be made to the good wife that if she will use one tablespoonful of honey to two loaves of bread instead of sugar in setting yeast the bread will keep moist longer and the yeast will rise more surely. One tablespoonful of honey is a small amount, to be sure, but its use requires honey in the house, which implies demand, and that is what we are desirous of creating.

It is not necessary or advisable to be a knocker; but, if such substances as Karo or maple syrup are mentioned it may be explained just what "Karo" is and why it is so cheap. It's made of corn, that's true, and corn is as pure as nature made it; but sulphuric acid is not pure and wholesome, and perhaps limestone is not either. And Karo is made of these things, too. Why, even the bees, as fond of sweets as they are, in all my experience would never even go near "Karo." Pure maple sugar is wholesome when made in a cleanly way. When actually pure it is seldom cheaper than honey, and also seldom competes with honey because it comes at a different season.

2nd. For the city it seldom pays here to canvass house to house. The game has almost always been overworked by magazine artists, sewing machine men and the like; and Mrs. Housewife is sick and tired of running to the door. Also in the city people buy in smaller quantities. In the country, when a smaller quantity is asked for, the customer should be directed to the nearest reliable grocer. Also, if only one canvass is to be made each year, people who buy honey should be told that their grocer will handle the honey for them if they need more later. But in the city soliciting doesn't pay. Yet placing free samples on the front door knobs can often advantageously be done. If the children get them, so much the better. But all free samples distributed at random should

have a seal of paper pasted over the cap so that the bottle cannot be opened without breaking the seal. In fact, now that the kaiser's agents are said to be distributing ground glass so freely in our canned foods, this idea is not amiss to all our honey packages.

Free samples can also be given away right at the grocer's in connection with a good window display. They should contain 3 or 4 ounces, net, in a labeled glass jar. But your grocer, unless watched, is apt to give them away in bunches, sell some, and appropriate the others. The grocer should be made to appreciate their value to him and the necessity for using each one efficiently. Perhaps he will advertise in the newspaper one free sample of honey with each dollar purchase at his store on a certain day. That is one very good plan. In connection with the window display in the city, the one-frame glass hive with some pretty golden bees is very useful to attract attention. A few of these hives will be a good investment. If for no other desirable quality, the golden bees are invaluable here, for on a comb they show up wonderfully.

As a good label is necessary to scientific selling, the discussion is in order. First of all, most people do not know the picture of a honeybee from a humbug, so why disfigure our labels? Also why put pictures of roses on our labels? Do roses secrete nectar? And straw skeps! For the love of common sense, forbear! Be original! If you cannot do better, just print "Honey" in great big red or blue letters in nice clear type, so people can see it and will believe it and buy it and go their way rejoicing. All labels should show the net weight of contents and the class of honey, and if possible the principal flowers from which contents were gathered; also, directions for melting in case of granulation, and the producer's name and address.

In selling to the grocer the grocer's profit of at least 20 per cent should be deducted from your retail price. It costs most grocers this to pay rent and expenses and make a moderate profit.

I advise all honey producers to sell for cash only. R. O. G. If you can't do this, call in the jobber and give him his 10 or 15 per cent for handling the credit risk.

But remember, you can't be producer, jobber, grocer, consumer and all. You've got to stop somewhere if you are to make money. Render unto Caesar the things which are Caesar's and unto the jobber and the grocer the profits which are theirs, and unto the consumer the best grade of pure honey you can produce.

Yakima, Washington.

My Neighbor's Garden

By C. D. Stuart.

IT was summer I had just gone to the apiary to swarm, artificially, the colony containing my new ten-dollar breeding queen, when bridal-like draperies above flying feet

all unhampered by insignia of the sex suddenly appeared among my beehives.

The apparition proved to be our new neighbor, Frau Clara, in the perspiring flesh. We had met at her artist husband's concert only two months before. The audience was on its feet clapping for a final encore when she spied me.

"Ah!" she cried, "I know you. You are the gen-tle-mann with the beans." And Herr Professor, still seated in front of the Club's baby grand, smiled dutifully in my direction.

The crowd around the platform parted, and those ladies who had not already discovered that I was the only male present, were now eager to observe one possessing money. Instinctively my hands sought refuge in my beardless pockets.

"Madame," I answered, "I haven't a single bean."

"Oh, yes; little yellow beans." Her tone was most insistent.

Nectarivorous and carnivorous "beans"

Could Frau Clara have confused me with the vegetable man, and was she taking advantage of the occasion publicly to rebuke me on the size of my produce? I wondered. Or, wait! she had specified **yellow** beans. In **her** tongue, might not "bean" signify a gold coin? The situation was perplexing; but I stood my ground.

"I have no beans, neither little beans nor yellow beans. I am an apiarist," I concluded, with conscious pride.

"Do I make meestake?" Frau Clara appealed to the women. "The gen-tle-mann he look always so," holding up her arms as though inspecting at close range a small platter.

"She means bees," volunteered a recently initiated neighbor.

"Yes," beamed Frau Clara, "beans."

And, having reached the end of our conversational rope, the Magic Girl came to the rescue by inviting them to come to see our "beans," and taste our honey. Whereupon Herr Professor beamed right out loud:

"You haf piano, yes? Then I come und blay for you."

So my good little bees had not confined their social activities to the visiting of flowers, and as we passed out we were followed by envious glances. For Herr Professor had arrived. The ladies of the Club no longer wondered if he were in America to avoid war duty, or had been banished for political reasons. Also they ignored the report that his marriage to Frau Clara had been sanctioned by neither Church nor State. He had made their piano speak to them in the one universal language. That was enough.

"On the day before Friday," bee fixtures, catalogues, magazines and a stack of beeswax were concealed in the basement; the piano was dusted, tuned and garnished with flowers; a square of honey placed on the best plate, the choicest amber mead set out; and, last of all, our bee uniforms regretfully exchanged for citizen's clothing. No sacrifice of personal comfort was too great in honor of Europe's favorite pianist.

It was quite late in the afternoon when at last we heard animated conversation, interspersed by intermittent howlings. Soon Frau Clara appeared, followed by Herr Professor tenderly carrying a small brown dog.

"Ve do not like your beans," she began, excitedly. "They will not let my leetle dog eat. Every day they come and take his dinner—an' meat so expensive! He get nothing. He starve. He is sting. He cry."

"Impossible!" I told her. "Bees don't eat meat."

"Yellow beans," she insisted.

"Perhaps it's yellow-jackets," suggested the Magic Girl.

"Of course," I agreed, relieved. "I'll show you. They eat bees, too!"

So I brought from the apiary a fly-trap filled with yellow-jackets that had been captured through the lure of a meat bait, a piece of which still remained in the trap. I also

Frau Clara in hastily improvised bee costume
(Photograph by W. B. Dickinson)

pointed out a honey-bee which the enemy had dragged in. Then I went out again and tapped gently on the side of a hive as I had seen the birds do at breakfast time. A bee peered inquisitively through the opening. At the second tap it came out and crawled up the front of the hive. In a second I had the insect by the wings and pinned alongside a yellow-jacket, where even Frau Clara could distinguish, though reluctantly, the carnivorous from the nectarivorous "bean."

Herr Professor radiated smiles, and, much to the disappointment of

the Magic Girl, he discarded the promised classics and improvised on the piano the weird things our beans had done to their dog, while the latter continued to howl its own version of the affair. But only with the serving of the amber mead was Frau Clara fully convinced. She grew confidential. It seemed she had always lived in a "beeg city, Vienna," had never owned pets, except "von leetle cheeken," and she would so love to have some beans, for "such good drink" she "hevair" tasted, so much, "what you call? Keek" (kick.)

It was the next morning that Frau Clara appeared, wraith-like, in my apiary to tell me that their garden was full of beans, and Would I give her a box like mine, "so they go in?" I handed over the hive just prepared for my own use in the artificial swarming project, and, like a true beeman, abandoned work to be in at the hiving.

Counting the few remaining "Beans"
(Photo by John R. Douglass)

When I arrived the bees had been settled in a cluster on the limb of a young fruit tree, presumably by the rhythmic tom tom of the valiant Professor, who still knelt just beneath, the baby grand having been temporarily replaced with dishpan and hammer, "so like old countree," and his concert attire, apparently for the garb of a hobo.

The bees were indeed yellow and of a rare, though singularly familiar shade. I examined them more closely, then hastened back to my apiary and opened the hive containing the new queen. My suspicions were correct. She was gone, together with most of her subjects, whether swarmed, absconded, abdicated, or merely enticed by the witchery of Herr Professor's music, was of small matter. It was the thought of my finest colony at that moment being made comfortable in my neighbor's garden, and in the very hive I myself had provided, that rankled, and,

Old "Countree" method of catching bees

involuntarily, strong, appropriately-worded sentiments escaped me.

"Are you stung?" called out the Magic Girl, sweetly.

"Am I stung!" I began, then remembered to restrain myself, as I continued grimly to count my few remaining "bees."

Los Gatos, Calif.

The Maintenance of Colonies From the Close of the Honey Flow One Year Until Its Beginning the Next.

By Geo. S. Demuth, Apicultural Assistant, Bureau of Entomology

(Continued from August issue)

This paper was prepared as an address, and not as an article for publication. This will explain certain passages in which the meaning may not be quite clear if the reader attempts to interpret it as a paper for publication.

Food

Fall Food—The most important of these requirements is food. A colony well supplied with stores at all times will stand a tremendous amount of abuse in the other two requirements. If an abundance of stores is present during late summer and early fall, brood-rearing does not cease, even during a dearth of nectar, but if stores are meager in quantity at this time, brood-rearing may be entirely suspended. It should be noted that, when there is no fall honey-flow, the winter colony must be reared in opposition to the instinct of the bees, which at this season is to rear but little brood during a dearth of nectar. If ample stores are not in the hives in August, they should be supplied without delay, if the beekeeper expects to have a colony in condition for winter.

Winter Food—During the winter not only quantity but quality of stores is important, especially if the bees do not have frequent flights. The practice of beekeepers shows a decided tendency to supply in the fall not only enough stores for winter, but also enough to carry the bees through the heavy brood-rearing period the next spring. Any deficiency in winter stores should be supplied not later than some time during October, in this locality.

Spring Food—During the third period, the stores are being so rapidly converted into bees that there is danger that many colonies will run short and curtail brood-rearing just at the time when the beekeeper can least afford it. I have seen many failures here and could cite tremendous losses, even among experienced beekeepers, resulting from a shortage of stores during the month of May. Unfavorable weather conditions often prevail during this period and the beekeeper, thinking each day that the next will bring better weather and permit the bees to replenish their depleted stores from the fields, is easily led to wait just a few days too long. To purchase large quantities of sugar

to tide over the period just before the honey-flow, when conditions may change even before he has had time to feed it, tests the metal of the beekeeper. Too often he goes through such a period with a feeling of security and does not appreciate the situation until after the mischief has been done. To cite one illustration of what I mean here, I saw at one time during the latter part of May a series of six apiaries in which about 10 per cent of the colonies were actually starving and the entire lot of about 600 colonies was practically ruined for the season, because the beekeeper thought they could pull through without help. Here a 600-colony man waited a few days too long before he began to feed. The honey-flow that followed was a 100-pound per colony flow, but his 600 colonies furnished an average of only about 10 pounds per colony. This is but one of many such instances that have come under my observation, in addition to some exceedingly unpleasant recollections of similar personal experience, which has helped to drive home this important lesson. It is not a question of a supply of food in the hive merely sufficient to keep the colony alive during a period when nectar cannot be obtained from the fields, since long before there is actual starvation, brood-rearing is greatly reduced, or even suspended, and some of the immature young are carried out of the hive.

Protection

Fall Protection—The protection afforded by the ordinary single-walled hive is usually sufficient during summer and early fall, since during that time the protection needed is largely protection against rain and cool nights or robbers and other enemies. In some localities shade is desirable during the hot days of summer to protect the colonies from extreme heat.

Winter Protection—It has been shown that when the temperature of a colony of undisturbed, broodless bees is above 50 degrees F., the bees are quiet and their temperature

drifts with the external temperature. A temperature of 57 degrees F. and above is maintained within the cluster of bees throughout the winter. This temperature is maintained during cold weather by an insulating crust of bees on the outer surface of the cluster and heat generation by muscular activity within the cluster. As the temperature of the air surrounding the cluster goes downward below 57 degrees F., the activity of the bees within the cluster must be increased in order to maintain the required temperature of 57 degrees F. and above within the cluster. This greater activity makes it necessary that the bees doing the work consume more stores to supply the source of the greater energy expended. More rapid consumption of stores results in a more rapid accumulation of feces, which the bees attempt to retain until a flight permits voiding them outside the hive. The presence of feces in large quantities acts as an irritant, causing activity in addition to that required to maintain the necessary cluster temperature, thus greatly increasing the energy expended and stores consumed. This results in a constantly increasing accumulation of feces until the bees are relieved by a flight in the open air. Poorer grades of honey and especially honeydew honey, when used in winter, result in a more rapid accumulation of feces for the amount of energy expended than do better grades of honey or sugar syrup. During the winter, therefore, except when the external temperature is between 57 degrees F. and 69 degrees F., bee energy is being expended in response to one or both of two irritants—cold and accumulated feces. Since to survive the winter the bees must live more slowly than they do during the summer, the problem of the beekeeper during this period is the conservation of the energy of the bees, and he must seek the solution in two directions—that of better food, if possible, but chiefly that of protection against low temperatures, that is, lower than 57 degrees F.

Part of the apiary of the Agricultural School at Rome, Italy; Prof. G. Montagano in charge

This added protection may be supplied in the form of winter packing-cases or double-walled hives, and a windbreak (outdoor wintering), or a winter repository (cellar wintering). In the light of the temperature requirement of the bees, the winter protection usually given is woefully inadequate.

Spring Protection—When brood-rearing begins, that portion of the brood-nest occupied by brood is kept at brood-rearing temperature and later, when there is brood in most of the combs, the temperature of the entire brood-chamber is usually about 90 degrees F. Under these conditions thin-walled hives permit a rapid loss of heat when the outer temperature is low. For this reason the winter protection is usually left on the hives until late in the spring. Protection of the entrance against robbers is also important during this period.

Room for Expansion of Colony Activity

Fall Room—The storage of food as well as brood-rearing comes in waves and usually at about the same time. If the hive is not large enough to contain the maximum of both at the same time, it may be necessary that the beekeeper provide additional room during a minor honey-flow, either during the fall or spring. When the hive is too small for both stores sufficient for fall and winter and for adequate brood-rearing during late summer and early autumn, it results either in colonies short of stores for winter or colonies for winter greatly reduced in strength, or both.

Winter Room—When brood-rearing space and storage space do not interfere, there is probably no advantage to be gained by an excess of room, and during the winter broodless period it may be advantageous even to reduce the size of the brood-chamber to fit the colony.

Spring Room—During the heavy brood-rearing period of spring, the strongest colonies may need more room than that afforded by a single hive-body, and it is at this time that additional room is of great importance, because of the bearing it has upon both the production of bees and swarming. The problem is usually solved either by adding an extra hive-body with empty combs or by expanding the brood-chamber of the stronger colonies into unoccupied space of colonies less strong by what is known as equalizing the brood. This is done by exchanging combs of sealed brood from the stronger for empty combs from the weaker colonies.

Providing the Three Requirements

It would seem that one of the greatest needs of the beekeeping industry is some stimulation to a better system of supplying any deficiency in these three fundamental requirements early enough to prevent loss. There are two extremes of method in supplying these deficiencies. One is to watch the colonies daily in order promptly to detect their needs and then to supply each

colony as the need develops. The other is to supply the three requirements, if not already present, for long periods in advance.

The former is the method usually used by the beginner. It involves a tremendous amount of labor, constant attendance in the apiary, and is largely responsible for our conception of the complexity of beekeeping. The latter method greatly simplifies the work, substitutes system for too frequent a lack of system and makes possible the operation of outapiaries. It may, however, sometimes involve the giving of something that could have been omitted without loss. A fall honey-flow may take care of the food requirements of the colonies at that time and a large hive may furnish enough room for both incoming nectar and brood-rearing. A mild winter may make it seem to have been unnecessary to pack the hives so well or to have furnished shelter from the wind, and, finally, the maple, dandelion and fruit bloom may supply an abundance of food for brood-rearing during the spring. But we cannot be sure of any of these things and cannot afford to take any chances of the requirements being supplied in this way.

When food is given in advance, it is stored, not wasted, and remains in storage until needed. We can also give protection for winter and room for expansion the next spring just a little ahead of the time they are needed. It is even possible as an emergency expedient, in localities having a single major honey-flow, to prepare every colony at the close of any given honey-flow for the entire period of preparation for the honey-flow the next year, or a period of ten or eleven months. Most of us would be surprised on our return ten months later to find how well the bees have been able to take care of themselves without us, if they have an abundance of stores for every possible need, an abundance of protection against the most severe winter the locality may afford, and an abundance of room for expansion before the honey-flow the next spring.

There is a growing tendency among

beekeepers to use a shallow extracting super or hive-body filled with honey, above the regular brood-chamber throughout the year, except possibly during the honey-flow. Its presence throughout the interval between honey-flows, together with adequate winter protection, leaves little that the beekeeper can do toward having the colonies strong in time for the honey-flow.

The Winter Problems of the South

By J. J. Wilder

UP on the mountains in the section of our country with high altitude, a little winter care might be of some value, as it is much colder and there is more snow and ice than in the lower country, where the average temperature is from 50 to 70 degrees during the winter months. But even there my observation leads me to believe that special winter preparation is not necessary.

I have never seen any colonies of bees frozen, except very small, neglected swarms. Nor have I seen many dead bees fall from the clusters during winter. Many times I have wintered a pint of bees in its hive on summer stands. So, actual winter losses are exceedingly small.

A few times I have spread brood a little too early, and this resulted in just a small loss of brood.

I kept a house apiary for a number of years where the bees had the best of winter protection, with results to the reverse. I don't know why. They consumed more stores, dwindled more and were far behind the others in the same yard out in the open.

The same thing that will keep bees in thriving condition in spring, summer and fall will keep them through the few winter months.

Many times more bees or colonies of bees die in the fall and spring than during the winter months. Every beekeeper knows this is true. So there is something far more vital than the average beekeeper would

Group of attendees at the Beekeeping Course under the supervision of Prof. Montagano

call "wintering," or "special preparation of packing and protection of hives, etc."

Let us look into all the winter problems we need to worry ourselves about.

Of course, bees should be kept in good hives all the time, and should have plenty stores when it is a long time until the next honey flow, winter or summer.

They should be requeened when they need it and not when it is too late to save the colony or have its good service during a honey flow. These are "all the time" problems.

A majority of beekeepers leave the supers, hive bodies and all storing apartments on the bees over the winter months. This is a great mistake, wherever it is practiced, and should be abandoned.

It is too much space above the bees. Better by far would it be to have all the brood, bees and plenty of honey in one single body and a good cover on it. Thus they have snug and contracted quarters, such as they need for their good.

When 8-frame hives are used it would not be amiss to leave one set of shallow extracting combs on, and they should have more or less honey in them. Bees have to maintain animal heat to exist, and a great space above them would be harmful.

The first zero weather will kill all scattering moths, both large and small. Then they are all right until time to put them back on next spring. If combs are removed and stacked up in the yard and covered just before the first freeze in the fall, they will need no special treatment. If much earlier they should be stacked up straight in high stacks and covered up well with straight water-proof covers, and all cracks daubed with clay, so as to be as near airtight as possible. Then give each stack a good, strong sulphur smoking, from the bottom, for not less than 10 minutes; then close up well. Or you can set in at the top of each stack a very small, flat vessel of carbon disulphide.

Cordele, Ga.

Winter Protection of Bees

By T. K. Massie

REGARDING the subject of winter protection, which of late has been receiving considerable attention, I wish to offer a few thoughts, as they, from long experience and observation appear to me.

The Government plan of outside dual winter cases, while all right for bees in thin-wall hives after the bees are placed in them, is so very costly that it will never be adopted by even one per cent of our farmer-keepers. The first cost of material and labor in their construction, the time and labor required to pack in the fall and unpack in the spring and the storage room and labor of storing them during the summer are so very great that few beekeepers will ever try the plan. Farmers do not have the time for all this kind of work.

The plan of using two hives packed in the same case where the entrances are close together and face in the same direction is not practical, because the stronger colony draws the bees from the weaker one, just the opposite of what we would like to have take place.

The Demuth-Pritchard plan of using two or three hive-bodies or two hive-bodies and a super for an outside case and an inside case of 3/4-inch lumber made large enough to hold six frames standing on end, which, of late, has been referred to and commented upon in "Gleanings" and illustrated in the American Bee Journal on page 13 for January, is open to several objections. With this plan the first cost of material and labor in making the cases, the time and labor spent in "fussing" with the packing and unpacking, the storage room, time and labor spent in storing the inner cases in summer and the storage room, time and labor required to store the surplus frames—the two or three frames removed from the brood-chambers—is too great. As a rule farmers do not have the time to spend in doing so much extra work, neither does the average beekeeper.

Four of the best colonies of bees I ever saw are owned by Mr. Ayres Hill, a farmer who lives four miles northeast of Princeton, our county seat. Mr. Hill knows nothing about bees and keeps them absolutely on the "let alone" plan. I inspected his bees on the 18th of July. I found them in old box hives made of 1 1/2-inch lumber, 18 inches wide and 27 inches tall. The bees had coated the entire inside surface of the hives with a considerable thickness of wax and propolis. The condition of the bees proved that they had wintered perfectly the winter before. They were "boiling over" with bees. There seemed to be more than the equivalent of two large swarms in each of those hives. Our honey season has been rather a poor one, but each one of those hives had 100 pounds of surplus honey on it.

Now, a few lessons here. Where did the bees in those hives form their winter cluster last fall for the

past cold winter? Evidently on the empty combs along the lower lines of their honey and over the cells from which the last brood emerged. The guess is sure. As their honey is consumed they can move upward for it and keep up with their diminishing stores. This is the normal way. Now, suppose man, with his superior knowledge (?), had gone to "messing" with those hives on his great idea of vertical contraction and removed some of those combs, thus separating the bees from their combs and wax-coated walls, all of which are non-conductors of heat and cold, and inserted wooden "dummies" which are conductors of heat and cold, would he not have done damage to the bees and defeated the very object he was trying to accomplish? Again, suppose that those bees had been put on combs filled solidly full of honey and pollen, no empty cells, where would we now find the bees clustered in very cold weather? Just as far away from the entrance as they could get, which would be at the tops of the combs. Then, if the honey over which they are clustered is consumed during the continuance of the cold spell, what would happen? They would all starve because they could not reach the honey below them. With the Demuth plan, the combs standing on end, the empty cells which were at the bottoms of the frames extending all the way from the bottom to the top along one edge and the honey along the other edge, or side, they are placed in a vertically contracted and abnormal position, and I would expect them to again form their winter cluster at the tops of the frames and starve. If I were to use this plan I would put the bees in the inside case early in the fall and feed liberally to cause them to fill the top part of the frames with honey and rear brood in the combs at the bottom so that they would form their winter cluster in a normal position at the bottom ends of the frames. Again, six frames, containing only about 825 square inches of comb, is not enough to supply room for brood-rearing in the spring. Very few beekeepers use hives large enough.

J. G. Norton, of Macomb, winters on summer stands.

When a good queen is laying 3,000 eggs every 24 hours it will require 1,350 square inches of comb to supply room for the queen, to say nothing of the comb-space to hold sufficient honey and pollen to supply the need of the colony.

Hatcher, W. Va.

A Summer and Winter Hive

By D. C. Noble

THE first picture shows the hive as it appears in use. The second shows it with cover removed in summer. It holds fourteen Hoffman frames. For winter two or three frames are removed from each side and division boards put in. The empty space is then filled with dry leaves or chaff for winter packing. At the rear of the hive there is also a 2¼-inch space to be packed in a similar manner. When packing material is removed, the hive may be pushed back if desired, to permit the space in the rear to serve as a ventilating chamber conducting fresh air to the top of hive.

Each super holds forty 4¼ sections. With the side frames removed, the hive has the same capacity as the standard Langstroth hive, so that parts are interchangeable.

Columbia City, Ind.

A Letter From Scotland

THE following letter from our learned Scottish friend of Aberdeen may prove interesting to our readers. We call especial attention to the last paragraph, which suggests a new thought.—Editor.

By John Anderson, M. A. B. Sc.

Many thanks for your delightful letter of April 29. It is so good of you to send me such a long letter when you must be so very busy with matters of much more importance. In your last two letters to me there were references to the war, references and sentiments with which I cordially agree, and it is interesting that both were opened by our censor. I hope he is pleased.

The May American Bee Journal is

Noble's all-year hive

at hand and I have read Fabre on parthenogenesis. I agree that the evidence is not sufficient, and that the conclusions are unwarranted. Possibly he makes too much of the eggs of drone breeders not always hatching. The bees get disgusted with those queens and weakened and sometimes neglect the grubs as well as the eggs, so it is not surprising that some of the eggs remain unhatched. I had the opportunity of examining two queens which laid abundantly and regularly, but none of whose eggs hatched. In both cases it was quite clear by microscopic examination that the queens had been duly mated. Cook has also verified this.

Fabre is always delightful, but one cannot always agree with him. He thinks, for example, that ants find their way home on common sense principles, by means of landmarks

can keep a stock all summer rearing batches of queens if you simply supply eggs at intervals. It doesn't matter how many cells they have already, or what stages these may be at. There may be even loose queens piping on the comb. I had a stock with five sealed queen-cells, to which I gave a comb with eggs; they have started fresh cells on those eggs.

We have coddled and fed our bees far too much, and we have been too successful in wintering. It does not seem to occur to you that the high winter death rate among bees in America is probably an important element in the success of Americans in honey production. There may be a loss of perhaps as high as 75 per cent, but the 25 per cent left have been sifted and are likely to be hustlers.

Good luck to you, and more power to your elbow.

Banff, Scotland.

Noble's Hive, showing the parts

but that bees, wasps and cats have a mysterious homing instinct, or sense of direction. If he had been able to watch the bees as closely as he could the ants, I think he would have concluded that these, too, found their way home just as we do.

I have read as much of your life as I could get hold of and envy you the great privilege of beginning where your father left off. I agree that a lifetime with the bees is not enough to exhaust the interest. Fortunately, the bee enthusiast need never, like Alexander the Great, weep for more worlds to conquer.

You may be right in suggesting that the supposed worker-egg-laying worker may be a small queen. My Punics have made bundles of queen-cells, as did Cyprians I had years ago, and some of the cells appeared quite small. I have divided into nuclei and laying-workers have already started in one of these, though the queens are not yet due to emerge. I shall have more to say later.

I have been trying out another of Hewitt's theories. He says that you

Hive Entrance

By A. F. Bonney

FROM time to time there appear suggestions for protecting the entrance of hives during the winter, but up to the present time nothing which meets general approval, and those who winter out of doors seem to trust to luck.

It is not only in outside wintering that the entrance of a hive needs protecting, for from the time the bees are removed from the cellar until settled warm weather comes they are in a critical position. They have to be protected with a wrapping of tarred paper, and the spring winds, some of which are very cold, rob the hives of heat, as much of it is sucked out of the hive through an unprotected entrance.

This is, of course, threshing over old straw, but in doing it, mentally, I think we have discovered one grain of wheat, in an entrance protector, which is convenient, cheap, easily applied, cannot get out of place, makes it practically impossible that the en-

trance clog with dead bees, snow or sleet, which almost every year cause the loss of many colonies to those who winter out of doors, and the number of those who do is increasing. The beginner, with a few colonies of bees is practically forced to, as he cannot afford a cellar, and would not know how to use it if he had one.

My idea of a perfect entrance protector consists essentially of a box, made of thin material, 14¼ inches long, 2 inches from back to front, and 2 or more inches deep. The top slants forward at an angle of about 20 degrees and projects past the front half-an-inch or more. Just under it is the entrance, and the edge of the

End View
Bonney's winter entrance

top is painted white to locate the entrance; the rest of the box is painted black. There is a back to the box with a three-quarter-inch opening to correspond to the hive entrance, and two lugs, each 2 inches long, one at each end, to slip into the entrance to hold it into place. A strip of wood extends down from the front edge of the cover to protect the entrance from wind and snow.

The advantages I claim for this idea are as follows: It conserves heat, as no wind can blow directly into the hive; dead bees cannot obstruct the entrance, as the ¾ inch opening is wide open all winter; the box being painted black and the strip over the entrance white, the bees easily find their way in; if the first rays of the sun will be absorbed to thaw ice and snow long before the bees are warm enough to fly out; the boxes can be made cheaply, and they will, if kept painted, last for years.

Buck Grove, Iowa.

Beekeeping Around San Francisco Bay

By E. D. Crowl

WE started out this spring with three nuclei in our back yard, no one of which was large enough to cover three frames. Brood-rearing in two of them had not stopped during the winter, which was un-

usually mild, and in the third, which was the smallest, had stopped about November 1 and begun again December 27. They grew strong rather slowly, probably due to the weak condition of the colonies. The nights are very cold early in the year (they are never warm at any time here) and this year the fruit bloom was late, apricots not coming into bloom until the middle of March, which no doubt hindered the building up somewhat.

On March 20 the strongest colony, in an 8-frame hive, had brood in all of the frames, and the bees were putting honey into the brood-cells until it interfered with the queen's laying, and there were not as yet bees enough to care for the brood and work in the super also. We had the same trouble with all three hives, filling everything with honey until it interfered with the brood. March 30, peach, early cherries and plums were in bloom, and work began nicely in the supers.

Fruit bloom lasts a long time here, almonds beginning usually in February and apples ending the season. This year the apple bloom was over about the middle of April, somewhat later than ordinary. This certainly gives the bees a good chance to build up. About the first week in June the flow diminishes, though there is some all summer. Then in August the fall flow begins and lasts till it gets too wet and cold for the bees to fly. The eucalyptus trees commence blooming in the fall and furnish a good deal of honey. The bloom from the different varieties lasts all winter and until late in the spring, but owing to the generally cold and rainy weather the bees cannot make the best use of it.

White clover amounts to nothing here, though there is a good deal of it in the lawns. It seems to have no nectar, as the bees are seldom seen on it. There is a good deal of dandelion, which blooms all summer, but the bees pay little attention to it. The bloom of the different varieties of acacia cover many weeks, usually beginning in early January, and the bees seem fond of it; but coming so early, the weather is usually too inclement for them to get the full benefit of the bloom. The excretion which they gather, in some varieties, at least, is found, not in the blossoms, but on the edges of the leaves. I have not had an opportunity to observe whether this is so in all varieties.

During July and August a bright red honey, in very small quantities, is gathered from something, I have not been able to ascertain what. It is a very well flavored honey, but only an occasional cell is filled with it. The honey gathered here is amber in color and of no particular flavor, being obtained from all sorts of sources—just honey. The usual sources of California honey, sage, orange, bean and alfalfa, are not, of course, to be had in a city.

The weather around the bay cities is, taken as a whole, too cold and foggy, and there are too many days

with high winds for good bee-keeping. We have, however, had all the honey we could use and a good deal to sell, and have five additional hives, formed on the nucleus plan, with queens raised above an excluder over the strongest hive we had. We could, of course, have had more honey if we had not used any of the bees for increase. These new hives will probably be strong enough to gather some surplus during the fall flow, as one of them already has five frames of brood in it and another three, although they were formed late. Our warm weather generally comes during August and September—in fact, it is about all the summer we have, so I hope for considerable honey during that time.

Berkeley, Calif.

A Winter Entrance

By C. W. Brimhall

THE photo gives a good idea of my special winter entrance and how it is used. Beekeepers, who winter outdoors in the north, are familiar with the clogged entrances that often result from the melted snow freezing in the entrance

Winter entrance of C. W. Brimhall

and filling it with ice. This special cover protects the hive from direct drafts of cold wind, as well as keeping the snow from melting and clogging the entrance with ice. The bees can readily leave the hive when conditions are favorable. A brick is placed on top of this guard, to hold it firmly in place.

Schaller, Iowa.

The Temperature of the Bee's Body

By Dr. Brunnich

IT is a well-known fact that bees are able to produce warmth, that they may, especially in winter-time, keep the temperature within the cluster at a point which surmounts, by far, the temperature of the outer air. Most of us have read with great interest the experiments

which were made in Dr. Phillips' laboratory.

As Berlepsch already stated, it is now generally known that the temperature in the brood nest in spring and summer is about 37 deg. C (98 deg. F.). This warmth must be produced either by the surrounding bees or by the brood itself. The latter is little probable, because it is clear that eggs and little worms cannot produce warmth enough. It is even a question whether the older brood is but a consumer of warmth (produced by adult bees) or whether it may generate some warmth itself. To solve those and other questions, I made the following experiments:

I wished to measure the inner temperature of bees and brood with an electric thermometer. The principle of this is a simple one. If we form a circle by two different metal threads, for instance of platinum and copper, there will be produced an electric current if the temperature of one soldering is higher than the temperature of the other. An exact and most sensitive galvanometer shows us the relative importance of the current. With the help of a professor of physics, I constructed a fine needle, which was formed by soldering a thread of platinum, 3-32 m m of diameter, with a thread of copper, 5-32 m m. The other soldering of the platinum thread with a thicker copper thread was about 1 cm from the point. The whole needle was fixed in a cramp and near the soldering of the platinum with the thick copper thread we placed an exact thermometer. The only fear I had was that it would perhaps be difficult to determine the exact temperature of the bee, because I supposed that at once a great loss of warmth would arise in three different manners:

1. The bee immediately ceases to produce warmth and therefore begins to cool by irradiating its warmth; however, this loss is significant and slow.

2. The threads of platinum and copper draw off by conduction a certain portion of the warmth of the surrounding animal matter.

3. The greatest loss arises, perhaps, by the formation of the electric current, because the current is formed by absorbing the surrounding warmth.

The success showed that my fear was well founded. To prove it I made a number of experiments where we noted the temperature shown by the galvanometer, first every 10 seconds, and later every 5 seconds. I will give the result of a single experiment, No. 47: A flying bee which was pierced with the thermo needle into the breast. The temperatures shown on the galvanometer were:

After 5 seconds	29.4 deg. C
After 10 seconds	34.5 deg. C
After 15 seconds	36.2 deg. C
After 20 seconds	36.1 deg. C
After 25 seconds	34.8 deg. C
After 30 seconds	33.3 deg. C
After 35 seconds	31.8 deg. C
After 40 seconds	30.2 deg. C
After 45 seconds	28.9 deg. C

After 50 seconds	27.5 deg. C
After 55 seconds	26.4 deg. C
After 60 seconds	25.3 deg. C
After 65 seconds	24.4 deg. C
After 70 seconds	23.4 deg. C
After 75 seconds	22.7 deg. C
After 80 seconds	22.0 deg. C

The other experiments showed the same scale and we established that the maximum was reached always after 15 seconds.

Of course, this maximum does not correspond to the beginning temperature, because in those 15 seconds the temperature of the surrounding medium will sink steadily. It would be the same if you wished to weigh a little portion of ether in an automatic balance; you would not be able to get the true weight, because a great deal of the ether would be evaporated, if the hand had reached its maximum. With the help of mathematical speculations, I could find that the real temperature—between the limits in question—would be about $1\frac{1}{2}$ to 2 degrees C. higher than the first maximum shown by the galvanometer.

I was certain to get the best results by piercing the bee in the breast, because there the inner body is most compact, while in the head, as well as in the abdomen, there are many air sacs. When I did not succeed in piercing the breast of the bee in a correct way, I got less temperatures; for instance, when the point of the needle penetrated the thorax so that it became visible, the temperatures of the abdomen were all 10 to 15 degrees lower than those of the breast; therefore, I did not note those results, with the exception of 2 or 3. The temperatures of the bee breast alone are to be considered as standard.

As to the temperature of the brood, I could only make experiments with capped brood, because, for my needle of 5 mm length, the worms were too little. It is natural that also with the brood I did not always succeed in pricking exactly enough, therefore some of my results may be too low.

The first five series are made with a mating box with three movable frames 12x6 in. with a fertile queen and with brood up to about 17 days. The other experiments were made with a queenless section of my construction, i. e., a single frame of 15x 4½ in., with brood also about up to 17 days, and later on with a few queen-cells.

115.—35.5 deg. W.

There is no great difference between fanning, or flying bees. Unhappily, I could not take brood bees, because the disturbance of the few bees was too great to distinguish them exactly. Also, there was not a great difference if the outer temperature was 7 deg. or 18 deg. On account of extrinsic circumstances, I had not the possibility to make the experiments, as they ought, i. e., in the very apiary, where I could operate with strong, normal colonies, I

suppose I should have gotten, especially for the brood, higher figures. But I hope that the same experiment shall be made by others with larger means, with finer instruments. It would be necessary to operate with thinner and shorter needles and with much more sensitive galvanometers. At all events, these measurings are possible and give interesting results.

My highest temperature for bees was 40 deg. C. (104 deg. F.), but I suppose this temperature should be still higher in time of the fullest development of a good colony. However, the temperature of bees is not constant and, may vary about 10 deg. C. (18 deg. F.) I observed that the temperature of a caged bee, especially if it is chilled, sinks rapidly. A bee which at 7 deg. C. outer temperature was caged for 15 minutes, showed then only an inner temperature of 9 deg. C.

The maximum of the temperature

of drones is very high—48.6 deg. C. (119 deg. F.), although all my drones were still young ones, and not very robust.

The temperature of the brood is most interesting, the maximum of a white nymph with brown eyes was 45.0 deg. C. (113 deg. F.) and it proves that the brood is indeed producing warmth. It is at the same time giving and taking. For in a temperature rather beneath 37 deg. the brood cannot thrive, but when the surrounding temperature is brought by the brood-bees up to 37 deg. C., then the little worms and nymphs represent little stoves themselves, and as such also produce warmth.

It would be a grateful task to continue those experiments on a larger scale than what in default of the means I unhappily must resign, but I hope that others who have the possibility will do so.

Reuchenette, Switzerland.

BEE-KEEPING FOR WOMEN

Conducted by MISS EMMA M. WILSON, Marengo, Ill.

War Beekeeping for Women

It is highly gratifying to see how beekeeping is appealing to women as "war work," and I would like to give my happy experience as a beginner for the encouragement of other housewives wishful of obtaining honey for their families, but who doubt their ability to make a success of an apiary.

I started with a swarm of hybrids in a W. B. C. hive on May 28 of last year. It gave me over 50 pounds of delicious clover honey and a fine nucleus as well, which is now strong on eight frames. In June and July I added two other swarms to our little apiary.

These four stocks were fed up in October on pink candy syrup, and were tucked into bed for the winter.

They are now the pride of my life, and as healthy and hard-working as anyone could wish. They are so interesting they almost make one forget there is a war going on, and I confidently expect to take a splendid surplus of honey before the end of the summer.

Some women say they would like to keep bees if they were not afraid of their children being stung. My experience in this has been quite the opposite. The children play all about the hives, being much interested in the busy workers, and only once have they been stung. That was when the little girl tried to push a chilled bee into the entrance of the wrong hive. One bee, only, seemed to object, and risked her life to protect the hive. My little girl held herself still, however, and let the bee pull out its own sting, which we hope saved its life.

No woman who has once known the joy of seeing her own bees

working her own cherished flowers, fruit, marrow and bean blossoms will ever enjoy gardening again without them. Even dull darning may be turned into sufficient excuse for taking an easy chair out by the hives and watching the bees carry honey for the household. And, say—it's a proud moment when your admiring family sits down to tea before your first wonderful dish of honey!—G. C. B. in The British Bee Journal.

School Teachers as Beekeepers

A school teacher says, in the British Bee Journal:

A lady beekeeper, whom I often assisted, sent for me one day. Her garden was surrounded by large trees, and a swarm had settled near the top of one of them, overhanging the road. The gardener, though not a beekeeper, had offered to climb the tree and cut the bough off, but the lady feared to give her permission without first consulting me, lest passers-by should get stung by infuriated bees in case anything went wrong. Tree-climbing is not in my line, but if the gardener was willing to make the attempt, and fixed a rope to the branch before cutting it off, I said I saw no reason to fear any bad behaviour on the part of the bees. A start was made at once, and before long the swarm was being carefully lowered, while I stood beneath, waiting to deal with it as soon as the bough came within my reach. In the middle of the operation numbers of boys began to troop by, on their way from their houses to the school, and the process of lowering the branch naturally attracted their attention. We warned them to stand clear lest the bees should come down with a rush. However, the lowering

took some time, and they had to proceed to their lessons before it was accomplished. My piano pupil arrived in the meantime and stopped to see the finish. At length the bough was carried into the garden, and the bees shaken off successfully in front of the prepared hive. Other swarms came from this apiary during the summer, all of which pitched on high branches, so that we got quite familiar with the tree-climbing business. I suggested the use of water as a preventive, but the bees always managed to forestall their owner and be well on the wing before she was aware they were out.

One day, when cutting out queen-cells, for this lady to prevent after-swarming, I noticed a fine young queen crawling among a number of cells I had laid upon a lift by my side, and presumably just emerged from one of them. Miss B. picked her up to show to a friend in the house, but let her escape. She took wing, and circling round and round at a great height, at length appeared to get tired, and began to come lower. My companion extended her arm, intending to catch her, when the queen calmly came to rest on the outstretched hand, and was secured.

tensive beekeeper in Monterey County. He was a native of Michigan and was 76 years of age.

An Illinois County Association.—

The Henderson County Honey Producers' Association met at Oquawka, Ill., August 3 and elected the following officers: R. R. Banta, President; J. L. Akin, Secretary-Treasurer. The objects of the organization are to cooperate in securing a more nearly pure race of better bees, an increased quantity of honey, and to establish a uniform price for our product, both to the producer and consumer.

R. R. BANTA, Pres.

Michigan State Meeting.—The date of the annual meeting of the Michigan State Association has been changed to November 19, 20 and 21, at Lansing. Correspondence concerning this meeting should be addressed to B. F. Kindig, State Inspector, East Lansing, Mich. A large attendance is expected.

North Carolina State Meeting.—The third annual meeting of the North Carolina State Beekeepers' Association is to be held in Asheville, Thursday, October 17. For particulars, address Dr. Franklin Sherman, Chief Entomologist, Raleigh, N. C. A large crowd is expected.

Death of Texas Pioneer.—Charles J. LeStourgeon, a pioneer of Texas beekeeping, died in Medina, Texas, on the morning of July 29. He was 75 years of age. Born in Western Illinois of French Huguenot stock, whose settlement of New France antedated the American Revolution, he emigrated to Texas in 1871.

Beekeeping always had a fascination for him. There being little opportunity of obtaining the new movable frame hives at that time, he and Wm. P. Hough started a factory near Floresville, Texas. They first manufactured the Van Dusen upright hive with a glass observation window and removable brood-chamber. Afterward the superiority of the Langstroth simplicity hive caused him to adopt it. Through his efforts the Langstroth hive became the standard for early Texas beekeepers. Mr. LeStourgeon was a beekeeper up to the time of his death.

He leaves, besides the widow, three sons and two daughters. One of his sons, E. G. LeStourgeon, is Manager of the Texas Honey Producers' Association.

Spray at Blossom Time Kills Bees.

The following circular is received from T. R. Johnston, Assistant County Agent Leader, at Lafayette, Ind.: "Experiments have been under-

taken at Purdue University by the Entomology Department to show the effect on bees of tree sprays applied at blossoming time to control the codling moth and other insects. The first step of the experimental work, which is to extend over a two-year period, has been completed and indicates that the spray on the blossoms kills the bees.

"Through the feeding of bees and analyzing of their bodies it has been found that it requires only .0000005 (five ten-millionths) of a gram of arsenic to put them out of business. In other words, the small amount of arsenate of lead used in the spray, if applied while the blossoms are open, means that the bees will gather no more nectar after visiting a few blossoms.

"Practical beekeepers and orchardmen in Indiana disagree on the question as to the effects on bees of spraying at blossom time. Analysis of the bees killed by arsenic and observations at spraying time this spring indicate that the spray is fatal to the buzzers. Sprays should not be applied while the blossoms are open, but wait until after they have fallen."

The National.—The next meeting of the National will be held at Chicago, date and program to be announced later.

A Wrong Address.—Those who know Friend Gilling's opinion on the liquor question will appreciate the following: "The telegraphic address of the Honey Producers' Association is 'Bees,' but owing to some men not being very good writers, a number of wires reached our friend addressed 'Beer.' Hawera and the customs people are trying to find an illicit brewery in the district."—New Zealand Beekeepers' Journal.

Necrology.—Mr. John Witham, a noted apiarist of Monrovia, Calif., died July 15 at Palo Alto. Mr. Witham was at one time a very ex-

Preparing the Bees for Cold Weather.

1. Unite any weak colonies to make colonies of normal strength. 2. See that every colony has sufficient food stores of good quality to last during the winter—25 to 30 pounds are necessary. 3. Provide adequate protection against the wind and pack the hives well, as described in detail below:

Beekeepers lose from one-tenth to one-half of their colonies every winter by failing to feed and protect them properly. That loss is too large, bee specialists of the U. S. Department of Agriculture believe, and in a statement issued they declare these losses of important sources of sugar can be reduced to less than 1 per cent.

Wintering bees is a problem of conserving the energy of the individuals in each colony, the bee specialists say. Three conditions in the hive cause a waste of energy. First, when the temperature of the air surrounding the bees falls below 57 degrees it is necessary for the bees to expend energy to keep warm. Second, when the temperature of the air is above 80 degrees the bees use energy by flying from the hive, removing the dead that may have accumulated, and in any other activities which the needs of the colony require. Third, an abnormal activity resulting in energy loss is caused by long periods of adverse weather which do not permit the bees to fly from the hive to void their excrement. This last condition may result in the death of many thousands of colonies, the specialists say.

Protection of the hive and providing of foods of good quality for winter stores will conserve the energy of the bees and enable the colony to pass the winter safely outdoors. If the hive is placed within a box about 6 inches greater in each dimension than the hive itself, and the space between filled with dry sawdust, leaves or other insulating material, the necessity of heat generation by the bees is reduced to a minimum. A small tunnel through the packing material will make a passageway for the bees to the entrance to the hive.

Care must be taken to see that the hives have proper food stores. Food such as honeydew honey or honeys, with a large percentage of gums, which may cause a rapid accumulation of excrement in the bees, are un-

desirable, but may be corrected by inserting a frame of honey in the middle of the brood-chamber after brood-rearing has ceased. Another remedy for undesirable stores is to feed about 10 pounds of a syrup made of 2 parts granulated sugar to 1 part of water. In either case, when such food is given after brood-rearing has ceased, it will be placed by the bees in positions most available for immediate use, and the poorest food stores saved until spring. When the

air surrounding the bees is maintained at about 57 degrees, and no other irritating factor is present, the bees live so slowly that very little food is consumed, the colony being almost in a dormant condition. A normal colony of bees thus protected and fed not only will endure six months or more of confinement, but have sufficient vitality left to be useful when spring comes.

Washington, D. C.

DR. MILLER'S

ANSWERS

Send Questions either to the office of the American Bee Journal or direct to

DR. C. C. MILLER, MARENGO, ILL.

He does NOT answer bee-keeping questions by mail.

Swarms

1. Someone advises to treat against swarming as soon as the eggs in cup are noticed. I have tried it and feel that I do not like it. Now, will you state just how the colony must appear inside for you to apply the "put-up" or other procedure for the same purpose? Let there be considered four stages, to-wit: (1). Egg in cups. (2). Young uncapped queen-cells. (3). Same as 2, but just about as big as capped. (4). Capped or sealed. At which of these stages do you operate? If you notice 1, 2 or 3, do you do anything, or just let them develop?

2. When you make nuclei with 3 or 4 frames, about what per cent are successful with first attempt?

3. Would you do anything in particular if you noticed rather commonly on the lower rim of brood-frame, capped drone-comb above worker-comb honey?

4. A week or so ago I received one-half dozen queens. I divided that many colonies: most all the brood and the new queen on a new stand. Today I found the latter with very small queens, and in each of that three, a lot of queen-cells. I concluded to leave in each of them the best queen-cell, without interfering with the queen. What do you think of that.

5. The following has happened: I had a swarm; secured it put the swarm on the old stand and the parent hive on a new stand. Some time after, that parent hive swarmed, but on investigation (I secured the swarm), in neither hive could anything like a queen-cell be found. Yesterday that same "parent hive" swarmed again. I secured it and today found just the same state of affairs. That "parent hive" by the swarming is resplit, but in neither part was there any queen-cell or anything like it. Another queer thing to me is, the swarm I put on the old stand (the last one to swarm), and parent hive No. 2, located aside, has many more bees than the hive I put on the old stand. To the last of these I gave queen-cells. Today another hive swarmed, also arisen from brood put on a new stand. I secured it and put the swarm on the old stand and the other part next to it. On finishing the work of the day I looked at these two, and again found that the hive aside has many more bees than the swarm proper placed on the original stand. In the parent hive of this I neither found anything of the nature of a queen-cell. I did not look through the swarm, as I did not care to disturb it so soon after hiving.

PENNSYLVANIA.

ANSWERS.—1. The first time around, everything in the way of a queen-cell is killed, whether it be an egg in a cup or a sealed cell. On the next round, perhaps ten days later, if the case comes under your 1 or 2, the cells are killed, and same thing upon succeeding rounds. In other words, no treatment is undertaken so long as nothing but eggs or quite young larvae are found. At any time after the first round, cases 3 and 4 are put under treatment.

2. About 100 per cent, if you mean success in forming the nuclei and having the bees stay

on their new stand. If you mean the number of cases in which the young queen succeeds to the point of laying, I should guess somewhere in the neighborhood of 75 per cent.

3. The drone-comb should be cut out, even if nothing were done but to leave the vacancy to be filled again by the bees with drone-comb; but it would be better to fill up the vacancy with a patch of worker-comb.

4. It often happens that a queen will not at first be allowed to lay, and if looked after a few days later the queen may be found missing, or she may be found laying. If she is still alive, I think her chances for continued life will be better if all cells are killed. A good many times cells will be started when a queen is introduced, and then the bees, if left to themselves, destroy the cells. It was entirely natural that the queens should be small so long as not in full laying.

5. When an aftermath issues, there should at least be found an empty cell from which the queen emerged. If none was really present, it looks as if it might be that the bees swarmed out with the virgin on her wedding trip. I don't understand why more bees should be in the old hive than in the swarm, unless enough time had elapsed for a force to hatch out, although there might be such a thing as part of the swarm returning.

Raising Queens

I have a suggestion as to raising queens which may be helpful to someone, and I have not seen the plan in print. I have several queen-excluders covered with wire screens and several hives with a three-fourths-inch hole bored in one end, with a piece of tin tacked under the hole and bent down for a door-stop. When I find a queen-cell I want to save I put my screened excluder over any colony I may select with my hive with a hole facing the front on top and raise two or three frames of brood from below, or from any source desired, and give them the frame with the queen-cell. When the queen is hatched and mated I can use her when I please, and removing my screened excluders leaves the colony intact. I find three advantages with this manipulation. 1st, it is simple and convenient to assemble with no extra equipment. 2nd, colonies are not broken up to form mating nuclei, and 3rd, if the new queen is raised over the colony where we wish to requeen, all we have to do when the young queen gets to laying is to remove the old queen and put the young queen and bees from the upper story in the lower story, with no introducing necessary. There is another advantage, in cool weather the bees from the full colony below help to keep our nuclei warm.

The plan of rearing queens above a colony with a laying queen dates back some years, and is mentioned by Doolittle in his book on

queen-rearing, written more than a quarter of a century ago. But the fact that one engaged in beekeeping several years has not seen it in print shows that it does not enjoy the publicity that it deserves, especially considering the advantages enumerated by our correspondent.

In the practice of others, the bees in the upper story are not entirely shut off from communication with the bees in the brood-chamber below, all that is necessary being an excluder over the brood-chamber. Indeed, in the first case on record there was not even a queen-excluder; four or five stories of empty brood-combs were piled upon a brood-chamber and a frame of brood put in the upper story. The bees reared a queen from the brood given, the queen laid, and a brood-nest was established.

Neither is it necessary to bore a hole in the upper story. The cover of the hive may be shoved forward enough to allow passage for the queen, or the body itself may be shoved forward to make the passage.

It seems to be a matter of some importance that the brood be as far as possible from the lower story containing the queen. If brood is put into a story immediately above the excluder, the chances are that no cells will be started, although if cells already started are put there they are likely to be rejected.

It should be added that not all are successful in getting queens to laying in an upper story at all times, the queens disappearing about the time they should begin to lay.

Mismatched Queens

Last summer a swarm issued from one of my hives. They were pure Golden Italian bees. I think the old queen was lost, because they tried to swarm before, but came back. A week later they swarmed again. I hived them in a new hive and a week later I examined this hive and found the queen. I think that she was a virgin that went with the swarm, because she was so small. The old queen was so large. Now there are bees in the hive that are black, some three-banded, and some golden bees. I wintered them in a two-story hive. They are now in excellent condition, as they have thirteen frames that have brood and plenty of honey and bees. I think the queen is mismatched. The bees are cross and not very quiet on the comb. Do you think that requeening would be all right? She is a good queen and I hate to kill her on account of her prolificness. The bees are continually fighting at the entrance. Do you think it is their own bees, or robber bees? What would you advise me to do? MINNESOTA.

ANSWER.—You are correct that the queen has mated with a drone of undesirable stock. But as she is doing such fine work, I think I would leave her undisturbed, at least until near the close of the season, provided you can stand the crossness of the bees. I don't know just what to think of the fighting at the entrance. It is more likely robbers than bees of the colony fighting among themselves—indeed the latter is not at all likely—but it seems strange that it should be a continuous performance, especially since the colony is strong.

Uniting

I have been told that to unite weak colonies of bees in the spring makes them no stronger. You say unite in the fall. Please write in the American Bee Journal explaining why it doesn't do in the spring to make one or more out of many weak ones and best plan to do so. If a hive is reasonably strong in the fall and hives to spare, which do you recommend, smother what you don't want, or unite? ONTARIO.

ANSWER.—If in the spring you unite two colonies that are weak and in good condition, the united colony will be stronger than either of the separate colonies was. But if you have one or more colonies that are what are called "dwindling," and unite them together, the united colony seems to dwindle in a short time to as little as either of the separate colonies, if

not less. Just why it is so I don't know.

The best way to unite two colonies is to put over one of them a sheet of newspaper, and over this set the other hive without any bottom. The bees will gnaw a hole through the paper, get together gradually, and unite without quarreling.

If I should want to make the number of colonies less in the fall, I would do it by uniting.

Time to Catch Drones

1. When is the proper time to catch drones? I had two swarms come off, and the old one was full of drones; so I used the drone-trap and destroyed them.

2. One swarm came off three times and went back each time to the old hive; so I trapped all the drones and queen and they seem fine now. Why did they go back so many times; the hive was a new one, with fresh starters.

3. If I have a new idea along the bee fixture line that I know is a good one, at least a big time saver, how am I going to protect myself so as to put my plan out for investigation and not have it taken by me, and if other people think it O. K., then have it patented? MINNESOTA.

ANSWERS.—1. You did all right, but the best time to catch drones is before they are born. Use full sheets of worker foundation, so there will be no chance to rear a lot of useless consumers. If you already have combs containing drone-comb, a good plan is to cut out the drone-comb and fill its place with patches of worker-comb.

2. I don't know why it is that a swarm will sometimes return and then issue again; possibly in some cases because the queen has difficulty in flying with the swarm; and in some cases it may be that a virgin may make her nuptial flight. I don't suppose that trapping the drones had any effect in making the bees stay.

3. Beekeepers are a considerable lot, and anxious to give credit where credit is due. But if you expect to patent anything, it should not be published in advance. One way is to submit your plan to some experienced beekeeper and get his opinion about it. But it's dollars to doughnuts that when a raw recruit has made a valuable discovery it will turn out to be something known years ago.

Swarming—Foulbrood

1. When a prime swarm issues from a hive, will another come out if I cut all remaining cells but one and leave the old hive on the same stand?

2. I hived a new swarm and put it next to the old stand and moved the parent colony on the eighth day. A few days afterwards a second swarm came out of the old hive. Why was that?

3. I have a foulbrood colony. I found the queen, put her on a healthy brood-frame from another colony, filled out the new chamber with foundation and placed the diseased colony over an escape-board on top of new chamber, so as to get the bees out of the diseased hive. Will that cure them?

4. Can I hive a prime swarm on starters, cut out all cells and place old brood-chamber on top of swarm and make the new swarm stay and work for extracted honey in top chamber without swarming again? NEW YORK.

ANSWERS.—2. It was an exceptional case, occurring because the old colony had become so strong it thought it could afford to swarm. Usually the first afterswarm issues something like eight days after the prime swarm, and moving the hive just before the afterswarm would issue puts the colony in too discouraged a condition to swarm "A few days afterward" sorry you didn't say just how many days gave time enough for the colony to recuperate. Eight days and then "a few days" more between the prime swarm and the first afterswarm is something quite unusual.

3. Possibly it may if the case is European, not if American.

4. Yes.

Purple Martin

Do purple martins eat bees? I recently purchased several colonies of bees and have been told that the purple martins eat bees. If they do I regret it very much, as I have some 30 or 40 pairs of martins that build on my place every year. Personally I do not believe that they do eat bees. What I mean by the purple martin is the martin that comes each summer and builds in boxes or gourds prepared for them, raise their young and immediately go south again. I don't know whether or not these martins go as far north as Illinois or not. The male is a black purple all over, while the females have a gray breast. All over the south boxes and gourds are put up on poles for these martins to build in and they will not allow a hawk to come near where they are raising their young. They make a peculiar clicking sound entirely different from the noise made by any bird. They are not the bee martin, or what is known as the king bird. ALABAMA.

ANSWER.—I am sorry to say that the purple martin (*Progne subis*) is a rather rare bird in the extreme northern part of Illinois, where I live, although plentiful in my boyhood home in western Pennsylvania, while it lived mostly—I rather think altogether—in little houses or boxes built specially for it, and put up on the tops of poles or else on buildings. I think you are entirely right in counting it innocent of the slaughter of bees.

Hoffman Frames—Foulbrood

1. Why are the bottom-bars of the Hoffman frames so narrow? I should think it would be better to have them as wide as the ends.

2. What causes foulbrood, both American and European? Now don't tell me it is caused by feeding foulbroody honey, for I know that will cause it to spread, but what are the conditions that are favorable for the breeding of the germs that cause it?

3. Would there be any danger in feeding wild honey that is so contaminated by bark, rotten wood, etc., and is unfit for table use, if it is gathered by healthy bees? PENNSYLVANIA.

ANSWERS.—1. I am not sure what are the principal reasons for narrow bottom-bars. One reason may be that the frames are sometimes used to hold extracting-combs, and a narrow bottom-bar is less in the way of the uncapping knife. I am rather partial to frames having end-bars and bottom-bars the same width as top-bars, and have been using them for years.

2. A microbe is the villain that starts the trouble, just as seeds of weeds make trouble in the garden. A weak colony and a weak strain of bees is favorable to its growth. A strong colony of bees with a pure Italian queen is favorable to prevention, and some think that such bees will almost entirely prevent the encroachment of European foulbrood.

3. Such honey will be all right to feed to bees.

Artificial Increase

1. In your October, (1917) number Mr. Pellet describes a method of artificial increase which I propose to try out next year, if I can be satisfied on one point, viz.: How long does it take for the bees to come and go through the auger hole in top story when this story is moved to a new location? In Mr. Pellet's example 41 days intervened from time of placing story on top and removing same. All brood in this story would, therefore, have hatched, and there should be a great quantity of field bees which know no other entrance than the auger hole. When top story is removed I should expect quite a swarm looking for that hole. Is it likely the bees will find the entrance to the hive below, and, if they did, is there not danger of them being regarded as intruders by the bottom colony, as the two hives have really been separated for a long time? This, of course, could be overcome by plugging the hole after the queen had been mated, when top bees would be forced to exit below. However, as that is not suggested by Mr. Pellet, I should like to know what happens.

2. Do you recommend two stories for wintering, as described by Mr. Romain on page 579 of your November (1917) number? I propose trying this plan next winter, if you think it O. K., but would utilize half-stories, not

having sufficient full-depth stories. Do you adopt the plan?

BRITISH COLUMBIA.

ANSWERS.—1. You are quite right; when the upper story is set on a new stand all the field bees, upon their return from their first trip to the fields, instead of going to their new home will go to the old location. I've watched with much interest their behavior when they find their accustomed entrance gone. They fly about the place for some time in evident confusion and distress, and finally settle in a cluster upon the part of the hive nearest to where they think their entrance should be. After a time some bee of inquiring turn of mind begins to explore for an entrance and finds the nearest one, even if none is nearer than the regular entrance at the bottom of the hive. Then she sets up a call, and it isn't very long before a line of march is started and the whole outfit make their way to the entrance. There is no quarreling; if the bees have been separated only by an excluder they will have the same hive odor. Even if entirely separated, as I have often had them, there will be no quarreling, probably because the bees coming from the field bring a peace-offering with them.

2. Wintering a colony over an empty hive is a plan in use many years ago, being especially championed by Rev. W. F. Clarke, and I don't remember that anyone who used it ever reported anything objectionable in it. I don't use the plan, as I winter in the cellar.

Raising Queens—Requeening

1. Is it more assured to attempt making a colony queenless by giving a frame of eggs for same to raise queen-cells than it would be to give a queen-cell from another colony?

2. In a publication I have, it is stated that a good way to requeen is to place a hatching queen-cell in the "super" of the colony to be requeened and paying not attention to the "inferior" queen below; chances being that the virgin will kill the old queen "below." Is it necessary for the above to have a super on the colony, supposing one is mostly in comb honey, and therefore having supers unfit as stated; does it do as well to insert in the brood-chamber a frame from another colony having a queen-cell? Two of my colonies had just one capped queen-cell. As eggs were there I presume the colonies had queens. Do you think they would have requeened without swarming from that one queen-cell? In each case the queen-cell was raised by the colony in question. PENNSYLVANIA.

ANSWERS.—1. I cannot answer too positively, but I suppose that bees conscious of their queenlessness have as much respect for a queen-cell, sealed or unsealed, that is given from another colony, as they do for one started from an egg or larva of their own brood. It is possible, however, that you might be a little more sure of success by giving a frame of eggs and young brood than you would by giving a queen-cell, for bees are somewhat notional, sometimes tearing down cells, even of their own building, when you can see no good reason for it.

2. If a queen-cell were put in a super, with no excluder under, I would expect in most cases that the virgin would be killed upon entering the brood-chamber. If, however, the old queen were one that the bees were about to supersede, the virgin would likely be allowed to take her place. If a frame having a queen-cell, from another colony, were inserted in the brood-chamber, the bees would pretty certainly tear it down unless they contemplated either swarming or superseding. In the case where there was only one queen-cell, and that sealed, it's a very safe guess that superseding was intended, and not swarming.

Apiary on Shares

I am writing to ask what is customary in the purchase where one leases ground for the purpose of placing an apiary, the rent to be

taken out in pounds of honey. How much honey should the owner of the land expect?
KENTUCKY.

ANSWER.—There is no rule, and no two cases are exactly alike. One man wants the bees on his place for the good they will do in the fertilization of fruit blossoms or other blossoms, and he wants no pay, and indeed would pay something rather than not have them. Another is not interested in bees, is afraid of them and wouldn't have them on the place for any price. In one case a fixed price of \$5 or \$10 a year is paid; in another 5 or 10 cents a colony. In one case where land is of very high value, the rent should be ten times as much as upon land of little value. If honey is given as pay, its honey value should be considered. A certain per cent of the crop might be given; one or more pounds for every hundred. In any case, if the site is desirable, the compensation should be such that the owner of the ground shall be more than satisfied, and shall want a continuance.

Robbing

Why does a strong colony of bees with a good queen and plenty of eggs let other bees carry out their honey? How can I prevent it?
MICHIGAN.

ANSWER.—It is doubtful whether a strong colony in good condition was ever robbed unless the keeper did some fool thing to start the robbing. When honey is coming in plentifully there is little danger of robbing; but when the flow stops, look out. Don't open a hive unnecessarily and give the robbers a start. If a weak or queenless colony is attacked by robbers, if you take it away, leaving nothing in its place, the robbers may pitch onto a strong colony close by, and overcome it. So leave the hive in its place until they have cleaned it out, or else put in its place another hive with empty combs, or perhaps a little honey, and when they have cleaned that up they will go about their business without troubling the strong colony. Be careful about spilling honey or leaving bits of comb with honey lying around.

Swarms

Does a prime swarm have swarms the first year?
WISCONSIN.

ANSWER.—When you have a swarm, you may feel pretty safe against its swarming before the next year. Occasionally, however, a swarm does itself throw out a swarm, which is called a virgin swarm.

Clipped Queens

1. Referring to your answer No. 2 to Idaho, in June number of American Bee Journal, I ask how would the owner know in the evening or later that the colony had swarmed?

2. If the queen had been clipped instead of being kept in the excluder, how could he know?

3. If the queen is not clipped and no excluder is over the entrance, can it be learned whether a colony has swarmed or not?

4. I have sufficient drawn combs for this season, but many are imperfect. I wish better ones for next season. The best of the flow will soon be over, but some nectar will be coming in till frost. Is it practical to get these combs drawn from full sheets of foundation this season, and if so, what is the best way?

ANSWERS.—1. If an excluder is used at the entrance it will be in the form of a queen-trap. Her presence there is sure proof that the bees have swarmed.

2. When the queen is clipped and the swarm issues, it generally returns upon finding the queen is not with it. In that case, it is not easy to tell that a swarm has issued, and only a guess can be made if sealed queen-cells are found in the hive.

3. Only guessing can be done; but if the colony seems weakened in bees, and dead cells

are found in the hive, swarming may be guessed.

4. Comb-building can be induced only by a natural flow or feeding. If there is no natural flow the feeding must be heavy, and it is hardly worth while to try to get comb built when the bees are not getting enough from the fields to get honey to put in the combs they build. For there is no way to get the bees to build comb that is not immediately put to use either for brood or honey.

Introducing Queens

What do you think of the following?

1. Two queens were bought and were placed with most all the brood of the respective colonies on June 24. Queens were accepted and eggs found on first examination. In colony No. 1, on the 7th of July, were many cups with eggs and queen-cells very young; the queen was present. Colony 26 did not have a queen but had a solitary capped queen-cell. To both colonies comb supers were given and good work done therein.

2. I took a queen from colony No. 2 and soon found a queen-cell. After while I found another just like it. The colony has not swarmed as yet. When I went to destroy the queen-cell I liberated a queen. She came out of the cell as I went at it. I put her in colony No. 34, which I had noticed was queenless but had a capped queen-cell. What do you think will become of colony No. 2 and No. 34?
PENNSYLVANIA.

ANSWERS.—1. Colony No. 1 had queen-cells present a week after the introduction of a new queen, the cells containing eggs or brood of the new queen. That's a thing that happens quite often when a new queen is introduced; and I think such cells are usually destroyed by the bees, but sometimes they are left and the queen superseded. In the case of colony No. 26, superseded evidently took place.

2. Judging from the empty queen-cells present, the probability is that a free virgin was in colony No. 2, which will be laying in less than two weeks. The virgin given to No. 34 was probably killed, having no effect whatever on the condition of the colony.

Swarm Prevention

1. I had a colony in an S-frame hive that wintered well. On May 5 I took an empty hive-body, put full sheets of foundation in it and put it under the brood-chamber, thinking they would not swarm; but they did not work down. On June 13 they sent out a swarm; it was hived and put on the stand of the parent colony, moving the parent colony so there was about 3 feet between them. Was that too far?

2. I would like to know why the bees didn't work down in the extra hive-body I gave them. Was it too late in the season?

3. The swarm that came out June 13 was given supers 2 days later, but on June 25, 12 days after they were hived, they sent out a swarm, and on July 5 a second swarm. How can you account for that, so soon after they were hived? I gave them one frame of brood when I hived them, the rest full sheets of foundation. This is the first time I have tried to exchange places with the swarm and the parent colony; it kept the parent colony from swarming any more, all right, but what is gained?
MICHIGAN.

ANSWERS.—1. Yes, it was too far. You should have set the swarm on the old stand and the old hive as close to it as possible without touching; then, 7 or 8 days later, moved the old hive to a new stand 10 feet or more distant.

2. I don't know why they didn't work down. Looks like pure cussedness, for any decent colony ought to have done so. As you gave them the extra room below May 5, and they swarmed June 13, it looks as if there was no excuse for them. Like enough you will not find it happen so again.

3. Giving that frame of brood may have made the trouble. Some think it advisable to give such frame, and then take it away after 2 or 3 days. In this particular case perhaps little was gained, but generally there will be a decided gain, for a strong force of bees will

be on the old stand to do good work in supers, and even as it was it was a gain not to have the old colony split up into weak afterwarms.

Sweet Clover—Alfalfa

1. On page 85, American Bee Journal for March, 1918, we are told that "when cut for hay, sweet clover should be mown before it begins to bloom to any extent." But, alas for the poor bee! If this is the practice, what is the use of the plant as bee forage?

2. I bought some buckwheat seed and tried out a small patch for my bees. The blossom is white, and although the plants have been in, full bloom for two weeks, not a bee visits them, full bloom is the botanical name of the variety. My man, who at one time lived in Kansas, says the buckwheat there is a pinkish purple blossom, and a marked odor. Apparently I have gotten hold of the wrong kind. Can you give me the botanical name of the variety the bees visit?
BRITISH COLUMBIA.

ANSWERS.—1. Don't worry. In the west, where alfalfa honey is produced by the carload, the same rule holds, and alfalfa must be cut for hay before the bees have much chance at it, but one way and another it turns out that the bees get carloads. Some of it is left to grow for seed, and of course the bees get the full benefit of that, and some cut for hay will by some means be cut a bit late—well, you see, the honey is gotten, somehow. You'll find it the same way with sweet clover.

2. Your buckwheat is almost certainly all right. Whether you have Japanese, Silver-bull, or just common buckwheat, it's all *Fagopyrum esculentum*, and honey-yielding. I think you would call the blossoms white that grow here, although some of them may have a pinkish shade, and it is possible that in other regions the blossoms may be pink. Like most honey-plants, there are seasons when no nectar is yielded. I think, too, that it is rather early for it to yield well if it blooms in the first half of July, as it is considered not advisable to sow out what before about the first of July.

Ownership of a Swarm

If my bees swarm and go on some one else's property, whom do they belong to?

ANSWER.—If you follow them right up you can claim them.
NEW YORK.

Put-Up Plan

The way I do, the Put-up plan might be better called the Put-aside or Put-away plan. I do not like to set one hive on the other, so at first I set the hive with the queen in it aside of the parent hive; but as I thought that the bees in the "aside" were not staying well (flew over into the old hive), I set the hive with the queen quite a ways off. If I would grow to a thousand years I would not hunt up queens, nor endeavor to get them, but I would separate the queen by setting the parent hive off the stand and put the empty new hive in its place; then put into the latter a frame with little brood, another with honey, and also one with empty comb, and may add some frames with foundation. On all that I place a queen-excluder, and in front, up against entrance, a large board, and on that I brush the bees out of the parent hive; then place latter upon the excluder. Then I brush the bees on that board at the entrance, and the bees walk into the hive-body below. In the evening, or morning, I set aside the parent hive, and then pick up the new hive with the queen in it and set it away on a prepared stand; then put the parent hive on the old site. At the time the frames of brood into the parent hive I do the best I can to destroy all queen-cells but the best one. Three or four days later I look over the frames in the parent hive again for destruction of all but the one best cell.

Thus I rarely have any other than good luck in securing the queen in the hive. The only trouble is, that in the hive on the old stand, the new queen may not be blooming, and the bees act queerly; they swarm, come back, and in one case repeated that, and both times after that action, on examination, there seemed to be neither eggs nor queen-cells. I really expected eggs only 12 days after the operation of dividing. My hopes were that thus the parent hives would find themselves with

new queens instead of by returning the old queens. Is my way right, by rule? If so, why does it not work?

This way looks to me just about the same as Fred W. Hall's whom you call a good beekeeper in answer to the first question in July American Bee Journal, page 243.

The way I secure lots of bees for the hive I set off is, that before I take away that hive I shut up the bees in it by a special contrivance of my own of wire netting (no stuffing up with grass for me), then in two days I remove the wire netting affair, and thus there is no lack of bees with the queen in the set-away.

PENNSYLVANIA.

ANSWER.—One of the pleasures of beekeeping is the constant opportunity to try new things and to do things differently, generally finding them turn out failures, but occasionally scoring a success. It's a good thing, but a good thing may be carried too far, and in your beekeeping you're an ultraist of the ultraists. If anything is common practice among beekeepers, that's reason enough for you to be fornest it. If they stuff grass in entrances, it's "no stuffing up with grass for me," if they hunt up queens, it's not for you in a thousand years, and you'll go to twice the trouble to avoid it. If you keep on some day it will occur to you that most beekeepers use hives with 8, 10 or more frames, and you'll decide to use only five, and then want it explained why you don't get bumper crops. I can sympathize with you in your discouragement. I've tried fool things enough to make quite a book, and felt the chagrin of failure; but when we find, as you say, "nothing works," we can quit doing so many things differently, do the same as others do and then there's no reason why we should not have as good success as they.

You can put the hive with the queen on a distant stand, and I sometimes do so if only a frame or two of brood are taken with her, but if a considerable amount of brood and bees is taken with her I prefer to put up on top, so as to keep the whole force of bees with the colony at the old stand; for if set for some days on a separate stand a goodly number of field bees would be left at the new stand.

As to the bees swarming out, it may be that you left more than one cell. Often a queen-cell is so hidden that one must be an expert at finding cells not to miss it, and if two cells are left in the hive the bees are practically certain to swarm. It is possible, also, that when the young queen went on her wedding trip the bees swarmed out with her.

My understanding of F. W. Hall's plan is that he removes the old queen and then destroys all queen-cells but one. That gives him the great advantage that he has a young laying queen in each hive, and the chance of such a queen swarming is a negligible quantity. While the plan is excellent in that respect, it is not every one who would want to adopt it, for it has the disadvantage of a rather bad break in egg-laying from the time the old queen is killed until the young one begins to lay, which may be as much as three weeks. Those who are working for constant improvement of stock will also object that the annual renewal of the queen does not favor the full testing of each queen so as to allow the selection of the best as a breeder. Mr. Hall is a very pleasant gentleman as well as a successful beekeeper, and when he sees this, if he finds any misrepresentation I shall be glad to be corrected by him. But the Hall plan is hardly for you, since hunting up queens is an essential part of the plan.

Queens—Feeding for Winter

I bought a nice queen bee in June of this year and she came in good shape, as far as I know about bees. I put her in a new colony,

which had been 10 days without a queen. About four or five days later I looked in to see what she had done and found that she had laid a lot of eggs, and in some of the cells were two eggs. I looked in again on the 17th and found that the queen was there, but not a single egg had been hatched out. Why is it that they will not hatch out? Do you think that the eggs will hatch this summer?

I also bought another queen, and I put her in the colony which I had just made queenless, and the bees received her all right. She has been in the hive for about 14 days, but has not laid any eggs.

3. I also find that my bees will not get more than 3 or 4 combs drawn out this summer. I put each swarm of bees on ten full sheets of comb foundation to each hive. Should I leave the undrawn sheets in each of the hives, or must I take out what is not drawn out and put them away for next spring?

4. My bees have not gathered honey as yet. The cotton is blooming here and it will bloom until about frost. I do not want to feed my bees until I have to. We have frost in the middle or latter part of October if we have an early fall, and if we have a late fall it will be the first of November before frost will set in to kill all kinds of crops that bloom. About what time in the fall would you start feeding my bees for the winter?

5. Can you furnish me honey to take on, and how much to each hive will it take, and at what price, or would it be better for me to feed sugar syrup? If sugar is used, how much should be used to the hive? Should it be cooked to a thick syrup? Will three-fourths syrup and one-fourth honey be a good feed?

6. Will I have to buy a feeder, or can you give me a good plan as to how to make a good feeder? I am thinking of putting on an empty super and having a tin box made, say about 12 or 14 inches long, 10 or 12 inches wide and 2 or 4 inches deep.

7. If any of the honey or sugar syrup runs out in the hive out of the feeder, will it drown the bees or cause robbing?

NORTH CAROLINA.

ANSWERS.—1. I have had a very few queens in my lifetime, perhaps not more than two or three whose eggs never hatched. I suppose from some defect in the queen. I don't suppose the eggs of this queen of yours will ever hatch.

2. Sometimes it happens that a queen is triterated by the bees a considerable time, although not allowed to lay, and then she may lay all right; or, she may be then killed. I wouldn't be very hopeful about yours.

3. The sheets of foundation that are not drawn out should not be left with the bees over winter. Indeed, it is not best to leave them there now, if the bees are making no use of them, for they are likely to daub them with bee-glue, and I have known them to daub foundation so badly that they would never draw it out afterward. So if they are making no use of it, it will be well to take it out until honey is yielding again, or until you feed.

4. It would be better to feed before everything is frozen; but to say you do not want to feed until you are bound to, you may as well wait till after frost, whether that comes early or late.

5. It is quite possible that your bees will get enough for winter from the late flow, but if not, I think Dadant and Sons can supply your needs, but would hardly be able to quote a price until later. Each colony should have not less than 30 pounds of honey, or its equivalent in sugar syrup; and 40 pounds would be still better. If you feed sugar syrup, it needs no cooking, only so that the sugar is dissolved. But it will dissolve more rapidly if you stir the sugar slowly into boiling water. Whatever you do, don't scorch it if you don't want to kill your bees. For such late feeding, sugar syrup should be thick, say at the rate of 5 pounds of granulated sugar to 2 pounds or pints of water. I would rather have honey than sugar for winter food, although some prefer sugar. At any rate, at the present prices of honey and sugar most beekeepers

would feed at least part sugar. I would very much rather feed the mixture you propose (one-fourth honey and three-fourths syrup) than to feed all sugar. If you feed all sugar you should use a level teaspoonful of tartaric acid to 20 pounds of sugar. If you use one-fourth honey, no acid will be needed.

6. For feeding you can use a box such as you propose, preferably of wood with melted paraffin or wax run around the corners, but there must be something to keep the bees from drowning, such as excelsior or cork chips.

7. There would be hardly any danger of drowning bees with a leaky feeder, but there would be danger of robbing. Feeding after bees stop flying in the evening makes the danger less.

Laying-Worker

This spring I purchased two colonies for \$25. I determined to run principally for experience, with possibly some increase this year. My first swarm came on June 18, I divided them on the old stand, gave them a full depth super, full of sheets of foundation. This colony has today two supers, seven frames full, and working like mad. On June 15 I hived what I first thought to be a swarm from my second colony, but on finding a queen in the hive of the second colony as well as with the swarm, I decided that it was an after-swarm from No. 1. I hived them and after two hours this swarm was in the French leave and left me where I was before.

I then, that day, June 15, went through my first colony, the one which swarmed two days before, and found not only the queen, but five or six ripe queen-cells. This certainly put me up in the air, so I decided that right here was where I began to do my first turn of increase. I took two frames of bees and brood with two cells, put them in a hive with two full sheets of foundation and sat down to await developments. In due time I went through my small nucleus and found both cells had hatched, but was never able to find a queen among them. Otherwise this division appeared to be contented and was bringing in nectar and pollen; however, in a short time I began to suspect laying workers. I found worker cells capped with drone cappings. I could not find queen-cells any place, so I took another frame of brood from the original hive. I had replaced the first two with foundation, and this made three frames taken from this hive. The division, however, did not build any cells on the third frame, and to my surprise, I began to find not only worker cells with drone caps, but also a few worker cells on the first frames with regular worker cappings. Here was another nut for me to crack. I had ordered queen from a breeder, realizing that my chances for a successful introduction was slim, and now I have read in the American Bee Journal for August an article by John H. Lovell on Parthenogenesis, in which the theory is that at times laying workers produce both drones and workers. So now, after what I fear a long drawn out introduction which will likely tire out your patience, I have arrived at a question.

First—Do laying workers at times produce both drones and workers? If so, what will be the functions of such workers produced from layer eggs?

Second—We are led to believe that bees work largely from instinct, governed largely by work necessity, and are not the intelligent creatures which fiction has sometimes led us to believe; then how do bees, in your opinion, differentiate between infertile eggs laid by workers in work cells and thus cap them with drone cappings?

These are the questions which are particularly disturbing me, although there are a hundred and one other which would like to know just exactly what is your opinion about. I will not, however, take the attitude of a Socratic questioner, who asks you asking you to ask one hundred and fifty questions, and answer them at the same time. I will, however, later buy your book, "One Thousand Questions," etc., and possibly I will find some of them already answered.

I have read several books on beekeeping and without attempting to flatter you, my dear Doctor, I can truthfully say that I never read any book which gave me the keen delight which your "Fifty Years Among the Bees" did.

I, with the rest of the bee world, big and

little, have become accustomed to reading not only in your delightful book but in your correspondence in *Gleanings* and the *American Bee Journal*, your characteristic "I don't know," and also your little joke, "I don't know enough to answer," but you do not fool us any; if you do not know, who does? My opinion is that you probably know as much about bees as any man could who is no older than you are and has devoted practically his whole life to the study; but as a man of high intelligence, you are only resorting to these harmless subterfuges in the knowledge that some of the works of old man Nature are beyond human understanding. For instance, we are led to believe by all writers that certain bees function in certain things at certain times. The "books" say young bees build comb, feed young larvae, do sentry work, etc., and goes on and says that they change and relieve each other at times. I shall not be simple enough to ask you why at certain times or what is the ruling spirit of a colony of bees—in short, who is the "boss," and what prompts these "insects with small intelligence" to do these things so methodically, but I would like to know just the same. In my small way I have found out, however, that they will often do the unexpected, and that "Old Man Experience" is about the best criterion to go by, and sometimes he fails.

W. E. MEANS.

ANSWER.—The story of your experiences, which you call "a long drawn out introduction," is very interesting, and I'm glad you gave it. If your question about workers being produced from the eggs of laying workers had been asked before the appearance of the *August American Bee Journal*, I should have replied that in no case do anything but drones proceed from the eggs of laying workers; but that if by any means laying workers should get into the business of rearing workers, I should expect them to be no whit different from workers in general, as to all their functions. But in the *August* number, page 270, John H. Lovell says: "It is less surprising to learn that in some instances there are laying workers of the honeybee which can also produce both drones and females." Prof. Lovell is a man for whose assertion I have high respect, and, moreover, he is a man for whom I have a decided liking, although I have never seen him. Yet, in spite of all that, I do not feel inclined to make much change in my answer, nor, indeed, to make any change, except to add, "the exceptions to the rule are so exceedingly rare as to be not worth considering in actual practice." And I feel warranted in saying this from the fact that for a good many years I have been reading a large part of what has been said about bees, and never before have I heard of such a thing as a worker bee being produced from the egg of a laying worker.

Now, it would be just like you to think—even if you don't say—"But how about that flat capping in the case of my own laying workers?" Well, if you don't mind, let's go back and look over your story. In the first place, although you raise no question about it, it is interesting to note that you report a prime swarm June 13, and an afterwarm June 15. Only two days between the prime swarm and the first afterwarm, although the rule is that the first afterwarm comes about 8 days after the prime swarm. It may happen, however, that when the first queen-cell is sealed, at which time the prime swarm issues generally, the weather may be bad, so as to delay the issuing of the prime swarm a day or more, thus lessening the time between the prime swarm and the first afterwarm. But to have the weather so bad continuously as to delay the issuing of the prime swarm 6 days is something unusual, and I feel inclined to account for the closeness of those two swarms in another way. Here's what may have happened: About June 5 a prime swarm issued without being observed by you, and the queen was in some way lost. Such things happen.

The swarm, being queenless, returned to the hive. June 13 the first afterwarm issued, and June 15 the second afterwarm. All of which is merely by the way.

(We come now to the nucleus charged with having laying workers. Pardon me if I say I don't believe there were any laying workers in the case, but a laying queen. You say you did not find a queen. That proves nothing. Queens are not always found, even when we are sure they are present. "But the drone brood?" Well, it often happens that a young queen seems not to get the hang of properly laying for some time, and a large part, or all, of her brood, is drone brood, and later she performs all right. Sometimes, also it happens that a young queen lays mostly drone eggs, and continues to do so as long as she lives.

You want to know how bees differentiate between the two kinds of eggs when both are laid in worker-cells. That's easy, at least if guesses are allowed. The drone-larva is so much larger than the worker-larva that the bees are obliged to build a canopy over it if they cover it at all.

You might send on, say about a dozen, of the 101 questions you have on hand. Maybe I can match most of them by drawing on the pigeon-hole labeled "I don't know."

UNITED STATES DEPARTMENT OF AGRICULTURE

Bureau of Markets

Honey arrivals since last report:

Medina, O.—Alabama 1133 lbs., Mississippi 26,971 lbs., North Carolina 15,665 lbs., Florida 11,284 lbs.

Shipping point information, August 14:

Los Angeles, Calif.—Supplies cleaning up. Demand active, firm feeling. Cash to producer on farm—Extracted: White, 21½-23c; light amber, 20½-21½c; amber, a few sales at 15-18c per lb. Comb honey: \$6-6.50 per case. Beeswax: 34-36c per lb.

San Francisco, Cal.—Shipments liberal. Demand and movement good, steady feeling. Wagon loads track side—Extracted: per lb., water white, 22-23c; sage white, 21-22½c; Alfalfa white, 20-21c; light amber, 19-20c; dark amber, 15-16c. Beeswax, 33-35c per lb.

Caldwell, Idaho—(unofficial) — No sales. Inquiry steady. Crop not made yet.

Yakima, Wash. (unofficial)—Shipments light. Growers holding for higher prices. Few sales reported. Cash to producers: Alfalfa white, in 5-gal. cans, 22½c per lb.

Portland, Ore., Aug. 14.—Demand active, strong feeling, some growers holding for higher prices. Cash to producers—Extracted: Amber, 15-18c per lb.; light amber, 17-21c; white, 20-24c. Comb honey: \$4.75-5.25 per case. Sales to manufacturers: Amber, 18c per lb.; light, 22c; white, 25c. Sales direct to retailers—Extracted: Water white alfalfa, 5-gal. jackets, 27c per lb.; 2-gal jackets, 29c per lb.

Spokane—Receipts very light. Sales direct to retailers—Yakima district: Alfalfa white, in 5-gal. cans, 25c per lb.

Cincinnati—1,700 lbs Florida, 988 lbs. Kentucky, 3,510 lbs. Alabama arrived. Supplies very light. Demand

and movement slow, market firm, few sales. Sales to jobbers—Extracted: California, white orange, 25-26c per lb. Beeswax: Demand and movement slow, market steady, few sales. Average yellow, 37-40c per lb.

Denver—Approximately 100,000 lbs. extracted, 1,399 cases comb arrived. Demand and movement good, firm feeling. Quality and condition generally good. Sales to jobbers—Comb, 24-section cases, No. 1 white, \$6.50; No. 2, \$6. Extracted: White to light amber, 23-25c per lb.

Kansas City—14,200 packages by express and approximately 750 lbs. extracted by freight arrived. Receipts very light. Demand poor, movement limited, weak feeling. Sales to jobbers—Comb: Native Missouri, quality and condition generally good, 24-section flat cases, light, \$6.50-7.50. Extracted, quality and condition generally good, 18-23c per lb. Beeswax: Receipts very light. Supplies light. Demand light, movement limited, firm feeling. Sales to jobbers, 35-38c per lb.

New York—317 bbls. and 25 tierces Porto Rico, 1 car California. Receipts moderate, demand light, movement slow, market firm. Sales to jobbers—Extracted, per gal., Porto Rican, \$2.35-2.45, mostly \$2.40; California, light amber, \$3.00-3.12; white, \$3.20-3.25. Beeswax: Arrivals 178 bags West Indies; 4 bbls., 8 boxes, 19 bales, 6 bags Porto Rico; 42 bags Cuba. Receipts increasing. Demand and movement good; market firm. Per pound, yellow, 43-44c; dark, 42-43c; some poorer as low as 37c.

St. Louis — No arrivals. Supplies light. Too few sales to establish market.

Chicago — Supplies light. Demand and movement moderate. Sales to jobbers—Extracted: White, 23-24c; amber, 21-22c per lb. Comb, No. 1, 27-28c per lb. Beeswax: Prime 33-38c per lb.

Minneapolis — Minnesota receipts very light. Supplies cleaned up. Very few sales. Sales direct to retailers—Comb honey: 24-section cases, \$6.50. Extracted: No supplies.

Philadelphia, Aug. 16.—Arrivals: 7,000 lbs. New York, 4,000 lbs. New Jersey, 1 car California, 3,000 lbs. Pennsylvania, 90,000 lbs. Florida. Sales principally to soft drink dealers; New York, Pennsylvania, New Jersey, 5-gal. cans extracted, 20-22c, mostly 20c per lb.; Florida and domestic, 22c; California, bulk, 22½c per lb.

St. Paul—Minnesota receipts very light. Supplies cleaned up. Very few sales. Sales direct to retailers—Comb honey; 24-section cases, \$6.50. Extracted: No supplies.

COUNCIL BLUFFS, IOWA

"Practical Queen-Rearing"

Is the title of the new bee book, cloth bound, 100 pages, which has just been written by Mr. Frank C. Pellett, who is well known to our readers.

For many years there has been a demand for a book which would give in concise form the many different methods of queen rearing, as the Doolittle, Pratt, Dines, Miller, Alley and others with variations as practiced by different large breeders.

You have this in the new book which is just out. Send for your copy now and get informed as to your best method of rearing queens from your best colonies. Good pointers in it also for the large beekeeper and veteran queen breeder.

Price, postpaid, only \$1.

By special arrangement we can offer it and a year's subscription to the *American Bee Journal* for only \$1.75.

(Canadian orders 15 cents extra.)

Buyers of EXTRACTED and COMB HONEY
Shippers and Exporters of HONEY

[The WORLD is Our Market]

Crop Report and Market Condition

For our September number we asked reporters to let us know how the crop compared to last year, and about what amount would be secured per colony. Also if they had sold their honey and at what price, and what offers were being made by buyers.

THE CROP

We are likely safe in saying that the crop will not measure up to that of last year, and last year's crop was hardly up to the average.

In the New England States there will be about half as much as last year, and the extreme losses during last winter will need another year to be recuperated.

New York has half a crop, or about the same as last year, possibly a little better. Some sections report much better, but the average is about as stated above.

Ohio claims a fine crop—much better than last year.

Illinois is probably a little better than in 1917, since the 1917 crop was a failure.

Indiana has little, Missouri is poor, as is Kansas, and most of Iowa has had a crop failure, the western portion being the exception. This is the region where sweet clover plays such an important part.

Michigan will hardly have half a crop, the State over. But in the northern peninsula there has been a very good crop and the new beekeepers there are enthused.

Wisconsin has had an absolute failure. It is reasonably certain that much sugar will have to be fed to bring the bees through the winter in any shape.

Most of Minnesota reports a failure, the biggest apiarist there stating that he may possibly get 20 pounds per colony.

The sweet clover part of the Dakotas and Nebraska will have more honey than last year, and the same is true of Oklahoma.

The South has a fair crop, though Georgia and Florida can hardly keep up to the 1917 crop, which was unusually large. Kentucky and Tennessee are probably a little above a year ago.

The Colorado average is probably up to last year, though one large association there claims only about a half crop. Some few claim more honey than in 1917.

Texas has had another hard year, but better even at that than 1917, when there was little honey.

In Idaho the crop is in excess of 1917, as it is also in Wyoming and Utah. Montana will have about the same as a year ago. In Washington the crop will hardly be up to average.

Reports from California are conflicting, but a majority of them report from two-thirds to three-fourths of last year, while some claim failure and a few state they think that the crop will about equal 1917.

HAVE LOSSES BEEN MADE UP?

It is very doubtful if we have as many bees yet as we had at the beginning of the 1917 season. Many beekeepers have put forth every effort to get their colonies

strengthened and have made divisions at least to cover all combs, but there are many of these divides that will have to be united to go through the winter, owing to the failure of the honey crop which would have helped made them strong colonies.

In our own yards, it is remarkable the amount of stores the bees have used up since the slow and small clover flow of spring. In preparing to move several yards into the lowlands of the Mississippi in the hopes of their filling up for winter, we found little danger of overloading the trucks with heavy colonies. Much honey has been consumed in the last month.

HONEY PRICES

Very few prices are being suggested at a basis lower than 20 cents f. o. b. producer's point for extracted. The majority of offers in carlots by buyers range between 20 cents and 22½ cents f. o. b. shipping point, put up in 5-gallon cans. One or two offers have been made f. o. b. California points as high as 23 cents, but we believe these to be the exception.

Comb honey is being offered at from \$5.50 to \$6.50 per case. f. o. b. shipping point, but relatively little of this has been sold, most buyers not being ready for the market, and waiting to see where the price will stabilize.

PRICES EXPECTED

Most beekeepers will be satisfied with a price of 25 cents for extracted honey, at least none have shown an attitude of holding for more than this, while many have sold their honey in the neighborhood of 20 cents, net.

One Wyoming beekeeper, who has 80,000 pounds of extracted and 70,000 pounds of comb, expects to get 25 cents and \$6.50 per case. A fair return for 1918, at least.

WHERE WILL PRICES GO?

It is hard to tell where prices will go on honey. Will they get up to 30 cents wholesale, as some seem to expect?

The demand by trades which must resort to other sweets besides sugar, such as fountains, ice-cream manufacturers, soda water men, etc., has helped stimulate the demand.

The foreign demand is still good, also.

The beekeeper who is profiting by these prices and selling his honey in car lots must remember, however, that when the time of stabilization comes he may be glad to have his home markets to fall upon, and that he should keep them supplied if possible now, goes without saying.

A recent letter from Australia states that there is one consignment of honey lying in port there of 400 tons, unable to move owing to the lack of ships. This is only one, probably, of many in different ports of the world. When shipping does become easier, this competition is bound to have its effect on our own prices here. When this will come it is hard to tell.

KEEP INFORMED ON TEXAS CONDITIONS

The **Beekeepers' Item**, a monthly paper edited by Mr. Louis H. Scholl, well known to our older readers, and an authority, has many interesting items which should interest beekeepers, not only in the Southwest, but throughout our country.

In order to allow you to become acquainted with this paper, we offer a special combination of **Beekeepers' Item** one year with **American Bee Journal** for only \$1.25.

Or, if you desire, we can send you your choice of **First Lessons in Beekeeping**, or **Practical Queen Rearing** with the **Item** one year for only \$1.25.

Send all orders to

AMERICAN BEE JOURNAL
HAMILTON, ILL.

Texas Queens

No more bees in packages, but queens galore from June 1 to October 1. Untested, 75c each, \$8 per doz.; tested, \$1.25 each, \$12 per doz. I have the Three-banded Italians and Golden Italians; very choice stock.

GRANT ANDERSON,
Rio Hondo, Texas.

Weis Fibre Containers

Queens, three-banded and Golden Italian, ready for delivery now. Untested, \$1 each; 6 for \$5.50; 12 for \$10; tested, \$2; 6 for \$10.

Safe delivery guaranteed, dead queens being replaced upon their return.

THE DEROY TAYLOR CO.
Newark, New York

Golden Italian Queens

RUSTBURG, VA., R. No. 3, March 18, 1918.

Mr. Ben G. Davis:

Dear Sir—Please find enclosed \$5, for which please send me the very best Golden Queen you have for the money. If you can't ship her at once, please notify me. I ordered one from you 3 years ago last fall that was the best I ever saw. Her bees stored 320 pounds of comb honey the first year. I have several of her daughters that are fine.

Hoping to get a good one again, I am yours truly,

J. W. LAWRENCE.

QUEENS Hardy, Long Lived and Disease Resisting QUEENS

Twenty-Two Years of Select Breeding Gives Us Queens of Highest Quality--Queens for Honey Production--Queens of Unusual Vitality

"There are few Queens their equal and none better"

WHAT BEES DO, HEADED BY OUR QUEENS

"One swarm made 185 sections of honey and another 296 sections. I am well pleased."—MELVIN WYSONG, Kimmell, Ind.

"Your bees averaged 150 pounds of surplus honey each. I find them not only hustlers, but gentle."—FRED H. MAY, Meredosia, Ill.

"I have tried queens from several different places and like yours best of all."—C. O. BOARD, Alabama, N. Y.

"We are only one mile from Lake Erie and exposed to high, cold winds; in fact, this is the windiest place along the great lakes. Your bees were able to stand the winter with only an insignificant loss, and we would have no others. As for honey, they averaged 175 pounds of extracted surplus, did not swarm, and gave an artificial increase of 30 per cent, which is as fine a record as can be had in this locality, especially when the work is done entirely by amateurs." Name furnished on request. North East, Pa.

Lumber that Lasts ?

Here's a Convincing Case of an Experienced Beekeeper who —

But let the gentleman tell it himself):

BUCK GROVE, IOWA, February 2, 1916.
"I have been a Cypress man for 16, these many moons. Almost all my dovetail boxes are of Cypress, as are bottom-boards, and I think, shallow telescope covers. My hive stands are of Cypress, and stand in the mud and wet all the time and are as solid as when I got the first one some years ago. Cypress is a trifle heavier than white (cork) pine, but not much more than the heavier grade of pine now used. The fact that it is 'everlasting' compensates for all this." (Signed) A. F. BONNEY, M. D.

For a job of repairing or for equipment, the lumber that will give you the greatest real investment value in the market is Cypress, commonly known as the "Wood Eternal." This wood does not rot down like most woods; it lasts and lasts and LASTS, and LASTS and LASTS. It is the Gopher Wood of the Bible—Noah built his ark of Cypress. Since the days of Noah, Cypress has been famous for endurance under the most trying conditions. **Cypress is the one certified Greenhouse wood. That's "some" test. Bottom-boards are another.**

GET A BOOK--IT IS FREE

There are 42 volumes in the internationally famous Cypress Pocket Library, and each is authoritative in its field, and all are FREE. Vol. 1 is the U. S. Gov't Report on Cypress—that is a good authority, surely. Vol. 4 is the Barn Book, with plans and specifications for building. Vol. 36 is the Carpentry Book, making easy a dozen hard jobs of carpentry. Vol. 19 is the Canoe and Boat Book. Vol. 37 is the Silo Book. All are free for the asking. Suppose you ask for one or a dozen, right away.

WORTH INVESTIGATING

This Cypress wood matter is worth investigating. Just write our "All-round Helps Department."

WINTER PROBLEM SOLVED

BY

THE HIVE WITH AN INNER OVERCOAT

The Inner Overcoats did it During the severe winter of 1917-18, there was a little apiary of thirty-seven colonies, near Grand Rapids, Mich. Seven of these swarms were in Protection Hives with the Inner Overcoats, all of which came through in perfect condition and without loss. Thirty of the swarms were in the hives without the Inner Overcoats and they suffered a loss of some 40% to 50%. This was a severe test, as the temperature went as low as 20 degrees below zero, for many weeks. The value of the bees that were lost, had they been saved, would have more than paid for new hives for the entire lot.

Have you ever stopped to think what it would be worth to you to insure your bees against winter losses? The life of a Protection Hive will be at least 25 years. Now figure what the cost will be per year, spread over its life time. You cannot afford to buy anything else. You need a certain amount of protection from cool weather during Spring and Fall. Get away from the winter packing-case nuisance, with all its expense, extra labor and inconvenience. With Protection Hives you have a neat, compact and efficient equipment.

Protection Hives are made of $\frac{7}{8}$ material in the outer wall and will last a life time, as they are not permanently packed. The packing in a permanently packed hive, in a comparatively short time, will absorb moisture, become matted down and not occupy more than two-thirds of the space, and will rot out the hive and otherwise get in bad order. When preparing Protection Hives for winter, a piece of burlap is placed over the top of the frames and then two bottomless corrugated paper boxes, Inner Overcoats, are telescoped down over the brood nest, in between the outer and inner hive walls. This provides the burlap with two thicknesses of the corrugated board on the sides and four thicknesses over the top as insulators. They are removed in the Spring, and it takes not over two minutes to insulate a hive for Winter or remove it in the Spring by this method. There are many dead air space compartments in this paper and between it.

Send for a special circular showing 10 large illustrations. It has been necessary to advance prices, but for the next 60 days we will sell from one to five sample complete hives in a place at \$5 each.

A. G. WOODMAN CO., Grand Rapids, Mich.

"falcon"

THINGS THAT ARE NECESSARY FOR YOUR APIARY

1. There must be a good location for the apiary.
2. Queens must be healthy and vigorous to put life into the hives. (Our queens are the best to be had and at reasonable prices.)
3. Your bees cannot do the work they should if you do not give them the best with which to work. If they have ample storage space, if they can work all the time without slack motion, they will be more contented and swarmless. To accomplish this, you must give them ample storage space, that is, the **RIGHT HIVES AND SUPPLIES. "falcon"**

Beekeepers should be placing their orders early for their early needs. He who waits is apt to suffer. These late beekeepers who want their goods in such a hurry at the last minute will lose some of the honey crop by not furnishing their bees with ample storing space. Railroad embargoes and rush business make deliveries slow.

Our famous "falcon" supplies will please you. Do not wait. Order now and strike while the iron is hot. "falcon" means the best, the standard of perfection. Red Catalog and Simplified Beekeeping upon request. Dealers everywhere.

W. T. FALCONER MANUFACTURING CO., Falconer, New York

WESTERN BEEKEEPERS!

We handle the finest line of Bee Supplies. Send for our 68-page catalog. Our prices will interest you.

The Colorado Honey-Producers' Association
 1424 Market Street, Denver, Colo.

A BOOK FOR BEGINNERS

"First Lessons in Beekeeping," written by the editor of this magazine, is intended primarily for the use of beginners in beekeeping. You should have it. Price, postpaid, \$1. or clubbed with the American Bee Journal, one year for \$1.75.

American Bee Journal, Hamilton, Ill.

REAL BEE EQUIPMENT

YOU are one of those careful beekeepers who is already figuring on bee supplies for your next year's use so as to avoid the freight congestion later, and also so as to take advantage of any early discounts.

We are in a position to co-operate with you by making *Prompt Shipment* and at *Prices that will Save You Money*.

More than that, you will want the best that you can get for the money. *Real Equipment*, such as we can send you, will not only save you money, but will be a pleasure to use.

Hives and Supplies

THERE is a big advantage in first-class equipment, something that when put up will stand hauling to your outyards; that will stand the weather when properly painted; in which frames will fit perfectly, and where all hives, supers, etc., are uniform.

If you want to exchange a frame of brood it is a calamity to find that frames will not interchange on account of faulty workmanship.

If you want to move a colony a knot-hole in the bottom-board increases your trouble.

LEWIS HIVES, Supers and Equipment, which we handle, are "Built Like Furniture," with every piece interchangeable.

Bee Comb Foundation

WE are Comb Foundation Specialists. **DADANT'S FOUNDATION** is perfected in manufacture to a degree that we feel justified in recommending to you as *the best there is*. In these days of high honey prices, the foundation which is quickest accepted by the bees means extra honey for the beekeeper. Do not lose sight of this point.

Specialties

TIME SAVERS are money savers. Such items listed in our catalog as Wiring Devices, Electric Wire Imbedders, Swarm Box, Foundation Cutting Box, etc., will save you time—will save you money.

Bee Books

THIRTY YEARS' experience with several hundred colonies of bees has led us to believe that we can furnish valuable information to the beekeeper. Our books are written with that in view. Some of the books of our own publication are, *'First Lessons in Beekeeping,'* *'A Thousand Answers to Beekeeping Questions,'* *'Practical Queen-Rearing'* and *'Langstroth on the Honey Bee.'*

Write us for a list of the supplies you wish—We will give you the very lowest prices consistent with first-class goods.

ORDER FROM YOUR NEAREST DISTRIBUTOR

NOTES ON ASTERS AS SOURCES OF NECTAR

Items of Interest About a Widely Distributed Family of Late Blooming Plants of Great Value to the Beekeeper

BY FRANK C. PELLETT

THE aster family is very widely distributed, being common in Europe, Asia and South Africa, as well as America. There are more than 200 recognized species, of which at least 125 are found in the United States. They are extremely common in the eastern and southern States, although some kinds are to be found in every State in the union, and from Canada to Mexico. Every American beekeeper may be sure that his bees are within reach of at least one species of aster, and, in most localities, there are several species. Some species produce nectar much more abundantly than others, and it is probable that the flow from all kinds is more or less affected by soil or climatic conditions. So few beekeepers differentiate between the species that it is very difficult to secure satisfactory information regarding their comparative value.

Asters are very seldom mentioned as sources of nectar in the southwest. Yet twenty-one species are listed as occurring in New Mexico. They seem to be of importance principally in the eastern States. There are numerous reports of honey from asters in the southeastern States of Georgia, Alabama and Mississippi, the amount of surplus increasing northward.

In most localities, the aster honey is mixed with that from goldenrod, and the two sources are usually spoken of together. In the September, 1917, issue of the American Bee Journal, appeared an extended article on goldenrods. Like the asters, they are of wide distribution, and, like them, they seem to produce nectar more abundantly in the moist climate of the eastern States. Both

bloom late in autumn, the crop often being cut short by frost.

According to Lovell, the asters are never common enough to yield a surplus in Maine, and the honey is always mixed with goldenrod.

As to the quality of the honey, there are many conflicting reports. Many reports are to the effect that the quality is poor and not suitable for table use. The fact that the honey is seldom unmixd with that of other fall flowers, may be responsible for

this impression. C. P. Dadant had one year, in Illinois, a crop of about six barrels which was almost pure aster honey. This honey was secured late in the season, after other plants had ceased to yield, and was almost white and of very fine quality.

There are numerous reports that a strong odor is apparent in the apiary when asters are yielding. We quote some of these:

"We had a fall flow from wild asters that filled the hives with honey for wintering and gave a few gallons of extracted honey. The honey is of good color and weight, but rather strong for table use. It also granulates very quickly. When the bees are gathering this honey the hives give off a rank and somewhat sickening odor, which can be detected for quite a distance away. * * * This odor disappears as the honey ripens and the flow ceases, but the strong taste never entirely disappears. It is as strong as basswood and not nearly so pleasant."

D. E. Andrews, Bloomington, Ind., page 98, American Bee Journal, 1907.

"The odor is not unpleasant, but is very noticeable when the bees are bringing much of it in, and it can be distinguished a considerable distance from the hives. The amount of 'smell' is such a good criterion as to the amount of honey that one can tell the quantity he is getting from these indications alone."

W. H. Reed, Herrodsburg, Ky. Page 228, Gleanings, 1911.

"In the Shenandoah valley in Virginia, where I lived for fourteen years, there were many

Fig. 1.—Arrow leaf aster. *Aster sagittifolius*.

acres of white aster. There were several years when the bloom was in sheets, affording a good yield of surplus. The honey was very light amber, of fine quality and was considered next to white clover. At such times a strong odor, which was distinctly sour, could be noticed."

Burdett Hassett. Page 257, *Gleanings*, 1911.

Much has been written concerning the danger of aster honey for winter stores. So many reports of disastrous results from wintering on aster honey have been published, that it is generally understood not to be safe for winter stores. However, it is probable that the trouble comes from honey gathered too late to be properly ripened, rather than because the honey is of poor quality. The fact that the honey granulates readily also probably accounts for the trouble in some cases.

In some localities, asters seem to be a dependable source of surplus, while in others they yield in appreci-

able quantity only in rare seasons. Kentucky seems to be in the heart of the territory where asters are important. The following are typical reports:

"We have never failed to get a good crop of surplus honey, and plenty left for the bees, from aster for more than twenty years, till this year."

H. C. Clemons, Boyd, Ky. Page 90, *Gleanings*, 1909.

"In this section the asters are invaluable as fall forage for bees. Let the season be cold or hot, we are certain to have a continuous bloom from early in September until a really hard frost occurs. My Italian bees have never failed to secure enough honey from asters to carry them through the winter, even when there was hardly a pound of honey in the hives at the end of August.

Daniel M. Worthington, Elkridge, Md. *American Bee Journal*, page 125, 1869.)

"Blue aster, aster azureus,

Fig. 4 Swamp aster. *Aster acuminatus*. (Photo by Lovell.)

known among farmers as blue devil or stickweed, in my judgment is one of the best we have, from the fact that it produces honey in the fall of the year. It is usually in full bloom until about the middle of October, and if the weather is warm enough for the bees to fly they get plenty of honey to winter on from this flower."

West Virginia. Page 869, *American Bee Journal*, 1906.

It is probable that most of the species are of more or less value for honey under favorable conditions. The writer has seen bees working on arrow-leaf aster, *aster sagittifolius*, on sunny days in Cass County, Iowa, the first week in November, after everything else had been killed by frost. Figure 1 shows this species, which occurs in dry, open woods, from New Brunswick to Ontario, and west to Dakota, and from New York to the Ohio valley, and along the mountains to Georgia and Alabama.

Generally speaking, the small-flowered species with willow-shaped leaves, are best for honey. *Aster Tradescanti* is probably first in the list as a source of surplus. It is found from Ontario to Saskatchewan, and throughout the States east of the Mississippi, south to the gulf States. *Aster salicifolius* is probably one of the best in Iowa and Illinois, being common on low ground.

In a private letter, F. W. L. Sladen writes concerning the asters in Canada, as follows:

"I have this year had confirmation that *Aster cordifolius* is a useful source of surplus honey in favorable seasons in the Gatineau valley in September. During a period of very fine weather between September 11 and 22, a crop of 12,000 pounds of honey, principally from this source, and from the late flowering species of goldenrod, was obtained by Joseph Martineau at Monterf,

Fig. 2.—Purple-stemmed aster. *Aster puniceus*. (Photo by John H. Lovell.)

Fig. 5.—Large-leaved aster. *Aster macrophyllus*. (Photo by Lovell.)

Quebec, from 300 colonies. The honey was light amber color, and a pleasant flavor, and not unwholesome for wintering, not granulating in the combs. (See experimental Farms report 1914-15, page 996). Other valuable species of aster in Canada for honey production are *A. lateriflorus* (Maritime provinces to Ontario); *Aster umbellatus* (Maritime provinces to Eastern Manitoba), and *Aster puniceus*, Fig. 2 (Maritime provinces to Ontario.)" Ottawa, October 2, 1917.

Aster puniceus, the purple-stemmed aster, Fig. 2, is found from Nova Scotia to the Rocky Mountains and south to Northern Alabama. It is one of the most attractive of the asters, growing on wet land and in the borders of swamps. Lovell writes that in Maine he has seen the bees on this species in large numbers on September 17.

The white field aster or frost flower, *Aster vimineus*, Fig. 3, is common from Eastern Canada to Minnesota, and south to Arkansas and Florida. It grows in dry, open fields, along roadsides, and in waste places. It is a late bloomer, belonging to the group of field asters which are important for nectar. Some other species, however, yield more freely.

The swamp aster, *Aster acuminatus*, occurs on wet land, but as far as available information goes is not valuable for honey.

The large-leaved *Aster macrophyllus*, Fig. 5, is a northern species, found in open woodlands. Graenicher observed ninety-five species of insects on the flowers of this species in Wisconsin, which indicates nectar in abundance in that State.

Several other species are known to produce nectar freely, *A. multiflorus*, *A. lateriflorus*, *A. dumosus*, *A. paniculatus* and *A. vimineus* being reported from various localities. *A. ericoides* is reported as valuable in Missouri:

"There is an abundance of *Aster ericoides* now in full bloom. The bees are working on it more

vigorously than they have on white clover or any other bloom." George E Wilkins, Wright County, Mo. Page 699, American Bee Journal, 1904.

So far we have been unable to find any records of surplus honey from asters west of the Missouri river.

Wintering Experience

By A. Coppin

LAST fall I had 160 colonies in 8-frame single-walled hives. I commenced packing them for winter in good time, putting them in clamps of either six or twelve hives.

My bees were in rows, one facing east and the other west, with about 4 feet of space between the rows, which gave me ample room to work with them.

When I got ready to pack them for the winter I moved each row back almost 2 feet, thus leaving them almost back to back, or, in other words, just enough space between the two rows to put in packing.

I then filled this space in with for-

est leaves and straw and covered them all in with the exception of the fronts, which were not protected.

I got 153 of the 160 packed before the big snow came, thus leaving 7 that were not packed, and as the snow staid with us practically all winter, these 7 were never taken care of.

Six of those 7 were in one-story hives, and the odd one was a two-story hive.

The result was as follows: The 6 in the one-story hives were dead this spring, while the two-story was alive.

From the 153 that were packed I lost 24, thus leaving 129 from what were packed, and one from what wasn't packed.

I talked with two other parties that have bees; one of these had 10 hives packed in one clump and reports them all alive.

The other party had 26 hives and did not pack them at all, and reports 20 dead.

While we had an unusually hard winter, I yet believe that it is better to either pack your bees or put them in a cellar.

Wenona, Ill.

AMERICAN BEE JOURNAL

Established by Samuel Wagner in 1861

The oldest Bee Journal in the English language. Consolidated with The National Bee Journal in 1874.

Published monthly at Hamilton, Illinois.

Entered as second-class matter at the postoffice at Hamilton, Illinois.

SUBSCRIPTION RATES—In the United States and Mexico, \$1 per year; three years, \$2.50; five years, \$4. Canadian postage 15 cents, and other foreign countries 25 cents extra, per year.

All subscriptions are stopped at expiration. Date of expiration is printed on wrapper label.

THE EDITOR'S VIEWPOINT

The Editorial Staff

Mr. Frank C. Pellett, who for the past two years, beginning March, 1916, has been staff correspondent of the Journal, is now with us in a more permanent capacity. He is our associate in the editing of the Journal. Mr. Pellett has been met by many of our readers, for he has attended numerous meetings of beekeepers. For those who have never met him, we will say that he has been State Inspector of Apiaries in Iowa, President of the State Association, Vice President of the National Association, author of "Productive Beekeeping," one of the leading modern bee-books, "Practical Queen Rearing," and of "Our Backdoor Neighbors," a delightful book of Nature study.

It is unnecessary to say more. Judge him by what he will do. We expect him to "make good" in his present position.

He is now settled with his family at Hamilton and his permanent address is at this office.

Beeswax Production

In another column our readers will find an account of experiments by Mr. D. A. Davis, at the University of Minnesota on the above subject. These experiments are interesting, but they still leave the matter of cost of wax in the indefinite condition we have always known. From the time of Martin John (Fribourg 1684) the man who is said to have first discovered that wax is a product of digestion, like milk, hundreds of experimenters have attempted to get at the actual cost of wax to the bees, in honey. The results have varied greatly, not only because of difference in food, warmth, condition of the bees and inaccuracies in the ex-

periments, but also probably because the amount of wax produced naturally by bees from a given quantity of food is as variable as the production of milk or of butter fat in animals.

But what is most important for our producers to know is the answer to the following question:

At what time of the honey crop is it most profitable to give the bees full combs or full sheets of comb foundation?

Some will reply without hesitancy: "At any time." But is not this wrong? W. Z. Hutchinson, a man who made his mark, as editor of the "Beekeepers' Review" and as author of "Advanced Bee Culture," testified to the fact that "in living swarms upon drawn combs, the loss was always so great that it seems like folly to repeat it." What explanation can we give for that experience?

That the building of combs by the bees is very expensive to them does not admit of a doubt. Those who have placed it at a low figure have always overlooked some factor which would have added greatly to the cost. But in the experience of Hutchinson, it is probable that the empty combs provided to the bees of a swarm at the height of the honey crop were filled with honey so quickly that the queen was actually deprived of breeding room, while in the delay caused by comb-building the queen would have had time to fill them with brood as fast as they were built.

This subject, mentioned by us in paragraph 425 of the Langstroth-Dadant "Hive and Honey Bee," brought us the following judicious

remarks from Mr. Oscar Ritland, of Elroy, Wisconsin:

"I should like to make a suggestion in regard to your excellent book, Langstroth Revised. In paragraph 425 you mention what Mr. Hutchinson says about living swarms upon drawn combs, but you have failed to say that he was talking about comb honey. This, in my opinion, explains why he found it to be a loss to have a swarm on drawn combs.

"If you have a strong swarm, in a good flow, in a hive full of drawn combs and give it one or two supers of sections with foundation at the same time, I suppose that in most cases the bees will jam the brood chamber full of honey before the queen can get a start, and the result would be as Mr. Hutchinson stated. But if you have a swarm, in a good honey flow, on a hive full of drawn combs and give them also one or two supers full of drawn combs, you would not expect that the bees would crowd the queen so that the swarm would decline in strength, would you?"

It seems to us that this suggestion solves the matter, but it is advisable for each beekeeper to understand fully the possible advantages and disadvantages of comb supply. There are times when the hiving of swarms upon full combs gives the bees opportunity to breed promptly, in the early part of the season, if the crop does not come in too fast, and perhaps double their capacity for increase before the end of the crop. There are also times, near the end of a crop, when the supplying of empty combs or comb foundation may be the saving of the swarm, since a scanty supply of harvest might be entirely inadequate for the building of the combs but would prove ample to sustain the colony till the next harvest.

These are questions for our college men to experiment upon. Practical apiarists who have neither the time nor the facilities for experimenting and keeping data will be glad of more tests, at different times, carefully recorded. But perhaps honey would give us a more correct result than sugar syrup, which was the food employed by Huber, Dumas and Milne-Edwards, by Professor Cook and dozens of others. Strange to say, sugar gave a greater percentage of wax than honey.

Gundelach, Berlepsch and others were also convinced by their tests

that more wax could be produced from a given amount of food when pollen was available than when it was not to be had. This is not because of the use of pollen in the actual production of wax, but because pollen appears necessary to sustain the bees during wax production.

Now that most of our colleges have experimental departments and practical apiarists, we should, before long, have some very useful information on the most profitable use of already-built combs and comb foundation. Will Mr. Davis and others make further experiments on the lines we indicate?

The Sugar Situation

There are many localities where the bees will not have sufficient honey for winter without feeding. Fortunately, the Food Administration has seen fit to provide for this emergency by making provision to supply the needs of the beekeepers. By the time this issue reaches our readers bees should be prepared for winter in northern localities, although it will not be too late to feed needy colonies.

Beekeepers who have harvested a crop of honey should in no case apply for sugar to feed the bees. The fact that beekeepers who have honey for sale find it necessary to buy sugar will certainly tend to throw suspicion on the craft. The publicity that has necessarily come in connection with the provision for supplying beekeepers with sugar to save their bees, has already created a suspicion in many minds that bees are fed with sugar for the purpose of making honey for sale. American beekeepers as a class are patriotic and are prepared to make any necessary sacrifice to win the war. It is reported, however, that a few individuals who have harvested a crop are disposed to take advantage of the general situation and extract all their honey for sale and feed the bees with sugar for winter. Such action would be very unfortunate, for it might result in the supply of sugar, necessary to feed needy colonies, being withdrawn by the Food Administration on a misimpression. It might also result in the prosecution of the guilty beekeeper, for the public is in no mood now, when every nerve is being strained to win the war, to trifle with those who turn national necessity to private profit.

The Government has met every reasonable demand of the beekeepers and it is important for the good of the industry that every violation of the rules be reported.

Sugar Versus Honey

We are informed that the Food Administration is allowing 100% of needed sugar for feeding bees that may be short for winter and 50% per cent of normal supply for "honey manufacture." Inasmuch as the adulteration of food is strictly prohibited, we can see no earthly reason for allowing any sugar for artificially manufacturing a product which cannot under any excuse be called honey, even if it contains 50% of real honey. There is evidently a misapprehension on the part of the Food Administration as to what constitutes honey.

Several of our beekeepers have written us that they find great opposition among consumers to the permitting of sugar being used in any quantity whatever to feed bees. Evidently the public is unable to discriminate between bee feeding and honey adulteration. We are writing this article for the purpose of helping the beekeepers in making the matter clear to the consumer.

Pure honey is the product of flowers only. When the flowers are wanting, or when they contain no nectar, owing to drought, excessive moisture, etc., the bees are sometimes unable to secure enough honey to carry them over winter. At least 25 pounds of honey is necessary for the purpose. Neither molasses, nor commercial glucose, nor corn syrup, can be used, as they are either rejected by the bees or, if used by them, make them sick and bring about the death of the colony. Pure cane sugar, diluted with half of its weight of water is the only possible substitute for honey. So when the bees are short of stores, as they are in many places during the present season, sugar syrup is indispensable to keep them alive.

Do beekeepers feed bees sugar to make honey? They do not, for two reasons. The first is that sugar syrup fed to the bees is still sugar syrup. Its chemical condition is not changed and it lacks the flavor, the essential oils which the flowers alone can give. A man feeding his bees sugar syrup and trying to sell it as honey would be liable to arrest for adulteration.

The second reason why sugar is not fed to bees for profit is that when it is used in large quantities as bee feed, there is a large consumption of it by the bees to build comb and to rear brood. This is highly unprofitable. Experiments conducted at different times, for a century past, one of which is published in the current number of the American Bee Journal, show that if the bees use any sugar syrup for this purpose, it costs them from 16 to 25 pounds of sugar for every pound of comb secured. Feeding to keep bees from starving allows them only to fill the combs already built and the feeding does not last long enough to induce them to breed to any extent or to build additional combs. But a plentiful feeding, such as would be necessary to secure a surplus, would induce them to rear brood and to build additional combs, seal the cells, etc. This would more than balance the difference in price.

It is, therefore, neither profitable, nor honest, nor safe, to feed bees in order to get honey for sale. The adulterer has a shorter method of mixing honey and syrup without the help of the bees. This is forbidden by law. No food product may be sold under any but its real name.

California and the Western Honey Bee.

We read in the "Western Honey Bee" that, according to Mr. Geo. S. Demuth, of the Washington Bureau of Entomology, California has now about two million colonies of bees, producing about a thousand carloads of honey annually. The beekeepers of California who have been having hard sailing in years past, when honey sold, at times, as low as 3 cents per pound, ought to have smooth sailing for some time to come.

And, by the way, we should urge the California honey producer to read the "Western Honey Bee." It is a neat little magazine, well managed and interesting. J. D. Bixby, its editor, will make a valuable paper of it, and he is not paying us for saying that, either.

New Bulletins on Wintering

Two new bulletins are just now issued by the U. S. Department of Agriculture, Farmers' Bulletin 1012, "The Preparation of Bees for Outdoor Wintering and," and 1014, "Wintering Bees in Cellars." Write the Secretary of Agriculture at Washington for either of these bulletins.

THE TEXAS QUEEN AND PACKAGE BUSINESS

The Fourth Article of a Series Dealing With Beekeeping Conditions in the Lone Star State

IN order to appreciate the problems of the queen breeders who supply early orders for bees and queens, one must know something of the vagaries of the Texas climate. While there are sections of Texas that are hilly or mountainous, and also sections covered with forest, for the most part the State is a monotonous level stretch of prairie. Prairie countries are very sensitive to changes in weather conditions, and Texas is no exception to this rule. The southern part of the State is covered with a sparse growth of low-growing, thorny shrubs and small trees, which break the force of the wind to some extent, but which give scant protection as compared to the dense forests of other regions.

The climate is generally mild, on account of the southern situation, but the wind sweeping down across the plains carries the cold and chill of the "northers" clear across the State to the Mexican border. In winter and early spring, a warm and balmy day will often be followed by a "norther" and a raw wind, that chills one to the bone. As in other sections, the weather of spring varies greatly from year to year. In some seasons, bees breed up early and with no apparent setback. In other seasons, "northers" are of such frequent occurrence that the beekeeper finds it difficult to get his colonies in shape for early queen-breeding. The farther south one goes, the more favorable the conditions become, un-

til in the lower Rio Grande valley we find, perhaps, the most favorable conditions for queen-breeding in the United States. Even here the influence of the "norther" is felt, although it seldom brings frost.

In traveling from Dallas to Brownsville, even though one is all the time in Texas, he traverses a greater distance than in traveling from Chicago, Ill., to Nashville, Tenn. One finds it hard to describe Texas conditions generally, because of the great variation in the different sections. This variation was touched upon in detail in the June issue.

The southern breeder has a great advantage over the man farther north, because of his longer season. It is the early orders that bring the higher prices, and which are filled at the best profit. As the season advances, prices tend to drop, until in the late summer there is little margin to the queen-breeder at the prices at which the queens are sold. The man who is prepared to fill orders in April and May finds an unlimited market at profitable prices, for either queens or bees in packages. Although the writer has visited a number of the larger shippers in Alabama, Georgia, Mississippi and Texas, nowhere has he found one who does not experience great difficulty in getting his bees up to the required strength to meet this early trade, except in the lower Rio Grande Valley.

Callallen, Texas, is farther south

than any portion of any other State except a part of Florida. The northern beekeeper would expect to find no winter problem there. Yet E. B. Ault, who is extensively engaged in shipping bees and queens, is experimenting with various kinds of winter protection in order to get his bees into prime condition as early in spring as possible. The writer was informed that the bees build up without extra protection in plenty of time for the honey-flow, but too slowly for best results in queen-rearing. Two pictures are shown herewith, illustrating Mr. Ault's methods of wintering. In one picture a row of hives is protected with a bank of dirt thrown up about the hives, and held in place with boards. The entrances are open in the same way as in the usual packing cases used in the north. This plan would not be advisable in a locality where rains are frequent, as the dirt would soon become saturated. The tar paper cases shown in the other picture apparently give as good results, and are much more easily and quickly prepared. The hive is not so easily opened with this case. The protected colonies build up about two weeks earlier than the unprotected ones, in spring, and save some honey in wintering. At first glance, we find here a strong argument for protection to all bees, even in this far southern climate. However, the beekeepers say otherwise, contending that the bees build up in time for the honey-flows anyway, and if they reach maximum strength two weeks early they will have the swarming fever and consume more stores in excessive brood-rearing, than will be saved in wintering.

At Sabinal, W. E. Edwards has twenty colonies in double-walled hives. He inclines to the belief that the extra protection with him is a decided advantage, and says that if it were not for the extra cost he would have all his bees in double-walled hives.

Whatever may be the case for honey production, there can be no question that anything the queen-breeder can do to hasten the early brood-rearing and save bees in spring, is decidedly to his advantage. The two weeks which Mr. Ault has been able to gain in building up is of great value at that early season, and enables him to supply numerous orders which would be otherwise impossible.

In some parts of North Central Texas, the first important surplus flow comes from cotton, about the 20th of June. In these localities, the control of swarming is a problem, since the swarming season comes in April, nearly two months ahead of the honeyflow. Wherever there are

1. W. Bushnell shows the way his beekeepers in packages in a place of the honeyflow

Ault's spring protection for cell-building colonies in South Texas.

dependable flows, the production of honey is usually considered more profitable than either queen-breeding or the package business. Some of the most extensive queen-breeders in America would be producing honey, if the honeyflows in the places where they live were heavy and dependable enough to give profitable crops. In this North Texas country the early package business offers a solution of the swarming problem. If the bees are allowed to continue ahead breeding for two months ahead of the honeyflow, large quantities of honey are consumed in rearing useless brood, and much manipulation is necessary on the part of the beekeeper to control the swarms. T. W. Burlison, of Waxahachie, is a large honey producer, having 750 colonies of bees. He has found that by selling bees to the early trade he can turn his excess bees to profit early in the season, and still give the bees plenty of time to build up for the honeyflow from cotton.

There are not many localities where the selling of bees and the production of honey can be combined to as good advantage. Where it can be done, it furnishes the ideal condition for profitable beekeeping. The bees are sold in early spring, at the time when prices rule highest, and the marketing of the honey crop, which comes on later, gives the beekeeper a long season with a dependable income. Mr. Burlison is of the opinion that one of the secrets of success, in shipping bees, is to gorge them before delivering the package to the express company. If given all the syrup which they will take, in advance of shipment, the bees cluster much more quietly and go through in better condition. A common way of feeding is to spread the syrup over the screen of the cage with a wide brush.

There are numerous queen-breeders in Texas, and each locality presents conditions peculiar to itself. The writer was not able to visit as

many of the queen yards as he wished, because the time available for the trip was not sufficient. In some important honey-producing sections of Texas, commercial queen-rearing is not profitable because of a shortage of pollen at some seasons of the year. This and other locality peculiarities will be considered further in later articles.

Co-Operation Brought Higher Prices

By Chilton Gano

BEESKEEPERS of the Northwest — Idaho and Oregon — have proved that successful co-operative selling of honey need not be confined to Colorado and Texas. The story of the Idaho-Oregon Honey Producers' Association has been one of financial success from the first

season, 1915. To indicate at the start the scope of this success it may be stated that in 1914 Northwestern extracted honey was selling as low as 5 cents, whereas this season the association's minimum price is 18 cents. This advance cannot, of course, be attributed entirely to the association. Advances in production cost due to the war, and the scarcity of sugar have had much to do with it. But an account of the association's history will show that the present prosperity of the Northwest beekeepers is due in part to organization.

The present organization is an outgrowth of the Southern Idaho-Eastern Oregon Beekeepers' Association, which was a social organization. Prior to 1914 members of the organization had from time to time bunched supply orders, or occasionally combined to make up a car of honey for shipment to the coast; but such actions were not included in the association's functions.

In December, 1914, the time seemed ripe for adopting a definite plan for co-operative buying of supplies and selling of honey. A meeting was held and the result was the incorporation of the Idaho-Oregon Honey Producers' Association. The association was to buy supplies of all kinds, bunching all members' orders, and to market all the honey of its members, withholding 5 per cent of gross sales to cover expenses and returning any surplus from this amount to the producers at the end of each season. Prices were to be determined by public discussion at the Annual Field Meeting, held in July of each year, a schedule being determined on for the three grades of comb honey. Producers of extracted, however, were to be allowed to set their own prices. The association was to endeavor to secure the schedule prices, but was empowered to sell at market price whenever it appeared advisable.

Big Savings in Supplies

First, as regards purchasing of

Hives protected with earth in Ault's yards. This would not do in a wet climate.

supplies, the contract signed by the members accords, among other privileges, that of buying supplies through the Association and deferring payment until crops are sold in the fall of the same season.

This is quite an advantage, in itself, but the actual saving through quantity buying has been great. Before the organization of the association, producers purchased from Pacific Coast and Colorado dealers, paying retail catalog prices and local freight to destination. The association, through assembling of orders, is now able to buy at jobbers' list, and goods are shipped in car lots, taking a reduced freight rate. As some of the individual orders of members runs as high as \$1,000, it can be realized what jobbers' list prices, ranging from 20 to 33-1/3 per cent below retail, means in money saving.

Higher Prices

Before the new plan was adopted extracted honey was selling as low as 5 cents in the Northwest, while comb sold as low as \$2.25 per case. This was, partly at least, because competition between producers forced the price down. Elimination of this competition between members resulted in the association securing for the entire crop in 1915, the first season, \$2.75 per case for No. 1, and \$2.50 for No. 2; whereas, individual producers in the district sold as low as \$2.50 and \$2.25. One large individual producer succeeded in getting \$2.65 and \$2.40. In the same season a producer of extracted carried over a full car, which he was unable to move. In the spring of 1916 he commissioned the association to sell it for him and they did so within one week, securing one-quarter cent per pound higher than the price he had set.

In the meantime the association's work for improving production and pack was progressing, and in 1917 a new grade of comb honey, "Fancy," was added. In that season cars were sold as high as \$3.50, \$3.25 and \$3 for the three grades—fancy, No. 1 and No. 2. Others sold at \$3.25, \$3 and \$2.75. Individual producers sold at around \$3,—\$2.75 for two grades.

One coast buyer bought a car from the association in July at \$3.15, \$2.75 net, f. o. b. Caldwell, Idaho, and the following month paid an individual producer \$3 and \$2.60, besides charging him 10 cents per case brokerage for selling to themselves.

In the same season extracted was sold, first cars, at 12 1/2 cents, thence on up to 15 cents, by the association. Individuals sold large lots at 10 cents, and some as low as 8 cents. An association member agreed to sell one car through the association at 8 cents, but the association advised holding it, and later got 12 1/2 cents for it.

The present season the price schedule calls for 18 cents for extracted and \$4.50-\$4.25-\$4.00 for comb. These are minimum prices, and the association actually refused \$5.00-\$4.50 for 10 cars and later got \$5.50-\$5.00. Since then a deal has been closed at \$6.00-

\$5.50, which will take up the balance of the comb. Individual producers began selling at the association's schedule of \$4.50-\$4.00, but have asked higher prices since they learned the association was getting them.

Equally fine have been extracted sales. With a minimum of 18 cents, the association actually refused 20 cents for its entire crop, and is now selling in 5-gallon cans at 22 1/2 cents. Individual producers started selling at 18 cents, but in this case, also, have raised their prices.

"If this association had not been in existence this season," says its secretary, P. S. Farrell, "coast jobbers would have made a killing on our honey this season, because only one or two producers were really posted on market conditions." One great secret of the association's success is that, handling so large a crop, it can well afford to investigate the national honey market thoroughly.

Low Operating Cost

Not the least of this association's financial triumphs is its low operating cost. It withholds only 5 per cent on gross sales, and has never yet needed the entire amount for expenses. In 1915 it operated for only five-thirteenths of its commission, repaying to the producers the remaining eight-thirteenths. In 1916, due to a partial crop failure, expenses were higher, approximating 4 per cent. In 1917 they were 3 1/2 per cent.

The association now has 146 members, located in the Boise and Payette Valleys in Idaho, and in the Malheur River Valley in Oregon.

The members are grouped into seven districts, and each district elects a Director to the Board of Directors. There are fifteen loading points from which honey is shipped, but cars of supplies are unloaded at two points—Caldwell, Idaho, and Ontario, Ore., reshipment being made direct to members.

Among the interesting provisions in the membership contract are the following:

1. That members must ship their entire crops through the association for 5 years from date of contract.

2. The selling prices shall be fixed by the directors, following public discussion, and the association shall obtain higher prices when possible.

3. That the association can refuse to accept honey from a member which is not properly graded and packed according to the association's grading rules.

4. That if a member fails to sell through the association, the association can take possession of his crop, and retain for selling it, in addition to the 5 per cent, any additional amount to cover the extra expense of this procedure.

5. That a member who actually sells any honey outside shall pay to the association, in lieu of liquidated damages, 5 per cent of the gross of such sales.

It is, of course, true that the success of such an organization depends largely on the business ability of its officers and secretary, yet that such managers need to be more than ordinarily good business men is not

indicated by the records. Such associations have had notable successes right from the start, in at least three States, which indicates that practically any average American community should be able to command the services of a manager and officers, of sufficient ability to insure the success of such an undertaking.

The Production of Wax by Honey Bees

By D. A. Davis

THE subject of Wax Production by the Honey Bee is one upon which theories are numerous. Some of the well-established facts about this subject are:

1. That a new swarm or shaken swarm of bees will make wax and build comb immediately after entering the new box or hive, if this box or hive does not already contain combs.

2. That the wax is secreted by the wax glands, which lie in pairs, usually four pairs, on the ventral interior side of the abdomen of the worker-bee. The wax being secreted oozes out through the minute perforations of the wax plates, which cover the separate wax glands. Upon coming in contact with the air the liquid wax hardens into a pearly white scale. (1) gives a good description of the wax organs and their functions.

"As is well known, wax is produced by the worker-bees only. The location of the wax-secreting surfaces, or wax plates, may be readily determined by an examination of the ventral surface of a bee's abdomen. By stretching the abdomen somewhat it will be seen that each of the last four visible sternal or ventral plates is divided into two regions, a posterior projecting edge which is distinctly hairy, and a smooth anterior half which is usually covered by the next preceding plate. This anterior region is divided by a median ridge into two distinct irregularly oval areas, which thus lie on either side of the mid-ventral line. These areas are the wax plates, and upon them the wax-scales are formed. Each one of the last four sternal plates bears two wax plates, making eight in all. (See Fig. 1.)

"The glands which secrete the wax lie on the floor of the abdomen immediately above and in contact with the wax plates, and their secretion is deposited upon the external surfaces of the plates. Upon coming in contact with the air the fluid wax hardens, forming a covering over the entire outer surface of the plate, which gradually increases in thickness with the addition of wax through the pores. In this way the wax-scales are produced, and since they are molded upon the surfaces of the eight wax plates, they cor-

(1) Casteel Ph. D., D. B. 1912—The Manipulation of the Wax Scales of the Honey Bee.

Fig. 1.—Wax plates of the worker bee. (Casteel.)

respond to them in number and in form.

"In its natural position each wax scale lies between its wax plate and the overlapping edge of the next preceding sternal plate. The scale thus fits into a little crevice or wax pocket and is well protected from injury. If the bee extends its abdomen the rear edges of the scales can be seen protruding from their pockets, or if the scales become very thick they will push the covering plates outward and will project from the pockets." (See Fig. 2.)

3. That worker-bees gorge themselves with honey before beginning the process of wax secretion.

4. That worker-bees cluster together in dense masses while secreting wax, evidently to generate sufficient heat for the secretion of the wax and formation of the scales.

The foregoing facts are well known, but there has been much speculation on the amount of honey or sugar that is used up in the metabolic process of wax secretion. Various writers have estimated that all the way from 5 lbs. to 40 lbs. of honey is used in the production of one pound of wax.

The experiments carried on during the past fall have disclosed the following facts:

1. It requires more pounds of sugar for old worker-bees to produce a pound of wax than for worker-bees of average age.

2. Young worker-bees can produce wax more economically than old worker-bees or worker-bees of mixed ages, such as found in the average colony.

3. The average colony, without exceptionally good weather conditions in the way of temperature, will consume on the average 16 pounds 9

ounces of sugar in secreting 1 pound of wax.

4. With beeswax selling at 40 cents per pound, that figure is only one-third the cost of its production. With sugar at 8 cents beeswax should sell at \$1.25 per pound or even higher, since honey is the food which is ordinarily used in its production and honey is always higher than sugar in price.

The following is a statement of the experiment and the data obtained, with the resulting tables derived therefrom and used in the final conclusions:

On September 17, 1917, five colonies of bees were shaken upon full sheets of medium brood-comb foundation in hives which did not contain a single drop of honey. The only wax which was present was that amount used in the foundation.

Colonies Nos. 1, 3 and 5 were average colonies with about equal portions of young, old and medium-aged worker-bees.

Colony No. 2 had a very large percentage of young worker-bees, that is, bees which had emerged within the past two weeks.

Colony No. 4 was composed mostly of old worker-bees, bees as old as six weeks or two months, very few young, newly-emerged bees.

Each colony was weighed at the beginning and end of the experiment, as were three other colonies of about the same strength, in the same location, which were not being experimented upon.

A sugar syrup, made of four parts, by weight, of pure granulated sugar and three parts, by weight, of cold water, was prepared and fed regularly, as fast as the bees could take it.

The colonies not fed or disturbed were found to have lost an average of 3 pounds and 3 ounces during the twenty-five days that the experiment was carried on. Since they raised during that time approximately as much brood as did the colonies un-

der test, the figure 3 pounds and 3 ounces of honey was used in computing the amount consumed by the bees and fed to their brood while the test was going on. This amount of honey was reduced to a sugar basis, since honey is only 80 per cent sugar.

After the feeding experiment was over, some of the representative combs were extracted and the combs melted up to find out exactly the amount of wax which had been added to the two-ounce sheets of foundation, as well as to find out the water content of the inverted sugar syrup. The fact that the sugar syrup had been reduced to the same water content as honey in spite of the coolness of the season, was a notable fact. In the wax production it was found that it was necessary for the bees to add an average of one ounce of wax per frame to the two-ounce foundation sheets, in order to build the comb out even with the end bars. However, it is very evident that more and more wax is added to these combs year by year as they are being used.

These figures would vary in the spring or summer when the weather conditions would be ideal for the activities of the bee and the natural building of comb.

Table No. 1.

Colony	Weight after shaking on full sheets of foundation.	Weight of bees and hives before feeding:
Colony 1	33 lbs. 6 oz.	31 lbs. 13 oz.
Colony 2	30 lbs. 3 oz.	24 lbs.
Colony 3	28 lbs. 1 oz.	28 lbs. 1 oz.
Colony 4		
Colony 5		

Table No. 2.

Syrup fed, 4.3 mixture.	Therefore, 7 lbs. sugar equals 4 lbs. sugar.	Weight of sugar syrup only, which was fed:
Colony 1	41 lbs. 1 oz.	41 lbs. 1 oz.
Colony 2	41 lbs. 1 oz.	36 lbs. 8 oz.
Colony 3	41 lbs. 1 oz.	41 lbs. 1 oz.
Colony 4	41 lbs. 1 oz.	41 lbs. 1 oz.
Colony 5	41 lbs. 1 oz.	41 lbs. 1 oz.

Table No. 3.

Final weights of colonies which were fed, at end of period of twenty-five days:	Weight of sugar syrup only, which was fed:
Colony 1	51 lbs. 10 oz.
Colony 2	50 lbs. 15 oz.
Colony 3	45 lbs. 8 oz.
Colony 4	41 lbs. 9 oz.

Fig. 2.—Ventral caudal view of abdomen of worker bees, showing wax scales between the wax plates and abdominal segments. Also some scales removed from the bee. (Original.)

Colony 5 44 lbs. 12 oz.

Table No. 4.

Net gain per colony.
 Net weight of evaporated and inverted sugar syrup which was stored during the period:

Colony 1	18 lbs. 4 oz.
Colony 2	19 lbs. 2 oz.
Colony 3	15 lbs. 5 oz.
Colony 4	17 lbs. 9 oz.
Colony 5	16 lbs. 11 oz.

Table No. 5.

Number of pounds of honey for maintenance added to the gain in weight. That is, net gain plus 3 pounds 3 ounces.
 Total weight of stored syrup plus the amount used by the colony during the twenty-five days:

Colony 1	21 lbs. 7 oz.
Colony 2	22 lbs. 5 oz.
Colony 3	18 lbs. 8 oz.
Colony 4	20 lbs. 12 oz.
Colony 5	19 lbs. 14 oz.

Table No. 6.

Number of pounds of dry sugar fed in the form of syrup:

Colony 1	23 lbs. 7 3/4 oz.
Colony 2	23 lbs. 7 3/4 oz.
Colony 3	20 lbs. 14 1/4 oz.
Colony 4	23 lbs. 7 3/4 oz.
Colony 5	23 lbs. 7 3/4 oz.

Table No. 7.

Number of pounds dry sugar equivalent stored in combs and used by colony, considering the difference in consistency of syrup at the time of feeding and after the syrup was stored:

Colony 1	17 lbs. 5 oz.
Colony 2	17 lbs. 13 5/8 oz.
Colony 3	14 lbs. 12 4/5 oz.
Colony 4	16 lbs. 9 3/5 oz.
Colony 5	15 lbs. 14 2/5 oz.

Table No. 8.

Number of combs built fully out during feeding period from the foundation furnished:

Colony 1	6
Colony 2	7
Colony 3	6
Colony 4	5 1/2
Colony 5	7

Table No. 9.

Number of pounds of sugar required to produce one pound of wax:

Colony 1	16 lbs. 7 oz.
Colony 2	12 lbs. 14 oz.
Colony 3	16 lbs. 4 oz.
Colony 4	20 lbs.
Colony 5	17 lbs. 5 oz.
Average	16 lbs. 9 oz.

From table No. 1 you will notice that the initial weights of the colonies after shaking upon foundation

vary greatly. This variation is due to the different sizes of hives, instead of the difference in number of bees.

Ontario, Iowa.

A Valuable Pest--To Beemen

By C. D. Stuart

"IS the Yellow Star or Russian Thistle a menace to Northern California?"

To decide the question, farmers from Butte, Tehama, Glenn and surrounding counties held a meeting December 2, 1916. The solemnity of the session presaged an affirmative answer, only a single dissenting voice being heard—the humble protest of some beeman, perhaps; but his identity is not revealed by official records of the proceedings.

Declared a pest and a menace, this nectar-secreting plant was condemned to death by fire, by water, by forceful removal from the soil and by burial. But at the end of the meeting in the late afternoon, the thistle still flourished, and to this day is obeying the ancient injunction to increase and multiply its kind, to the secret satisfaction of apiarists.

According to the report, the *Centurea solstitialis*, or yellow star thistle, was discovered in Northern California about twenty-five years ago, only an occasional bunch growing at that time along a short-cut road through a hay field. About the same date other small plants were imported from Russia. (The report does not say for what purpose, or if they were brought in by accident.) One of the farmers at the meeting said: "It looks something like the saffron we had back east," but later he concluded that it was "some kind of a weed," and paid no further attention to it.

In a few years the thistle had spread, and it became increasingly difficult to run a mowing machine through the "nail-heads," as one man called them. From the level grain land it spread to the foothills thirty miles away, and still further, the seed being carried by birds, in the wool of sheep and in the winds and rain. The overflowed land suffers the most. The seeds are carried down to it by the rivers, and in these rich soils the thistle often grows to a height of 6 or 8 feet and forms an impenetrable jungle.

The ordinary hoeing method of eradication was reported to be ineffectual, as the "root is a very determined root," and the thistle will adapt itself to the land—that is, lie on the ground like a burr clover and blossom and seed itself there. It can be plowed under periodically until it will finally disappear in highly cultivated fruit orchards, but it still retains its hold in fence corners and along the roadsides. One orchardist reported that he had removed all of his fencing in order to plow the thistle under, but it was only a temporary relief, as it still flourished in untilled fields and rocky foothills; others, that it had no effect on crops, as its growth is now confined to out-of-the-way places. A wool grower discovered that a herd of sheep will stamp out the thistle. They crop it down as fast as the tender shoots appear, so that it is not allowed to become hard and unfit for fodder, or to go to seed.

But all who own farms in Northern California are not wool growers, especially on land that is adapted to nuts and fruit.

And so the fight is on, and like other kinds of warfare, had its inception in money-making projects. A man of large holdings naturally opposes the eradication of thistle through individual effort, because it "would cost more than the land is worth." On the other hand, a man of small, intensively-cultivated holdings would be able to control the pest on his own land were it not for the seeds constantly supplied from the neglected fields of some absentee landlord. But all agree that it is going to be a man's job totally to eradicate the thistle, the large land-owner naturally advocating State appropriations to check its inroads; the small land owner objecting to such paternalism because of the increased taxation to those who are already coping more or less successfully with the situation.

Meanwhile, from one-half to three-fourths of Butte county's honey crop, averaging about 60 tons, is gathered from this pest, now said to be growing on two-thirds of the county's area. Should the thistle continue to spread, in spite of legislative appropriations, in defiance of the State University and of the Horticultural Commission, to say nothing of existing laws, Northern California will be compelled to "eat honey" or starve. There will be little else to eat, if the pro-eradication faction is to be taken seriously.

Yellow Star Thistle. (Courtesy, C. D. Stuart.)

Star thistle begins to bloom about the first of July and continues till frost, which usually comes between October 1 and November 1. The yield of nectar is slow but continuous; if it is stopped by too long drought, it will start yielding nectar again after a rain. The plant has the faculty of existing in arid soils for long periods of drought, and, when apparently dried up, it will start to grow and blossom after a rain. Some cattle growers find that thistle hay can be fed profitably when cut and dried like other hay, if it is moistened just before feeding. The dampening of the fodder takes the sting out of its leaves and blossoms.

Star thistle honey is heavy-bodied, white, almost as cloying in its sweetness as orange, and has a greenish yellow tinge, like olive oil. It is considered by large buyers equal in quality to any white honey in the State, and with the price at 2 cents a pound more than light amber honey of the alfalfa type, and still rising, beemen in Northern California should worry.

Practical Queen Rearing

A Review by John Anderson, M. A.

MR PELLETT set himself to write a concise manual on the art and practice of queen rearing, and right well has he succeeded. He has done more than he promised in the preface; he has passed the grist through his own mill, has added the distinctive Pellett touch, and in the very limited space at his disposal has clearly indicated the principles underlying the various methods. The book is not therefore a catalogue of directions which must be followed in every detail or not at all. Each one can judge of the methods for himself and select those most suitable to his particular condition.

The illustrations are most helpful and many are of high artistic value. Securing that frontispiece of the queen, drone and worker, must have entailed much patient waiting before the desired grouping was obtained.

There are many little hints and devices which make for greater dexterity, smoothness, and success, in the various processes. When using the Miller method I used to trim up to the eggs according to instruction in a British book, but I rarely succeeded in getting cells on the edges of the comb. The writer of the book had forgotten that bees in a hurry select larvæ and not eggs for queen-making. Dr. Miller gives the necessary hint on page 56. The horse-hair spoon is a cute idea calculated to neutralize much clumsiness on the part of the operator. The grafting house is another valuable suggestion, and a great improvement on the kitchen. If thought advisable, the atmosphere in such a house could readily be given that degree of humidity which Signor Penna thinks so desirable.

Opinions may vary as to some of the theory on which certain practice is based. It is difficult, for example, to believe that food and space

during larval life make all the difference between a queen and a worker. If so much royal jelly, and so much cell space, develop in a worker pollen-combs or baskets of a certain size and complexity, one would expect that the larger queen-cell with unlimited royal jelly would produce still better pollen-combs. But the queen has no pollen-combs, no pollen-baskets, no wax glands, a smaller brain, weaker jaws, less perfectly developed eyes! If the queen were uniformly better developed than the worker we might be content with the food and space theory, but it obviously cannot explain such differential development.

The attempt to practically eliminate the drone is perhaps not entirely well advised. Although the drone is unfitted for the more familiar duties discharged by the worker, there are certain ancillary activities, or rather passivities, in which the drone may not be a negligible quantity. At night, when the important duty of ripening the honey is being performed, the burly drones must help considerable in keeping up the necessary temperature. On moderately cold days, when mating is impossible, but nectar is being gathered, the presence of the drones on the brood may release an equivalent number of workers. Some of us think that bees are more contented, work better, and are less likely to need queen excluders if a moderate quantity of drone-comb be permitted. This drone-comb should be placed at the sides in order that drones may not appear too early.

Mr. Pellett accepts the general view that the first virgin to emerge is accountable for the destruction of any other cells in the hive. This is not invariably the case. One or more cells may be destroyed before any queen is due to emerge; and I have seen every cell destroyed by the workers except the one which afterwards emitted the chosen virgin.

Are cells quite as delicate as some would have us believe, and is the orientation so very important as indicated on page 78? A cell which I carried on a motorcycle for four miles yielded a nice queen just a week later. I have seen naturally built cells horizontally placed, and I have been in the habit of placing cells in nuclei almost horizontally just under the quilt. This ensures their being kept warm, and enables one to see if the queen has emerged without the necessity of disturbing the combs. If cells must always be point downward we shall have to revise our practice.

The analysis of introduction methods is most illuminating, and probably sound, both as to theory and practice. It is a pity that Mr. Pellett did not specifically mention the Simmins method of direct introduction. It is as simple as any, and usually successful. Cheshire was delighted with a method by which he could have a queen laying in half a dozen hives in a week.

It is sometimes difficult to tell without waste of time whether a virgin is actually present in a hive, and

it is frequently recommended that one should place in the hive a comb with eggs and young larvæ to see whether cells will be formed. Hewitt is positive that the addition of any but sealed brood will make the bees ball the queen on her return from mating. Dr. Miller seems to be coming around to this view. (July Gleanings.)

The suggestion that queens may convey disease through heredity is most interesting. The experience of Poppleton with paralysis is particularly apt, since Britain is being depleted of bees by a disease something very like what troubled Poppleton. It is frequently stated that the queen is immune from Isle of Wight disease, and it is quite true that she almost invariably survives to the last, and seems not to die of the disease, but from want of attendants. I have in recent years repeatedly introduced such a surviving queen to a fresh stock, and the result has invariably been that sooner or later her offspring developed Isle of Wight disease. Indeed, so far as I am aware, this is the only artificial way of producing the disease.

The library of an intelligent beekeeper cannot be considered complete without a copy of "Practical Queen Rearing."

COLLEGE OF AGRICULTURE,

Aberdeen, Scotland.

(Mr. Anderson maintains the popular sentiment in favor of the usefulness of drones to keep the hive warm. In view of Dr. Brunnich's studies (September American Bee Journal), which show the drone to have a higher temperature than the worker, we might agree to this "ancillary" usefulness, were it not that drones have to be reared previously, often at a time when warmth is at a premium in the brood-combs; were it not also that whenever a return of cool weather decreases the flow of honey the drones are mercilessly destroyed, whether full grown or in the cell; even when they may be needed a few days later. In addition, we must call the attention of Mr. Anderson to the much greater heat of the summer climate of the Mississippi Valley, where the question, during the swarming time, is not "how to keep the hive warm," but how to keep down the excessive heat.)

The Simmins direct introduction method and all similar methods are good to introduce queens that are fresh from the hive. But for queens that are fatigued from a long voyage, there is very little success in any method of direct introduction. We have had proof of this in hundreds of cases.—C. P. D.)

The Seventh Annual Meeting of the Iowa Beekeepers' Association will be held at Des Moines, Ia., on Wednesday and Thursday, November 6 and 7. The Mid-west Horticultural Show occurs the same week. Every beeman should be present. Many prominent beemen, specialists in various lines of bee work, are to be present.

HAMLIN B. MILLER,
Secretary-Treasurer.

Marshalltown, Ia.

Women and the War

By Mary G. Phillips

WHEN the history of this eventful year is written, there will be many dramatic stories to be told, individual deeds of heroism as well as stirring events involving whole nations, such as the recognition of that strange people without a home, the Czecho-Slavs. But among all the thrilling incidents of the year 1918 there is none which stands out more strikingly as an example of the patriotic spirit of sacrifice than the story of how the American housewife saved the wheat situation—saving lives by her saving food.

In a letter to the President, Mr. Hoover says, concerning the amounts of food stuffs sent by us to our allies: "I am sure that all the millions of our people, agricultural as well as urban, who have contributed to these results should feel a very definite satisfaction that in a year of universal food shortages in the northern hemisphere, all of those people joined together against Germany have come through into sight of the coming harvest not only with health and strength fully maintained, but with only temporary periods of hardship. The European allies have been compelled to sacrifice more than our own people, but we have not failed to load every steamer since the delays of the storm months last winter. Our contributions to this end could not have been accomplished without effort and sacrifice, and it is a matter of further satisfaction that it has been accomplished voluntarily and individually. It is difficult to distinguish between various sections of our people—the homes, public eating places, food trades, urban or agricultural populations—in assessing credit for these results, but no one will deny the dominant part of the American **women.**"

There is a "very definite satisfaction" to be felt, isn't there, if you are

one of the American women who has refrained from using that extra spoonful of sugar in your cooking, who has struggled with bread-making with no wheat, and who has racked her brains for meat substitutes. The "temporary periods of hardships" have not really spelled hardship for most of us—inconvenience, perhaps, a little difficulty in preparing meals, small sacrifices at most compared with the sacrifices of our allies, and yet these amazing results have been accomplished.

The civilian populations of our allies were long ago reduced almost to the danger point of privation, and as the months have gone by it has become increasingly evident that any help in their extremity must come from and through America, and so we have been sending food in increasingly large amounts across the ocean to meet the shortage. The food we have exported has gone to supply our own and the allied armies, the civilian population behind the lines, the Belgian relief, and the Red Cross. Last year, our first as a belligerent, it seemed remarkable enough to be able to export such suddenly increased amounts of food as the following: The export of corn was 2.5 times greater than in pre-war years; oatmeal, 22 times greater; rice, 170 times greater; wheat flour, 5 times greater; condensed milk, 747 times greater; refined sugar, 26 times greater. But all these exports were last year, when we had surplus above our needs. This year has been a different story.

Last spring the wheat crop was largely a failure, and the entire surplus of the 1917 crop had already been sent across. At that critical moment the allied food controllers sent an urgent appeal for 75,000,000 more bushels of wheat—the allies could not continue the war without it. Where was it to come from? It had to come from the amount normally consumed by the American people,

from our own home loaves. On March 29, 500 hotel men had gathered in Washington to discuss the food situation, and when they learned of this need, they voluntarily took the wheatless pledge. The dining car services followed their example, the propaganda spread, and the country was aroused. Churches, clubs, committees, began to pledge "no wheat until harvest," and as a result, instead of the extra shipment of 75,000,000 bushels asked for, we shipped 85,000,000 bushels of wheat! That is this year's wheat story, and it is regarded by the Food Administration as one of the finest manifestations of patriotic spirit since America entered the war.

What we have done with regard to wheat, we can do with regard to sugar. We are now asked to remember that sugar which is mainly a luxury with us, has become an essential element for the success of the war, therefore we must see to it that our armies have what they need and the allied peoples must not be restricted to the lowest ebb. The only way to secure a fair distribution of the sugar available is to restrict ourselves in its use more than we have, for the situation this year is serious. Not only are the sugar bins in homes, bakeries, factories and stores almost empty, but the crops of sugar beets and sugar cane in the United States have been disappointing. The yield from Porto Rico has likewise been less than was hoped for, and it becomes increasingly difficult to obtain sugar from distant sources, because of the need for ships for other purposes. Then as our army and navy grow by leaps and bounds, they require greater amounts of sugar, and we must also send larger amounts to Italy and France to take the place of all that was lost through the German and Austrian invasions. The Germans not only overran much land devoted to beet culture, but they also destroyed many factories. Finally, over 50,000,000 pounds were lost recently through submarine sinkings off the Atlantic coast.

The situation is so critical that every possible means of conservation should be observed. Again it is the housewife who must take the responsibility.

Beekeepers' wives are especially fortunate if there is always honey in the house, but it is their responsibility then, too, not to buy the two pounds of sugar allotted to each member of the family. With the sugar that you do buy, it is a good plan to portion it, putting the daily allowance for each one in an envelope with his name on. This is a boarding house method, and may be a little trouble, but it insures a fair division. There are 96 level teaspoonfuls of sugar to a pound, so that three level teaspoonfuls daily would make a monthly ration of one pound, which is the Italian allotment at present. Think how much sugar it would mean for export if every American family would voluntarily adopt the Italian ration until January.

If the children get candy hungry,

Apnity of Engineer Coppola, at Uge, Italy, in January, 1918.

here are two recipes that will satisfy that longing for something sweet:

Hunky Dory

- 3 cakes sweet chocolate.
- 2 tablespoons rich cream.
- 2 cups popped corn.
- 1 cup nut meats.

Break the chocolate into small pieces and melt it over hot water. As soon as it is melted add the cream, corn and nuts. Stir quickly with a silver fork and lift out in small lumps. This makes the sweet chocolate go twice as far.

Parisian Sweets

Put through the meat chopper one pound of dates, one pound of figs and one pound of nut meats. Add one tablespoon of orange juice, a little grated orange peel and one-fourth cup of honey or syrup. Mould into balls and roll in chopped nuts, coconut or chocolate. This mixture may be packed in an oiled tin, put under a weight until firm, then cut in 1-locks. Melted chocolate may be added to the mixture before moulding if desired. A little of this would take the place of dessert.

Treating American Foulbrood

By M. Wyszong

I HAVE been having bad luck treating American foulbrood this spring. We have been pestered with it for several years; have had a few cases every year. We are unable to find the source; rather think that it is in some of the many beebreeds in the neighborhood. I have been successful in treating the disease until this spring, but failed completely this time. The method that I use is: Cage the queen for 10 days, then shake the bees in a clean hive with 5 frames of 1-inch starters for 3 days; then take the starters out and give them full sheets of foundation. The old brood-hive is on top with 2 super-covers, the top one with a Porter bee escape; leaving the old hive for about 20 days; leaving the young bees plenty of time to go below. Have never had the disease to reappear in the same hive until this spring. Last fall I even took the top hive that was partially filled with honey by a colony of American foulbrood and shook the bees in that hive-body, and they came through perfectly clean, as the hive has shown no sign of the disease. This was done after the honeyflow, when the queens were not laying, and I rather think that that is the secret of the success.

This spring I had 4 colonies with diseased combs, so treated them as before. I looked in the hive a few days later; saw that the queens were laying, so did not look at them for several weeks. Imagine my surprise in finding them in worse shape than before treatment. Of course, I was not long in going through the other hives, but found all the hives free of disease.

I treated them in a good fruit-bloom flow. Now there were no bees that got out of the old hive, as I al-

ways fasten the two covers on with staples.

Two of my neighbors had the same experience.

Did the bees from the old hive carry the disease down? (That would be my guess), or did some of the old criminals remember the source from when they got the honey and do the same thing over? I wonder whether shaking them in a good honeyflow was what caused it.

Would like to hear from some more experienced man than myself.

We have had just a fair flow here. Weather conditions were against us for the last two weeks. Everything was very forward here, the basswood bloom was over about one week ago. Usually it does not begin until about the 10th of July here.

Kimmell, Ind.

(The most successful method with us is to shake the bees during the honeyflow as soon as possible after the disease is discovered. Of course, if you shake after they have quit breeding, there will be some chance of doing away with the disease between that time and the next spring. But there is always more or less danger of robbing when manipulations are done in a time of scarcity.)

It is quite possible that your bees are getting the disease again from colonies in the woods. In that case it is a good plan to hunt the bee trees. But those would soon run out, on account of the disease.—C. P. D.)

Bee Hunting in a Hot Air Balloon

By C. E. Fowler

YOUR August number just received, and I started to read it just before dinner, and although very tired and hungry I felt I must skim some of the cream off. I read transferring bees by using sulphuric

ether, how far bees will go for honey, by L. B. Smith; then I ran right into a mountain of honey, by Lou Sites. I got so mad at Lou for leaving \$400,000,000, worth of honey just because a few bees chased him that I immediately asked a friend to lend me his flying machine, but as he could not spare it, he lent me his hot air balloon; so, after stopping at a drug store to get some sulphuric ether, and calling at Smith's to get some of his strain of bees, I started out to find that mountain of honey.

Every mountain I would come to I would let out a few bees. Like Noah's dove, most of them returned until finally all the bees in the box got crazy, and when I let them out they started like robber bees for a mountain in the distance.

At first I thought it was a volcano in full blast, but it was the bees going in and out that fooled me.

I let loose some of the sulphuric ether and the cloud of bees dwindled until they were all lying quietly in a pile on the side of the mountain many feet high.

Upon examination I found these to be a distinct and entirely new kind of bee (*Apis imaginata*). Instead of putting their honey in small cells or long cells like the bees of Jerusalem, they put it in **one large sell** 100 feet in diameter and one-half mile deep.

While marveling at this great sell I met John D. Rockefeller on his summer vacation and I made arrangements to have him build a pipe line to tide water for half of the honey, but he wanted his share to be the first half, which did not suit me very well, and while we were quarreling over who should have the first half, the bees woke up. John got stung, and I heard the dinner-bell ring. (And the price of honey is still going up.)

Hammonton, N. J.

The Capponi apiary in May. The bee shed was built by Austrian prisoners, except the tiles of the roof.

A Paper Winter Case

By A. F. Bonney

I HAVE evolved a plan of wintering which will, I believe, prove as good as any other, and at a cost, for material, of not more than 25 cents to the colony. As to time, two hours should be enough to make a case, ten or fifteen minutes to prepare the bees for winter.

I shall use a material of which hundreds of thousands of pounds go to waste in this country annually. I allude to the corrugated paper used in making boxes and packing cases, between fifteen and twenty thousand tons of which are made daily in the United States. All that a man can ever use may be had for the asking, and any sized pieces can be utilized, but the larger the sheets are the better.

Begin by making a box one-half inch larger than a standard Langstroth, in width and length, and as much deeper as required. If no cushion or packing material is to be used above, the form may be 12 inches high, but if the absorbent cushion is wanted make the form 14½ inches high, which will allow 3 inches for the cushion. Nail this box, open side down, to a board which must extend four inches beyond all sides of the form. Then across one end, which will be the front of the form, nail a board three-fourths of an inch thick and four inches wide. The ends of this must come flush with the sides of the form, and make the opening in the case for the entrance. Finally, give the form a coat of boiled linseed oil, so that accidental glue will not adhere to it.

The next step is to cut up paper boxes, getting as large sheets as possible; trim them, using a steel square and a sharp knife, then proceed to cover the form. This done, cover all cracks with strips of cloth put on with glue. In my experimenting I have found it better to cover the

form with newspaper a couple of inches, which insured ready removal of the finished case, and the separate pieces of paper board must be held in place with nails until dry. Treat the other corners in the same way. Fill in between these pieces with corrugated paper, and now spots of glue will be all that is needed; then cover the sides, using nails, and let dry. You now have two layers finished.

In building subsequent layers put the bent corners first on the ends of the top, then on the sides of the top, then on the sides again, building up between pieces as at first, which will strengthen the case and make it warmer.

I do not know how thick this outer case should be, but as it rests on cleats nailed to the edge of the bottom-board, sides and back, enclosing the rim of the bottom-board, and is impervious to heat and cold, as well as air tight, one inch might be enough, while three would do no harm.

Finally, bind the bottom edges of the case with cloth, and coat the whole case with liquid asphaltum, such as is used in painting roofs. This will penetrate one or more thicknesses of the paper and make it impervious to air and water and inside heat. This paint retails at about 25 cents a gallon, and that will probably cover several cases.

The case being ready, nail ¾x¾ inch strips around the bottom-board, sides and back. I mean by this, on the edge of the bottom, not on the rail, on which the brood-chamber stands, then make a board of the corrugated paper one-half inch thick, bind the edges with cloth and coat with asphaltum. This must be 19½ inches long and scant 1¼ inches wide and is to lie on the bottom-board inside the rails. This allows a clear half inch between the inside of the front wall of the brood-chamber and the edge of the insulating board, which added to the quarter-inch between the board and the bot-

tom of the hive gives a good, large entrance, and one that opens downward, thus reducing the danger of clogging with dead bees or sleet.

The ¾-inch opening under the front edge of the case, at the entrance may be reduced by inserting a ¾x¾-inch block. My choice is for a 3x¾-inch opening, protected from mice, which would call for a block about 11 inches long. Moreover, I want the entrance of one corner of the hive, as it tends to protect the interior from direct effect of wind.

The cost of such a case should be small. The form, which could be made of cheap lumber, would last a long time, and need not cost more than sixty (60) cents for lumber and nails, while the glue and paint for the cases should not cost more than ten cents. If but ten cases were made the total cost should not be more than \$1.60, or 16 cents per case. One hundred cases would cost about 10.06 cents each. This, of course, for material alone, against \$5 to \$7 for a quadruple case.

It would not be impossible to raise the rail of the bottom-board and use a thicker insulating board under the brood-chamber, but as heat goes up, and none escapes in this case, the half-inch insulating board may be enough.

Buck Grove, Iowa.

A Letter From Italy

Friend Dadant: We have had a very late season here, the bees swarming as late as July 14. I have adopted your advice to spread the combs. I now place 11 where I formerly used 12.

The hives of my apiary, which you have once shown in the American Bee Journal, of which I again send you photos, have been painted with paint and oil of light yellow color, with double slope covers and look very elegant. But I have noticed that:

1. Unpainted hives are more healthful for the bees than painted hives.

2. However greater the cost, it is better to keep hives of bees under a shed than in the open air; they suffer less from the cold or the heat and work much better.

The past winter the snow has crushed the "pergola" which covered my hives, as you may see in the snow picture; so the past spring I rebuilt it with the help of Austrian prisoners. They made everything except the tiles of the roof.

I send my best wishes to yourself and your lady, to whom I wish to be remembered.

ENGINEER CAPPONI,
San Remo, Italy.

Our good friend, Engineer Capponi, is of the same opinion as Dr. Miller in his preference for unpainted hives. This preference is probably still more important in the mountains near the "Riviera" than in our dry climate. The advisability of a bee-shed or "pergola" is also

CUT 1.

A, form; B, block ¾x1; C, platform.

greater there. But a shed is good for any apiary, were it not for the cost. Deep snow, so near the sunny Riviera, reminds one of Southern California, where you may make a big snowball and, in the space of a couple of hours, bring it down to the bathing beach, where it will melt on the warm sand of the Pacific shore.—Editor.

The Winter Cushion

By L. A. Greeley

USE shallow extracting supers and metal covers. For a winter cushion over the frames I find that an ordinary sack is just the thing, without any cutting off or sewing shut. The super is laid down on a level floor and the sack is loosely filled with maple or other forest leaves. The leaves are now crowded down until the sack will go into the super lying on the side. By reaching inside the sack the leaves are now carefully pushed into the corners of the super, after which the top of the sack is smoothly laid back over the cushion. Next I get out the cushion with both feet and tramp it until it fits the super so closely that it may be carried to the hive without falling out. All is then placed over the frames and a 1-inch strip of paper is pasted over the intervening crack to exclude every particle of wind or air. This pasted strip is protected from rain and moisture by a curtain of oiled paper 7 inches wide hanging from top edge of super. Lastly, the metal hive cover is put in place on top of the super. Fertilizer sacks are thoroughly washed and aired before using.

Morenci, Mich.

Taking Bees From a Tree

In your August, 1917, issue, South Dakota wants to know how to take bees from a bee tree. In answer, I will give my experience.

Make a shelf or bracket on the tree where the bees enter; bore a hole in a hive and insert a rubber hose or short piece of gas pipe. Connect with the tree, plugging all spaces around pipe so that bees must go in and out through hive and pipe. Before doing this, prepare the hive by putting in full-sheet foundation, or, if you can get it, drawn-comb is good; or, better yet, if you can get it, use a frame of young brood. In four or five weeks all the bees and brood will be in the hive, having transferred themselves. If left there too long, until the hive is filled with bees and honey, they will store the surplus in the tree. Look in at times, and when the hive has eggs and brood in it, remove it; but leave long enough for the brood in the tree to hatch. This may be done from April until in August. It is best not to use good hives, as there is danger of them being stolen or destroyed. After losing seven good hives I used common store boxes with Hoffman brood-frames. By the above method

I got 20 stands of bees. All my neighboring bee-men thought I did fine. The next spring I had sixteen nice stands of European foulbrood. So, in my case, I don't think it paid to bother, as I lost the hives and got foulbrood. It is better, I believe, to buy a stand from a good bee-man, buy a good queen, increasing slowly, and whenever possible make the bees pay for their own supplies and fixtures. In this way an amateur may gain bees and experience together, and much information not obtainable in books. CHAS. L. PIERCE, De Pue, Ill.

Breeding Good Queens

By L. Sherman

HERE is the plan I follow to rear good queens: Select your two best colonies to rear drones and your third best to furnish queen-cells. In the rest of your yard have in each hive an upper story with a queen excluder under it and an outer entrance for that upper story with a drone trap. Place all the combs containing drones in those upper stories and you will have no inferior drones to mate with your queens and no drone traps at the main entrance to bother the bees in their flight. Alabama.

Results of Wide Spacing for Extracting

By Alphonse Veith

DURING the past season I closely observed the advantage of wide spacing for extracting. The average yield of honey from 7 combs, full depth L. frames in an 8-frame hive-body, was 46½ pounds. The yield of 8 combs in the same kind of hive-body was 40 pounds only. Consequently, there would be a difference of 150 pounds for every

hundred combs in favor of wide spacing. In using a 10-frame hive, how would it work to use 8 combs only, for extracting, with equal spacing?

Old Time Subscriber

I started back in the 50's with Quinby's "Mysteries of Beekeeping" and have been at it ever since. I read the American Bee Journal when Newman published it in Chicago. I lived in Montana, near the Bozeman tunnel in 1883, '84 and '85. I bought a colony of bees from James Heddon, of Michigan, which cost me \$18 delivered by express. The altitude was too high, as there was about 2 feet of snow fell on June 14 and half an inch of ice on the 4th of July. We went to a picnic at Bozeman with Buffalo overcoats on. My poor bees took to the boarding-house table after sweets and drove the boarders out. The boarders were going to mob me and I had to destroy the bees. JAMES HERON, Kittitas, Wash.

Packing Bees for Winter

By Alphonse Veith

THE late Henry Alley once wrote an article on this important subject, and he put special stress on the importance of top ventilation. He said bees need for their comfort about the same as a human being—a warm bed and plenty of fresh air. If bees are packed heavily, without any top ventilation, they will surely suffer from foul air and moisture. Therefore, do not place your top-board on the packing too tight; raise it about an eighth of an inch, and there will be a slight current of air that will dispel the moisture that would otherwise remain in the top packing. Long ago I made the experience that want of fresh air will kill the bees quicker than a severe cold winter.

AAA, brood-chamber; B, inner cover showing bee-escape hole; C, bottom-board; D, bottom insulating board, in place on bottom-board; EEE, sbadow of packing case, resting on extra rim; GG, entrance; H, space for absorbent cushion.

What Can Be Done Through Organization

In order to introduce the subject which we have in mind, we will quote from two letters which have recently come to this office:

"There are places in the Dakotas where the rate—4th class—is higher than from here to New York City. There are points east where honey from California by car lots can be shipped in far below what it costs from here. That these rates are unjustly injurious to honey producers in this section any fair minded man will admit." MONTANA.

"Two years ago a town in Northwestern Ohio considered prohibiting the keeping of bees, but a fight was put up and the ordinance fell through. At the present time another town is considering the same thing. I appeared before the council a few nights back, but have not the least idea what they will do. It is usually too expensive for the individual beekeeper to fight, but I believe that thousands of beekeepers would join an organization formed to combat unjust legislation. I will gladly pay \$10 per year for this sort of protection." OHIO.

Since the above letters were not written for publication, no names are given, but they show the kind of legal problems that are constantly arising. For more than a year past the legal service department has had under consideration a plan of organization that would meet the needs of the beekeepers. After devoting considerable time to investigation it has been found that to be of real service, such an organization must be prepared to undertake legal assistance along broad lines.

Not only must it be prepared to fight unjust legislation, but the growing importance of the business makes it necessary to give much attention to freight rates. When discrimination is apparent it is necessary that the matter be taken up with the proper classification committees and evidence be collected to justify a fairer rate. Further, it must be prepared to handle claims for losses in shipment by freight and express for its members. In short, if there is any justification for an organization of this kind, it must be prepared to look after all kinds of legal matters for its members. One member will be threatened by an ordinance which attempts to make beekeeping illegal within the city limits; another will be unable to collect a small loss from an express shipment which is too small to justify litigation. In another locality the

beekeepers will be seriously hampered by a freight rate which is too high, but individuals cannot undertake to spend two or three hundred dollars in taking it up. In another State there may be urgent need of legislation for the control of foul-brood or other disease.

In this big country of ours there are many problems, any one of which represents hundreds of dollars of loss to the beekeepers as a whole, but which can only be met collectively. Whether honey be given a third or fourth class rating in the freight classification will amount to many thousands of dollars every year to the beekeepers of a single State.

The only practical solution of these matters is the employment of a firm of competent attorneys by the year. They should be located as near to the center of the country as possible. Kansas City would be a logical location, since the beekeepers of New York, California or Texas would be within about equal reach. Every member of the organization should be entitled to turn over legal matter except actual litigation, without further expense than his membership fee. Shippers of package bees who have losses from express shipments could turn in their claims to the attorneys for collection; beekeepers threatened by unjust legislation could notify the organization and the matter would be looked after. At the start the business would not require the entire time of the attorneys, but there would be enough business from the first to require competent service of a high order, and this would of necessity be expensive. If the beekeepers generally will support such an organization all this service can be secured at a probable cost of from \$3 to \$5 per year per member. With a small organization the cost per member would be much higher. With a membership of 3,000 to 5,000 it would be easily possible to save in freight rates, losses recovered and other charges, several times the membership fees every year.

It would be the idea to attend to every kind of legal service relating to beekeeping for its members entirely without cost except when it became necessary to go into court for trial. In this event the association might furnish the attorneys' services for trial of the cases, leaving the litigant to pay his own court costs.

Our older readers will remember that in 1885 a Wisconsin beekeeper was sued by a neighbor who had lost some sheep and who claimed that the presence of the bees in the white clover in his pasture was responsible. The claim seems very ridiculous now, but it was a serious matter to the beekeeper who was sued. At that time there was very little in the way

of legal decisions for the beekeeper to stand on, and it became necessary to spend a good deal of money in fighting the case. Out of this litigation there grew an organization known as the National Beekeepers' Union. The membership fee was 25 cents, and in addition each member contributed one dollar toward the defense fund. For a number of years this organization fought the legal battles of its members, and through its activities favorable decisions of legal questions were secured in a number of instances. It was later joined to the National Beekeepers' Association, and the legal protection was finally dropped when the National was reorganized. Thus the value of such an organization to its members has already been fully demonstrated.

We will be glad to use the space available for this department in a discussion of this subject by our readers. If enough beekeepers are interested it should be an easy matter to effect an organization, and The American Bee Journal will be glad to be of service. Tell us what you think of it.

Advocates Heavy Packing

I THINK there is too much red tape about the question of winter protection, as some things ought to be very plain. The time to pack ought to be no later than October 10, for this latitude, and enough packing should be used to give the required amount of protection, which would be 10 inches on sides and 12 inches on top.

JUDSON A. JONES,
Continental, Ohio.

Double Stories for Winter

For the second winter I am experimenting with a full body of honey over the usual brood-nest. The result last year satisfied me that I got splendid interest on the money represented in the extra honey left on the hives. I am coming to believe that winter losses are more largely due to scarcity of stores of good honey and to spring flying on cold days than to other causes.

H. R. SMITH,
Houghton, N. Y.

Good Crops in Quebec.—We are sorry to hear of your small crop in Illinois. Here, after selling 35 colonies at \$15, I have harvested 2,925 pounds of honey from 89 colonies, spring count, and increased to 152 colonies. These we reduced since to 142 and may reduce them down to 135 for winter. They are in excellent condition. Honey is selling at 25 cents wholesale, but we cannot secure much more at retail.

JACQUES VERRET,
Charlesbourg, Quebec.

Every beekeeper should plan to attend at least one convention this winter.

Disease Diagnosis.—"The Diagnosis of Bees by Laboratory Methods" is the title of Bulletin No. 671, by Mrs. A. H. McCray and G. F. White, of the United States Bureau of Entomology. This short Bulletin is intended to tell expert investigators, in a few pages, how to detect the different diseases, American foulbrood, European foulbrood, sacbrood and the nosema disease. Four cuts accompany the descriptions.

Atkins to Iowa.—Arrangements have recently been completed whereby E. W. Atkins, of the Extension Service Bureau of Entomology is to devote his entire time to work in Iowa. Atkins was experimental assistant to Professor Webster before entering the government work, and his friends in Iowa are glad to know that he is to return to that State, although in different work. With the return of Mr. Atkins, Iowa has three men devoting their entire time to the beekeeping work. Prof. F. Eric Milten, the State Apiarist, has charge of the teaching of beekeeping at the college, in addition to his official duties; Mr. Wallace Park is engaged in experimental investigation in apiculture, and now Mr. Atkins will be employed in extension work. When all the States are as fully organized, there will be rapid advancement of beekeeping as a commercial enterprise.

The Field Day of the Federated Massachusetts Beekeepers' Association, held jointly with the Eastern Massachusetts Beekeepers' Association, at the Norfolk County Agricultural School at Walpole, on August 17, drew a large and enthusiastic audience to hear the excellent program. After the address of welcome by the director of the school, Mr. Kingman, Mr. J. E. Crane of Middlebury, Vt., told delightfully of the curious marriage customs of the different flowers, and by his charming tale brought home the vast service rendered by the honeybee, apart from her value as a honey-gatherer. Following Mr. Crane were practical talks by Mr. Arthur C. Miller, of Providence, R. I., on "The Wintering Problem in New England"; Mr. Allan Latham, of Norwichtown, Conn., on "Pasturage," and Dr. Burton N. Gates, of Amherst, on "The Beekeeping Situation Today and the Future of the Industry in Massachusetts." Mr. Dallas

Lore Sharpe also contributed a few words.

The announcement of the retirement of Dr. Burton N. Gates from the office of Inspector of Apiaries and Associate Professor of Beekeeping at the Massachusetts Agricultural College caused expressions of real regret from all sides. Dr. Gates has built up an apicultural department at the college second to none in the country, and while the beekeepers of the State felt that his call to a wider territory was to be expected, his loss to Massachusetts will be widely felt.

A rising vote of thanks was tendered Dr. Gates for the inspiration and aid which he has been to the beekeepers of Massachusetts and complimentary resolutions were adopted by the society.

DOROTHY QUINCY WRIGHT,
Secretary.

Beekeeping Essentials.—This is the title of a Bulletin, published by the Massachusetts State Board of Agriculture, No. 14, of which Professor Burton N. Gates is the author. It contains 32 pages and a number of good illustrations. It compares comb and extracted honey production, gives advice as to locating an apiary, the number of colonies which may profitably be kept in one spot, outapiaries, hive materials, supers, comb foundation, equipment, buying bees, italianizing, queens, management, wintering, diseases, etc. Massachusetts beekeepers should send to the State Board of Agriculture for this Bulletin.

The Annual Meeting of the Northern Illinois and Southern Wisconsin Beekeepers' Association will be held in Memorial Hall in Rockford, Ill., on Tuesday, October 15, 1918. All interested in bees are invited to attend.

B. KENNEDY, Sec.
2507 W. State St., Rockford, Ill.

Wintering in Cold Cellar.—I placed some bees this winter in a cellar under an outbuilding where I supposed the temperature would be about right, but instead I find it is too cold. The thermometer stands at freezing most of the time, and, according to tradition and all known authorities, this means sure death to the bees before spring. Now, why is this so? Why is there not some chance for bees to pull through under these conditions as well as when left out of doors without protection through all extremes of winter temperature, ranging from freezing to

20 or 25 below zero? If the bees in a cold cellar stand a poorer show, what is the reason for it?

The cellar I refer to is dry, well ventilated, temperature quite uniform at 32 degrees, and the bees are fairly quiet. I will either have to leave them where they are or set them out in the open air. Which would you advise? WISCONSIN.

Answer.—It is an error to think that the bees will not live because the temperature gets below the freezing point, but it has been proven that they will fare better either in a cellar where the temperature is kept between 40 and 45 degrees, or out-of-doors, if they can have a flight often. If the outdoor temperature is such that they cannot have a fly at all, during the same length of time, then they are better in that cellar.

The reasoning is as follows: When at a temperature between 40 and 45 degrees, the bees eat the least amount and therefore do not load their intestines with feces. So they can remain several months, the maximum of endurance being where the temperature is the nearest to the mentioned point and not over 55 degrees.

When wintered out-of-doors, but if they can have a flight on each warm day they relieve their bowels of the load. If the temperature out-of-doors remains low, say below 32 degrees, for several months, then the relief is not to be had and the cold cellar is better.

From your description, I would judge the chances very fair for your bees to winter well, especially if you have such low temperature as we have had to stand during the past winter in the Mississippi Valley. But if your bees have to remain for several months in a temperature below the freezing point, while the outside bees get a flight every few days, you will have less satisfactory results.—Ed.

Bees and Red Clover.—In a recent issue I noticed a discussion of the possibility of getting honey from red clover. There are localities where bees work on red clover oilener than they do on the white. I remember that one season in the Big Horn Valley, Wyoming, we left a piece of red clover go for seed, and the bees paid more attention to the red clover than they did to either sweet clover, alfalfa or white clover. As long as it bloomed they were continually on it. There are places where it is quite a honey-plant, and other places where it is not. Alfalfa, in the corn belt, is not a honey plant, but west of the corn belt it is.

The belief that red clover does not

yield honey to bees is a superstition brought from the old country. They say that when the Lord made the bees they insisted on working on Sunday and, since they would not desist, He forbade them the use of red clover. That superstition is all there is to it.

J. D. KAUFMAN,
Kalispell, Mont.

(We insert this letter because of the legend, of which we had never heard, and also because it is another evidence that red clover does yield honey in some places. But our own experience in the matter leads us to believe that red clover often contains honey that the bees cannot reach because of the depth of the corolla. Otherwise, why should only bumblebees be seen upon it when we can smell the honey in it and can actually taste it by picking a blossom and sucking at the base of the calyx? Friend Kaufman's experience has evidently been upon clover the corolla of which was more or less stunted by the dryness of the climate. But he is right when he says that some plants yield honey in some localities and not in others. The Swiss beekeepers are practically unanimous in saying that there is no honey in white clover in Switzerland.—Ed.)

Another Experience.—I have read Mr. Pellett's letter on "Red Clover as a Honey Plant." I wish to add my experience on the same.

In my first beekeeping I gave very little attention to the different sources of honey. I was too closely confined to my business, and kept a few colonies as a side line. It was in 1901 that I first took notice of red clover as a honey-plant. In that year, up to August, the honey crop was a failure. I had given no attention to the bees except to give them plenty of room for extracted honey. My folks would leave the honey-house door ajar occasionally, and still the bees did not give any trouble. It was in the latter part of August that I went out to see why the bees were so modest about invading the honey-house, thinking that there was no honey. Imagine my surprise on finding every space filled and the bees busy, all going east in the direction of a fine field of second crop red clover, much dwarfed by the dry weather. On my way through town I met another beekeeper, Mr. Pritchett, who kept an apiary of about forty colonies. I asked him to come and extract the honey for me, as I was getting ready to make an extended trip south. His reply was, "I don't know anything about extracting, and you haven't any honey to extract; my bees haven't any, and I know yours haven't."

I went on and investigated the clover field and found the bees in full force and, as busy as I ever saw them, gathering honey from red clover. On my way home I met Mr. Pritchett carrying two full crates of as fine section honey as I ever saw. I said to him, "Where did you get that?" His reply was, "After meet-

ing you I went home and found I have plenty of it."

His apiary was within three rods of his kitchen door, but so quietly had the bees worked that he took no notice of their progress.

Again, in 1916, we had a fine crop of white clover, but the dry weather in July and August cut it off. Yet my bees continued to bring in honey. I again investigated the red clover, which was very much dwarfed, and the bees as busy as could be.

In both these cases the same conditions existed—the extreme dry weather had dwarfed the red clover and there was a complete absence of other honey-plants. The quality of the honey in both cases was the best. Perhaps a shade darker than white clover. It was very heavy. Of the 1916 crop we used the last in sections a few weeks ago. It kept in perfect condition.

B. A. MANLEY, Milo, Iowa.

Losses in Southern Beekeeping.

What is it? I had last year three yards of bees; in one yard I noticed, about the first of June, a patch of brood that had every aspect of European foulbrood. As I had never seen any disease at all I sent a sample of the brood to the Government and asked them what was the matter with it. They wrote back saying that there was no trace of disease at all and that the brood probably became chilled or overheated. I know that they had died of neither of these causes. The disease(?) affected several combs in this one hive and one comb in another hive. This was all that I could find in the three apiaries of 200 hives.

The larvae died for a period of about fifteen days and the disease then disappeared.

This year, about June first, I found a hive affected with the same thing at another yard several miles from the one that had it last year. I also found, out of 75 hives, at least a third of them affected, and in a few days all were affected. I then looked over the other two yards and found that all of them were affected, also.

I at once sent a large sample to Washington. In about fifteen days I got a report saying "No disease at all," but to send another sample. Well I could not find any more. The disease had cleared up. And now all colonies are as healthy as I could wish.

But for a period of about a week I do not believe that a single egg that was laid in the 200 hives ever got to be a full-grown bee. They would begin to die, from a 3-day larva up to just about time to seal the cell over the cocoon.

There was no odor at all; the larvae would turn a blue color and in a few days die and begin to shrink and gradually dry up to a scale, if the bees didn't carry them out before they got dried up; while a few would get rosy, just a little. Most of them were carried out of the hive after they had shrunk some.

I have looked into every book on

bees that I have (and I have quite a few) and I can find nothing like it except a description of European foulbrood, and this has no odor. Most of these hives were Italians and some blacks. The blacks got it first and had it a little longer than the Italians, but I could not say that they showed less resistance to it than the Italians; in fact, I don't think that either of them showed any resistance to the attack; no eggs laid for a period of seven or eight days, matured into adult bees.

In Wilder's "Southern Bee Culture," edition of 1908 page 47, he says:

"While there is a loss, more or less of young bees in all stages of development, in many apiaries of the south, yet it is not always owing to disease, but to the source of feed, for there are certain plants that yield nectar or pollen that seems to poison the young bees, and they die rapidly for a short time, but soon it is all over and no more symptoms appear till that time next year. This loss of bees is small, and not of enough consequence for treatment."

But with me, with 200 hives in which for a period of seven days not an egg matured to a live bee, the loss is more than "small."

Next year, if the disease appears again, I will send brood to the Government and to anyone else who wishes to see a sample, and also to the editors of the different papers; but in the meantime, can anyone shed any light on the subject?

JOSEPH C. SCOTT,
Mt. Pleasant, Ala.

Supers for Sections.—I would like to give my experience with different styles of supers in hopes that it may be of some help to others who, like myself, may have found fault with some of the more common styles. I began keeping bees in 1908, with the regular beeway super and style 2 scalloped sections $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{3}{8}$ inches.

In 1909 I bought some plain section supers of both 4x5 and $4\frac{1}{4} \times 4\frac{1}{4}$ styles and liked either much better than the beeway, as the separators were more durable and furnished a more comfortable place for bees to work.

But I was reading about this time a series of articles from Mr. Townsend to beginners, in which he advocated the placing of sections and frames in some supers at same time. I liked this plan from the start, and still use it to advantage. But for some time I did not find a super that would admit both sections and the regular Hoffman shallow frame.

In 1912 I bought some supers that used $3\frac{3}{4} \times 1\frac{1}{2}$ sections, five in a tier, thus an 8-frame super holds 30 sections and a 10-frame 35. I liked these so well that I have bought nothing else since, though I am still using the other three styles mentioned above, but think I shall change them to conform to the last mentioned this season.

I claim the following advantages for them:

1. They are more economical and

convenient, i. e., they cost no more than other supers and hold more honey, and having no inside fixtures to nail, much time is saved in nailing. With no ends to section holders they are more convenient to fill, as sections always drop in place easily and fit so snugly to slats there is no room for bees to fill with propolis, consequently they are easier taken out and cleaned.

2. It is the only super I know of that is interchangeable with sections and regular Hoffman frames, except where sections hang inside of frames, which is undesirable.

3. If I need to feed in a super I can stack the slats and fences to one side, leaving room for feeder without having inside fixtures misplaced.

I speak strictly from a producer's standpoint, as I have no occasion to ship honey, and my neighbors do not care what style of section they get. For my use I would not consider any other section, as I think these are perfect. Am surprised that more is not said of them in bee journals and catalogs. G. E. LEMON,
Nash, Okla.

Uniting Nuclei.—I will describe a device that I find very useful in uniting nuclei or weak colonies. It has worked more perfectly with me than anything I have yet tried. I make a division-board of strips that fit tight on the bottom-board and sides and even with the top of cover. I cover both sides of this skeleton frame with wire cloth, so the bees can't fight through.

I move, let us say, three frames to one side and put in the division-board and a piece of oil cloth over the frames and then block up the entrance at night and move this colony to the stand of the one I want to unite it with. I slip the frames from the other colony in the other side of the hive, having the wire cloth division-board in, and leave that side of the entrance open.

In three or four days I release the other bees; or I can leave them longer, as they get ventilation through the wire cloth. They unite without a bit of quarreling.

I always kill the poorest queen when I first unite them.

Perhaps this is an old device, but I have never heard of it.

FRANK HAACK,
Marion, Ore.

Wraps for Outdoor Wintering.—When it is desired to wrap hives for outdoor wintering it is entirely unnecessary to buy building, roofing or other expensive paper. Use newspaper for all except the outside layer, which should be a fair quality of wrapping paper, such as merchants get in rolls for wrapping goods. This can be bought of almost any desired width. After all is in place, tie down firmly and then, with a paint brush, give a coat of the following mixture: Kerosene oil, 1 pint; raw linseed oil, ½ pint. This will so waterproof the paper that it will stand constant exposure to rain and sun for a year or two. L. A. GREELEY,
Morenci, Mich.

Another Feeder.—A good deal has been said in regard to feeding and feeders, but as I have never read anything in the American Bee Journal that comes up to my feeder, I am giving a description of it, as I think some of the subscribers may be benefited by it. I take a lid from a 2-lb friction-top honey can and cut a hole through it about an inch and a half across. Over the top side of it I solder a piece of galvanized screen wire, then I put it over the hole in an escape-board upside down, over this I turn a 5-pound honey pail with the lid closely perforated, and the bees can come up and reach through the screen wire to the perforations in the pail that contains the syrup. If it is desired to use more than one pail as many holes can be made in the escape-board as is desired. This keeps the bees out of the extracting super and yet you have an inside feeder less the trouble of the bees while replenishing the syrup. C. H. WILEY,
Harrisburg, Ill.

Device for Transferring Larvæ.—I have used many styles of spoons and scoops for the above operation, but not being satisfied with any of them, I designed the following tool, which works quicker, easier, and with no danger of injuring the young larvæ: Take a piece of wood about three-sixteenths of an inch thick and 4 inches long and shave one end down to a long tapering point; next take a piece of horsehair about 6 inches long and double it and twist the two strands together to give strength

and firmness. Now double again and lay the two doubled ends on the pointed end of the stick, leaving the horsehair project beyond the point of the stick to form a loop or ring about five-thirty-seconds of an inch in diameter; wind fine thread around horsehair and point of stick and it is ready for use. Hold brood-comb so that the light will shine down to the bottom of the cell, insert the ring or loop of horsehair to the bottom of the cell and with a gentle and slightly twisting movement you can easily get the young larva lying snugly through the ring when it (and most of the jelly) may be lifted out and placed in the artificial cell cup.

JOHN GRUBB,
Woodmont, Penn.

Beekeepers' Conference.—We have recently received a report of the fifth annual conference of the National Beekeepers' Association of New Zealand. It reads much like the reports of the conventions in our own country, with the usual problems of disease control, marketing, etc. The organization seems to be in a prosperous condition, with more than a thousand dollars in the treasury.

Those Honey Stickers.—The "Eat Honey" stickers which originated with Dr. Bonney and which have been sold here in America by millions are now finding their way into foreign land. They are being advertised to the beekeepers through the foreign journals and bid fair shortly to come into world-wide use.

The Saunders Feeder.

A New Feeder

By Charles Boone Saunders

MY invention is a bee-feeder which is made on the style of a brood-frame, or made to fit into brood-chamber the same as a brood-frame. This feeder has a reservoir and a trough, and with holes so placed with reference to each other as to conduct the syrup or honey from the tank to the trough. There is space left between the reservoir and trough large enough to let the bees to the syrup or honey. There is a rod in one end of the reservoir which is used to regulate the

flow of syrup or honey from reservoir to trough. I fill the feeder through the hole in the top of the reservoir. After reservoir is filled I place a cork or wooden plug in the hole and after I have put the feeder in the hive I turn the rod that is at one end of the reservoir, as shown in the photograph.

This feeder can be made of any suitable material. The feeder can be used in the hive any time of the year. Bees, also, will not drown. It is a good feeder to use in winter or early spring. When used in spring for feeding you need not use a super.

Barrington, Ill.

DR. MILLER'S ANSWERS

Send Questions either to the office of the American Bee Journal or direct to
DR. C. C. MILLER, MARENGO, IL.
He does NOT answer bee-keeping questions by mail.

Swarming

June 15 a colony was divided, leaving queen with very little brood on the old stand. Yesterday, just before dinner-time, this colony, to all appearances, swarmed, setting near by. Very soon all the bees returned to the hive, and, it being extremely hot, I let them alone for the time being. This morning I went to examine this colony, and on 3 frames found 7 or 8 queen-cells, most of them capped. There were also eggs (some) in the hive. The bees appeared so profuse in quantity that, beyond doubt, they desisted from swarming, for the time being at least. What should I do with this colony? PENNSYLVANIA.

ANSWER.—As I understand it, the question is this: A colony swarmed yesterday and returned. This morning's examination shows sealed cells present, also some eggs. The question is what to do this morning. It seems to be a case of swarming, with nothing unusual in the case except the return of the swarm, that return being likely caused by the inability of the queen to go with the swarm. Your guess is that the bees have given up swarming, at least for the present. My guess is that they are just as much in the swarming notion as ever, and that they will swarm again in the course of the day, or later. Possibly the queen may be able to go with them; possibly not. If not, then I should expect the swarm to issue with the first virgin that emerges.

The question, however, is: What shall I do this morning? There is a possibility, of course, that nothing need be done, but I wouldn't trust that possibility. If I wanted increase, I should take away all brood, with adhering bees, putting it in a new hive to build up. If I didn't want increase, one of the ways that might be adopted would be to destroy all sealed cells, put the brood above an excluder, leaving the queen below, and destroying cells above the excluder again about 3 days later.

Beeswax From Honey and Pollen

In the August American Bee Journal, page 280, question 2, "What Do the Bees Get to Make Comb of?" your answer is: "Honey and pollen." Now, Doctor, I am in the position to dispute your word, and would not do so anyway, but I have answered this question a great many times, saying "The bees make the wax from honey."

Just simply asserting anything does not prove it to be a fact.

Some years ago I found a colony of bees that had been robbed in November. I took the bees and put them in a box, without any comb. They were fed in sugar syrup. In February I looked into the box and saw as white comb as was ever built. The bees had not gathered any pollen during this time.

Whether we are right, or both wrong, will not make much difference in the honey crop of the world, but I desire to know the truth. It is your turn to offer an opinion now. OKLAHOMA.

ANSWER.—I do not see that there is necessarily any difference between my answer and your experience. For even though it should be a fact that bees cannot comb without pollen, that does not mitigate against the possibility that they can do better with pollen than without it, and that they will use the pollen when they can get it.

I can offer nothing from my own experience, but find the matter treated quite fully in Dant's Langstroth at page 104, 1907 edition. It will be there seen that before Huber's time

most apiarists believed that wax was made from pollen, either in a crude or digested state. Huber demonstrated, as you have done, that bees can construct comb when fed honey or sugar, with or without pollen, and that they cannot make it if fed pollen without honey or sugar; but he fell a little short of getting the whole truth, for "he did not prove that when *permanently* deprived of it they can continue to work in wax, or if they can, that the pollen does not aid in its elaboration.

"Some pollen is always found in the stomach of wax-producing workers, and they never build comb so rapidly as when they have free access to this article. It must, therefore, in some way, assist the bee in producing it."

"The experiments made by Berlepsch show that bees, which are deprived of pollen when they construct combs, consume from 16 to 19 pounds of honey to produce a pound of comb, while, if provided with it, the amount of honey is reduced to 10 or 12 pounds. If the experiment is continued without pollen for some time, the bees become exhausted and begin to perish. It is therefore demonstrated that although nitrogen, which is one of the elements of pollen, does not enter into the composition of beeswax, yet it is indispensable as food to sustain the strength of bees during their work in comb-making."

No Swarms, Full Hive—Feeding Granulated Honey

1. I have 10 stands of bees, all in most thrifty condition. None of them have given me a swarm this season. I put on the queen-excluders and supers when the orchards were in bloom. Was that too soon, and cause of none swarming?

2. I have one lumber 3-story hive, supers being full size 10-frame. All well filled with honey. When it is time to take off the surplus I shall be in trouble, for the colony is so large it will be impossible for the mother hive to build all the bees. What had I better do to save the bees and also the honey?

3. Can I feed last year's granulated honey successfully to my bees by setting it out in the orchard where the bees will easily find it? I have about 100 pounds of it, all in extracting frames. Will the bees work it up and store it? ILLINOIS.

ANSWERS.—1. Undoubtedly the abundance of room given, especially so early, had a tendency to keep down swarming. Most beekeepers, however, would consider it a desirable thing. At the same time it should be said that it is not generally desirable to give unnecessary room in fruiting time, because it costs something to warm up space not needed when all the heat should be conserved for building up. But when there is danger of crowding in the brood-chamber, then more room should be given.

2. Don't you worry about these bees having room enough. If there isn't room in the hive they can hang on the outside, and when it comes cold enough you'll find them inside. A few days most of my colonies were three to four stories high, and every story seemed full of bees. I reduced them to two stories each, and the bees didn't appear any more crowded, and later in I don't expect them to have any trouble crawling into one story.

3. Yes, you can lay the combs flat on the ground under the trees, where the sun will

not melt the combs, and as fast as the bees lick the combs dry sprinkle water upon them with a sprinkler. You may also set them out in hive-bodies, but it will be more trouble to keep them sprinkled. In either case you stand a chance of dividing with neighboring bees. It should also be added that if the honey from such combs is stored in supers, there is more tendency to granulation than there is on honey gathered directly from the flowers.

Mixed Italians—Requeening

1. I have 10 colonies of 3-banded Italians that are mixed with the black bees; am thinking of requeening with Golden Italians. Are the Golden hardy? I mean, can they stand our cold climate as well as the 3-banded? Are they as good honey-catchers, and as gentle as the 3-banded?

2. What time in the year is best to requeen? How is the best way to requeen?

MARYLAND.

ANSWER.—1. Golden's vary greatly. Some are as good as 3-banded in storing and hardiness, while others are inferior.

2. Other things being equal, you cannot do better than to requeen in fall, but not too late. Instruction for introducing a new queen hardly belongs in this department (it would take more than a whole number to give half that has been written about it); but you will find instructions in your beebook, and instructions for introducing are sent by mail with the queens.

Swarms—Comb Honey—Indian Corn

1. Suppose I get me a "swarming box" and have it ready for next spring; should it be put where bees are expected to swarm? or should I hold it among bees while swarming and before they settle? Are they worth while?

2. Do bees prefer any certain kind of tree to settle on?

3. Should combs be wired in shallow frames if you run for comb honey?

4. When I have full story and full size frames and run for comb honey is it necessary to wire the same?

5. Are Indian corn tassels honey producing? TEXAS.

ANSWERS.—1. Much has been thought and said about swarming-boxes or swarm-catchers of different kinds, but if you have your queens' wings clipped you will find little use for anything of the kind. If you use the Manum swarm-catcher you will wait till the bees settle, and then you will try to get the swarm into the swarm-basket, generally by shaking the limb on which the swarm has settled so as to make the bees fall into the basket, when you will dump the bees in front of the hive into which they are to enter.

2. I don't know that they prefer one kind of tree to another, but they have a decided preference for a place on which a previous swarm has settled, so that if a swarm settles on a certain branch of a tree today, several swarms may settle on the same branch on succeeding days in succession.

3. No wire should ever be in comb honey.

4. You cannot very well produce comb honey in deep frames, unless it be in deep frames containing sections. For wire is out of the question in comb honey, and without the wire, foundation thin enough to be used in comb honey would be likely to be torn down by the weight of the bees. You might use thin foundation in a deep frame by having a horizontal bar through the middle of the frame, making the frame equivalent to two shallow frames.

5. I think Indian corn is not considered a honey-plant, although bees get pollen from the tassels, and I have heard of their getting something like nectar from the joints of the leaves.

Queenless Bees

1. How many ounces of honey are supposed to be in a pound in Pennsylvania?

2. Is there any State bee man in this State; if so, what is his address?

3. Will bees carry in pollen if they have no queen with them in the hive?

4. Is cutting out queen-cells a good plan to keep bees from swarming?

5. If I put a late swarm in a hive, in a few days another small swarm issues and I put that one in the same hive, will the queen that is in the hive kill the one that is run in with the last swarm, and will the hive of bees do well?

6. One of my colonies swarmed this season. I put the swarm in the hive and in half an hour they all went back to the old hive. The next day they came out again. I tried to hive them, and they went back again. In two weeks they came out again. I tried to hive them, but they would not go in the hive, but went back and lit on the roof of the old hive.

What was the cause of these bees doing this?

PENNSYLVANIA.

ANSWERS.—1. Honey is sold in all the States by avoirdupois weight. 16 ounces to the pound.

2. Address Prof. T. G. Sanders, Harrisburg, Pa.

3. Yes and no. I think it's this way: When a colony becomes queenless, the bees continue to gather pollen; but when there is no longer any brood to feed and a surplus of pollen is on hand, little or no pollen is gathered.

4. In some cases cutting out queen-cells will prevent swarming, but generally it will only delay it for a time, if it delays it at all.

5. If both queens are laying queens, or both virgins, the bees are likely to do well; but if one is a laying queen and the other a virgin, there may be fighting. In any case, one of the queens will be killed, perhaps by the bees rather than by the other queen.

6. I don't know. It might be, however, that there was some trouble with the old queen, so that she could not go with the swarm, which would account for the return of the swarm the first times, and then two weeks later there was a young queen (the old one having been killed), and then it might be that the bees merely swarmed out with the queen on her wedding trip and then returned.

Gasoline for Foulbrood

Is it true that gasoline will kill foulbrood germs? If so, how would it do to paint hives, cover and bottom with it? Do you think the bees would again work in built-up frames dipped in gasoline after having been cleaned out?

ANSWER.—I don't think gasoline would be at all effective. I think bees would use combs that had been dipped in gasoline; but I don't know how long it would take for the combs to dry out enough to be used.

Speed of Extractors

1. What number of revolutions per minute should an extractor make?

2. How long should a comb be revolved to obtain best results?

3. Is there any arrangement by which the slip gear improvement can be applied to the old Cowan reversible basket extractor?

4. Is an alcohol barrel, such as can be obtained at the druggist's, suitable to store honey in?

MASSACHUSETTS.

ANSWERS.—1. To give a definite answer to your question definite conditions should be given. If one extractor has 6 inches from the central shaft to the comb and another has a less distance, the latter will require a greater number of revolutions in a minute. If it has a greater distance, it will require fewer revolutions. If the combs are old and tough, it will be well to run them faster than would be safe with new and tender combs. The proper speed for honey that is very thick and rather cold may be four times as great as for honey that is thin and warm. With extractors of different sizes, combs of different strength, honey of different thickness, and of different temperature, you will see that there might be a thousand different answers. So there is wisdom in not attempting to give a definite number of revolutions per minute. After you have

had some experience, and have broken a few combs in running too fast, there is little doubt you will be able to tell about what is the right thing in your case.

2. Again I don't know. It varies with varying circumstances, and you'll have to learn by experience, just as others have done.

3. I doubt it. But I don't believe the slip-gear makes such an immense difference.

4. Yes.

Fall Treatment of Foulbrood

I have what I believe to be American or European foulbrood in one of my colonies. I want to use the McEvoy method of brushing the bees on frame foundation and keeping them confined for four days. I note you say wait until the honeyflow is on. That would be next June. Could I at once, after confining bees four days, put them into a hive containing about 30 pounds of honey? Or should I wait until spring? NEBRASKA.

ANSWER.—If it is European foulbrood, I wouldn't use the McEvoy treatment, but cage the queen for 10 days. That's in case the disease is not bad and the queen is a good one. If the disease is bad, destroy the queen and manage so that a week or 10 days later there shall be laying in the hive an Italian queen of best stock. If it is American foulbrood, don't wait till next June, but follow McEvoy's advice, and as soon as there is no longer any unsealed brood in the hive exchange the combs for combs of sealed honey. That's all the treatment required. Before doing anything, better right away send a sample of the diseased comb to Dr. E. F. Phillips, U. S. Department of Agriculture, Washington, D. C. and he will tell you which foulbrood it is and send literature as to treatment. If you write in advance he will send you a box in which to mail the comb. It will cost you nothing.

Removing Foundation

I have a strong stand of bees and they had three supers on that were pretty well filled. I raised the three up and put on a super filled with the one-pound sections that had foundation in them. When I looked in them the other day I found that they had taken all the foundation out of the two outside rows of sections. Now, what caused them to do that? I have another hive that has got a super on that I put on the same way, only I put it on top, and this hive has got the 27 pound sections nearly full of honey. ILLINOIS.

ANSWER.—I don't know. I should guess that it was pretty hot and a heavy mass of bees might have broken down the fastening of the foundation; but in that case it would be more likely to be the inside instead of the outside sections.

Prime Swarm Swarms

In 1916 we brought a queen and 3 pounds of bees. Same proved to be of excellent stock. This same colony, on June 4, this year, cast a prime swarm of immense size. We hived it in a 10-frame hive, and on July 20 this same prime swarm cast a swarm, also of large size. Now, I understand a young swarm hardly ever swarms again that season. The hive that cast the swarm had 4 supers on, 2 of them had 56 well filled sections, and some work done in the other. Why did this swarm act as it did? MINNESOTA.

ANSWER.—I don't know that I can give any reason why a swarm occasionally sends out a swarm. Possibly because very strong and of swamy stock, or because in some way the queen feels crowded.

Poison From Propolis

I have been keeping bees for a few years and have been right successful. But something about the wax poisons my skin and makes me break out, so I am afraid I will have to quit. I went to a local druggist physician and he recommended washing in a saturated solution of borax water. This gives me relief in a measure for the time. Can you recommend something which would enable me to get rid of the trouble without quitting the bees? COLORADO.

ANSWER.—I am sorry to say I cannot help you out. I think it likely it is the propolis that makes the trouble, some skins being peculiarly sensitive to it. The trouble comes especially at the time of scraping sections, when more or less dust must be flying from the dry propolis. In such a case it is better to give up comb honey and extract. If, however, the trouble comes with you when producing extracted honey, I'm a little afraid the best thing is to give up bees. Something was written on this subject in the June number, page 202.

Queen-Excluder—Drone Combs

1. Do the Dadants usually use an excluder for queen in their large hives to produce extracted honey? Do you advise an amateur to secure queen excluders if he uses the Dadant bees?

2. I often notice this advice: "Cut out all drone-comb found on brood-comb frame and replace with foundation or worker comb." How can this worker comb be fastened? Won't it make a very uneven brood-frame, and won't the honey-cells be cut and honey run out and injured brood-frame?

3. In wintering in 10-frame regular hive, is it necessary to leave on one or more supers, or do you remove all supers? All bees are wintered outdoors in our climate.

ALABAMA.

ANSWERS.—1. The Dadants use no queen-excluder under their extracting-supers, but these last contain shallow frames. If you use them the same as the Dadants, it does not seem necessary to use excluders.

2. The patch of worker-comb to fill in the hole made by cutting out the drone-comb is made a trifle large, and is squeezed into place and held there by the tight fit. After the bees are done with fastening it in, you will hardly notice any unevenness, and the comb will be as good as if there had been no patching. The dripping of honey would be easily cared for by the bees, out this patching is usually done at a time when little honey would be in the way.

3. Usually all supers are removed at the close of the honey season, although some leave on a super for winter, generally packing it full of some light material, such as chaff, leaves, or planer shavings.

Increase—Foulbrood—Apiary on Shares

1. Would it increase the population of the hive to leave full supers on hive till late in the fall? I should think that feeling rich, they would be more lavish in brood-rearing.

2. How could I unite the bees of an American foulbrood colony to a clean colony without danger, in the fall?

3. What kind of an agreement could I propose to a farmer regarding an outapiary? I drew one up on a typewriter with the aid of a young lawyer which so scared the farmer that he turned me down flatly. ILLINOIS.

ANSWERS.—1. I don't believe it would make any difference.

2. If you wait till there is no more unsealed brood, I don't believe there would be any danger.

3. In most cases there is no agreement in writing, and in most cases there is no trouble. Indeed in most cases there is no agreement as to anything the farmer is to do, only he gives permission for the bees to be put on his land, and then, if the beekeeper is wise, he will give the farmer enough honey so that the farmer will want the bees to continue. In some cases, however, the farmer is to do something in the way of taking care of the bees, as living swarms, in which case a definite agreement in writing would be advisable.

Bees on Shares

G. has 6 swarms in old box hives and has no time to give them.

F. would like to transfer them, introduce Italian queens and run them for extracted honey.

Would you suggest a plan of division of profits that would be fair to both parties, F. doing all the work, but bees staying on G.'s place?

NEW JERSEY.

ANSWER.—It is hardly possible that there can be any fixed rule that would apply in all cases, and each case must stand for itself. Suppose G. is perfectly competent to take care of the bees himself, but is so crowded for time that he would rather have some one else do the work, while F. is only a beginner, and would like to do the work for the practice. In that case F. might be well satisfied to get one-fourth of the honey, leaving G. three-fourths. But if G. knows nothing about the care of bees, while F. is thoroughly competent and has all he really cares to do in taking care of his own bees, the latter might not care to do the work for less than three-fourths, or even more, of the honey. Possibly conditions might be such in most cases that an even divide would be not far out of the way.

Winter Protection

I have wintered my bees the past three seasons in quadruple winter cases with very satisfactory results, but as I increase in number of colonies I would like to get a simpler method and am planning to arrange as follows: I group my colonies in twos, use three brood-chambers for each, putting the bees in the first and second stories, packing the exposed sides and top story with leaves or chaff, and packing the rear with leaves, held in place with poultry netting. I have never seen this plan suggested, but it certainly is economical, and I believe that with the stores arranged as above the accessibility of stores and the conservation of the heat of the colony will be better secured than with bees confined to a single story. What do you think?

NEW YORK.

ANSWER.—I have had no experience in the case, and one can seldom be sure how a plan will turn out until it is tried, but I see no reason why you should not make a success with the proposed plan.

Swarm Would Not Stay in Hive

A telephone lineman asked me to get a swarm out of a cable box on the top of a telephone pole. I had an extra hive, but did not have any frames for it, so got the bees into the empty hive and as the comb was fastened in among the telephone wires, I got the best I could and put it in the hive and took it home. I left it just as it was for five days and the bees seemed to be working and nicely settled, having some brood and some honey. The hive was an 8-frame, of which I had three full sheets of foundation, took out brood and comb, fastened it all in the other two frames and put all eight frames in, the two with brood in the center.

While fastening in the brood-comb some of them were just emerging and crawling about, unable to fly. The bees were not very cross, and it took only a short time. I did this toward evening.

The next afternoon, about 4 o'clock, these bees swarmed. I put them back in the hive. Next day at noon they swarmed out again. I looked the hive over, but saw nothing wrong. Young bees were emerging and the bees had done nothing to repair the comb. I put them back in the same hive and they got right in. The next morning, about 7:30, all bees were gone except the young bees just hatched, who were crawling around the entrance.

What do you think caused the bees to act in this manner? I did not suppose they would go away and desert their young. The hive is one from which I transferred a colony into a new one this spring and which I cleaned up and repaired in good shape.

IOWA.

ANSWER.—Without any fuller information, it's a matter of guessing, and the safest guess is that the hive was in too warm a place, and enough ventilation was not given. That's the cause of such desertion in the great majority of cases. When bees are put into a new hive, the hive should be well shaded. Even if shaded, there may not be ventilation enough, and, for a few days at least, it is well to raise the hive on blocks an inch or more, and to shove forward the cover so as to allow a space of half

an inch on top at the back. It should be said, however, that it is quite unusual for bees to leave a hive with brood in it, and it may never happen to you again.

Foulbrood

1. I am sending you some kind of a bee. Can you tell me what it is? I caught it working on the red clover. There were a good many of the same kind of bees gathering both pollen and nectar from the red clover. I never saw a bee like it before.

2. My bees are diseased, I think, with European foulbrood. I have caged the queens for ten days, then released them. The foulbrood was still in the hive at the end of the ten days. Will the bees clean out the foulbrood, since I have released the queens?

3. How soon will I need to look at them again?

4. If there is any foulbrood when I look at them, what shall I do?

5. Had I better kill those queens, or cage them again?

6. If I kill the queen, will it do to let the bees raise their own queen from their own brood, or from brood from other colonies?

7. If foulbrood shows up after the honey-flow, what shall I do? IOWA.

ANSWERS.—1. It has the appearance of a megachile, or leaf-cutter bee.

2. If it is the European variety of foulbrood, in all likelihood you will find it disappear. At the end of ten days there may be black-looking dead brood in the hive, but the bees will not eat it to continue the disease. But why don't you send a sample to Dr. E. F. Phillips, U. S. Department of Agriculture, and learn for certain what the disease is? It will cost you nothing, and you will not be working in the dark.

3. It is not very important just when you look, but it might be ten days, two weeks, or more, after the queen renews laying. If you then find no large unsealed brood with a distinctly yellow tinge, you may know there is no European foulbrood, although, being in the neighborhood, it may reappear at any time.

4. Treat it again.

5. If the case is mild and the queen a good one, cage her; otherwise kill her, for in a very bad case it seems to affect the queen so she is not worth saving. At any rate, you should get into each hive, as soon as you can conveniently, a good Italian queen.

6. Yes, only to let them raise a queen themselves will make an unnecessary break in brood-rearing, which need not be longer than ten days, and possibly less.

7. I'm not sure whether you had better do anything till honey yields next year, only you should, right away, send to Dr. Phillips and get free literature informing you pretty fully on the whole subject.

Introducing Queens—PICKLED BROOD

1. Which is the best way of introducing in the fall, when there is no more brood in the hives, nor any honey coming in. Earlier I would have used your plan, to set the colony male queenless, on a new stand, leaving a frame of brood on the old stand to catch the old bees. Do not you think such a dividing at fall season would disturb the colony too much for successful requeening? (They are valuable queens from Italy.)

2. What do you think of the distress method of Mr. A. C. Miller and of Baldwin's smearing plan, in the June number of American Bee Journal?

3. Which treatment would you recommend in the following disease, which I believe to be pickled brood (please state whether I am correct)? Brood dies in the combs after they are sealed. The pupae shrivel up so they may be easily shaken out of their cells, of which capings show a large perforation, with rims cocked up. The pupae are not dried up nor modified in color. In fact, the bees pull them out of the hive and, as no hatching takes place, the colony dwindles rapidly. The queen, however, keeps laying, and even several eggs are sometimes to be seen in the same cell. The larvae seem ordinarily not to be suffering before they are capped over (except in very bad cases, when they are also thrown out of the

hive.) The disease seems very contagious, as all the hives in an apiary may be affected. In rare colonies it cures by itself, but in most cases it causes sad havoc. Transferring bees from skeps to modern hives in such apiary is sure to result in diseased brood in the new hive. I must add that there is no disagreeable stench, and I have found none of it in a sample sent me. Such disease is not described in our modern books. Ancient authors like De-beausays and Hamet mention it in their writings, but do not seem to consider it very serious (though Hamet-Seville says it might result in foulbrood). FRANCE.

ANSWERS.—1. Introducing a queen very late in the season may be the same as at any other time, except in one particular. When it is so late that you no longer expect brood to be reared, then you can allow the queen to remain caged in the hive 3 or 4 days, or even a week, before allowing the bees to release her. This longer time of allowing the bees to get acquainted with the queen—or allowing the queen to get the colony odor—will make the introduction safer.

I don't think any ill results would come from ridding the colony of the older bees, even late in the season, by moving it away, leaving a frame of brood in a hive on the old stand to catch the returning field bees. Instead of putting it on a new stand, I would proceed in this way: Set on the old stand a hive containing one or more combs (with brood in one of them, if brood is to be had), then on top of this put the hive of combs and bees. Of course this top hive has its bottom-board, so that there is no communication between the two stories. In a few days, when the queen is well introduced, all may be put together in the lower story.

2. Each of these methods is successful in the hands of some, while others do not succeed.

3. I'm not an expert on bee diseases, and don't dare advise. If you send a sample of diseased comb to Dr. E. F. Phillips, Washington, D. C., you may get the desired information.

Packages vs. Nuclei

1. Which would you consider better in my climate, to buy about May 15 for increase, 2-pound packages at \$5, or 3-omb nuclei at \$6?

2. Will bisulphide of carbon be satisfactory to kill a swarm of black bees lodged in the walls of a house? Sulphur has had no effect upon the bees, the cavity being so deep.

3. Will sweet clover seed itself down year after year if it is planted in waste places and roadsides?

4. What is a good way to transfer a colony in a Danzenbaker hive to a 10-frame Langstroth without cutting the combs? \

5. Do bees ever seal honey before the cells are full, as in case of a fall flow, where there is not enough honey left to fill them up?

6. Can I get combs built from full sheets of foundation in the fall by feeding a little thin syrup every day? NEW JERSEY.

ANSWERS.—1. Perhaps the nuclei.

2. As you say the cavity is deep, that sounds a little as if the entrance is at the top of the cavity. In that case the bisulphide should work better than the sulphur, for the fumes of the sulphur rise and those of the bisulphide fall. If you use enough of the bisulphide and keep it closed tight, not opening for 24 hours, it may succeed.

3. Yes, but it yields seed only in its second year, so, if you want it to bloom each year it must be sown two years at least.

4. I don't know of any way unless it be to get a set of combs, Langstroth size, or frames filled with foundation, and brush the bees upon these. Then you could put on this an excluder and the old combs on top for the brood to hatch out.

5. I don't think they ever do.

6. No; you would have to feed a good deal, unless the bees were gathering, and if they were gathering enough you would not need to feed at all.

Packing—Bees Dying on Snow—Old Comb

1. Our hive covers are 6 inches deep. Will a gunny sack filled with wheat straw, placed in the cover make a good packing above the frames, absorbing the moisture, etc?
2. May the sack of straw be allowed to rest directly on the top-bars?
3. Would it be well to place paper on top of the sack?
4. Last winter a number of bees would come out of the hives, carrying dead bees; alighting on the snow, they would become numbed and freeze. Were the hives too warmly packed, or should the snow have been cleared away?
5. When bees begin to tear down old comb and build in new in patches, should the old comb be replaced with foundation?
6. Do the bees use the old wax from such combs over again?

MISSOURI.

ANSWERS.—1. Yes; leaves would be much better.

2. It would do all right, except that the bees will gnaw holes in the sack. So there should be something for the bag to rest on in the way of a thin board covering, but not entirely close, or else some kind of cloth.
3. It would not make such a great difference, but still might be of use. Paper is good to stop air currents.
4. Sweeping the snow away for a few feet, or covering it with straw or something else would have been good. Even tramping the snow would help, as it is the softness of the snow that makes the trouble, the bees sinking down into it.
5. I don't know that bees ever tear down comb merely because it is old, but because it is objectionable in some way. Anyway, if only a small spot appears objectionable, it may be patched with foundation, or, still better, with drawn-out comb. If the whole comb is bad, as it may be when left for a long time out of the care of the bees, then it should be replaced with a new frame of comb or foundation.
6. Not as a rule, although I'm not sure but they sometimes use it in prowl'is.

Royal Jelly—Transferring

1. What is royal jelly and what color it is?
2. Where is royal jelly found?
3. How much is needed to rear a queen?
4. What is best to do, let bees swarm, or use Alley trap to keep them from swarming?
5. I had to transfer some bees from a box-hive; I used the drumming plan, and, to my surprise, they wouldn't drum out at all. I will tell you how I went about it, and my question is, tell me where I made my mistake? I put an empty box on top of the old box-hive, but first I smoked them good and turned it upside down, then I started drumming, and I drummed about an hour; did not drum a bee out of it.
6. After transferring I found it necessary to feed them. I fed with a division-board feeder. Soon after I fed them they made quite a noise around the front of the hive. There was no robbing or fighting; but why did they make that noise?
7. If bees are left out of doors in winter should they have an extra cover over them?
8. Should each hive have a cloth cover between the frames and top, or does it make any difference?
9. Which pays the best, extracted or comb honey?
10. Do you know where I could get some basswood trees? If you do, give the address.

ILLINOIS.

- ANSWERS.—1. It is the food given to the larvæ which are to be reared as queens, and in color and consistency looks much like thick cream.
2. In queen-cells.
 3. I don't know. In a queen-cell about to be sealed you will find as much as the size of a pea; but it is not all used by the larva, for when the young queen emerges from the queen-cell you will find quite a portion of it left in the cell, dried into a stiff jelly, quite a bit darker than when fresh.
 4. For you it will probably be better to let them swarm. The Alley trap does not pre-

vent swarming; only catches the queen when the bees swarm. Then the swarm returns. Only to swarm again if nothing is done.

5. Likely you did not drum hard enough. You must drum hard enough so the bees will say, "This place is going all to pieces; better we climb out as soon as possible."
8. It was because the bees were excited.
7. Yes.
8. Many use no such cloth, but have only a bee-space between the top-bars and the cover.
9. Extracted, generally speaking.
10. Try any nurseryman.

Strange Behavior

I have had a peculiar experience with an Italian queen. She was with 2 pounds of bees and she soon had a fair colony, but one day I noticed quite an uproar among my bees. I soon saw quite a lot of bees entering another hive, and bees all around fighting, and many dead. I stopped the entrance. I soon saw a bunch of bees near the entrance of the hive, and when I brushed them apart the queen was there. I picked her up and put her in her own hive and put a queen-cage over the entrance. A short time after that I noticed quite a disturbance around another hive and noticed the queen with almost all of her colony near the entrance of that hive, which was a double hive, and not knowing it was the same queen, I took off the upper hive and set it aside and put her in the lower hive. I soon discovered she was the same old queen. I then took the hive and brood she left and put it in the hive she was in. I would like to know what was the cause of the trouble. She had plenty of brood and of honey.

IOWA.

If I had been on the spot to see the whole performance, maybe I could have told what was the trouble, and maybe I couldn't. It looks a little like regular swarming, the bees foolishly trying to enter other hives. Sometimes they do that way.

Transferring Bees in Georgia

By F. M. Baldwin.

Mr. J. O. Hallman, who was with J. J. Wilder of Cordele, Ga., last season, is setting up for himself. He uses 8-frame hives and runs for chunk honey. Cypress dressed on both sides is bought by the car load and cut out on a small power saw as he has time and his needs require.

His yards are scattered over a radius of 25 miles and he uses a one-ton Maxfr truck in visiting them. Bees were bought where he could find them in reach of his home yard. Many of them were in old-fashioned gums, but he also found a goodly number in L. hives at a reasonable price. He has over 200 colonies.

The roads are fairly good, only one yard being off the main thoroughfare. This yard is the farthest to which he has to go, being a few miles beyond Rhine, on the Seaboard railway. He has only about two miles of bad road in this journey.

There were 35 gums in the home yard, four of which swarmed and were hived on full sheets of foundation in 8-frame Langstroths. Most of these old gums are made of inch and a quarter lumber, the outside measure being 12x18½ and 12 inches deep. They are an attempt at a movable frame. Cleats are fastened on the inside of the ends of the box and five frames made of plastering lath are hung on them. No attempt is made to keep the combs straight. But in the super, which is six inches deep, full sheets of foundation are fastened in the five lath frames, the

plan being to have straight combs for the chunk honey trade of the neighborhood. The space between the top-bar of the hive and the bottom-bar of the super is rather more than an inch and is usually full of brace combs when the super is removed. I believe Mr. Hallman bought 30 of these and five of the long, slim gum, so dear to the hearts of our fathers. These have been brought to his home and are about 50 feet west of the factory, in a long, straight row near the fence that separates this yard from the house.

The gums are on the ground and a one-story L. hive is set on top. This is filled with foundation wired in the frames. If there was any honey in the super it was put on top of the new hive as a bait to draw the bees into the new hive. When there was no old super with surplus left over from last fall a bait comb was used as soon as it could be spared from a hive in which the bees had been industrious enough to start work above the brood-chamber.

No attempt will be made to confine the queen to the new brood-chamber. She will be allowed the freedom of the whole hive. About the first of October, or as soon thereafter as brood rearing is reduced to the minimum, the old box is to be taken from under the new hive and torn to pieces; whatever honey and wax may be found in it will be cared for and the bees will then be in modern hives. Of course, they will be given a good smoking from the bottom to drive the queen up if she is down below before the bottom is disconnected from the top. Mr. Hallman used this method of transferring when he was with that most extensive of all our beekeepers, our friend J. J. Wilder, of Cordele, who has 5,000 colonies in some 75 yards of southern Georgia and northern Florida. Most of Mr. Hallman's bees are the black kind, and he does not plan to Italianize them at present. They are industrious and doing well. Two hives are worth careful attention. The treatment in their case is different. They have been turned down on the side, a 3-inch strip removed from the upper side to make a good-sized opening, and an 8-frame L. body set over the opening. Then a board is nailed on the bottom to close up that big open space, leaving as much entrance as may seem desirable.

The above plan cuts out a lot of muss and leaves the actual work of transferring largely to the bees themselves.

Perhaps a word as to the probable flow at Helena and through this section of South Georgia may be in order. Our work begins with maple in January. Fruit bloom and chinaberry carry us to poplar in March and April. Gallberry begins before poplar ends. In the summer we expect nectar from cotton and in October and late September the fields are full of what I think is burdock. Just what the average crop in the neighborhood will be under modern management is a matter of guess, as no one has tried it out.

Apiary of H. M. Leach & Sons, Hiram, Ohio

Gates to Ontario

Dr. Burton N. Gates has resigned his position at the Massachusetts Agricultural College at Amherst, to become Provincial Apiarist of Ontario. He succeeds Morley Pettit, who recently resigned to devote his entire attention to his commercial apiaries. Doctor Gates has been a prominent figure in the beekeeping world for some time. He was formerly a member of the apicultural staff in the U. S. Department of Agriculture and later head of the beekeeping department at Amherst. An extended announcement by Mr. Pettit will appear in a later issue of this journal.

Australian Surplus.—According to the Australasian Beekeeper there is a large surplus of honey still waiting for shipping space for export to Europe. There is said to be a surplus from this year's crop in New South Wales alone of two thousand tons. The total available from Australia is estimated at from three to four thousand tons. The better organization of New Zealand beekeepers is given by another journal as the reason for their better success in getting their product to market.

Value of Co-operation.—The New Zealand Co-operative Honey Producers' Association announce that they have a good selling organization in Great Britain and that they have secured a guarantee of a minimum net price of 15 cents per pound to their members for a period of three years following the war. This is nearly double the guaranteed price previous to the war. To beekeepers who have to go half way round the world to get to market a guarantee of 15 cents net for their product for three years after the war is very good. This is a striking instance of the value of organization. Just now our American beekeepers are profiting by the foreign demand, but unless they can get together and act in harmony they will soon find that the beemen of other countries have captured the

foreign market when the war is over. Now is a mighty good time for the beekeepers to organize and prepare to offer their crops together. Organized beekeepers are getting, even now, higher prices than the unorganized ones are getting. A total of several carloads attracts the big buyer, who cannot be tempted by the small offering of a single beekeeper. Colorado beekeepers set the example, but other States are rapidly falling into line. Idaho, Texas and now California, are getting well organized.

Honey for the Boys at the Front.

According to the New Zealand Beekeepers' Journal, honey has been collected for shipment to their boys at the front, under direction of the Red Cross. Approximately five tons were sent, the packing being superintended by Mr. L. Bowman, who was formerly Government Apiarist at Christchurch. Since many of the boys write that they miss the sweets which they have been accustomed to, the honey should prove acceptable.

Classified Department

Advertisements in this department will be inserted at 15 cents per line, with no discounts of any kind. Notices here cannot be less than two lines. If wanted in this department, you must say so when ordering.

BEES AND QUEENS

FOR SALE—About 90 colonies bees at four fine locations, small auto truck and lot of empty hives and supers. J. W. Seay, Lancaster, Texas.

FOR SALE—Three-banded and Golden Italian queens; tested \$1.25, select tested \$1.50, each. Also 140 hives bees and equipment. If interested, write. C. H. Cobb, Belleville, Ark.

FOR SALE—Bees in 10-framed hives spaced 9 frames to the colony, each \$10. P. J. Rettig, Wabash, Ind.

FOR SALE—22 colonies in fine shape for winter, together with supers and extracting equipment. Priced to sell. Goodwin Dahlen, R. 1, Harmony, Minn.

FOR SALE—Three-banded Italian queens; untested, one, \$1; six, \$5; twelve, \$9. Tested queens, \$1.50 each. Rob't B. Spicer, Wharton, N. J.

FOR SALE—125 8-frame, one-story colonies, extra fine honey-gathering strain Italian bees, at \$6 per colony, all free from disease, with stores for winter, and about 600 extracting supers built from foundation, and some empty supers and extra bottoms and lids, all in first-class condition, at proportionately low price, f. o. b. station. W. C. Meiratto, Council Bluffs, Ia., Route No. 2.

ITALIAN QUEENS—Northern-bred, three-banded, highest grade, select untested, guaranteed, queen and drone mothers are chosen from colonies noted for honey production, hardiness, prolificness, gentleness and perfect markings. Price, one, \$1; twelve, \$10; fifty, \$35. Send for circular. J. H. Haughey, Berrien Springs, Mich.

NO MORE QUEENS this season. Root's beekeepers' supplies. A. W. Yates, 3 Chapman St., Hartford, Conn.

FOR SALE—Northern Bred Italian Queens; hardy, prolific goldens, each, \$1; six, \$5. Allen R. Simmons, Claverack, N. Y.

BEES AND QUEENS from my New Jersey apiary. J. H. M. Cook, 141f 84 Cortland St., New York City.

GOLDENS that are true to name. Untested queens, \$1; 6, \$5; 12, \$9; 50, \$35; 100, \$67.50. Garden City Apiaries, San Jose, Calif.

THREE-BANDED ITALIANS ONLY—Untested queens, each \$1; 6, \$5; 12, \$9; 50, \$35; 100, \$67.50. H. G. Dunn, The Willows, San Jose, Calif.

SWARTS GOLDEN QUEENS produce golden bees of the highest qualities; satisfaction guaranteed. Mated \$1, 6 for \$5; tested \$2. D. L. Swarts, Lancaster, O., Rt. 2.

GOLDEN QUEENS that produce Golden workers of the brightest kind. I will challenge the world on my Golden and their honey-getting qualities. Price, \$1 each; tested, \$2; breeders, \$5 and \$10. J. B. Brockwell, Barnetts, Va.

QUEENS—H. D. Murry's strain of 3-banded Italian bees, with select tested queens, in new 1-story 8-frame single wall-hives, standard full-depth, self-spaced Hoffman frames, \$10 each, f. o. b. here. The bees are free from disease. Wilmer Clarke, Earlville, Madison Co., N.Y.

FOR SALE—Colonies of extra fine strain Italian bees, with select tested queens, in new 1-story 8-frame single wall-hives, standard full-depth, self-spaced Hoffman frames, \$10 each, f. o. b. here. The bees are free from disease. Wilmer Clarke, Earlville, Madison Co., N.Y.

FINEST ITALIAN QUEENS, June 1 to November, \$1 each; 6 for \$5. My circular gives safe methods; free. J. W. Romberger, 3113 Locust St., St. Joseph, Mo.

THREE-Banded and Golden Italian Queens and pound packages from the Sunny Southland. Grant Anderson, Rio Hondo, Texas.

FOR SALE—Pure 3-banded Italian queens, as good as you can buy with money, from June 1 to September 1. J. F. Diemer, Liberty, Mo.

REQUEEN with Simmons's Italians; bred for business. Each, \$1; six, \$5. Allen R. Simmons, Claverack, N. Y.

HONEY AND BEESWAX

WE are in the market for honey and beeswax. Send best price on comb honey and sample of extracted honey. State quantities you have, also style, size and weight of package or section. Charles Israel Bros. Co., Inc., 456-490 Canal St., New York.

WANTED—Shipments of old comb and cappings for rendering. We pay the highest cash and trade prices, charging but 6c a pound for wax rendered. The Fred W. Muth Co., 204 Walnut St., Cincinnati, Ohio.

WANTED—White or light amber extracted honey in any quantity. Kindly send sample, tell how your honey is packed and your lowest cash price; also buy beeswax. E. B. Rosa, Monroe, Wis.

QUICK CASH for comb or extracted. Send sample and say how packed, how much and price. Bruner, 3836 N. Kostner Ave., Chicago.

CASH paid at your bank for carlots and less of comb and extracted honey. Wesley Foster. Boulder, Colo.

WANTED—Comb, extracted honey, and bees-wax. R. A. Burnett & Co., 6A12t 173 S. Water St., Chicago, Ill.

HONEY LABELS

SEND TODAY for samples of latest Honey Labels. Neat, attractive labels at lowest prices. Catalog free Liberty Pub. Co., Sta. D, Box 4-H, Cleveland, O.

WANTED

CASH for extracted honey, white and amber, in 10-pound cans. Thomas Lang, 1572 N. Halsted St., Chicago, Ill.

WANTED—Barnes No. 4 circular saw. Otto Bender, 2813 Osceola St., St. Louis, Mo.

WANTED—A good honey location to start a line of apiaries; will give a suitable reward for the best reliable information. D. E. Lhommedieu, Colo, Iowa.

WANTED—White sweet clover seed; send sample; state quantity and your lowest price in first letter. Dadant & Sons, Hamilton, Ill.

WANTED—Your old combs, cappings or slumgum to render into beeswax by our high steam pressure wax presses. Dadant & Sons, Hamilton, Ill.

WANTED—Second-hand honey extractors; tell me what you have and price; also wax presses. W. D. Soper, Jackson, Mich. Dealer in all kinds of Bee Supplies.

WANTED—Samples of honey from the different plants for our office collection. We will pay for the honey and send a parcel post can for mailing. Samples to be of value should be from one kind of flowers only and unmixed with honey from other sources, as nearly as possible. A pint will be sufficient for each kind, but we wish to secure samples of the same kind of honey from several widely separated locations. American Bee Journal, Hamilton, Ill.

FOR SALE

FOR SALE—Three hundred, 8-frame extracting supers, painted white, filled with good combs, mostly built on full sheets of foundation, full depth Hoffman frames, seven frames for extracting; no disease. \$2,900 8-frame hives, \$2.50. Chester E. Keister, Clarno, Wis.

FOR SALE—40,000-lb. car of white extracted clover-alfalfa honey; state best offer, f. o. b. Hardin, Mont., in first letter. Sample if wanted. S. F. Lawrence, Hardin, Mont.

FOR SALE—Cedar or pine dovetailed hives; also full line of supplies, including Dadant's foundation. Write for catalog. A. E. Burdick, Sunnyside, Wash.

BEAUTIFUL FARM HOME—Improved, rich soil, well located, good buildings, 100 colonies of bees, up to date, best honey-producing location in State; not crowded; average for past seven years 105 lbs; 5 acres of ginseng golden seal, all ages, in fine shape. One-half artificial shade, one-half natural. Price \$80 per acre; \$7,000 for farm and bees, 150 extracting supers with combs, 100 excluders, 2-frame extractors, 2 large honey tanks, 150 shallow supers. Terms, \$3,000 cash, balance on time. Will sell a part or all. A wonderful opportunity; a bargain. Poor health, reason for selling. W. M. Penrod, Ronney, Minn.

FOR SALE—Good second-hand 60-pound cans, two cans to the case, at 60 cents each case f. o. b. Cincinnati. Terms, cash with order. C. H. W. Weber & Co.

Cowan Extractor, \$18; white leghorn cockerels, \$1; fox terrier puppies, \$2. Lorenzo Clark, Winona, Minn.

FOR SALE—35 Thale bee feeders, new, \$10. Mason, Mechanic Falls, Maine.

YOU can make your own comb foundation and can a big money making it for others. New, easy, rapid process. Machine and all apparatus complete, with full instructions, \$100. Wax worked on shares or for cash. J. J. Angus, Grand Haven, Mich.

QUEENS THAT WILL PLEASE

OVER 20 YEARS OF CAREFUL SELECTING AND BREEDING

GUARANTEE

You take no risk in buying my Queens, for I guarantee every Queen to reach you in first-class condition, to be purely mated, and to give perfect satisfaction.

They are bred from **Imported** stock. The very best bees for honey gathering and gentleness. They are not given to swarming and are highly resistant to disease. Give me your order and if, after you have given my queens a fair trial, you are not satisfied in every way that they are as good as you have ever used, just return them and I will send you queens to take their places or return your money with any postage you have paid out on returning the queens.

	1	6	12
Untested	\$.75	\$4.25	\$8.00

Untested, \$60 per hundred.			

L. L. FOREHAND : : FORT DEPOSIT, ALA.

"Practical Queen-Rearing"

Is the title of the new bee book, cloth bound, 100 pages, which has just been written by Mr. Frank C. Pellett, who is well known to our readers.

For many years there has been a demand for a book which would give in concise form the many different methods of queen rearing, as the Doolittle, Pratt, Dines, Miller, Alley and others with variations as practiced by different large breeders.

You have this in the new book which is just out. Send for your copy now and get informed as to your best method of rearing queens from your best colonies. Good pointers in it also for the large beekeeper and veteran queen breeder.

Price, postpaid, only \$1.

By special arrangement we can offer it and a year's subscription to the **American Bee Journal** for only \$1.75.

(Canadian orders 15 cents extra.)

Crop Report and Market Condition

Compiled by M. G. Dadant

For our October report we have asked our reporters to write us a brief summary of about the size of crop secured, demand for honey, whether bees will need feeding for winter, condition of honey plants, and honey prices.

THE HONEY CROP

In the New England States, Maine reports about 40% of last year, with other States reporting about the same as last year, with the exception of Connecticut, which has more honey than in 1917.

In New Jersey, the crop is very small, and New York expects a total of from 50 to 75% of last year. Spots in this State report a full crop, with others much under last year.

Ohio has more honey than in 1917, averaging about 50 pounds per colony for those reporting.

The South is hardly up to last year, though likely up to the average of a five-year period, since last year was above the ordinary. Louisiana is the exception, with very little surplus, with Tennessee about 50% of last year, and Kentucky normal.

Indiana, Illinois, Missouri and Southern Iowa have had near a failure, much of the short crop being due to severe drought, which cut off the white clover in spring and spoiled any chances of a fall crop. With our own bees, we moved 300 colonies from 20 to 35 miles to get them in the Mississippi bottoms to avert a famine. Last examinations reveal that they have filled their brood-chambers well, and may make enough surplus to pay for the haul, which was done by trucks.

Michigan had a poor spring crop, followed by a very good fall flow in some localities. It is certain, however, that the crop will be far below the total of 1917, and one large dealer reports that very little Michigan honey will be sold outside of Michigan.

Wisconsin has had as near a failure as possible. Practically all reports are uniform, except a few in the northern part of the State.

Minnesota's crop is poor, averaging hardly 20 pounds per colony. South Dakota is the same, except in the southeastern part, or sweet clover section, where the crop was fine, as it is in the sweet clover section of western Iowa and eastern Nebraska and Kansas.

Texas will certainly not have over 25% of a crop, but even this will be more than the failure of last season. The irrigated sections of New Mexico and Arizona have had almost a normal crop.

Colorado reports close to normal crop, as do Utah and Wyoming, while the reports from Montana are very good, and from Idaho and Washington, far above last year.

California will have about half a crop.

Taken all in all, the crop will not equal that of 1917, which was below normal.

FEEDING OF BEES

Roughly speaking, bees will need feeding in all localities where the crop was a complete or near failure this year, and this means some feeding in New Jersey, parts of New York, Indiana, Iowa, Illinois, Wisconsin, parts of Michigan and Minnesota, Louisiana, Texas, Missouri and possibly some in California.

CONDITION OF PLANTS

The condition of plants varies, especially in the white clover region. Some of the States which show the effects of the drought most are Indiana, Illinois, Wisconsin, Southern Iowa, Missouri and parts of Texas. Copious rains in some parts of these areas have tended to make the outlook a little better for the clover, but conditions are far from roseate.

HONEY DEMAND AND PRICES

Everywhere, without exception, the demand for honey is extremely good. Many reporters are selling to their local trade at about the same figures that they could get by shipping their honey all in one lump to the larger dealers in the big cities, very likely because they want to hold their local trade and are entirely satisfied with the prices obtained.

Retail prices for honey, the country over, vary from 25 to 50 cents, depending on the container and on the attitude of the seller.

Wholesale prices obtained by the beekeeper vary from 22 to 25 cents for extracted and from \$6 to \$7 per case for comb, depending on quality and freight rates to the largest terminals. Not a few of the reporters had been offered 25 cents for white extracted, a price for which they had been holding since their honey was ready for market, and several are holding for even a higher price.

It is certain that anyone wanting to sell can get rid of his honey crop at a price of 25 cents f. o. b. Chicago or New York.

To show the hungry demand for honey, we quote from the report of a Missouri correspondent, a big beekeeper who has developed a large local trade and must find honey this year to fill orders. He says:

"The honey prices here are gone plumb crazy, or maybe it is the beekeepers. I am retailing extracted honey for 30 cents—could get 40. Six hundred pounds I bought got here September 7—all gone in two days. I have to hide from my old customers; but I will take off 4,000 pounds or more soon, and can then face them again for about five days. After that I will take a little trip, as I can't buy any more. No, I can't take a trip, because we must save gasoline—guess I will buy a rope."

The export demand is still good, and with the present activity all honey will probably be sold and into the hands of the consumer, or the hands of the big buyer and wholesaler by the time Christmas vacation comes.

KEEP INFORMED ON TEXAS CONDITIONS

The **Beekeepers' Item**, a monthly paper edited by Mr. Louis H. Scholl, well known to our older readers, and an authority, has many interesting items which should interest beekeepers, not only in the Southwest, but throughout our country.

In order to allow you to become acquainted with this paper, we offer a special combination of **Beekeepers' Item** one year with **American Bee Journal** for only \$1.25.

Or, if you desire, we can send you your choice of **First Lessons in Beekeeping**, or **Practical Queen Rearing** with the **Item** one year for only \$1.25.

Send all orders to
AMERICAN BEE JOURNAL
HAMILTON, ILL.

Texas Queens

No more bees in packages, but queens galore from June 1 to October 1. Untested, 75c each, \$8 per doz.; tested, \$1.25 each, \$12 per doz. I have the Three-banded Italians and Golden Italians; very choice stock.

GRANT ANDERSON,
Rio Hondo, Texas.

Five and ten-pound pails, also five-gallon cans and glass jars. Queens, three-banded and Golden Italian, ready for delivery now. Untested, \$1 each; 6 for \$5.50; 12 for \$10; tested, \$2; 6 for \$10. Safe delivery guaranteed, dead queens being replaced upon their return.

THE DERROY TAYLOR CO.
Newark, New York

Golden Italian Queens

RUSTBURG, VA., R. No. 3, March 18, 1918.

Mr. Ben G. Davis:

Dear Sir—Please find enclosed \$5, for which please send me the very best Golden Queen you can for the money. If you can't ship her at once, please notify me. I ordered one from you 3 years ago last fall that was the best I ever saw. Her bees stored 320 pounds of comb honey the first year. I have several of her daughters that are fine.

Hoping to get a good one again, I am yours truly.

J. W. LAWRENCE.

AMERICAN BEE JOURNAL
HAMILTON, ILLINOIS

WINTER PROBLEM SOLVED

BY

THE HIVE WITH AN INNER OVERCOAT

The Inner Overcoats did it During the severe winter of 1917-18, there was a little apiary of thirty-seven colonies, near Grand Rapids, Mich. Seven of these swarms were in Protection Hives with the Inner Overcoats, all of which came through in perfect condition and without loss. Thirty of the swarms were in the hives without the Inner Overcoats and they suffered a loss of some 40% to 50%. This was a severe test, as the temperature went as low as 20 degrees below zero, for many weeks. The value of the bees that were lost, had they been saved, would have more than paid for new hives for the entire lot.

Have you ever stopped to think what it would be worth to you to insure your bees against winter losses? The life of a Protection Hive will be at least 25 years. Now figure what the cost will be per year, spread over its life time. You cannot afford to buy anything else. You need a certain amount of protection from cool weather during Spring and Fall. Get away from the winter packing-case nuisance, with all its expense, extra labor and inconvenience. With Protection Hives you have a neat, compact and efficient equipment.

Protection Hives are made of $\frac{7}{8}$ material in the outer wall and will last a life time, as they are not permanently packed. The packing in a permanently packed hive, in a comparatively short time, will absorb moisture, become matted down and not occupy more than two-thirds of the space, and will rot out the hive and otherwise get in bad order. When preparing Protection Hives for winter, a piece of burlap is placed over the top of the frames and then two bottomless corrugated paper boxes, Inner Overcoats, are telescoped down over the brood nest, in between the outer and inner hive walls. This provides the burlap with two thicknesses of the corrugated board on the sides and four thicknesses over the top as insulators. They are removed in the Spring, and it takes not over two minutes to insulate a hive for Winter or remove it in the Spring by this method. There are many dead air space compartments in this paper and between it.

Send for a special circular showing 10 large illustrations. It has been necessary to advance prices, but for the next 60 days we will sell from one to five sample complete hives in a place at \$5 each.

Bee Primer for the prospective beekeeper or beginner. A 24-page pamphlet, finely gotten up, with illustrations. It gives a general outline of bees and beekeeping such as desired by the amateur. Two pages are devoted to instructions to beginners. Price, postpaid, 15 cents, or sent free with a year's subscription to American Bee Journal at \$1.00.

A BOOK FOR BEGINNERS

"First Lessons 'n Beekeeping," written by the editor of this magazine, is intended primarily for the use of beginners in beekeeping. You should have it. Price, postpaid, \$1, or clubbed with the American Bee Journal, one year for \$1.75.

American Bee Journal, Hamilton, Ill.

REAL BEE EQUIPMENT

YOU are one of those careful beekeepers who is already figuring on bee supplies for your next year's use so as to avoid the freight congestion later, and also so as to take advantage of any early discounts.

We are in a position to co-operate with you by making *Prompt Shipment* and at *Prices that will Save You Money*.

More than that, you will want the best that you can get for the money. *Real Equipment*, such as we can send you, will not only save you money, but will be a pleasure to use.

Hives and Supplies

THERE is a big advantage in first-class equipment, something that when put up will stand hauling to your outyards; that will stand the weather when properly painted; in which frames will fit perfectly, and where all hives, supers, etc., are uniform.

If you want to exchange a frame of brood it is a calamity to find that frames will not interchange on account of faulty workmanship.

If you want to move a colony a knot-hole in the bottom-board increases your trouble.

LEWIS HIVES, Supers and Equipment, which we handle, are "Built Like Furniture," with every piece interchangeable.

Bee Comb Foundation

WE are Comb Foundation Specialists. DADANT'S FOUNDATION is perfected in manufacture to a degree that we feel justified in recommending to you as *the best there is*. In these days of high honey prices, the foundation which is quickest accepted by the bees means extra honey for the beekeeper. Do not lose sight of this point.

Specialties

TIME SAVERS are money savers. Such items listed in our catalog as Wiring Devices, Electric Wire Imbedders, Swarm Box, Foundation Cutting Box, etc., will save you time—will save you money.

Bee Books

THIRTY YEARS' experience with several hundred colonies of bees has led us to believe that we can furnish valuable information to the beekeeper. Our books are written with that in view. Some of the books of our own publication are, *'First Lessons in Beekeeping,'* *"A Thousand Answers to Beekeeping Questions,"* *"Practical Queen-Rearing"* and *"Langstroth on the Honey Bee."*

Write us for a list of the supplies you wish—We will give you the very lowest prices consistent with first-class goods.

ADVANTAGES OF LARGE HIVES

A Discussion of the Principles of Commercial Honey Production

BY C. P. DADANT

THE discussion of this question is called for, following an editorial in *Gleanings in Bee Culture* for September, 1918, entitled "Bigger Hives and Colonies." The same number of *Gleanings* bears upon its cover the picture of two Langstroth-Jumbo hives tiered to 6 and 8 stories and kept from tipping over by fence rails, with the legend, "Rails to the Rescue." Readers of the *American Bee Journal*, knowing that its editors have, for years, been favorable to large brood chambers, asked for articles upon this subject.

Charles Dadant became a supporter of large hives, and a user of them on an extensive scale, as early as 1868. He had, however, noticed the advantage of large brood chambers long before using them. He often related the first intimation he had of the advantage of a large hive body. This was when he purchased bees from a box-hive beekeeper. The man had one hive which had a capacity of about 2 bushels. This was his oldest colony. He refused to sell it. He had owned it for over 30 years, and although no particular care had been taken of it, the same colony had lived for that entire time. Other hives of less capacity had died in winter or had become weakened in bad seasons until they were robbed, or lost by moths, but this had come through numerous trials and had seasons without mishap.

A similar experience was later given, in the *American Bee Journal* of April 18, 1883, by Wm. Ashcom, of Ligonier, Pa. He said: "On June 14, 1881, I drove a swarm, for a neighbor, out of a box hive that was 60 years old; it had been put in the box when it was new; and when I drove the swarm, it was so rotten I could hardly handle it; there were cracks and holes from top to bottom; it stood the hard winter of 1880-81,

without any protection, and the bees were very strong in numbers when I drove the swarm. That beehive would hold about 2 bushels."

These might be considered accidental instances, were it not that the theory of beekeeping confirms them.

When considering the subject of frames and hives, Chas. Dadant had three teachers before him, Debeauvoys as his former teacher in France, and Langstroth and Quinby in the

United States. Debeauvoys had used a square frame, about 12x12 inches, and Chas. Dadant followed his methods in this country. This was in 1864. A very short time after, having learned the English language—with which he was totally unacquainted—through the use of newspapers and a pocket dictionary, he read the "Mysteries of Beekeeping" of Quinby, and a little later "The Hive and Honey Bee," of Langstroth.

Quinby's hive pleased him best. It was away ahead of the Debeauvoys invention. Besides, Quinby had just been reported, in the "American Agriculturist," as having harvested a crop of 22,000 pounds of fine honey—a rare occurrence at that time—for which he had obtained some 30 cents per pound. This was enough to induce a beginner to follow him.

Quinby, in the book above mentioned, discusses the size of hives and criticizes Bevan, an English author of an earlier date, for recommending a hive of only 1,200 cubic inches. After two pages of considerations, he concludes that the best size for box hives is a capacity of not less than 2,000 cubic inches. Beekeeping was not far enough along, then, for him to recommend the casting aside, entirely, of the box hive.

But when he made his movable-frame hive, Quinby gave it a much larger capacity, 2,925 cubic inches. However, some of this space was taken up by the movable feature of the frames, the bee space all around. But his 8 movable frames, 11¼x18½ inches, outside measure, gave a comb surface of approximately 1,584 square inches, or, for both sides of the comb, 3,168 square inches of cell surface.

The original Langstroth hive, 10-frame, on the other hand, being shallower and shorter, supplied only about 2,800 square inches of comb surface. Nowhere in his book, how-

Moses Quinby, original champion of the large frame

ever, did Langstroth recommend a smaller hive than 10 frames. His experience indicated that ample room was needed. He wrote: "Many hives cannot hold one-quarter of the bees, comb and honey, which, in a good season, may be found in my large hives; while their owners wonder that they obtain so little profit from their bees. **A good swarm of bees, put, in a good season, into a diminutive hive, may be compared to a powerful team of horses harnessed to a baby wagon or a noble fall of water wasted in turning a petty water-wheel.**"

These words ought to be inscribed in capital letters on the wall of every bee house, accompanied by this other maxim, which Langstroth called "Oettl's Golden Rule: **Keep your colonies strong.** If you cannot succeed in doing this, the more money you invest in bees, the heavier will be your losses; while, if your colonies are strong you will show that you are a **bee-master**, as well as a beekeeper, and may safely calculate on generous returns from your industrious subjects."

But neither Quinby nor Langstroth gave any hint, in their writings, that they had calculated the space needed by a colony containing a prolific queen. They suggested that much depends on the locality and the season. This is true. But there are first principles to consider, if we wish to get large returns, no matter what locality we live in. The prolificness of the queen is the main criterion, for the measure of hive size.

When a farmer builds a barn he is a poor manager if he does not consider first the number of animals, farm implements and farm produce.

that he wishes to shelter in it. Why, then, should the beekeeper neglect to make the same calculation on the necessary capacity of the brood-chamber of his hives?

The requisites of success in beekeeping are all in a strong force of bees **at the time of the honey crop.** As bees live only about 35 to 40 days, on the average, during the summer, the strong force of the colony must be secured quickly and be ready at the height of the harvest. Should the harvest last several months, it would be necessary to continue with a great force of bees until it ends. For that purpose, the necessary room for breeding must be unobstructed by stores. So there must be sufficient capacity for the breeding of the best queens and ample room for surplus. This is one of the reasons why the production of extracted honey is so much greater than that of comb honey.

There are, of course, differences between different breeds of bees as to activity, strength and other qualities of the worker bees. But given the colonies of same breed, the most successful will be the ones with the best queens, if they have room in plenty and a sufficiency of food. It has been said very truly that a queen which is allowed to lay eggs at her utmost capacity for months will wear out or become infertile in shorter time than a queen whose prolificness has not been put to the test. But a prolific queen, well fed by her bees, as should be the case, will often lose eggs, if they develop faster than she can find cells for them. Queens have been known to lose hundreds of eggs when deprived of cell room for a short time. Loss of eggs, when pre-

paring for the crop, is loss of honey.

If our queens wear out faster because of their ability to lay is put to full extension, we need only to replace them oftener. Queens are known to live from 3 to 4 years, occasionally 5. If they are given free space and encouragement to lay, it may be necessary to replace them every two years. Some of our leaders in beekeeping are already recommending this, and a few even advise the annual replacing of the queens. So we might as well use their full powers, and secure the profuse laying at the proper time, so as to have the densest population, in the hive, for the crop.

If two colonies, side by side, with the same opportunities, have queens of so unequal fertility that one will produce only half as much progeny as the other, we must not accept for granted the conclusion that the latter will gather only twice as much honey as the former. All tests and experiments have indicated a much greater difference in results, for the number of bees required at home will be about as great in the one case as in the other and the force of field bees of the stronger colony will be in excess of double that of the other. So success lies, entirely, in the utmost prolificness of the queen at the proper time.

Although Langstroth, like Berlepsch and others, had seen a queen lay eggs at the rate of 6 per minute, he hesitated to give the maximum ability of a queen, suggesting between 2,000 and 3,000 eggs per day. Quinby was a little bolder and placed it at "frequently over 3,000." But it is to be wondered that they should have been timid in making bolder assertions, when such men as Reamur and others placed the active egg-laying at about 200 eggs? In a similar way, Langstroth hesitated in denying entirely the popular fallacy of the ability of the moths to destroy healthy colonies of bees, though in some parts of his work he gave us proofs that he knew they could not injure strong colonies, since he inaugurated the luminous comparison of the impossibility of a healthy colony of bees being killed by moths versus a similar danger for a healthy cow from carrion flies.

A prolific queen—and we should tolerate no others—often averages over 3,500 eggs per day in the active season. Some experimenters put it at an even higher figure.

By comparative experiments, first with 8-frame Quinby hives—Quinby's standard—then 10-frame Langstroth, and Quinby hives up to 16 frames, Chas. Dadant reached the conclusion that 9 or 10 frames, Quinby size, was the best number. But he tried several other styles, in addition to the 12x12 inch frames of the Debeauxvoys hive, Americanized, with 14 to 16 frames in a hive. He made experiments on hives with frames 18x18 inches, looking like diminutive barns; also frames shaped as near as possible in the form of a circle, because he had noticed that the bees preferably put their brood in circular shape. It may be interesting to

L. Langstroth. (From original frame his became the standard in America)

state that these hives proved exceedingly proficient in securing populous colonies. But the difficulty with them was the locating of supers, for which no adequate provision could be made, and they were ultimately discarded. It will therefore be readily understood that his acceptance of 3,500 eggs as the probable average of a prolific queen was not based upon guess, but upon experience. Numerous other apiarists reached similar conclusions, some even placing the possible laying of a queen at 5,000 eggs in 24 hours. Many, however, did not give sufficient weight to the advisability of securing the greatest possible rearing of worker-bees in time for the honey harvest.

The reasoning is that a good hive should accommodate, in its brood-chamber, the breeding of a good queen for 21 days, at least, since it takes 21 days for the developing of the worker from the day the egg is laid to the day of its emerging from the cell. An addition of about 20% of the breeding room is needed for adequate supplies, honey and pollen, for the sustenance of the growing larva. This is none too much. Our 8-frame hive beekeepers generally notice that the outer sides of the two outer frames are thus used, besides quite a portion at the upper and rear edges of all the frames. Besides these requirements, some allowance should be made for drone-cells, which are larger than worker cells, 18 to the inch instead of 27, and also for the unavoidable delay caused by the queen not always finding the empty and burished cells which the workers hasten to prepare for her as soon as empty. Drones are also slower than workers in hatching—24 instead of 21 days. All these matters require consideration.

If we multiply 3,500 by 21 days we find 75,500 as the number of cells actually needed for brood at the height of the breeding season. Adding the 20% for supplies and a reasonable space for the larger cells and the delays above mentioned, we reach a figure of about 90,000 cells. Eight Quinby combs contain approximately 85,500 worker cells, so they are not sufficient. Ten Langstroth combs contain only about 75,600 worker cells, being short about 14,400 of the number required for ample room.

Starting from the above proposition, sustained by experience, Chas. Dadant became the main champion of large hives, in the United States, as he was, in Europe, the leading champion of American ideas on movable frames. But the public did not, by any means, accept his views unconditionally. During the year 1885, 9 articles on the subject of "Small versus Large Hives" appeared in the American Bee Journal, mainly from his pen and that of two opponents—Heddon and Hutchinson. Six additional articles appeared in 1889.

To illustrate how much opposition there has been to large brood-chambers, it is sufficient to quote 2 writers. In 1885, page 709, of the American Bee Journal, Franklin P. Stiles wrote that a brood-chamber of from

4 to 7 frames, Langstroth size, was best. This man—if he figured at all—was figuring on a maximum capacity of 1,200 eggs per day for his queens. In 1889, in the May number, B. Taylor, a noted apiarist, asserted that he had a hive of the right size, 1,000 inches of comb surface. This was allowing hardly more than 1,000 cells per day for the capacity of the best queen.

On the other hand, Bertrand, the noted publisher and editor of the "Revue Internationale D'Apiculture," wrote in 1879, that, with small hives, "one quickly has many colonies and quickly very few;" meaning by those words to suggest that small hives swarm much and winter badly.

In 1885, when Langstroth made arrangements with Chas. Dadant for the revision and re-writing of the "Hive and Honey Bee," the question of capacity of hives was fully discussed. Mr. Langstroth said: "If I were to change from the 10-frame hive to any other, I would enlarge it, instead of reducing it." Yet, at that time, the 8-frame hive was very popular. Its popularity has been due partly to its cheapness and its lightness, and partly to the profuse swarming that it causes. Many people want plentiful swarming.

There are, however, successful men who use the 8-frame hive. Wilder, in Georgia, wants no other. He piles them up 2 or 3 high and gets brood or honey, as the case may be, in the different stories. He practices rough-and-ready beekeeping in a country where bees have small value. The Atchleys, years ago, in Southern Texas, wrote that they wanted small colonies for winter, as large colonies consumed too much honey. But large colonies also produce much honey. In the North, a colony is never too strong for winter.

Among the successful 8-frame hive men is our own associate, Dr. Miller. But Dr. Miller gives his prolific queens two hives, or 16 frames, in which to breed. When the honey crop comes, he again reduces them to one 8-frame story for the brood. This requires manipulations which increase the labor at the rush time of the honey crop. Sixteen frames are also beyond the capacity of the best queens. That is another reason for our dislike of such a double hive.

The Jumbo hive, mentioned at the beginning of this dissertation, was the result of a discussion, concerning large hives, in Gleanings in Bee Culture, which was carried on for several years, between 1893 and 1899. The Dadants, of course, held the argument in favor of large hives, with numerous dissenters on the small hive side of the argument. At last, in the May 1st number of 1899, A. N. Draper came to the rescue of the large frame and hive advocates, by giving his comparative experience on hives. Then he quoted the "Hive and Honey Bee" Revision, in which Chas. Dadant wrote: "We would counsel beginners to use a frame as long as the standard Langstroth and as deep as the Quinby." Draper then urged upon the Roots the experiment of making a 10-frame hive of this size.

They did so, but instead of calling it, as some of the Europeans do, "the modified Dadant hive," it was called the "Jumbo," on account of its larger size, when compared to the standard Langstroth. The hive is now sold in Europe under the name of "Dadant-Root hive."

The 10-frame Jumbo hive contains over 3,600 inches of comb surface, giving a capacity of over 95,000 worker cells, so that even if a dummy is used in place of one of the frames, it will still have nearly sufficient capacity for the prolific queen. But the principal objection to it comes from beekeepers who use full upper stories and who find these too large for convenience. Indeed, they are very heavy to handle when full of honey. But personally the writer thinks that all full-size upper stories are inconvenient and objectionable, even if only of the shallow 8-frame standard Langstroth size.

After an experience extending over 50 years with several hundred colonies, in both Dadant-Quinby large hives and frames, and 10-frame Langstroth hives of the standard make, the writer is still in favor of a shallower frame for the extracting super. The principal difficulty, with the beekeepers who have used shallow supers, comes from their having used too shallow frames, from 4½ inches deep to 5¾. There is too much handling in these ultra-shallow stories. The original suggestion of Mr. Langstroth for extracting supers was a 6-inch super. We followed this from the first, using a frame with a 6-inch side bar, a super 6¾ inches deep. Such a frame permits the use of an uncapping knife in the most practical manner, as a single stroke of the knife takes the entire depth of the comb.

Our objections to full-sized upper stories, after trying a hundred or more of them, in Langstroth hives, are as follows:

1. The addition of a full story to a middling colony gives too much space above, in spring, when the weather is still cool, as it doubles the capacity of the hive at one stroke.

2. The addition of this full-story, to a populous colony which is overflowing its brood-chamber, entices the queen away from the lower story, if the lower story is not sufficient for her laying capacity. So, with 10-frame Langstroth hives, we often find powerful colonies with brood scattered over 2 stories. This is inconvenient if we wish to extract. A deep lower story and shallower upper story tend to retain the queen below. At least this is our experience. We never use queen excluders, considering them a hindrance to ventilation. They are rarely needed, with deep, ample brood-chambers.

3. The addition of full stories, of the depth of the Jumbo frame, increases the objections made to full stories of Langstroth depth, for they are still more cumbersome to handle.

4. Honey in full upper stories is much more difficult to handle in using the extractor and there is much more liability for the combs to break down by the heat.

AMERICAN BEE JOURNAL

Established by Samuel Wagner in 1861

The oldest Bee Journal in the English language. Consolidated with The National Bee Journal in 1874.

Published monthly at Hamilton, Illinois.

Entered as second-class matter at the postoffice at Hamilton, Illinois.

SUBSCRIPTION RATES—In the United States and Mexico, \$1 per year; three years, \$2.50; five years, \$4. Canadian postage 15 cents, and other foreign countries 25 cents extra, per year.

All subscriptions are stopped at expiration. Date of expiration is printed on wrapper label.

(Copyright 1918, by C. P. Dadant.)

THE EDITOR'S VIEWPOINT

Our Cover Picture

We are showing a corner of one of the apiaries of Roy Bunger, of Eskridge, Kansas, in our cover picture. Mr. Bunger is a young man who is making commercial honey production an exclusive business. We will have more to say concerning his methods and locality in a future article.

A New Bee Journal

The first number of a new bee journal from far-off Australia has just reached us. It is known as "Victorian Bee Journal," and is published at Melbourne. It is published by the Victorian Apiarists' Association as a means of disseminating information among its members.

It is a well printed little journal of 12 pages whose monthly visits will be awaited with interest. "Education and Organization" is the slogan of the organization. Long may it prosper.

An Interesting Source of Loss of Brood

In our October issue Joseph Scott, of Alabama, described a most unusual condition of loss of brood. In this number T. W. Livingstone, of Georgia gives a similar experience, and credits the trouble to the food given the larvæ. We would like more information concerning this trouble, the extent of the area in which it appears, duration of the attacks and other items which will throw light on the nature of the disorder.

More About Texas

Our Texas series is interrupted from time to time to make room for other matter. There is yet an article about the cotton belt, one about East

Texas and one on the inspection system of the State, besides some shorter ones. East Texas is a most interesting section, with wonderful possibilities for commercial honey production. Our readers will be interested in Bankston's method of mating queens with only a few dozen bees in his mating nuclei, and in the fine organization which Prof. Paddock has perfected for fighting bee diseases. Texas is a great State, and offers much of interest for beekeepers. Unfortunately, a part of the photographs taken by the Associate Editor on his trip were spoiled by the photographer to whom they were sent for finishing, so that we are unable to present many interesting things which we would like.

The Punic Bees and Parthenogenesis

The article from Mr. Baldensperger on the above subject in this number of the Journal calls for some comments upon this bee and the claim made for it.

Mr. Baldensperger is a man of great experience with both Punic and Syrian bees. Therefore his opinion and his reminiscences are of great value. We are ourselves very skeptical upon the possibility of the Punic and South African bees having the capacity of laying eggs that will hatch into the female sex without previous impregnation. The fact that some races of insects have this peculiar ability is hardly sufficient to justify this belief without clear proof. We are under the impression that some females of this race may be so small as to pass for nenters and create the occasion for this wrong conclusion. But we want to be fair, and so we insert the following quo-

tation from the June number of the "Western Province Bee Journal," of Cape Town, South Africa, treating of this subject and, inserted by the editor, Mr. Attridge, without comments:

"We quote from the Journal of the Royal Microscopical Society, the following results:

"Rupert W. Jack, Rhodesian Entomologist, reports on some interesting experiments made by G. W. Onions on the Cape May honeybee. It exhibits a divergence from the European varieties, in as much as a far greater proportion of the workers are apt to develop the habit of laying eggs, which may produce workers, queens or drones, but do mainly produce workers.

"In the Cape worker-bee, probably belonging to the race *unicolor* Var. *intermissa* Latr., the spermatheca is not vestigial, as in the typical worker-bee, but in a nearly spherical body, 0.54 mm. by 0.45 mm. But the laying workers showed no trace of spermatozoa, and the possibility of insemination must be discarded.

"A hive with a strong nucleus of bees was twice thoroughly inspected by Jack and found to be queenless; there was systematic egg-laying on the part of the workers. In many cases several eggs were laid in a cell. The eggs developed into workers, even when the eggs had been laid in drone cells. Later on drones developed from capped cells. From another queenless hive numerous workers and several queens were reared. The possibility of the eggs having been brought in from outside was excluded. The experiments detailed seemed straightforward and careful, and it looks as if Onions had proved his case: that the eggs of laying-workers of the Cape variety of the honeybee produce mainly workers, and that they develop into queens as readily as the fertilized eggs of queen bees."

This matter will be elucidated sooner or later. Possibilities of error should make us very careful. It looks to us as if, the above being true, the fact would have been accepted long ago by expert beekeepers in South Africa and wherever the Punic are cultivated. In Tunis, where eminent modern apiarists have kept bees and taught beekeeping for years (see American Bee Journal, June, 1914, page 204; also October, 1912, pages 294-300), no one has yet recognized anything of this kind. Mr. Baldensperger is decidedly opposed to this so-called discovery. We might add that Mr. Attridge, the editor of the magazine quoted above, published a book of 96 pages, in 1909, entitled "The South African Beekeeper," and in this book mentions laying-worker bees, but states positively that their eggs produce only drones.

However, since there are many insects in which parthenogenesis is carried even farther than in the claims of Hewitt, Onions and Jack, this peculiarity is possible, though undoubtedly not with any variety of European bees.

Wintering the Bees Successfully

The great majority of our readers live in localities where the question of wintering is a problem. But there are a few essentials which, if they are fulfilled, make the average winter a safe one.

Bees need a sufficiency of good food, not less than 25 pounds. Thirty-five is better. There must be neither fruit juice nor honeydew in the combs. Sugar syrup is much better for them than inferior honey.

The hives should be sheltered from strong winds. If there are flying days, 3 or 4 weeks apart, the bees should be so located that they may take advantage of those flying days. By flying days, we mean days when the thermometer rises to 40 or 50 degrees in the shade.

In localities where there are 2 or 3 months when the bees cannot get a flight, it is usually better to winter in the cellar or in some repository where the aeration will be ample without lowering the temperature of the room below 40 degrees. We have ascertained long ago that bees are quietest at from 40 to 45 degrees. If you are located north of the 42d degree it may be best to winter your bees in such a place. Put them into it at the first severe cold spell and do not remove them till warm days in March or April. The blooming of the first maples is a good indicator.

Be sure and keep a good thermometer in your bee cellar. Watch the temperature at which they are the quietest. Then keep it at that.

Do not attempt to winter weak colonies. It does not pay. Better unite 2 or 3 weak ones into a good colony.

Queen Excluders Unnecessary

How do the Dadants run for extracted honey without using queen-excluders? If I could get along without them, I would have just that much more to spend for hives and supers.

F. P., Millbrook, N. Y.

Queen-excluders are needed only when the queen does not have enough room to breed below, or when she seeks for drone-cells and

cannot find them below. Our hives are of the same depth as what is called the Jumbo, $2\frac{1}{2}$ inches deeper than the Standard Langstroth. With 9 or 10 frames of that size, a queen usually has sufficient room for all her brood. By repeated tests, we have ascertained that if we put extracting supers full of combs on Langstroth hives, in over half of the cases the queens will lay in the super, unless we use excluders. With the deeper frames in the same number, the queen has enough laying space, so that not over 3 or 4 per cent will ascend into the supers, and these are usually in the hope of finding drone-cells in which to lay, and not for want of room.

So we have been in the habit of using altogether worker combs in the supers, as it discourages the queens from going up into them.

If the queens have ample room, the colony is less apt to swarm. The first honey harvested is placed in the first super. After that, other supers are added above the first, as there is then some distance between the brood chamber and the empty cells, and that space is occupied with honey, there is very little danger of the queen subsequently leaving the brood-chamber.

In our own practice, we have considered the queen-excluder as little better than a nuisance, though we are free to say that the wire excluder is much less objectionable than the old perforated zinc. But if we used the regular Langstroth frame, we would probably need excluders, like the majority of beekeepers.

The Great Intelligence of Bees

Are bees capable of reasoning? We already know that when we give flour to bees, in boxes, out-of-doors, in early spring, to be used in lieu of pollen, they bring honey from the hive to dilute this flour and knead it into a soft paste that may be loaded in their pollen baskets. But they might do this without previous reasoning. However, here is a statement from Professor Gaston Bonnier of Paris, the author of "Les Nectaires" and president of the "Société Centrale D'Apiculture" of France. We translate from L'Apiculteur:

"The railroad line of Paris to Lyon passes by my Vegetable Laboratory of Biology, and the Georges De Layens apiary is very close to the railroad tracks. A few nights ago a freight train suffered a collision and

a car, loaded with crystalized sugar in coarse grains, being broken in two, all the sugar was scattered on the ballast.

"The following morning the field workers were not slow in discovering it, and its presence was signalled to the divers colonies. Swarming of bees hastened to the open barrels used for sprinkling and to the little basins in which aquatic plants are grown; from thence to the sugar that was spread upon the railroad track.

"From that time on, there was general traffic, from the hives to the water, from the water to the sugar, and from the sugar back to the hives. What a godsend! especially this year, after the failure of the locust bloom and the shortage of nectar in the sweet clover and other wild honey plants. But it was some work to convert this mass of sugar into syrup and to store it in the hives. However, at the end of four days there was not a trace of sugar left, the entire carload had been stored away.

"We must say that the workers displayed extraordinary activity and got up earlier and went to bed later than usual.

"We must say, also, that quite a portion of the sugar was taken away by bipeds, but the latter often desisted in the fear of stings from their competitors, the bees; for many did not know that in such an occurrence the bees do not sting.

"Finally, the latter secured the greater part of the booty, and this unexpected harvest will enable them to keep up their colonies till the blooming of the heather, which is just commencing in the Forest of Fontainebleau."

Isle of Wight Disease

The British Board of Agriculture and Fisheries has appointed a committee to study the life habits of the honey bee with the object of improving the conditions under which beekeeping is carried on in England and Wales, and to investigate the epidemic diseases of the bee, more especially the disease or group of diseases which pass under the name of "Isle of Wight" disease. The committee consists of: The Master of Christ's College, Cambridge (Dr. A. E. Shipley, F. R. S.); Professor Punnett, F. R. S. professor of genetics, Cambridge; Dr. G. S. Graham Smith, M. D.; Professor G. C. Bourne, F. R. S., D. Sc. (professor of zoology and comparative anatomy, Oxford); Professor W. Somerville (professor of rural economy, Oxford); Mr. T. W. Cowan (chairman of the British Beekeepers' Association); Mr. G. W. Bullamore; Mr. J. C. Bee Mason, and Mr. A. G. L. Rogers (head of the Horticulture Branch, Board of Agriculture and Fisheries). Mr. R. H. Adie will act as secretary. It is proposed to undertake the study of healthy bees at Cambridge and the investigation on Isle of Wight disease at Oxford. The committee would be glad to receive specimens of bees suspected of suffering from "Isle of Wight" disease for examination and experiment.

BEEKEEPING IN THE ARKANSAS VALLEY

Notes on an Auto Trip Among Kansas Beekeepers by a Party of Enthusiastic Beemen

BY FRANK C. PELLETT

GIVEN good roads, a congenial party of beekeepers, a good car and plenty of gasoline, and one could wish for no better vacation. In June, Dr. J. H. Merrill, of the Kansas Agricultural College; Charles D. Mize, President of the Kansas Beekeepers' Association; L. V. Rhine, Deputy Inspector, and the writer made a long drive among the beemen of the Arkansas valley in the vicinity of Wichita, and Hutchinson, Kansas. It was desperately hot, the thermometer registering 110 in the shade, but nobody minded that. The days were spent among the bees, and the evenings in holding miniature convention in the hotel parlors.

The Arkansas valley is especially interesting from a beekeeping standpoint from the fact that entire furrow is unknown in this section. Although southern Kansas is subject to frequent droughts, much of the valley is planted to alfalfa, which is sub-irrigated from the river to a sufficient extent to insure a crop. Alfalfa seems to yield honey most dependably where the roots have plenty of moisture and the atmosphere is dry and hot. As much of the valley as is sub-irrigated thus furnishes the ideal condition. In addition, sweet clover has been widely scattered, horsemint is present in abundance, and heartsease adds a dependable flow. With four such honey plants available, it would be hard to find a more desirable field for profitable honey production.

A branch of the State Beekeepers' Association has been formed here, known as the Arkansas Valley Asso-

O. J. Jones releasing bees from the package in which they were shipped

ciation. The meetings are well attended, and although the total number of commercial honey producers in the valley is not large, as yet, they make up in enthusiasm what they lack in numbers. At Wichita, O. J. Jones is perhaps the most extensive beekeeper. In a discussion of the possibilities of the pound package of bees, he reported that in 1916 he bought 25 one-pound packages.

These were hived on full-drawn combs. In addition to filling the ten-frame hives, he sold \$190 worth of honey from them, and left the bees in prime condition for winter.
