## CASES OF MALIGNANT DISEASE OF THE CÆCUM.

By J. S. BRISTOWE, M.D., F.R.S.,

Physician to St. Thomas's Hospital, President of the Pathological Society.

ALTHOUGH malignant disease of the large intestine is common, it is the rectum and sigmoid flexure which are its almost exclusive seats, while the cæcum is seldom implicated. Rokitansky, in reference to this matter, says, "The colon is almost exclusively the seat of cancerous degeneration, but there is a gradation in the proclivity of its different sections to the affection. The rectum is most frequently attacked, in second order the sigmoid flexure, and the remaining portion of the colon but rarely." This statement accords, I believe, with general experience, and certainly with my own. It is curious, therefore, that within a space of six months two cases of malignant disease of the cæcum should have come under my care in hospital practice. The cases are interesting; but the comparative rarity of the disease gives them additional interest, and it is for this reason that I put them on record.

The patients were both elderly, and their symptoms were of chronic progress. It is remarkable that there was little bowel disturbance. In both cases there was merely a tendency to constipation during the greater

part of the illness. And there was nothing special in the character of the evacuations, excepting in the first case; in which during the last few days of life, diarrhoea came on attended with much fœtor, and the occasional passage of blood-clots. The position of the tumour in both cases rendered it not improbable that the cæcum was the organ involved; but in the woman the tumour was higher in the abdomen than one might have expected the cæcum to be, and it was this circumstance that made some of those who watched her case mistake her tumour for a movable kidney, and others regard it as a mass of mesenteric glands or a peritonæal growth. The patient had, in fact, a movable kidney on the right side; but it was not the kidney that was felt during life. Towards the end of life an abscess formed in both instances between the abdominal wall and the tumour. In one case the superficial abscess had, certainly at first, no communication with the cavity of the bowel, for the pus which escaped was orthodox pus and sweet. Latterly, there was, no doubt, free communication in both cases. In the last place, it may be mentioned that any doubt there may have been as to the tumour in either case involving bowel was set at rest during life by the performance of paracentesis, which was attended with a slight escape of liquid faecal matter and gas through the cannula.

CASE I.—Arthur B., a dissenting minister, 53 years of age, was admitted under my care on the 21st November, 1883.

His present illness began about 18 months before, with pain in right lumbar and inguinal regions, which has gradually increased in severity, and for months past has kept him awake at night. He has, especially latterly, become very anæmic, and lost flesh and strength, and for some months has been so weak as scarcely to be able to walk. The legs have been swollen for two or three weeks. He has lost appetite and has occasionally vomited. But the bowels have acted pretty naturally.

He is a very pallid, much wasted, and feeble man, with an aspect of long-suffering, and complains of aching pain in the right lumbar region. The abdominal muscles are generally rigid; but in the lower part of the right lumbar region, near the anterior part of the crest of the ileum, and extending thence downwards and forwards to just below the anterior superior spine, can be felt a hard tumour; the full extent of which, owing to the extreme tenderness of the parts, and to muscular rigidity, cannot be determined; but of which the more superficial portion, situated near the anterior superior spine, is about as large as a tangerine orange. The tumour causes slight projection of the parietes. There is resonance between it and the ribs. No evidence of disease elsewhere in the abdomen. Thoracic viscera all healthy. Tongue pale and clean; bowels regular; urine free from albumen; pulse 88; respiration 22; temperature 99°; legs œdematous.

He was treated with tonics and the subcutaneous injection of morphia. But, excepting that his pain was much relieved, there was no improvement. By the 28th, just one week after admission, the tumour was found to have become more prominent, in the situation of its chief projection, and to be softer and more yielding; and hence it was decided that it should be punctured. Consequently Mr. Pitts aspirated the tumour in its most prominent part. The needle was passed through hard substance, and it was not until it had reached a depth of about three inches that any fluid came away. Then thin fœcal matter and air escaped through the cannula. After three ounces had been thus removed the cannula was slowly withdrawn; and when its point was about an inch or so from the surface a small quantity of thick healthy-looking pus came away. The instrument in its passage inwards had evidently gone through a shallow, comparatively superficial abscess, into the cæcum (whence the fœcal matter had escaped), and in its withdrawal had tapped the abscess which it had previously transfixed.

No improvement ensued. On the contrary, diarrhœa, which had come on a day or two before the operation, continued with little or no abatement until his death, the motions being offensive, and on several occasions containing largish black blood-clots; and the abscess, superficial to the tumour, increased in area, until the collective mass measured superficially about three inches by four. On the 4th of December, a small incision was made into the abscess, and some offensive pus escaped. He continued to get weaker; and on the 6th died. The temperature was generally about the normal; but on the day on which the first puncture was made it rose in the evening to 101·8°. The urine was always free from albumen, and somewhat scanty.

*Autopsy.*—Body much emaciated. On the right side, just above the anterior part of the iliac crest, was an incision which was subsequently found to communicate with the cæcum.

On opening the abdomen, the cæcum and the intestines in its vicinity were found matted together and adherent to the parietes; and, on endeavouring to remove them, pus escaped; and an irregular abscess was found superficial to them, and extending into the intervals between them. The cæcum was evidently the primary seat of disease. Its walls, and especially

the parts in the neighbourhood of the ileo-cæcal valve, were much thickened with new growth, so that the organ remained uncollapsed, like a thick india-rubber bottle. The growth extended thence, and involved to a considerable extent the connective and muscular tissues of the iliac fossa. The bones were not implicated. The ileo-cæcal valve was somewhat narrowed, and the interior of the cæcum was deeply congested, ulcerated, and roughly granular throughout. The growth did not extend to the ascending colon, or to the ileum. But the last three or four inches of the latter tube were thickened from inflammatory deposit. The tumour was a cylindrical epithelioma. There was no important disease of any other organ.

CASE II.—Frances T., a married woman aged 66, came under my care on the 25th February, 1884.

She had never had any serious illness, and on the whole had had good health up to three months ago. She was then attacked with pain across the epigastrium which, however, only lasted for a short time. Two months ago she first complained of pain and tenderness on the right side of the abdomen. These have continued ever since, but have increased; and she has lost flesh and strength. For the last month she has been confined to bed. Her appetite has been bad, her bowels constipated.

She was a spare, fragile, somewhat melancholy-looking woman. In the right side of the abdomen, lying between the ribs above and Poupart's ligament below, was a hard, ovoid, somewhat nodulated and very tender tumour, about the size of a large orange. Its right side reached the right side of the abdomen, its left approached within about two inches of the umbilicus. Its upper margin was on a level with the lower part of the costal arch; its lower margin descended to a little below the anterior superior iliac spine. It lay mid-way between the back and front, and was not adherent to the abdominal wall either in front or laterally. Within narrow limits it was pretty freely movable; but could not be made to fall back into the region of the kidney. It was somewhat resonant on percussion. The abdomen generally was flaccid, and in all other respects seemed free from disease. The thoracic viscera were healthy. Tongue coated, appetite poor, bowels confined, temperature 100°, pulse 76, urine 1020, acid, clear, free from albumen.

Prior to admission it had been thought that the tumour was a movable kidney; and that view was still entertained by some persons long after she came into the hospital. But if a kidney, it was obvious that it was a diseased kidney, and from its hardness, tenderness and irregularity of form almost certainly the seat of cancerous growth. But there was no history of any bloody or other unnatural discharge from the bladder; and the urine we examined was perfectly healthy. On the whole, though not denying that it might be a kidney, I was indisposed to accept that view for the reasons above given, and from its situation, which was not that usually affected by this organ. The situation of the tumour was somewhat high for the cæcum, and against its being either that or any portion of the ascending colon, infiltrated with cancer, was the fact that beyond the presence of habitual constipation there was no history or evidence of bowel-disturbance. The fact of its being somewhat resonant, and of the presence of a small area of marked resonance between its inner and lower margin, and the situation of the uterus, precluded any serious thought of ovarian tumour. I assumed that it was either a primary malignant growth of the peritonæum, or (as I thought still more probable) a cancerous tumour, originating among the mesenteric glands in that portion of the mesentery related with the lower extremity of the ileum, and very likely involving the wall of the contiguous portion of gut.

Though the patient remained in the hospital for many months, the case presented very few noteworthy incidents. Very slowly the tumour enlarged, and very slowly she got thinner and weaker. The pain and tenderness in the growth were extremely severe, and could only be kept in abeyance by systematic morphia injections. Her appetite continued poor, but she had little or no sickness; her bowels were somewhat variable, but the evacuations were not unnatural; and her urine was always of healthy quality. Her temperature was normal.

The extreme hardness of the tumour had always made me regard it as improbable that it was cystic; but, having thought the matter over somewhat fitfully and vaguely for some time, I finally determined, on the 15th July, to pass a fine trocar and cannula into its substance. The instrument was passed in for a depth of about two inches, encountering much dense tissue in its passage, and then entering a cavity. On removing the trocar, a rush of foetid gas took place, and with it a few drops of dark liquid faecal matter. And on withdrawing the cannula its further end was found blackened. The instrument had evidently gone through a considerable thickness of dense solid matter into the bowel.

No immediate ill-effects followed. About ten days later she caught cold, had a cough, and apparently in consequence of her cough vomited from time to time for several days.

On the 3rd August, over an area about the size of a shilling, and corresponding to the seat of puncture, there was a fluctuating hemispherical and very tender swelling. This gradually increased in size, until about the end of the month it was quite as large as a good-sized orange, was extremely tender, was red at one or two points, and fluctuated. She had persistently declined to have the abscess punctured, and on the night of the 27th August it broke, discharging a large quantity of foul-looking, ill-smelling pus. This relieved her pain, but her strength, which had been failing rapidly of late, still diminished. The discharge continued offensive for a few days, then changed into healthy pus and became scanty. Without any material change in her symptoms, she gradually sank, and died exhausted on the 17th September. The tumour at the time of her death was, speaking roughly, about half as large again as it was when she first came under my care, and somewhat more irregular and nodulated in form.

*Autopsy.*—Body much emaciated. Just above right anterior superior spine are two small round holes, communicating with the subcutaneous tissue over the front of the abdomen, the skin being undermined over an area about two inches in diameter. This cavity contains a small quantity of pus, but no communication can be traced between it and the abdominal cavity.

On opening the abdomen, it is seen that the great omentum is adherent in the right iliac region, hiding the caecum, and that the small intestines in this locality are also united to the caecum. In the adhesions, which readily break down, are some white hard nodules of new growth. On removing the caecum and adherent tissues, it is found that the walls of this organ are extremely thick, and infiltrated almost universally with new growth. The inner surface is generally broken down, excavated, and very ragged, and the cavity contains a good deal of loose sloughy tissue, and small masses of pigmental-looking material. There is no evidence of actual obstruction to the passage of faecal matter, and the ileo-caecal valve is healthy. The rest of the bowels and the stomach are sound. The right kidney is movable, and somewhat lower in position than normal, but of usual size and free from disease. All the other organs, both abdominal and thoracic, are healthy.

## AN ADDRESS ON MEDICAL EDUCATION.<sup>1</sup>

By W. T. GAIRDNER, M.D., LL.D.,

Professor of Medicine in the University of Glasgow.

THERE is an old Scotch proverb which seems to me—I may quote so rough and rude an expression in this academic hall—to express in one point at least very well the reason why I am here. The proverb is, "Teaching the cat the way to the kirn." Now, every proverb contains certain implications without which it would not be what I believe the late Earl Russell used to call it—"The wisdom of many and the wit of one." This particular proverb seems to me to contain two implications—one of which, if applied to the present subject, I am most happy to endorse; the other I shall quite as firmly and decidedly repudiate. The first implication is that the cat does not usually require to be taught the way to the kirn. Clearly pussy knows the way as a general rule, and if left to herself has no difficulty in finding it out. In like manner I do not think any one can, after hearing the admirable report which Principal Peterson has just read, help seeing that Dundee and the people of Dundee, and University College and the Principal and Professors thereof, clearly know the way to the higher education. The cat knows the way to the kirn. But the second implication contained in the proverb is that pussy ought not to be allowed to get to the kirn—in other words, as applied to the present subject, that the Dundee people ought not to have the higher education, or at all events ought not to have it unless they take it in the old and authorised ways, through some of the old Scotch Universities, or through some of the other regularly established schools. Now, it is that second implication that I wish, on my own part and on the part of a very large number who think as I do, to emphatically repudiate. It is from having repudiated it in conversation that I have been invited in the midst of those engagements referred to to appear here to-day.

But although I have willingly acceded to this request, I feel bound to say to you, as I before stated to Principal Peterson and other gentlemen who kindly asked me, that I could not engage under the circumstances and in the midst of our clinical examinations to prepare a formal and elaborate address. What I understand to be the position is that the question of the higher education in the main is already settled for Dundee. Dundee is to have the higher education, and why should she not have it at her own doors? The liberality of Miss Baxter and others has given her a fair and excellent start. The success of that start so far has been as great as anybody possibly or legitimately could have expected. At present the question is whether medical education is to be a part of the future ambition of Dundee in this respect. Now, I not only think Dundee justified in entertaining this ambition, but I think she is bound to entertain it. She has, as the Principal has stated, a large and important hospital—the Royal Infirmary, which is admirably administered, and well supported by a generous public—and she has besides numerous other medical institutions, which are there because, with reference to the general need in this great and populous city, they must be there—the Asylum for the Insane, the Workhouses and Workhouse Hospitals, &c.—and she has a staff of medical officers, public and private, quite equal, as far as my own personal knowledge goes, to any town of her size and importance. The question is,

<sup>1</sup> Delivered at University College, Dundee, June 27th, 1855

Is she entitled to throw away all these great advantages and opportunities, with a centre of higher education in her midst, without making some attempt to bring the higher medical education into her curriculum? With a college of science and of the arts actually here, is she entitled to omit medicine from among those sciences and arts which she is to endeavour to teach? I think the question only requires to be put in order to be in general terms answered. Difficulties there may be; jealousies there may be. No doubt it is utterly impossible to start anything of this kind in a new form without exciting some of those jealousies and creating some of those difficulties; but if the position is sound, depend upon it those difficulties will be overcome, and those jealousies surmounted.

I was led to think this morning, when talking to Principal Peterson about the matter—I don't know how it came into my mind—of a passage in Shelley, applied, however, not to Dundee College nor to any college of science, but to love. I think with the substitution of the word "science" for "love" you might make the the passage applicable to the present occasion:—

True love in this differs from gold and clay,  
That to divide is not to take away.

Now, my appearance here to-day, whatever in other respects may be its result, will at least show that I am not, personally, in the least degree influenced by such local jealousies. I have such an abiding faith in the immensity, in the practical infinitude, of the desire of the human mind for knowledge as to believe that in no case almost is to divide to take away. In no way is the rise of one school the detriment of another. Possibly if Dundee goes on and adds medical education to the rest of its programme, instead of being a disadvantage it will be a positive advantage in many ways to all of us who are labouring in their vocation in the old Universities. In considering this subject it is not possible to overlook the fact that Dundee has not at present, and is not likely, as matters go, to acquire the power in itself of giving degrees. But it is equally impossible to overlook the fact that at only a few miles distance there is an ancient University—the most ancient University in Scotland—which I say frankly in my opinion, and certainly in the opinion of a very great number of persons besides myself, sustains discredit by the fact that its power to give degrees is not connected with and supported by an equally valid power of teaching. It may be in the one notable instance of the University of London that the power to give degrees, as severed from the teaching function, is not abused, and is in a certain sense advantageous. But I think that this is quite exceptional, and that the true ideal of a University never is and never can be that of a mere graduating institution, but that it must in the very nature of it be a teaching institution as well. Otherwise it never can even maintain a high standard, unless under peculiar and exceptional circumstances; and under any circumstances it never can appear in the eyes of the public to do full justice to its own power of graduation. The University of London, being supported by large donations of public money for the exclusive purpose of maintaining a high standard of examination in the greatest city, and for the richest country in the known world, has no doubt done a great deal of good work in its day. But, as we see now from an agitation going on in London itself, and as I have said any time these twenty years, it utterly fails in fulfilling the purpose, broadly considered, of a university centre for the metropolis; and it especially fails with regard to the organisation of medical instruction in the numerous and excellent teaching institutions at its own door. But all this has no reference to our present position. The University

of St. Andrew's certainly cannot make itself another University of London. It must seek its function, if its true prosperity is to be sought in connection with medical education, on a different plan and model. Therefore it appears to me that Dundee has all the materials, as yet inchoate and unorganised, for a school of practical medical education. It has the materials in this Science College—the commencement of that high-class scientific training. It has in the University of St. Andrew's—I would say almost at its own door—the power of appealing for degrees; and with the organisation of a teaching staff in connection with these degrees it is, it seems to me, clearly the business of the two—the natural and instinctive tendency founded upon interest of the two—to come into combination, and to exercise these two great and invaluable privileges in harmony with each other.

This, I may say, is no new idea of mine. Many years ago—so many years now that I hardly like to remember them—I was for a time an examiner in medicine in the University of St. Andrew's, and in those days (when as yet, too, and for many years thereafter in Scotland, clinical examinations were things unknown, and not even spoken much about), I always made it a point to bring the honour students with me to Dundee to undergo a strictly clinical examination in the Royal Infirmary, and many of the men so examined remain in my memory to this hour as some of the best men I have ever had to deal with. The physicians of the hospital in those days lent themselves most kindly to my efforts, and owing to that circumstance the association, in my mind, has always existed between Dundee and St. Andrew's.

Now, in England we have had, in past days, a most noticeable example of what to avoid in this matter. In England we had throughout the days which preceded the present century two great and noble universities, organised in the main on such a mediæval type, and looking with such absolute scorn upon the great and popular mass of Englishmen in their blind desire and struggle towards the light, that they made themselves—though things are changed now—so entirely the Universities of the aristocracy and the more fortunate members of the community that it may be said they did not even make an effort to reach or in any way to interfere with the education of the medical practitioner at large. What was the consequence? The consequence was that the medical practitioner in England—I am not speaking of Scotland—grew to be of a type quite unknown in any other western European country. He grew up a man who was apprenticed to a trade like any other workman, and who had hardly been taught in those days to admit into his mind even the merest notion of a scientific training. The medical student of those days—for in this, as in every other case, the child is father to the man, the student is father to the practitioner—may be said to be caricatured of course, but not on the whole very unfairly, by the immortal picture of Bob Sawyer in "Pickwick." Everybody who knows that marvellous tale will at once recognise what I mean. It is not necessary to go further with the description of the animal. How did he come to be so? Because he was bound over in the beginning as an apprentice to a handicraft, and if in his soul he ever came to feel a little above this his aspirations were completely and entirely checked. Now, I will not trust to my own memory or to my own knowledge in laying this before you, but shall quote an extract from a leading article in the *Times* of October 3rd, 1882, which I had occasion to quote some years ago in another academical address. It says:—"Five-and-twenty years ago, except in the case of the small number of men who graduated in medicine at Oxford or Cambridge with a view to consulting practice as physicians, the education of a

medical student commenced by an apprenticeship to a licentiate of the Apothecaries Company, which was then the chief source of the medical qualification for general practitioners. The apprenticeship was rendered necessary by the Act of 1815, from which the Company derived its powers, and it usually commenced at about the age of fourteen years, so as to break prematurely into school education. The first year of the apprenticeship was often spent in the work of a surgery boy, varied by the preparation of medicines and by the attainment of some knowledge of their properties. The later years were devoted to learning the business of conducting a medical practice, the art of talking to patients, and so forth, and when the apprenticeship was concluded a short term of hospital study formed a prelude to the single examination which, when passed successfully, permitted the candidate to work his will upon the sick under the protection of the law. Originally, the full term of five years' apprenticeship was served in the house of the master; but as the term of hospital study was gradually extended from one year to nearly three, the two demands were found to consume an inordinate amount of time; and the two last years of apprenticeship were commonly remitted, and were suffered to form part of the period of hospital study. Even then the total period of professional as distinguished from general education extended over about six years, and as the examination might be passed at the age of twenty-one, was usually commenced not later than fifteen."

Now, with reference to that statement, I have simply to say that the type generated in England was utterly anomalous, when compared with that of any other country in Europe. In all other countries, either the universities or the State have seen to it that a man professing medical qualification at all—that is, recognised in any sense as a medical practitioner at all—has been in some sense or other qualified all round, so as not to be wholly uninstructed in any ordinary department of practice. But in England, the apprenticeship system on the one hand, and what I must term the almost supercilious attitude of the universities and the colleges towards the general practitioner on the other, gave rise to what we now call the double qualification—that is to say, that a man may be either an apothecary or a surgeon or a physician, and in order to be a complete practitioner he must have two diplomas. There is no such idea in any other country, of letting loose on the public men licensed to practise as surgeons or as apothecaries, and who have the opportunities in after life, owing to the necessary wants of humanity, of extending their practice, and this without any real previous training for it, to every possible department. That was the result of the old Universities of England, and I may say also of the Royal College of Physicians in London refusing to have anything to do with the average, or ordinary, medical education at all.

The Scotch Universities were wiser in their generation. From the beginning or middle of last century the Scotch Universities, in a kind of blundering way, and no doubt with instincts that often led them wrong, did take up the position that it was the proper function of a University to aid in the establishment of medical education. To this fact beyond all doubt we owe the high appreciation which now exists, and which more or less has existed all along, for Scotch degrees in England. But good cannot be done without an evil also following, and it has always been objected by those in England to whom the old apprenticeship system was dear as a relic of the past that in the new system, by which medical education was regularly organised as part of the University curriculum, we have sacrificed something that was valuable in the

old apprenticeship system. It was said, and no doubt with truth, that the apprenticeship system of education turned out practitioners who were very rough and ready, but who were still practitioners. It was said, on the other hand, that this University system turns out men crammed full of certain novelties called science, who are not in any true sense of the word skilful practitioners. Now, I am not willing to admit—indeed, I have often maintained the contrary—that this is true to the full extent. But it may be admitted nevertheless, that there is a tendency to some extent in that direction, that there is a tendency so to monopolise the mind of the young candidate with the earlier branches—chemistry, anatomy, biology and the other departments of a scientific training—as to leave far too little time and far too little opportunity for the student to get an adequate and proper insight into what may be termed the work of his life.

(To be continued.)

---

## LECTURES ON SOME OF THE DISTINCTIVE CHARACTERS OF DISEASE IN EARLY LIFE.

GIVEN AT THE HOSPITAL FOR SICK CHILDREN,  
GREAT ORMOND STREET.

By OCTAVIUS STURGES, M.D., F.R.C.P.,

Physician to the Hospital.

### LECTURE III.

#### *Convulsive Cough.*

WHATEVER the speculations in which we may indulge, whatever is the best expression of the truth in this matter of whooping cough which we have been discussing, let no one doubt for a moment that convulsive cough is very apt indeed to spread from child to child; that so spreading, the gravity of any pre-existing complaint is very much increased; and that there are no means whatever of discriminating at the outset between the contagious and the non-contagious forms of convulsive cough.

Yet even here we are not rid of the apparent anomaly of the complaint. Nothing can be more certain than the spreading of whooping-cough throughout a household. There is no affection more contagious; and if what happens in families—not invariably, I must remind you, but in the majority of instances—were to happen also in hospital wards, a children's hospital would be an impossibility. But it does not happen. Convulsive cough, indistinguishable from whooping-cough, shows very little tendency indeed to spread in this place; and while we are continually worried by the appearance and the tenacity of other infectious diseases, of measles, and scarlatina, and diphtheria, whooping-cough gives little or no trouble. And yet whooping-cough has a far ampler opportunity for spreading than any other infectious disease whatever, for, by the allowance of everyone, it may go on for an indefinite time in its catarrhal stage before its nature is suspected. Over and over again in this hospital, and at the Convalescent Home at Highgate, children with catarrh will begin to cough convulsively, then to be sick after coughing, then to whoop. And so soon as these characters have developed, and whooping-cough seems certain, the child is sent away. What happens afterwards at the child's home I know not. Nothing happens here. Whooping-cough, which, from its character in our homes would

seem to be a quite intolerable intruder at a children's hospital, gives hardly any trouble at all.

From this, and from other facts to be mentioned presently, I am led to believe that it is when and where epidemic catarrh is prevalent that whooping-cough is chiefly—I do not say solely—contagious; and that whatever is specific, and whatever in the zymotic sense is infectious, resides not in the cough, but in the catarrh, of which it is the note and signal.

Now, let the precise nature of epidemic catarrh be what it may, no one will be found to question, no one has ever questioned, the reality of those periodic occurrences during the centuries that they have been under the observation of civilised nations. Whooping-cough, on the contrary, regarded as a separate disease, is comparatively modern. And observe that all that I asked you to notice in my last lecture in reference to childish catarrh and childish cough—the emptying of the lungs, the liability to lung collapse, the need and the violence of diaphragmatic and glottis spasm—would lead to the expectation that epidemic catarrh in children should be signalised, now more and now less, by the occurrence and by the diffusion of convulsive (or whooping) cough. I say now more and now less in the belief that it is legitimate to make use of the admitted fact that every epidemic, whether catarrhal or other, has characters of its own.

There is a convulsive cough that spreads, and there is a convulsive cough that does not spread. They are not otherwise distinguishable than by their conduct. The one is a specific zymotic disease highly contagious—*whooping-cough*; the other is a form of spasm to which children (and particularly those with catarrh, and, according to some, those with enlarged glands) are naturally prone—*spurious whooping-cough*. Such is the prevalent doctrine. May it not be possible, without doing violence to facts, to separate convulsive cough as such from all that is specific and zymotic; and by attaching such characters to the catarrh alone, leave undisturbed in their natural place those purely nervous elements of pertussis—sex preference, long intermission, indefinite duration, sudden arrest, sudden cure, even cough convulsion itself—which can never be made integral parts of a “specific fever.” Every young child is from its nature, and apart from its danger in the way of infection, extremely liable to convulsive cough. Every young child with catarrh is more likely than not to develop convulsive cough anyhow. But the wide prevalence and rapid spread of convulsive cough among children are the sign and the measure of epidemic catarrh. If this distinction can be maintained, and the convulsive cough of child's catarrh be regarded as a nervous adjunct, more or less prominent according to the particular character of the prevailing catarrhal epidemic, but no necessary part of the disease, much of the apparent confusion to which I have alluded will disappear, while, at the same time, the separation of this complicated disease which we call whooping-cough into its two elements, the catarrhal and the nervous, makes it easy to interpret certain symptoms which properly belong now to the one and now to the other side of it.

You will, I am well aware, be ready with objections to this hypothesis, and perhaps the earliest and the most obvious will be that whooping cough spreads anyhow, epidemic or no epidemic. You will quote instances of children removed from an infected district and placed with others where no epidemic catarrh exists. I know very well that children so introduced to a healthy community will sometimes impart their convulsive cough to their new companions. We hear often enough of whooping cough so introduced into schools. But I know also—and to be impartial you must take the two facts together—that convulsive

cough thus transported to a new soil, when, and so long as epidemic catarrh is absent, will often (as is habitually the case with us in this hospital) altogether fail to produce its like. And what is more, that it will sometimes itself suddenly disappear.<sup>1</sup>

But he must be a careless student of nervous disease, and, indeed, of the habits and customs of his species who would deny that there is a *nervous* contagion as well as a zymotic. If only I can assure myself that the convulsive cough of childhood is a nervous disorder, proper to that time of life, I should expect to find—as I do find—that it would display now more and now less, according to the nature of its subject, the characteristics of all functional nervous disorders. That the coughing of one child should be the signal for the coughing of the rest; that convulsive cough in an adult, having no other character of so-called whooping cough, should yet excite that disorder in a child<sup>2</sup>; that children who have long lost their convulsive cough should again be reminded of it by the ear and take it up afresh—all this would seem to me accountable. It is on a par with the observation that not children only, but older and more stable people cough in company, and that they laugh and shudder and sigh for sympathy, no corresponding idea being suggested to the mind, even that the strongest of us cannot, by taking pains, resist yawning when others yawn in his neighbourhood. It must be exceedingly difficult, of course, in large or crowded communities to say in any given instance whether the convulsive cough has been thus acquired, or whether it has developed out of a simple catarrh, or whether, again, it is the child's signal of its taking part in an epidemic. We may attribute too much or too little to the operation of this principle of imitation. Personally it may be that I have relied too much upon it. But it is there; just as it is in hysteria and chorea, and even in tetany.<sup>3</sup>

And, indeed, there are arguments freely used by those who deny all this which, when overpressed, are apt to break down in the hands of those that use them. Whooping cough in households, it is well known, may not confine itself to the children, but attack the grown-up members—notably the girls—as well. It has even been known to affect the middle-aged father of a family. Such an event, rare as it is, seems to me best explained by supposing that the nervous characters of the prevalent catarrh of the house were eventually shared by the parent who was within constant sight and hearing of them. Whether that be so or not, it can hardly add strength to the argument of

<sup>1</sup> The comparative immunity of children's hospitals in respect of pertussis, a strong argument for the views expressed above, seems absolutely fatal to the contention of some physicians that whooping-cough contagion may be conveyed from child to child through the medium of persons or clothing. We have patients from all parts of London and visitors also, and when whooping cough is prevalent the importation of its specific germ, assuming it to exist, must be of almost daily occurrence.

<sup>2</sup> Dr. Meredith, of Wellington, Somerset, writes:—“I have now three young children with whooping-cough where I am inclined to attribute origin to a youth who was much with them and who suffered from fits of coughing.” Dr. Cheate, of Burford, writes:—“A delicate boy, of 12, had a cough and bronchitis which gradually assumed a ‘whooping’ character. There was no pertussis in the neighbourhood. Presently his brothers took it. All recovered without bad or prolonged symptoms and whooping cough did not appear beyond the house.”

<sup>3</sup> In his “*Maladies des Nouveau-nés*” Bouchut writes:—“Whooping-cough is transmitted like a large number of nervous affections, like hicough, vomiting, hysterical attacks, &c. This is a fact fully established” (p. 376, 5th edition). Dr. West, however, declines to listen to any suggestion of the kind, and dismisses it with contempt, along with the doctrine that whooping cough may develop independently of contagion, as amongst “the vagaries” prompted “by the mere love of paradox.” I am aware, of course, that this decided rebuke from so high an authority, my teacher, as well as once my colleague, is a strong argument against the views I am expressing. But I may at least plead that it is not the love of paradox, but rather the intolerance of it—and Dr. West repeatedly admits that whooping-cough is paradoxical—which has led me heretofore to lay perhaps undue stress upon a principle which I still believe to be operative.

those who assert that convulsive cough is conveyed by some specific organism to call attention to the fact that only in the rarest instances are adults capable of receiving it, that it has a natural preference for women, and that the notion of a father so affected going amongst his customers or clients at market or exchange, and conveying to them the poison which he has brought from home, is so unlike anything that actually happens as to be almost ludicrous.

But, it may be said, granted that convulsive cough is sometimes contagious and sometimes not, and that the contagion of whooping-cough is partial in regard to age and sex, still a specific conveyance of some kind or other there cannot but be, inasmuch as children do not develop whooping-cough of themselves. They catch it from another and pass it on to others again. That no doubt is a strong argument. If it cannot be established that convulsive cough, whether contagious or not, is a common incident in childhood, often originating spontaneously (so to speak), and quite apart from any conceivable source of contagion, then assuredly the whole contention breaks down, and whooping-cough must be accepted on the present terms with all its anomalies and contradictions. Let us look at the facts.

Early in the present year I addressed some questions concerning the apparent origin of whooping-cough to practitioners in various parts of the country, carefully selected as having large experience in the matter. They were as follows:—

(1) Have you met with pertussis arising out of catarrh, measles, &c., but as far as could be ascertained apart from direct infection? if so, how many within the last (say) three years?

(2) In what proportion of such cases has pertussis been prevalent at the same time in the immediate neighbourhood?

In response to these enquiries, I was favoured with replies from 47 medical men, to whom I owe my thanks, and especially to those who were so good as to write at length.

The answers may be classed thus:—

(1) Eight say "No" simply to both questions.

(2) Ten say "No" to the first question, the spontaneous origin, and answer the second as to epidemic prevalence variously.<sup>4</sup>

(3) Six are doubtful and decline to commit themselves.

(4) Twenty-three say "Yes" to the first question and answer variously as to the second.

Thus, while half of the number say "Yes" to the spontaneous origin, much less than half assert the negative.

Time will not admit of my quoting more than a few specimens of these communications:—

"No other case in the neighbourhood and no epidemic for five years."

Child in question was "in the country and had been kept free from exposure to infection for months."

"Whooping-cough in my experience undoubtedly follows measles and catarrh completely free and apart from direct infection."

"I have seen it without any kind of pertussis prevailing."

"Best enquiry has failed to discover infection."

"I have seen many (*i.e.*, apart from whooping-cough infection), chiefly after measles."

"Certainly; many."

Of more lengthy communications let me quote three:—

(5) One is from Dr. Behrendt, of Burringham, Doncaster: "I am strongly of opinion that pertussis does sometimes arise out of catarrh. I have, now and then, come across cases occurring in out of the way houses when no sort of contagion could be discovered, and where catarrh preceded for some time the appearance of the disease. They were, so far as I could ascertain, the only cases in the district."

Another is from Dr. Illingworth, of Clayton-le-Moors (who is, I believe, engaged upon a special enquiry into the clinical characters of pertussis): "I have known of many cases arising directly out of measles and catarrh, and altogether apart from infection. Such cases are, in my opinion, of very frequent occurrence."

(6) A third is from my friend and colleague, Dr. Donkin, physician to the Westminster Hospital and to the Children's Hospital at Shadwell: "Two boys aged three and five had scarlet fever and were confined to two communicating top rooms of the house, no one being suffered to see them, except their father, a medical man, and a nurse who was constantly with them. For about a week during the father's absence another doctor visited them. Both children had marked bronchitis during the fever, and one had broncho-pneumonia. About five weeks after the onset of the scarlatina, both began to whoop, and both continued to suffer from typical whooping-cough for many weeks after recovery from all signs and sequelæ of scarlet fever. During the whole time of their isolation, a carbolic sheet was hung outside the door, and carbolic vapour or creasote was constantly diffused through the rooms."

Narratives such as these may be robbed of their significance by the assertions of some that no limit of time can be assigned to the incubation of whooping-cough, and no limit of space or of agent through which the contagion may travel. Those who thus argue have the issue very much in their own hands. Yet must they, in turn, be called to account for the consequences which their arguments involve. And how will the doctrine of an all-pervading and long-enduring material of infection accord with the actual facts of the case? Take this vast and crowded city of London, where convulsive cough prevails now in one district and now in another, but is never co-extensive with the metropolis, and never fixed for any great length of time in one locality. If it be considered that in every instance of prevalent pertussis a large proportion of the sufferers are not notably ill, and are left to mix intimately with other children, we ought to find—upon any hypothesis that makes the infecting modes and distance very various and considerable—convulsive cough habitually spreading throughout London. There would hardly be such a thing in so thickly populated a city as a localised epidemic. And not in London only, but in towns and villages, why should the infecting organism periodically die out and revive again? why should pertussis forsake one locality and appear in another, not adjoining, but some distance off? I have information of districts where the disease pays annual visits with unvarying punctuality, and where in its periodicity and uniform duration we are equally at a loss to discover how it comes and why it goes.

Now, upon the assumption that convulsive cough is but the child's signal of epidemic catarrh (catarrh, it may be, from which adults shall be exempt), these difficulties disappear. The manner and conduct of the cough will be that of the catarrh upon which it depends. It will be gradually developed out of it, and, as a nervous habit, it may long outlive it.<sup>5</sup> True,

<sup>4</sup> Among these Dr. Ransome, of Manchester, may be quoted, who is of opinion that "the definite incubation period of pertussis (14 days) is a sufficient proof of its specific character." Precise statements such as this are much wanted at the hands of those who share Dr. Ransome's views in this matter.

<sup>5</sup> "Epidemic whooping-cough," says Dr. West, "very frequently succeeds to epidemic catarrh, the former disease being gradually

there remains a difficulty as to the nature of epidemic catarrh itself. But of the occurrence and natural history of such epidemics there is no doubt whatever. And one mystery is better than two. The question is whether the universally admitted facts in regard to epidemic catarrh may not be made available for whooping cough also.

But it is said there is small profit in speculations like these. If convulsive cough, whether in association with epidemic catarrh or not, is apt to spread from child to child; if the effect of such cough is always injurious and sometimes fatal, and the contagious form indistinguishable from the non-contagious, if this be so, then beyond question our actual practice is the best, namely, to regard convulsive cough in children as an infectious disease, and to isolate those that are suffering in that way. And I would relax by no jot or tittle the present precautions against the spread of pertussis. Yet from the point of view of pathology the enigma of whooping cough is intolerable. If Nature is consistent there must be some way out of it, and it is but reasonable that we should try to find it.

In conclusion, let me put the substance of what has been said in such dogmatic shape as may be most convenient whether for acceptance or contradiction. Provisionally, then, and not unconscious of the difficulties which surround the subject, I would venture to formulate my propositions as follows:—

(1) Convulsive (or whooping) cough is a purely nervous phenomenon, the expression of a special liability of childhood in respect of spasm, of which other illustrations are to be found in laryngismus and spasm of the glottis.

(2) Pulmonary catarrh in young children may at any time give rise to convulsive cough, and does, as a fact, frequently give rise to it apart from any special infection.

(3) Convulsive cough in childhood, being thus intimately associated with catarrh, is apt to excite special attention at such times as catarrh is epidemic, and to have ascribed to it the characters that properly belong to such epidemic.

(4) The occurrence of convulsive or whooping cough adds appreciably to the danger of catarrh in young children, and affords ample grounds for their separation from others, since it is beyond dispute that such convulsive cough is often communicated.

(5) The fact that in the epidemic catarrh of children this nervous adjunct of convulsive cough is sometimes present and sometimes not, is accounted for by considering that every such epidemic has characters of its own, that functional nervous disease of whatever kind is very unequal in its geographical distribution, and that once developed it has a tendency to persist and to spread by the operation of sympathy or unconscious imitation.

---

*developed out of the latter.*" (Italics are mine.) But, he adds, and the remark deserves attentive study, "the persistence of cough long after the decline of catarrh is one of the first signs of the commencement of an epidemic of whooping-cough" (p. 481). Now, it is universally admitted that the actual commencement of whooping-cough is inscrutable. If, therefore, in deference to that fact the word "existence" were put for "commencement," Dr. West would himself be not very far from views which he condemns as "bad for the advance of medical science."

---

## CLINICAL LECTURE ON A CASE OF MI-CROPSIA WITH OTHER SYMPTOMS, FOLLOWING A BLOW ON THE EYE-BALL.

GIVEN AT THE MOORFIELDS OPHTHALMIC HOSPITAL.

By E. NETTLESHIP, F.R.C.S.,

Ophthalmic Surgeon to and Lecturer on Ophthalmology at St. Thomas's Hospital; Assistant Surgeon Royal London Ophthalmic Hospital, Moorfields.

CASES of injury to the eye are often of great interest on account of the many parts that may be involved and the consequent variety of symptoms. The case you have just seen is a rather uncommon one. The patient, a delicate looking man, a working goldsmith, aged 29, received on May 5th a severe blow upon the right eye by a piece of gold, weighing about half an ounce, which slipped out from beneath a punch with which he was working on it. Although not made sick, he shortly afterwards felt so ill that he was obliged to leave his work. The eye was inflamed next day, and for a few days afterwards was painful and weak when exposed to light. When these symptoms had abated, so that he could use his eyes again, he found that all objects looked smaller when viewed by the injured eye than by the sound one, and that distant objects seemed to be surrounded by a mist. These symptoms were worse on some days than on others, and on May 27th he came to the hospital because the eye did not get well, and had, in fact, been more aching and troublesome for the last few days.

On reading Snellen's distant test types with the right (injured) eye, he succeeded well till he came to  $\frac{6}{18}$ ; these letters, though legible, seemed to him to have a white margin at the top. The letters of  $\frac{6}{12}$  and  $\frac{6}{9}$  were drawn out upwards so that he could not read them. He said the largest letters seemed smaller than with the left eye. On trying the affected eye with glasses, it was found that with  $\left\{ \begin{array}{l} -0.75 \text{ D. Sp.} \\ -0.75 \text{ D. Cyl.} \end{array} \right\}$  he could read  $\frac{6}{6}$  quite well, and he stated that the letters seemed quite as large with this combination as they did with the other eye, that they showed no white margin and did not seem drawn out. There was no affection of accommodation, for he could read 1 J. as well, and at as short a distance (5 inches or 12 cm.), with this eye as with the other. The pupil was slightly larger than that of the left, but it acted well to light and accommodation. On examination, after the pupil had been dilated with homatropine, there was no conclusive retinal change; a whitish appearance seen around the yellow spot region being, I think, natural. At the outer part of the fundus, however, in front of the equator, was a row of round patches of atrophic choroid with a good deal of pigment on them. These patches graduated in size from before backwards, the largest being near the centre and the smallest ones in front. In the cornea, at a point opposite to these patches, over the upper and outer part of the pupil, was a well-bounded patch of slight haze. The lens seemed unchanged. The other (left) eye was emmetropic and healthy.

The points to be decided in this case are: Why the damaged eye ached, why the man saw things indistinctly and too small, and whether the corneal haze and the atrophy of the choroid were due to the injury.

The pain may be accounted for by the bruising which the anterior region of the eye, the ciliary region included, has undergone from the blow. It comes on whenever he uses his eyes in near vision, whether the damaged eye be covered up or left open. It is absent,

even with both eyes open, when he is not looking at near objects. Thus the pain is not dependent on the entrance of light into the affected eye, but is related directly to use of the ciliary muscle; for, when the ciliary muscle of the sound eye contracts for near vision, that of the damaged eye involuntarily acts also, whether the latter be open or covered.

In respect to the patch of haze in the cornea, we need not hesitate to ascribe it to the direct action of the blow in setting up a slight degree of traumatic inflammation in the part actually struck; it may not improbably disappear.

The choroidal changes have the appearance of being old. The choroid is atrophied, and there is a good deal of pigment; one of the patches only is grayish and rather hazy, as if from recent exudation or the remains of blood, but even this is doubtful. The first question here is whether the choroid can go through such complete atrophy in so short a time as three weeks, or, in other words, what is the shortest time for the appearance of atrophy after traumatic choroiditis? The usual damage which the choroid sustains as the result of a blow, is rupture near the posterior pole of the eye; hæmorrhage occurs, and the neighbouring parts are obscured by blood-clot. In two or three weeks the blood-clot clears off and shows one or more crescentic stripes, or more rarely large patches, of atrophic choroid with some pigment at their edges. I do not remember having seen anything like the changes in the present case with so short a history; but this is a point on which evidence needs to be collected. The situation of this choroidal disease, opposite to the corneal opacity which, no doubt, marks the seat of the blow, is in favour of its having been caused by the injury; for we know that ruptures and traumatic inflammations of the choroid are situated opposite to the point of impact of the striking body. Again, the patches are not arranged as they are in cases of spontaneous choroiditis, where they are more often equatorial than meridional in direction.

Why is the sight disturbed and altered in this case? The defect of vision is chiefly apparent for distance, and is due to the compound myopic astigmatism; that near vision is good shows that there is no defect of accommodation. The change in the refraction of the eye just alluded to is probably the result of an alteration in the crystalline lens rather than in the cornea. Astigmatism of low degree following blows upon the eye and passing off after a time is well known, and I believe that it is generally myopic; whether it be due to change in the position of the lens, to alteration of its curves, or to increase of its refractive power, I am unable to say. Alteration in the curvatures of the lens could be caused by irritability of the ciliary muscle, and if this were greater in some parts of the zone than in others, astigmatism would follow. It is believed that in ordinary cases of astigmatism the defect is sometimes partially corrected by the unequal action of the ciliary muscle; for we sometimes find that the amount of astigmatism is smaller before atropine has been used than after, showing that the astigmatism had been partially corrected by the ciliary muscle. Change in the curves of the lens might also follow any rent or permanent stretching of the suspensory ligament. This man's defect of visual acuteness, may therefore, be put down either to slight changes in the lens, or to the unequal action of the ciliary muscle, perhaps to both.

The micropsia might depend upon one of several causes, and we have to ask which of these is present? You must first observe that this symptom may depend upon either an actual diminution of the retinal image; or, as is more common, upon an error of judgment

caused by an alteration in accommodative muscular effort, or in the number of retinal elements which are covered by an image of given size. In our patient the size of the retinal image, as formed without artificial aid, is increased rather than diminished, for the eye has become slightly myopic; further, the concave lens which corrects the myopia, and thereby rather lessens the true size of the image, instead of aggravating the symptom of micropsia removes it. We must therefore fall back upon some subjective explanation. Micropsia is common whenever the deep layers of the retina, especially near the yellow spot, are disturbed in such a manner that an image of a given size covers less than the proper number of rods and cones. It is met with from this cause in central syphilitic retinitis and central retinal hæmorrhage; but our patient has not had syphilis, and his retina appears healthy. Again, if, in order to see clearly at a given short distance, too great an effort of the accommodation is needed, owing either to weakness of ciliary nerves or muscle, or to diminished elasticity of the lens, micropsia is the result. Micropsia from this cause is sometimes observed in commencing presbyopia, and constantly in paresis of the ciliary muscle whether from the action of atropine or from disease. Just the opposite effect is produced if the ciliary muscle be thrown into tonic spasm by eserine; much less than the usual voluntary effort is then required for seeing clearly at a short distance, and objects so seen appear larger than usual. A strong contraction of the muscle of accommodation is naturally associated with the act of looking at small things, because, the smaller the object, the nearer it must be brought to the eyes in order to be easily seen; hence, whenever a strong effort to accommodate is made, even with only partial success, this *effort* comes to be mentally associated with the idea of smallness in the object. Our patient's micropsia cannot, however, be thus explained, for he has the symptom when looking at distant objects and not making the least effort of accommodation; moreover, there is no defect of accommodation at all in his damaged eye. Again micropsia is met with in some hysterical affections of sight, and is then probably due to an affection of the elementary visual areas in the brain; but this does not apply to the case before us.

Can any other explanation, besides pretending, be suggested for this man's micropsia? I think that his case is really an instance of what is very common, viz., that if any object, such as a test-type letter, be seen slightly out of focus, it will look rather smaller than when it is seen with perfect clearness. When slightly out of focus, the image consists of a nebulous or grey border and a well-defined black centre, and this centre is really smaller than the whole image is when clearly focussed. Now, it is by this well-defined central part that we judge of the size of the nebulous image. If the image be very much out of focus it will contain no black central part, and its size will therefore not be judged in the same terms. Those who are emmetropic may prove what I have said by looking at the distant test-types through a very weak convex lens (+ 0.5 D.); the letters, especially the smaller ones, will now have a rather blurred margin with a narrowed black centre, and to many persons they will look smaller than if viewed by the naked eye. The converse is seen in very slightly myopic persons; these sometimes say that the correcting lens "magnifies" the distant types, because it destroys the hazy margins. The latter is the condition in our patient: his injured eye having become slightly myopic sees a hazy border to small objects, and accordingly judges them to be smaller than they are; the correcting concave lens, whilst it has, on the whole, a slightly diminishing effect, produces an image rather larger than that portion of the hazy image from which his conception of size had been derived.

REPORTS OF  
HOSPITAL PRACTICE IN MEDICINE  
AND SURGERY.

SAMARITAN FREE HOSPITAL FOR WOMEN  
AND CHILDREN.

CALCULI REMOVED FROM THE KIDNEY BY  
COMBINED ABDOMINAL AND LUMBAR  
SECTIONS.

(Under the care of Mr. KNOWSLEY THORNTON.)

IN November, 1883, C. N., single, aged 25, was admitted under my care in the Samaritan Hospital, suffering from pain in the right lumbar region and hæmaturia. She had noticed at the end of the previous summer (1882), that she was easily tired, and also that the urine was thick and high-coloured. The pain had only come on four months before admission.

Careful examination of the abdomen and of the renal regions failed to give any assistance in diagnosis, and pelvic examination was also negative in its results. A very considerable increase of the pain on the right side, and of the amount of blood in the urine, followed the examination, and there was also so much pain in the left lumbar region that a suspicion arose that there might be stones in both kidneys. When keeping quiet in bed, there was but little pain, hardly any blood, and the amount of urine passed in twenty-four hours was from 1 pint to  $1\frac{3}{4}$  pints; when moving about, however, there was always much blood in the urine, much lumbar pain, chiefly on the right side, and the quantity of urine passed was considerably increased. She had suffered from irritable bladder, and also from occasional retention since the beginning of her symptoms. While she was kept quiet in bed, one specimen of clear and fairly healthy urine was obtained, with a mere trace of albumen. Pus was usually present in considerable quantity, but no casts were ever detected.

*Family History.*—Paternal grandfather and grandmother both had gout. Father died of renal calculus and dropsy at fifty-two. Mother living, but delicate. Two of mother's sisters died of phthisis. All the father's brothers and sisters died young. Patient has three brothers all alive and well, and six sisters, one of whom has Bright's disease. The only previous illness that she could remember was sickness and diarrhoea with fainting fits, about seven years ago.

After carefully considering the case, I decided to open the abdomen on the right side by Langenbüch's lateral incision, to examine both kidneys, and if I detected a stone in either, remove it by a separate incision through the loin. I was encouraged to the performance of this novel operation by the wish to examine both kidneys, by the confidence I possessed that a simple antiseptic exploration of the peritonæal cavity was free from serious risk, and by the hope that in the event of finding a calculus in either kidney, its extraction would be much facilitated by being able to grasp the kidney from within the peritonæum, push it towards the loin and hold it fixed in the position which appeared most favourable for reaching the stone by a small lumbar incision. On December 12th, 1883, the patient was anæsthetised by Mr. Doran, and with Mr. Meredith's assistance I performed the following operation. Langenbüch's incision on the right side, five inches long; free hæmorrhage from parietes; passed

my hand into the peritonæum, examined bladder, ovaries, and uterus; replacing the latter, which I knew was retroverted from the vaginal examination before operation, I attempted to trace up the ureters from the bladder, but found it impossible to feel them distinctly. I examined the left kidney, and thought there was some fulness in the pelvis, but not having felt many living kidneys through the peritonæum was doubtful; I examined the right, and believed that I could feel a stone in the pelvis, and to make quite sure, pushed my finger through the peritonæum and cellular tissue till nothing but the wall of the pelvis intervened between my finger and the stone. Grasping the kidney firmly, I turned it so as to reach the stone through the pelvic wall and not through the substance of the organ. This part of the operation was performed by pushing a blunt director from within outwards, till it bulged the skin in the loin, and then cutting on its point from without, enlarging the opening with a probe-pointed bistoury, then passing the director from without inwards till its point pressed upon the stone cutting through the pelvis of the kidney, and extracting the stone with a small pair of lithotomy forceps. A red rubber drainage tube was then passed through the loin opening into the pelvis of the kidney, the peritonæum was sponged out, and the abdominal incision entirely closed by silk sutures. A separate dressing was applied to the abdominal incision and to the small lumbar opening, the latter being arranged for frequent changing. The operation occupied one hour to the time I commenced to put in the sutures. It thoroughly fulfilled my expectations in so far as the examination of both kidneys, the safety of the proceeding (the patient's pulse and temperature were normal two days after the operation), and the advantage obtained by being able to fix the kidney. It failed in part because, from want of experience in such examinations, I was obliged to open the peritonæal covering of the kidney before I could feel certain as to the presence of the stone, and this, together with my method of making the lumbar incision led to a continuity between the lumbar and peritonæal wounds which I had decided to avoid when planning the operation, and which it is of the utmost consequence to avoid if the peritonæal incision is to be in all cases free from serious risk. It will be seen that when next performing the operation, I was able entirely to carry out my original plan. The stone has not been cut, but I have no doubt that it is chiefly uric acid, and it weighed on removal 90 grains and was thickly coated with blood. The after progress of the case was very satisfactory. The morning of the day after the operation I found the tube in the kidney causing so much pain that I removed it and shortened it, the tube dressing was changed under the spray every twelve hours, and the tube gradually shortened, the urine ceased to flow on the fourth day, and the tube was removed on the eighth day, when the bowels also acted naturally for the first time. The sutures had been removed from the abdominal wound on the sixth day, when it had entirely healed by first intention. On the seventh day the bladder urine, which had been clear and free from albumen, contained epithelial tube casts, much renal epithelium, crystals of uric acid and some triple phosphates, and after the closure of the loin wound it became albuminous again. During the remainder of the time that she was in the hospital, the urine contained a good deal of pus, and generally uric acid crystals, but the casts gradually disappeared and there was never any blood.

Some weeks after she left the hospital she walked some distance to church and back, the result being severe hæmaturia, and from this time it became evident that the operation had not cured her, and as she com-

plained chiefly of pain in the left side of the back I concluded that there was a calculus in that kidney also.

In March of this year she was again admitted into the hospital, looking somewhat anæmic, but upon the whole in a better condition and with less pain than when first admitted. The urine examined on March 11th was faintly acid, containing  $\frac{1}{5}$  of albumen on boiling after filtration, much pus and blood, triple phosphates, and no casts. The quantity passed in twenty-four hours corresponded closely with the amount before the operation. She stated that at times since the operation the urine had been clear for a week at a time, but any exertion would cause thickness and blood again, and she was never entirely free from pain, except when the urine was clear. The latter had been on both sides, but worse on the left than on the right.

Having since operating upon this patient, removed two calculi from males by lumbar incision with most satisfactory ultimate results, but with very tedious convalescence, I hesitated somewhat as to which method I should employ in the second operation, but at last decided to explore the left kidney by the abdominal method, being partly decided by the wish to examine the kidney which had been already operated upon, and see what condition it was in. The result proved not only the wisdom of the decision, but also the great value of the abdominal exploration in these cases.

The operation was performed on March 25th, 1885, Mr. Malcolm administering chloroform and Mr. Meredith assisting me. I first made Langenbüch's incision on the left side of the abdomen, and carefully examining the left kidney failed to detect any stone; I therefore passed my hand across to the other side of the abdomen, and found that the right kidney was as mobile and as easy to examine as if no operation had been performed upon it, and I at once detected the presence of a stone in its pelvis. I was now able to finish the operation as I had originally planned it. Steadying the kidney with one hand in the peritonæum, I cut down upon it from the loin with a long, sharp-pointed, narrow-bladed bistoury, and thus reached the stone through the substance of the kidney without wounding its peritonæal covering. The stone was round, flat, and smooth, and slipped about so readily that its extraction was very difficult, but I accomplished it at last with the aid of the lithotomy scoop. As it was evident that I had missed this stone when extracting the first, I determined to be very careful this time, and proceeding to manipulate the kidney from the peritonæum between my finger and thumb, I soon detected another stone high up in one of the calyces. The extraction of this was a very tedious business. First I had to dilate the opening from the pelvis into the calyx with my finger, and then the space to pass anything through and seize the stone was very small; at last, by squeezing the stone down with one hand, grasping the kidney from the peritonæum, I managed to seize it with the smooth-ended polypus forceps which I use for sponging out the pelvis in ovariectomy. I thus got it into the pelvis of the kidney, but it slipped out of the forceps there, and was only extracted after much manipulation by the aid of the scoop. I believe that it would have been impossible either to find or to extract this second stone through a simple lumbar incision with no possibility of securely fixing the kidney. In this particular case this is but a small portion of the benefit derived from the abdominal incision, for had I not used it I should have cut into the left kidney from the lumbar region, made a useless wound into a healthy kidney, and missed the two stones in the right kidney altogether. If I had been a little more thorough in my examination of the kidney at the first operation, I have no doubt I should have extracted all three stones then,

but I was too readily satisfied when I had found and extracted the one stone. The smooth nature and the shape of the last two extracted makes me think that they had both formed in the calyces (I have found similar stones in the calyces of a kidney removed by nephrectomy), and that the one found in the pelvis at the second operation had only found its way into that situation after the removal of the first, which was moulded somewhat to the shape of the pelvis.

The patient suffered very much more from shock than after the former operation, and when the catheter was first passed, a few hours after the operation, there was no urine in the bladder. The kidneys had both been much more freely handled than on the previous occasion, and the whole thickness of the right kidney had been cut through and the openings from the pelvis into the calyces successively dilated. The next morning the temperature was only normal, and the pulse quiet and weak (124), respiration irregular, and tongue dry and brown. There had only been  $7\frac{1}{2}$  ounces of urine from the bladder in about 16 hours, and but little had drained from the loin into the dressings. The highest temperature was recorded on the fourth day,  $100\cdot8^{\circ}$ , pulse 108, and after this it rapidly became normal. The bowels acted naturally on the fifth day and regularly daily afterwards. The sutures were removed from the abdominal incision on the seventh day, when it was practically healed. But whereas the urine ceased to flow from the lumbar wound on the fourth day after the first operation, when the pelvis only was cut through, it flowed in this second operation till the eighteenth day, and there was still a loin tube in on the forty-eighth day, when the urine suddenly began to flow freely again, and continued to do so for some days—an experience corresponding with that obtained in the two lumbar nephro-lithotomies, in both of which the urine flowed long from the wound, and then broke out again after it had ceased to flow for some time, and when one hoped that the deeper parts of the wound were quite healed.

The patient was in the hospital 30 days after the first operation, and 78 days after the second, the difference being solely due to the rapid healing of the kidney wound on the first occasion, and its slow healing on the second. Whether it is better that it should heal slowly or rapidly I think is at present an open question. When it is slow, the tube is apt to get coated with phosphatic deposit, and there must be some risk of similar deposit on the edges of the wound, and in the kidney substance or pelvis, a re-formation of the very thing the operation was to cure. On the other hand, it seems possible that if the wound heal too quickly without the pelvis of the kidney being thoroughly drained, there may be risk of small blood clots, &c., remaining behind, which may become nuclei for fresh deposits. The happy mean between too slow and too quick healing is therefore a matter of much importance, but one only to be learnt by careful observation and experience.

In considering this operation, the first question to be answered is whether the abdominal incision adds much to the risk for the patient. I maintain that it does not, if the surgeon will only make his abdominal exploration thoroughly aseptic; or, in other words, if he will take full advantage of the scientific surgery of the time. If he is not confident in his ability to do this, he had better be content with the lumbar incision.

Granting that the risk is slightly, if at all, increased by the abdominal exploration, what are the advantages obtained?

- (1) We are certain that the patient has two kidneys.
- (2) We are certain, as shown by my second operation, not to incise the wrong kidney and miss the stone.

(3) If the stone should have become impacted in the ureter too low down to be reached by the lumbar incision, it can be readily felt and removed by the abdominal incision. In this case certain special precautions will be necessary to avoid escape of urine into the peritonæum, but it is outside the present case to discuss them.

(4) We can select the point at which it is most desirable to incise either the substance or pelvis of the kidney, and hold it in the best position for reaching this point from the lumbar incision.

(5) We can steady the kidney while extracting the stones—a point of very great importance in a fat subject, or in one with a very mobile kidney, which may slip out of reach from the lumbar wound.

(6) We can avoid with certainty accidental injury to the renal vessels, the ureter, the peritonæum and the intestine, all possible dangers in the lumbar incision and of very serious risk, because they may happen and yet escape detection till they become apparent by after bad results. I do not maintain that every case should be operated upon by this combined method, and I have obtained two splendid cures by lumbar incision alone, but I do maintain that in certain cases it offers great advantages, with no serious counter-balancing risks, and it is not lightly to be dismissed from a mere foolish dread of opening the peritonæum. Careful selection of cases suitable for the combined operation, or for the lumbar operation alone, and equally careful examination of the results obtained, must decide which method shall be adopted in any given case.

I have just had the satisfaction of seeing a gentleman from whose right kidney I removed a stone a year ago. He is in perfect health, and passes clear normal urine. Before the operation he was a mere skeleton, existing on milk and water, because attempts to take other food brought on such terrible attacks of renal colic. This is a triumph for the lumbar incision, but there was considerable difficulty in steadying the kidney during incision and extraction, though he was so emaciated, and had so little abdominal muscle to resist palpation, that I thought it a specially suitable case for simple lumbar incision. He was 56 days in the nursing home, and the loin tube had to be re-inserted more than once after the wound had apparently healed.

It is too soon yet to judge of the result of the second operation; when the patient left the hospital there was still a good deal of pus in the urine, but so there has been in my two successful cases for some months after the operation, and they are now both passing healthy and clear urine.

## APPOINTMENTS FOR THE WEEK.

*Friday, July 3 (this day).*

OPHTHALMOLOGICAL SOCIETY.—General Meeting. Living Specimens at 8 p.m. Discussion on the President's paper, "On Reflex Ophthalmitis"; Mr. Anderson Critchett, "Case of Extreme Retinal Irritability"; Mr. J. B. Lawford, "Tubercle of Choroid"; Messrs. Walter Edmunds and J. B. Lawford, "Pathological Anatomy of Optic Neuritis." The Business of the Annual Meeting will be commenced at 9.30.

*Tuesday, July 7.*

UNIVERSITY OF LONDON.—Meeting of Convocation at 5 p.m. Election of Senatorial Candidates.

## MEDICAL TIMES' SPECIAL ARTICLES.

THE following series of Special Articles are in course of publication in the *Medical Times* :—

1. CLINICAL PAPERS, *being practical articles by Physicians and Surgeons of experience on important points in the diagnosis and treatment of common disorders. The 22nd paper of the Series appears in the present issue.*
2. ESSAYS ON MEDICAL CLASSICS, *being studies on the lives and works of celebrated medical writers. Essays have already appeared on Sydenham, Cheyne, Armstrong, Graves, Cullen, and Brown. The three next papers will deal with Heberden, Marshall Hall, and Conolly.*
3. NOTES ON FOREIGN HEALTH RESORTS, *embodying practical information for the use of practitioners, supplementary to that which appears in the ordinary Guides and Handbooks. Madeira, the Canary Islands, Tarasp-Sehuls, Meran, and Helwân have already been dealt with, and the following will form the subjects of future articles: Corfu, Sicily, Algeria, Athens, The Cape and Natal, and the Orange River Free State.*
4. MEDICAL CONSULTATIONS, *a series of colloquies on topics of medical interest, in which an attempt is made to present fairly the different sides of the question dealt with. No. 15, on The Title of "Doctor," is published in the present issue.*
5. LETTERS TO UNDISTINGUISHED PERSONS.

## Medical Times and Gazette.

SATURDAY, JULY 4, 1885.

THE annual election of Members of the Council of the Royal College of Surgeons took place on Thursday, and as will be seen from our report in another column, resulted in the re-election of Mr. Savory by an enormous majority, and the election of Mr. Oliver Pemberton and Mr. Macnamara. The forecast we made a few weeks back is thus well justified. The opposition which at one time appeared to threaten Mr. Savory's seat aroused a corresponding reaction in his favour, and no one but the extreme wing of the "Reform" party will deny that the case was one in which political considerations might fairly be expected to yield to those of personal eminence. By the election of Mr. Pemberton, the just claims of the provincial Fellows will be satisfied, while in Mr. Macnamara the Council gains a member who is understood to be heart and soul with the reformers.

THE usual monthly meeting of the Obstetrical Society was held on Wednesday. The chief part of the evening was occupied with a paper by Dr. Priestley, giving an account of a visit paid by him to the lying-in hospitals in Copenhagen, Helsingfors, and St. Petersburg. He described the manner in which antiseptic precautions are carried out in those hospitals, and the great reduction in the mortality and morbidity which has followed the introduction of antiseptics. Dr.

Matthews Duncan, who was the first speaker, spoke of the introduction of antiseptics as the greatest improvement in midwifery that had ever been introduced, and said that more lives were saved by antiseptics than by vaccination. Dr. John Williams related the excellent results obtained by Dr. Champneys and himself at the General Lying-in Hospital. He not only was able to state a very low rate of deaths and morbidity, but he described the extreme care which he and his colleague took to ascertain the termination of each case, so that their statistics might be perfectly accurate. Dr. Champneys urged the importance of getting the totals accurate; not basing estimates of results upon distinctions between puerperal and non-puerperal deaths. Dr. Playfair described the precautions which he himself insisted that his nurses should observe; and he, as well as other speakers, lamented the prevalent indifference of medical men in the carrying out of antiseptic precautions. Sir Joseph Lister, who was present, spoke briefly on the invitation of the President. Before the paper of the evening a unique specimen of rupture of the uterus apparently due to peritonæal adhesions was shown by Dr. Harvey of Calcutta.

THE Annual Meeting of the Ophthalmological Society will be held this day (Friday), when the officers and Council will be elected for the ensuing Session, and some alterations in the Rules will be proposed. A preliminary catalogue of the library has been printed and sent round to the Members with the notice of the meeting. We understand that the Council are specially anxious that this department of the Society should be a great success, and we therefore willingly call the attention of our readers to it. Anyone who is willing to present books to the Society is requested to communicate with the Librarian of the Ophthalmological Society, 11, Chandos Street, Cavendish Square.

CONVOCAION of London University meets on Tuesday next to vote for three candidates, one of whom will be selected by the Queen to fill the place in the Senate vacated by Lord Cardwell. The candidates who have been nominated are Mr. Carey Foster, Mr. Philip Magnus, and Dr. R. F. Weymouth. Mr. Carey Foster has obtained a greater amount of support from his brother graduates, especially in the medical faculty, than either of his colleagues, and will no doubt be indicated to the Queen by a preponderance of votes, as the individual by whom Convocation desires to be represented on the Senate. If elected, he will reinforce the Liberal party on the Governing Body, though it is possible he may oppose that whittling down of the Preliminary Science standard, which will be necessary if the London Medical Degree is to become in any sense a popular one. Whether Convocation would be with him on this point will possibly be seen on Tuesday, when it will be asked by Dr. W. J. Collins and Dr. E. W. Roughton "to express its approval of the resolve of the Senate, as intimated by the Vice-Chancellor, to maintain the standard and scientific character of the medical degrees of this University." There ought to be a good discussion on that resolution,

but unfortunately it comes last on the agenda, and probably will not be reached.

As we announced last week, a dinner is to take place this (Friday) evening at the Holborn Restaurant under the presidency of the Marquis of Salisbury, in support of the Conservative candidate for the representation of the Universities of Edinburgh and St. Andrew's. The candidate in question, Mr. Macdonald, the new Lord Advocate for Scotland, and his opponent on the Liberal side, Mr. Æneas Mackay, are both lawyers, and neither is very well qualified to represent a university which derives all the importance it possesses from the fact that it is the most flourishing medical school in the United Kingdom. It is not creditable to the Edinburgh medical graduates that they should allow political exigencies to impose upon them a representative whose culture, however high it may be, has little relation to theirs.

WITH regard to the representation in the new Parliament of the other Scottish universities, Glasgow and Aberdeen, we hear with pleasure that a movement is on foot for obtaining a medical candidate. The movement is one with which we heartily sympathize, seeing that of the eight university representatives in the present Parliament one only, viz., Sir Lyon Playfair, is in any way able to express the views and wishes of the important medical faculties; and he will shortly have to vacate his seat to a lawyer. We are glad, therefore, to hear from our Glasgow Correspondent that if a medical candidate actually stands for the Universities of Glasgow and Aberdeen, in the Liberal interest, his prospects of success are very considerable. Mr. Asher, it will be remembered, who was the defeated candidate at the last general election, had an actual majority of a score or thereabouts in Glasgow, but was beaten by the large majority in Aberdeen. Since then, however, the majority in Glasgow has rapidly increased, a majority of Liberals having been enrolled in the Council each year since the election. Aberdeen graduates have all along sought a medical candidate, and now that there seems almost a certainty of their getting their heart's desire in the person of a most distinguished member of the profession, they will, no doubt, bestir themselves to the utmost to aid his return. There seems a prospect of such a candidature uniting the two Universities in more vigorous action than has characterised them for some time past. The prospect is due to the graduates of both Universities resident in London; but we believe the members of the constituency resident in Glasgow will cordially approve what the London graduates have been able to do in the matter.

THE report which we see in a contemporary, that Mr. Ernest Hart, in his candidature for the representation of Mile-end in the next Parliament, has promised to vote for the unconditional repeal of the Contagious Diseases Acts, will cause considerable excitement in medical circles. We are not at all sure that he has not acted wisely. The apology for inspection still in force is worth less than nothing from a

preventive point of view, and the question is whether it is not worth while initiating a grand experiment in the method of difference by repealing the Acts entirely. By that means we may possibly, at the expense of our soldiers and sailors, obtain such evidence as may perhaps convince those who are not absolutely bigots on the question, *i.e.*, the vast majority of reasonable men, that a great and general effort is absolutely required in the interests of the public health to limit the ravages of these diseases. It is quite arguable whether a similar course for a similar purpose may not be in the end advisable in the case of the Vaccination Acts. At any rate, there is a great excuse for medical men, worried by the everlasting opposition to their benevolent intentions, throwing up the sponge and saying, as Mr. Hart practically does, "Well, have your own way, but don't blame me if it turns out badly."

THE cholera is daily invading fresh territory in Spain, and besides the three provinces of Valencia, Murcia, and Castellon, to which it was at first confined, and in which it still continues to rage, though with abating vehemence, it has shown itself in six other provinces, including those of Alicante, Toledo, Saragossa, and Teruel. During the second week, which ended at midnight on Monday, 7,849 cases and 3,699 deaths were officially declared, and since then the daily roll of cases has amounted to some 1,400 and the deaths to some 700. The province of Valencia has suffered most heavily during the past week, the daily number of fresh cases amounting to between five and six hundred and the deaths to something over half that amount. At the latter end of last week the disease made its appearance at Aranjuez, where it is now violently raging. The people of that beautiful summer resort are panic-stricken, and, as usual in Spain, flying from the invader by thousands, to be fumigated wherever they arrive. Meanwhile, be it noted, the more the cholera spreads the less we hear of Dr. Ferrán, who is, presumably, too busy to give the newspaper correspondents any account of his doings.

A SCIENTIFIC mission, headed by Professor Brouardel, has left Paris for Spain to study the present epidemic of cholera in that country and Dr. Ferrán's method of vaccination. It is strange that while Spain was hardly infected during last year's epidemic in France and Italy, she should now be so severely handled. Whatever may be thought of the cholera bacillus, it is quite certain that (if it exists) we know little or nothing of the conditions which favour its propagation or hinder its development.

PROFESSOR RAY LANKESTER makes an article on Recent Progress in Biology in the *Nineteenth Century Review* the vehicle for a reiteration of his well-known views on Dr. Koch and the comma-bacillus. After stating the facts, which are by now pretty familiar to our readers, he complains that "the medical world is being diverted from the real question at issue, which is not whether gelatine is liquefied by a particular organism, but whether cholera is produced by the comma-shaped organisms which occur in the intestines

in that disease." "Of this," he continues, "not a particle of real evidence has been forthcoming, and we may dismiss the statements of Dr. Koch as rash and extremely harmful assertions, which were not warranted when they were made according to the accepted principles of scientific investigation and have not as yet had the luck to turn out to be well-directed guesses." All this may be as Professor Lankester states, but we doubt the wisdom of the *severa indignatio* with which he states it. The *Times*, however, is equally absolute in its opinion. "It may be questioned," it writes, "whether any single person whose judgment upon such a matter is entitled to consideration has any vestige of belief in the alleged connexion between the microbes and cholera, or regards the former in any other light than as the results of common decomposition." We cannot but deprecate the *animus* shown in the sentences we have quoted, but it is not to be denied that our prophecy, made months ago, that the comma-bacillus will at the end turn out a common bacillus, is very likely to be justified.

THE only striking paper of medical interest in the July magazines is Dr. H. B. Donkin's reply in the *Fortnightly* to Dr. Morell Mackenzie's much-talked of article on Medical Specialism, which appeared in the same magazine last month. We noticed Dr. Mackenzie's paper on its publication, and expressed a hope that some competent writer would come forward to expound the other side of the question. We hoped that one of our big guns, with their long range projectiles, would have, not demolished Dr. Mackenzie, but given him a little friendly battering, to show the onlookers that he was not to have it all his own way. In default, however, of older men, this office has fallen to Dr. Donkin, whose closely reasoned and philosophical article will be read, we hope, with equally close attention. It may be remembered that Dr. Mackenzie's main thesis was, that specialism is destined to become the general rule in medicine, that in the near future the profession will be divided into specialists and general practitioners, while, as for the pure physician or surgeon, his occupation is as good as gone, and it only remains to write his epitaph, which indeed Dr. Mackenzie has attempted, in a style somewhat different from that usually employed in such compositions. The main objection to Dr. Mackenzie's assertion is that it is too absolute. He has witnessed specialism triumphant in certain lines of practice, in connection with which it was once furiously and we think mistakenly attacked, and he assumes that the same process will be repeated in those other forms of specialism, the objection to which rests on entirely different grounds. As we said at the time, the question of specialism will have to be settled in the final resort, on a *posteriori* grounds—by experience and not by argument. But, as it is one which, for good or evil, will have to be very largely decided by the popular voice, it is very desirable that the public should have placed intelligibly before it the grounds on which the large majority of the medical profession deprecate that undue extension of specialism, which consists in dividing the human body into its different organs, and allocating each to a

separate group of practitioners. This task Dr. Donkin has taken up and accomplished with undeniable success in the current number of the *Fortnightly Review*.

THE gist of Dr. Donkin's main argument is to be found in the following sentences:—To justify universal specialism "it must be shown," he writes, "that the whole territory of medicine can be sub-divided, without injury to its cultivation, into small and separate fields. But it is clear to those who, without technical knowledge, even for a moment seriously contemplate that territory—the human body—that no such division can possibly take place; and it follows from this that unlimited specialism has no scientific basis, and must therefore in practice be unspeakably harmful to the public. The body is an organism, not a mechanism; its systems and its parts are intimately interdependent; it cannot be studied piecemeal, and no argument from professional expediency or from the difficulty of any but specialists 'coming to the front' can shake the fact that he who has the widest knowledge of that body and its disorders and diseases is best able to find out what is the matter with his patients, and consequently with certain exceptions to tend or help them best towards recovery." This position Dr. Donkin reinforces by illustration from two or three classes of disease. For the profession this is enough, but writing as he does for the public we think Dr. Donkin would have done well to have multiplied his illustrations, which he might have done to an almost illimitable extent. As we said a month ago, the specialist himself, with his rigidly limited experience, is very apt to think that all cases are cases for the specialist, but every general practitioner will admit that the majority of the cases in which he feels the want of further help are cases for the pure physician and not for the specialist, even in the widest meaning of that term. We think that Dr. Donkin's argument would have been more easily appreciated by the general reader if he had given briefly a score of such illustrations, instead of the two or three which he has deemed sufficient. After reiterating that "the wider a man's knowledge the better a physician he will be," Dr. Donkin proceeds to meet the objections of those who would point to the men who make a special study of nervous disease and of fevers, as supporting Dr. Mackenzie's argument. In such spheres, Dr. Donkin argues, "considering the extent and multiform relationship of their material, the word 'specialism' in the limited sense of 'concentration on one object' cannot be properly applied. . . . That some men must and do limit their study and practice is no argument for the extinction or uselessness of all who refuse to concentrate themselves on the study of one organ alone. Science shows, both by the aid of advancing clinical study, and by the painstaking investigation of disease in the body after death, that but few maladies are really specialised, but few organs suffer alone. The more scientific the boundaries of the physician's territory become, the less specialised does he find his work to be." The above quotations from Dr. Donkin's article will be sufficient to show the spirit in which he deals with the question, and sufficient also, we hope,

to tempt many a reader to its careful perusal. For the medical profession the question is almost the most important of the day, and we think it will be generally admitted that Dr. Donkin's paper is a most valuable contribution to the discussion, which, however the public may take it, will certainly do much to crystallize opinion within the profession itself. Dr. Mackenzie may be congratulated on having met with an opponent so worthy of his steel.

THE Managers of the Metropolitan Hospital Saturday Fund, the receipts from which have doubled in the last decade, are contemplating a considerable increase of activity this year. The street collection, which last year brought in nearly 3,000*l.*, will be held during the London season, viz., on July 18th, instead of in September when town is comparatively empty, and it is hoped that this change will result in a large addition to the collection. The cabdrivers, too, who largely use the hospitals and are correspondingly grateful, have undertaken to display the colours of the Fund, and to make a collection amongst themselves and their fares on the same day. It is perhaps a pity that a collection could not have been organised amongst the thousands of operatives who crowded to Hyde Park last Sunday to protest against the disfranchisement of rural voters who have received medical relief. It might have been pointed out to them with some force that but for the fact that the London hospitals and dispensaries save them from relying on the Poor-law they might have been agitating for the retention of their own votes instead of those of their fellow-labourers in the country.

THE great meeting in question was successful as such meetings go, though the majority of those present seemed to regard it rather as an occasion for agitating against the House of Lords than as a means of putting pressure on the House of Commons to pass Mr. Jesse Collings' Bill. It remains to be seen what course the present Government, whose chief, as we all know, has a lordly contempt for people who think to promote political reforms by walking about the streets, will take on the question of disfranchisement for medical relief. The Conservative party have so often stolen leaves out of their opponents' book that we should not be surprised if they were to propose a measure even more far-reaching than that of Mr. Collings, which only suspends disfranchisement for a single year. We hope they will. Two or three years of such suspension are at least necessary in order to give time for that extension of the provident system, by which alone the principle of disfranchising paupers can be maintained without working injustice to individuals.

DURING last week 1,279 deaths were registered in London, being 5 less than the previous week, and 189 below the corrected decennial average. There was a slight rise in the deaths from zymotic diseases, entirely owing to diarrhoea, which caused 44 deaths; in 31 instances the victims being under one year of age. Measles caused 90 deaths, and whooping cough 46, in both cases the victims being almost exclusively children under five years of age. There were 28 fatal

cases of small-pox, and 134 fresh cases, leaving exactly 1,000 patients under treatment at the end of the week. Scarlet fever had 13 victims, diphtheria 14, and enteric fever 11. There were only 183 deaths from diseases

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past ten weeks.

of the respiratory system. The weather was fine, rain only fell on one day and then only to the extent of .11 inch; 35 hours of sunshine were recorded out of a possible duration of 116 hours. High zymotic death-rates were reached in Birkenhead, Liverpool, Manchester, Salford, and Newcastle.

THE Royal College of Physicians' Conversazione came off on Wednesday evening, and was well attended. In the library there was a fairly good selection of oil paintings, water-colour drawings and engravings, and an admirable show of "still-life," from the beautiful banks of roses on the mantelshelves, to the hideous reptiles sent by the Zoological Society. Dr. Cobbold's microscopical specimens of rare entozoa were abundantly scrutinized. But as usual and proper at such gatherings, for most of the guests conversation formed the chief entertainment, and indeed was the main object of their presence.

THE admirable address which Professor Gairdner delivered at Dundee on Saturday last, and of which we regret that the exigencies of our space only allow us this week to publish the first and less important half, will do much to help forward the movement for establishing a medical school at Dundee. There is plenty of room in Scotland for another medical school, and if the proposed arrangement with St. Andrew's University can only be completed, there is every prospect of Dundee taking a recognised place as a centre of

medical education. It has already a Science College and abundant clinical material at its Infirmary, whilst among the practitioners in the town there are men thoroughly competent to undertake the duties of teaching medicine, surgery, and the other practical subjects. In order to complete the School, Professors of Anatomy, Physiology and Pathology would have to be appointed at fair stipends, and dissecting rooms and laboratories provided. It is hoped that support might be obtained through the Royal Commission on Scottish Universities, but, even apart from that, the inhabitants may surely be counted on to raise the comparatively small amount sufficient, if the arrangements in view are successfully completed, to raise Dundee to the rank of a University town.

DR. GAIRDNER'S address forms beyond doubt a most important contribution to the discussion of a question which is at present largely occupying the minds of medical teachers, and which has thoroughly nonplussed the Medical Council. The question is, how to reconcile the claims of the scientific and the practical subjects in medical education. Two proposals have been made, (1) To throw as much as possible of the preliminary scientific teaching upon the schoolmasters; and (2) To extend the curriculum to five or six years. The Medical Council has wavered between these alternatives, inclining first to one and then to the other, and we fear that the third course suggested by Prof. Gairdner will not do much to help it out of its perplexity. The proposal will, no doubt, scandalize educational pedants—Dr. Gairdner is prepared for that—but it is based on the soundest sense, and would be well worth a trial in a new school. If Dr. Gairdner's system should be adopted at the school which it is to be hoped will ere long be started at Dundee, we should not be surprised to see the students taught under it taking a very exceptional position in the profession. The gist of the proposal is that the pupil, from his very first entrance into a medical school, should be a student of the living human body; that side by side with his theoretical studies, he should be taught their vital application, instead of having to wait to learn the latter until he has forgotten the former, which means never learning them. There should be, in Dr. Gairdner's words, "an organisation such that at every stage of the student's training an illustration could be sought out of the field of disease. He should be brought more or less face to face with the business of his life all through his course, so as at no time to lose touch with it altogether, and yet be in a position to apprehend the relation to it of thorough and genuine scientific work. The method could be followed in the learning of physics, chemistry, and the whole realm of graphic physiology. There are facts in connection with all these sciences which could be explained in the lecture and illustrated at the hospital." The scheme would involve the employment of well-paid tutors, who would have to devote themselves with enthusiasm to their duties. And here indeed is the weak point of the proposal, for to secure its successful working born teachers would be necessary; and though born teachers are said to drop from heaven more plentifully in Scotland than elsewhere, even Scotland is not embarrassed with them. The

scheme demands living teaching, not the dead-alive lectures that in London and Edinburgh make up the recognized ideal of medical education.

OUR Paris Correspondent writes: The great biennial prize of twenty thousand francs has been awarded by the Academy of Sciences to Professor Brown-Séguard. His principal competitor was the celebrated African traveller, M. Savorgnan de Brazza. The biennial prize is awarded in turn by each of the five Academies which form the Institute; it is, therefore, in reality a decennial prize so far as each Academy is concerned. While the reward, which thus crowns the life and labours of a most eminent man, is hailed with universal applause, it is a matter of regret that Professor Brown-Séguard should not be a member of the Academy of Sciences or of the Academy of Medicine. In other countries these scientific distinctions would have been conferred upon him long ago by acclamation. In France the system of "close boroughs," which prevails throughout the scientific organisations, seems to result in the exclusion of many an eminent man, who has excited the jealousy or dissatisfaction of certain members of the scientific aristocracy. Many a man of second-rate capacities enters the hallowed precincts, because his very moderate capacities have never given offence, while candidates of the highest rank are left out in the cold. Nothing short of a radical reform will break down these artificial barriers, which seem rather to keep out science than to protect it. Professor Brown-Séguard has, however, obtained a mark of public esteem which may well be set in balance against the lavish abuse which has been heaped upon him by the Anti-vivisectionists. These erratic worthies are hard at work trying to obtain the permission to lay fetters on experimental physiology in France, as they have already done in England. A "Congress" has been held in Paris, where, among a certain number of foreign members, some French adepts were present, among whom, of course, the ladies were conspicuous, including the notorious Mademoiselle Marie Deraismes, "and other wandering crazies." If, however, the French members were content with the interdiction of public experiments in lectures upon living animals, nothing short of absolute and total interdiction would satisfy the Anglo-Saxon element. When John Bull once gets upon the wrong tack, he is sure to stick at no absurdity. His motto is "thorough."

ALL those who love books and are interested in the history of medical progress, will be glad to hear that Dr. Sieveking's persevering efforts to obtain a reprint of Harvey's MS. Lectures are likely to be crowned with success, Messrs. J. and A. Churchill having undertaken the publication of the work. Further particulars as to the conditions of publication will be found on pages vi. and vii. of the half-yearly supplement, published in the present number. It is almost superfluous to call our reader's attention to the value, present and prospective, of this volume of Harvey's Lectures. It should meet the taste of both the practical and the sentimental, for owing to the limited number printed, each copy will increase in value as the years run on, while its possessor will have

always on his shelves a most worthy monument to the memory of the first of English physiologists.

WE have been requested to call attention to a letter from Dr. Neale, which appears in another column. The "Medical Digest," an appendix to which it is proposed to issue at the end of the present year, is a work of great practical usefulness, both to the medical writer and to the practitioner; but its value can only be maintained by the frequent issue of appendices. The truth of this may be gathered from the fact that as many as 2,000 entries have been made with a view to the publication of this first appendix, which by the end of the present year will, it is estimated, contain a fifth part as much matter, all of it new, as the edition of 1882. More periodicals have been drawn upon than formerly, and the editor has steadily kept in view his aim of making the work a "Digest," rather than a simple index.

AT a meeting of the Barrow Drainage Commission in Dublin last week, Dr. F. X. MacCabe, who recently resigned his appointment as Medical Inspector under the Local Government Board for Ireland, to become a member of the Irish Prisons' Board, gave some very interesting evidence as to the effect of floods and undrained land on the general health. He said that when peaty lands were flooded, the solar heat was wasted in evaporation, and a foggy cloud-laden atmosphere was the result, together with increased rainfall and a general lowering of the temperature. Hence, constitutional diseases, pulmonary phthisis, bronchial catarrh, and "bog lameness," which was really chronic rheumatism, arose amongst the labouring poor. Malaria was not altogether unknown, and, what was more significant, other diseases that did not belong to the malarial group. The injurious effects in towns and villages affected by flooding were very great. Pulmonary diseases were frequent where the inhabitants slept over marshy and flooded lands. The floods carried back the sewage, and enteric fever and gastric derangements in children became common. When the rain was great and the land flooded, compulsory confinement to the houses followed, the people crowded together, and typhus fever was amongst the results. A general lowering of vital power was also one of the consequences of the absence of sunlight and the presence of a cloud-laden atmosphere, and chronic and acute rheumatism frequently prevailed in badly-drained districts. No doubt, another result was a craving for stimulants, and he ventured to think and hope that an improvement in that direction would be the result of an improvement in the drainage of the river. When the Barrow was flooded at Carlow, especially after a moderate drought, gastric derangements and even enteric fever became very prevalent. The connection became so persistent that he had come to look at the two as in relation of cause and effect. There can be no doubt that the districts in question, providing as they do a nursing-ground for fever, constitute a standing danger to the health of Ireland.

UNDER the heading of "Andrologists: a Plea for Man," the *Boston Medical Journal* expresses its sur-

prise at the absence of any distinctive nomenclature corresponding to that of the gynæcologist. Attention is called to the term Andrologist, not to suggest its adoption, but to emphasize the wonder that, amidst the modern multiplication of specialties, it has never been used to distinguish a class of practitioners which undoubtedly exists. Every city of any size, we are told, contains men who are almost exclusively devoted to the diseases of the male sex, but as yet they are without a name. Genito-urinary diseases covers well enough the class of work, "but the practitioners themselves can only be designated, without such a term, as gentlemen devoted to genito-urinary diseases." Doubtless the chief obstacle to the professional recognition of such practitioners, as a class, is presented by those less reputable members who would have, or would claim, to be included in it in the hope of gaining status by a nominal juxtaposition with men of deservedly honoured reputation and integrity. It may be urged that the adoption of a recognised title for this branch of practice would tend to increase the *amour propre* of all who follow it. But those who still believe that "the proper study of mankind is man," and who regard the science of Anthropology with proportionate reverence and respect, would be rather taken aback on discovering that Andrology was synonymous with the study of the genito-urinary maladies peculiar to the human male.

---

#### HOW IS IT WITH THE PROFESSION?

WE are sure that many a reader in some remote country town could answer this question better than we can. We know fairly well, we are bound to know, how things are going on at head-quarters, but to settle the above question it is equally, if not more important, to know what is transpiring in the quiet backwaters of the profession, just as in gauging the vigour of an individual, the feel of the hands and feet will give information that cannot be obtained from the examination of more central organs. It has often struck us that those who flatter themselves that they are contributing to make medical history here in London, are very much like a company of bell-ringers, who, perspiring at the ropes and shaken and deafened by the vibration they themselves create, are unable to realize what emotions their efforts are exciting on the distant hills and valleys around. They do their best according to experience, skill, and muscle, and are perhaps apt to be a little careless as to whether their message is one of peace and comfort or one of discord, of sweet bells jangled out of tune. But assuredly there is one frame of mind in their hearers that they do not count on—that of indifference. Surely the chime that comes round with such weekly regularity, deafening and "succussing" the ringers in their belfrey, will not pass over the heads of the workers in distant fields without raising some response of praise, of thankfulness, or even of criticism. We fear that those who write weekly for medical readers, with a laboriousness only equalled by their sense of their own importance, are in much the case of these same trustful bell-ringers. What says the hard-worked country doctor to their weekly chime?

How does it affect him? Or does he let it pass over him with indifference as so much sound and fury signifying nothing? Who shall tell us? Who shall come in to bring word how the chimes sound in the distant pastures?

We cannot help fancying, for instance, that these questions of so-called medical politics, which excite so much discussion in London, and which have articles written on them by the score, and letters by the hundred, interest the distant members of the profession very little, because they affect them little, and can be affected by them even less. Those who stand in the thick of things necessarily have a much less perfect sense of proportions than they who stand far off. To a country practitioner in full practice, a little fact discovered in a Vienna laboratory—viz., the virtues of cocaine—has probably ten times more importance than all the long discussed arrangements for establishing a teaching university in London. And why? Because the latter question affects him as little as he is able to affect it. The people who decide these matters are determined that they will decide them alone. The teachers and their friends who are agitating for this reformed university, mainly with an eye to their future pupils' advantage, though also with a side glance at their own, are unanimous in this, that the new university shall be a teachers' university and that the graduates, as such, shall have no voice, or next to no voice, in its counsels. Complacent bell-ringers! What matter whether the chime be good, bad, or indifferent, it shall ring out all the same, and the people away there in the fields may take it or leave it as it pleases them.

Again, twenty-four practitioners drawn from the consulting ranks of large cities meet once a year or oftener in London to settle the affairs of the profession. They talk for a week or more, and pass resolutions which may be supposed to affect their brother practitioners in the remotest villages of the three kingdoms. They are well paid for their verbose labours from the pockets of these same practitioners. But again they have to take it on trust that their message will be a welcome one, received with satisfaction and gratitude. No one approaches them to say how it sounds afar off. They go on raising the standard of medical training, for instance, laudably anxious, no doubt, that every one who enters the profession shall approach as nearly as possible to their own high degree of culture. But assuming for a moment, what might perhaps claim to be more than a mere assumption, that the well-meant strictness of the Medical Council is really cutting off the supply of qualified practitioners in poor and distant neighbourhoods, and throwing their inhabitants into the hands of quacks and herbalists, who is there to warn the Council of this result? The Medical Bill of last year contained a provision which would to some extent have obviated this want of necessary information; but the Bill displeased certain authorities at certain head-quarters of medical education, and it fell through, leaving the mass of the profession still without the means of making their wants known to those who are commissioned to provide for them. Take, again, the English College of Surgeons, the governing body of

which has in its hands such resources for good or evil to the mass of the profession. Instead of gratefully welcoming, as they might have been expected to do, the proposal to secure for them fuller information as to the condition and aspirations of the mass of their constituents, the Council of the College are fighting it inch by inch, fully resolved not to hear the voice of the profession except upon compulsion. We must hear and obey what they say, but they, as a body, are sternly determined that they will not hear what we say, much less obey it.

Amongst all these bodies, who control the destinies of the profession with a complacency and an indifference to criticism rare in present experience, one alone stands out as theoretically based on the broadest suffrage, as able to draw information from the most distant channels and to utilize it for the general good. But theoretically influential as is the British Medical Association, for that, of course, is the body we allude to, practically it is impotent. It has diffused multi-form information throughout half the profession, and it has given to its members the opportunity of expressing their views on different subjects. But its practical influence may be gauged by the fact that it was possible only a year ago for an important Bill, long demanded by the Association and supported with all its strength, to be defeated by a small Scottish cabal.

All these facts appear to provide a sort of answer to the question we have placed at the head of this article. It must be well with the profession when its attempts to secure improvement meet with such small success, and their failure excites so little indignation. A man who is healthy and contented, makes little effort to improve his condition. Discontent is the fertile mother of reform. From this one may fairly argue, we presume, that the profession's health is satisfactory, and that the indifference which all efforts of medical grievance-mongers to promote reform encounter, is an indifference bred of content or of absorption in the daily duties of a serious and interesting calling. Or is it the indifference of impotence, the indifference of the invalid who lets the doctors do as they will with him, knowing, in his own heart, that all their remedies cannot aid him? This is a question on which we, and all journalists, writing as they must do from data drawn from a limited area, need "more light." Will any of our readers—and this week they will be very numerous—supply it?

---

#### CHANGE OF AIR.

THE formula which is constantly invoked to explain and justify a recurrent phenomenon which originates in motives most mixed and various in their nature, must necessarily possess a corresponding elasticity. Sanitarians of repute have told us that change of air, in its therapeutic sense, means really change of soil; that it is an alteration in the ground air—the air, that is, which the chimney-like action of a dwelling-house is ever sucking in from the soil around and beneath it—that constitutes the essential difference between living in this district and in that. To some extent

this is doubtless true, and for both good and evil this suction action is one too little understood or reckoned with. But, although the medical officer of health cannot yet claim to have changed all that, it may be doubted whether there is now-a-days such an essential difference in this respect between a modern suburban residence and one even in the favoured city of Hygeia. Certainly it is not misgiving as to his cellars or his subsoil which prompts the average Briton to undertake his annual holiday, or, let us hope, which makes him often anxious to obtain a desirable and careful tenant for the furnished house which he forsakes for some weeks of seaside leisure or foreign travel. To the invalid as to the holiday-maker a change of air often implies less a conscious alteration in the atmosphere he breathes than that variation of environment both of men and things which accompanies a change of place. But the two conditions necessarily go together, and one expression stands conveniently for both. Indeed, in the case of the great mass of those to whom a summer holiday is a not less welcome boon because it is a necessity of the artificial life which they are mostly obliged to lead, it is the change of atmosphere which most impresses and entices them. To be, for a few weeks at least, no longer condemned to "take" the air as it grudgingly enters a stuffy counting-house or sitting-room in limited doses of so many cubic inches, laden with the dust and noise of never-ceasing traffic, and permeated with the humanity which toils and sweats around him; to be able, if he will, to spend the whole day from sunrise until dark out of doors, to bathe, to revel in an ocean of diluted oxygen, to watch the sun sink beneath the waves or the moon rise out of them, to realise that chimney-smoke is a casual and accidental contamination of the atmosphere and not one of its necessary and most important constituents; all this and more is included in the new conditions which an ideal "change of air" brings to the toiler, literally sickened with a great City's ceaseless life.

And to the hard-worked dweller in the country change is not less grateful, and may often be not less necessary. The possession of two powerful legs marks man as an ambulatory animal; and the exigencies of his mental, no less than those of his physical nature, indicate a necessity for at least the occasional exercise of his powers of locomotion. The fact that he often fails to realise this need for change of place is no valid argument against its value; rather the reverse. When people in the early stage of invalidism begin to express an unreasoning dislike for leaving home, it may generally be accepted as an indication that they need above all things change of scene. Again, there is a stage in convalescence beyond which it sometimes seems impossible to make further progress, when, despite all care and attention, the patient remains at a standstill; but a change of locality lifts him, as it were, on to another platform, his nervous energies respond to the stimulant irritation of an altered environment, and from this new standpoint the progress to complete recovery is rapid and uninterrupted. For change of air, meaning change of place, brings change of all the conditions of one's being; a change of objects seen through the changed air, noted and

commented on in a changed spirit; a change of speech, of faces, of men, and of manners—and so insensibly a change of self. Man is undoubtedly largely a creature of habit—that is, of nature moulded to and ultimately stereotyped upon familiar surroundings. Thus, one now and again meets with Londoners so deeply branded with their citizenship that they complain that new-laid eggs are singularly destitute of flavour and that only one kind of milk is obtainable in the country. Yet even on such of her detractors nature works a kindly and unconscious vengeance. A man breathes more easily and deeply in a tweed shooting jacket and a soft hat, than when encased in the orthodox frock-coat and surmounted with that hideous emblem of respectability which the discriminating German aptly terms an “anguish-pipe.” The business cares and worries of yesterday are less absorbing than the question whether that big trout still lies under the old willow where we hooked and lost him last year; and for many of us the power to hold our own in the struggle of life might almost seem to consist in the annual administration of some subtle mingling of the scents of wild rose and honey-suckle and new-made hay.

Popular opinion is still apt to associate the curative value of “fresh air,” with some special or supposed constituent. Iodine and ozone are public favourites of this kind, and both are considered to be most abundant in the neighbourhood of the sea. As regards the former, it is to be suspected that the effluvia of decaying sea-weed and even sea-strewn sewage not seldom masquerade under its title; certainly if free iodine were as abundantly present in the air of some sea-side resorts as has been claimed, the powder with which some of the fair visitors affect to protect themselves from the sun should become “violet” in a chromatic sense quite unintended by its vendors—supposing, of course, that it consists of nothing less innocent than the starch which it claims to be. Ozone, no doubt, is to be detected on and near the sea, though not markedly in sea-side towns; for the presence of free ozone, however originated, indicates a comparative lack of those complex and easily decomposed organic compounds with which a part of its loosely combined oxygen is always ready to associate itself, thus ensuring their destructive degradation into simpler and less noxious substances; and an absence of putrescible material is not an ascertained characteristic of any known town, sea-side ones included. That ozone possesses any special value as an ingredient of respirable air, apart from its indirect and purifying action, is at least doubtful. Indeed, were it possible to breathe ozone as ozone, the consequences would be disastrous to the experimenter; and it is fortunate that the powerful action of the atoms of nascent oxygen, which ozone so readily parts with and to which it owes its chemical potency, is exhausted upon atmospheric and other impurities before it has an opportunity of destroying the blood and other tissues of our breathing apparatus. Nor is ozone always most abundant in or confined to the neighbourhood of the sea. It is produced mainly in one or other of two ways (which further research, indeed, may prove to be really identical), by the action of electricity upon

ordinary oxygen, and during the liberation of carbon and oxygen from the carbon dioxide of the atmosphere by the joint action of chlorophyll and sunlight. Wherever friction takes place, electricity is generated. The constant motion of air and of water, together with the action of atmospheric electricity, will explain the presence of ozone over the surface of the ocean, where there is comparatively little impurity to induce its decomposition. In like manner, wind, and the joint action of sunlight and green vegetable matter, explain its production on land, where, however, it is more quickly dissipated by combining with other organic compounds always present in more or less amount. Those, then, whom the sea-side does not suit, need not bewail the loss of its ozone-laden air. The breezy common, and the wind which blows over sunny stretches of green meadow and woodland is as pure and rich in oxygen as that of any sea-side resort, and probably more so save when the wind sets inland from over a wide stretch of sea. A walk across the fields or moors, or through the woods, is thus at once more energising and more purifying than the same amount of exercise taken on the high road or “between rows of stuccoed houses.” The shadow of a rock on the glistening beach is grateful; but the air perhaps is less pure than that compassed by the shadow of a leafy tree. And the absorption of energy which goes to the wrenching apart of the oxygen and carbon atoms is probably shown to some extent as a loss of heat; so that the dusky nooks of a deep wood are really cooler than the equally dark shadows of a rocky valley. These, however, are details as to which the holiday health seeker will do well not to be too particular. His great aim should be, having first of all and as far as possible chosen time and place well, to make up his mind to a contented enjoyment of all and anything that may fall to his lot. He will believe in good fortune, and will cultivate that good-natured acquiescence with his surroundings which is the very opposite of mental worry, and which will most readily ensure rest and recruiting time to his mental energies. He will not overdo exercise, or behave as though untrained muscles must be abused because the brain has been overtaxed, nor will he play tricks with his digestion. If he be a dilettante in medical literature, he will know that man is, in the fashionable phraseology of the day, an aerobic organism, and he will gratefully remember that while endeavouring to fulfil his destiny in that direction, he must necessarily be exposed to the influence of the many other new conditions which are conveniently comprehended in the expression “a change of air.”

## CLINICAL PAPERS.

---

### XXII.—“INDIGESTION” AND ITS TREATMENT.

THERE is no complaint of which the diagnosis and the treatment are more often vitiated by gratuitous theorising, and consequently meddlesome drugging, than chronic indigestion. Moreover, this same love of theory and “treatment”—a curious source of ready

satisfaction to many medical minds--leads to a great exaggeration of the number of cases which are dubbed dyspeptic. Satisfied with a supposition of some derangement of the secretions or movements of the stomach which cannot be proved or observed, but is all the more elaborately and dogmatically enunciated, too many of us are apt to search no further than this organ for the ultimate cause of the complaint which we have to treat. And yet it may be boldly stated that an immense majority of the patients who come to doctors for relief from pain, or discomfort of some kind, be it "fulness" or flatulence, or flushing, after taking their meals, have little or nothing the matter primarily with their stomachs, and do not require, but should rather avoid, any medicine directed thereto, or indeed any drug at all. This proposition will be found to be true just in proportion to the *apparent* freedom of these patients from any ailment except that of the stomach. In considering this question, cases of organic disease, as cancer, or ulcer, or gastric catarrh from obvious irritatives, such as alcohol or patently immoderate living, are left out of sight; for they are evidenced by other symptoms beyond those to which we refer, and, generally revealing themselves to the careful medical enquirer, are not ticketed as dyspepsia. Equally of course are ignored the common derangements of the stomach which would more properly be termed acute, occurring in the course of fevers and inflammations, or as the immediate results of acts of gluttony or drunkenness. The *ordinary* dyspeptic patient is one who suffers at certain times after taking food; and even if never quite free from his complaint, which is not often the case, is at all events much worse at such times than at others. Many, indeed, both claim and appear to be quite well except at the fatal after-dinner time.

To come to a correct conclusion as to the diagnosis and treatment of these cases, a comprehensive knowledge is brought into requisition, and the more such knowledge is practically applied, the smaller will be the number of patients who will be vaguely called dyspeptics. We shall then eliminate the gouty, and the sufferers from the less obvious forms of renal disease, and what is often lost sight of, the victims of unsuspected cardiac mischief. It is not altogether rare to find patients persistently treated, and treated in vain, for "dyspepsia" by so-called stomachic remedies, be they acids, or alkalies, or bismuth, or the many artificial and almost useless so called physiological "digestives" the names of which end in *-pepsin*, whose symptoms, though incidentally referable to gastric congestion, are really due to disease of the heart, and especially of the mitral valve. Again, the sufferers from chronic pulmonary affections, and notably from bronchitis, furnish a considerable contingent of cases which for the patients' sakes should not be put down as "indigestion." The host of neurotics, whose prominent complaint is dyspepsia, will certainly be more successfully treated by general hygienic or "tonic" methods than by "stomachic" medicines, or indeed, very often, than by giving much attention to even dietetic rules; and a change of habits or social surroundings will frequently succeed where all the resources of the cook and the druggist have been taxed

in vain by the "therapeutical" physician. Psychical dyspeptics are misunderstood and maltreated by thousands.

It would seem perhaps scarcely necessary to insist upon the all-important part played in the production of some of the most troublesome cases of indigestion by the deficiency or absence of teeth. But this cause is surprisingly often overlooked by the most ardent treaters of disease, and cases might be quoted in numbers where many doctors, including those the most eminent "for the stomach," have vainly drugged for years a healthy organ whose owner has been at last relieved of his intolerable sufferings by the art of the dental mechanician.

Most prominent of all perhaps among the dyspeptics who apply for relief are those whose sufferings, sometimes of great severity, are due only to neglect of proper intervals between their feeding-times. Not quality or quantity of food is here at fault at all. These are they who take good breakfasts, because their digestive organs have had their physiological and therefore un-starved rest; who do not suffer much or at all after luncheon (if they take any); but from an over-late dinner, when their possibly idiosyncratic stomachs have been long empty, undergo tortures which only an unnatural appetite can drive them to endure. Drugs are not good for such as these.

From this small and imperfect selection of commonplace sketches from life it will be seen that "dyspepsia" ought not to be so great a bug-bear to the doctor as it often appears to be. The despair of the therapist should decrease with his dwindling drug-list. Useful as in very many cases of organic disease of the stomach various medicines are, and indeed, indispensable as perhaps the only means of relieving the patient, they are in such cases only palliative; and the same, in a modified sense, may be said of most of the remedies in the forms of acids or alkalies which are given at certain times and with certain rules with the often plausible notion of affecting the secretions of the stomach. A dose of such medicine may relieve the pain or discomfort which follows a meal, or may even, though more doubtfully, prevent such pain in rare cases by promoting digestion; but the effect is only temporary; the cause is not touched, and the theory which prompts their administration is elaborated more in the study than at the bed-side. The stomach rarely suffers alone; never, perhaps, in indigestion which is *curable*. In curable dyspepsia drugs reach their lowest, in incurable disease of the stomach their highest, point of utility. Pepsin may relieve discomfort for the moment; but it seldom does, and at best it is a sorry therapeutic crutch. Opium, and even bismuth, are often a god-send to a cancerous stomach. And with respect to the purely dietetic treatment of dyspepsia, there are two sides to the question. Doubtless the dyspeptic should not disobey the accepted dicta of physiology and of general experience with regard to his manner of living; and broad rules should in most cases be enforced. But in proportion as a man is dyspeptic, so he often finds out best for himself what to take and what to avoid; and as long as his meals are moderate in quantity and regular in time he will often be better with a comparatively unrestricted diet-table. The most "dietetic"

of doctors rarely practise themselves what they preach, to the healthy, and the least dyspeptic of dyspeptics are verily not those who are always taking thought for their daily meat and drink.

Σ.

## REVIEWS AND NOTICES OF BOOKS.

### PHARMACOLOGY, THERAPEUTICS, AND MATERIA MEDICA.<sup>1</sup>

UNDER the above title, Dr. Lauder Brunton introduces to the medical world a work which marks a distinct epoch, a turning point in the history of medicine. It is not a mere compilation, a *résumé* of all that has been said during the last few years of drugs and their actions, but it is essentially a new departure, breaking away from well-worn tracks into a new and almost unknown region. It is significant to find a reversal of the order of the terms *Materia Medica* and *Therapeutics*, and it is satisfactory to see from the preface that this is no haphazard arrangement, but the result of a conviction in the author's mind that *Materia Medica* should hold a distinctly subservient position; a feeling that time and energy are wasted in presenting the reader with a mass of facts, numbers and minutiae of tests, more particularly volumetric tests, which it is impossible to commit to memory and which should only find a place in manuals of reference, not in text-books. This idea removes from the book a number of details with which works on *Materia Medica* are commonly clogged, and with the elimination of so much material it might be thought that the student's work would be rendered lighter, and that the absolute amount of reading would be diminished. We find, however, that this newest text-book consists of over eleven hundred pages, and there are but few of these pages which can be hurried over without missing important facts. For this vast increase of the work of the summer session the student may well ask for some justification, and the justification is furnished most amply by Dr. Lauder Brunton's first title of his book, *Pharmacology*, and the way in which he deals with it. He defines it as being a "knowledge of the mode of action of drugs upon the body generally and upon its various parts," and he widens this definition later by saying that in discussing pharmacological questions, we are accustomed to speak of the *action* of a drug on the body, or on its various parts, but we must remember the effect produced is not due to a one-sided action, that what we actually mean is the *reaction* between the drug and the various parts of the body.

The development of this subject practically forms the *raison d'être* of the book. The section on pharmacology is by far the most thorough, and, as might have been anticipated from a consideration of the author's former publications, it is based purely on advanced physiology of the modern school. In order that no mistakes may be made, no erroneous deductions drawn from the reader and the author approaching this section with different data, Dr. Lauder Brunton repeats, somewhat exhaustively, the physiology of the various organs, remembering, as he naïvely remarks in the preface, that students sometimes find a difficulty in applying physiology to pharmacology and therapeutics, and that many are apt to forget those parts of physiology which they are not constantly studying. This "aptness to

forget" Dr. Brunton constantly endeavours to meet in his pages, going out of his way a little in various directions where his experience as a teacher and examiner has shown him that forgetfulness is most marked. This is the case, apparently, not only with physiology, but also with chemistry: *e.g.*, when speaking of the carbon compounds, we find that under the heading of the fatty series and aromatic series he prefaces his remarks by some pages of pure chemistry, commencing with the tetrad character of carbon and ending with graphic formulæ for pyridine, naphthaline, and chinoline.

This direct application of previous knowledge, this forcing home the importance of work of the preceding session, is undoubtedly of inestimable advantage. It shows the results that have been obtained by the experimental method, it explains these results fully so far as our present knowledge allows of explanation, it furnishes scores of suggestions for new investigations, and it supplies also numerous invaluable hints as to the deductions to be drawn from experiments. Perhaps one of the most interesting sections is that in which we meet with the ingenious application of the theory of inhibition by interference, this hypothesis being made to explain the opposite results so frequently obtained by the use of small or large doses of the same drug, results which are almost inexplicable on any other theory. Another portion of the book which leaves a lasting impression, a feeling that something has been distinctly gained by the author's system, is that in which he deals with the action of drugs on the eye, and explains the way in which simple alterations in the size of the pupil may be effected.

As a sign of the times we find a chapter devoted to the action of drugs on invertebrata, the author remarking that the "study of the action of drugs on invertebrata has not been carried out methodically to any great extent, but it offers a very promising field for investigation, and probably in the course of a few years may yield very valuable results." Those accustomed to read between the lines will see a special significance in the interest attaching to the action of drugs on medusa, mollusca, ascidians and annulosa, and cannot fail to admire this tacit protest against the limits applied to the work of the scientific investigator. It is now more than fifteen years since Dr. Brunton deferred the publication of his original book on *Materia Medica*, in order to clear up many unsatisfactory statements and uncertainties by a few experiments, and now the whole conditions of research are altered completely, but not before much has been done, as this book shows, to render the employment of remedies far more scientific, far less empirical. The author's sympathies have evidently been mainly with the pharmacological element, and as a consequence we find this portion of the book full of new material most carefully worked out. The parts dealing with Therapeutics are not so full and not so satisfactory; and the *Materia Medica*, from an insular standpoint, is still less satisfying—it is, to say the least of it, perplexing to have it complicated by the addition of remedies and preparations from the United States Pharmacopœia.

Although we regard this as an error of judgment, and wish that Dr. Lauder Brunton had contented himself with writing a work on *Pharmacology* only, there can be no doubt that the book will be widely employed, and will greatly add to the author's already high reputation. The style is easy and lucid; opportunities for light writing are but few, as the book deals so largely with stern facts. The author has, however, contrived to stamp his individuality on every page, and his quaintness of diction will frequently amuse, *e.g.*, when speaking of invisible respirators, he says, "An instrument is sold bearing this name, consisting of a thin plate of metal; but what is perhaps quite as

<sup>1</sup> "A Text-Book of Pharmacology, Therapeutics, and *Materia Medica*." By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S. Adapted to the United States Pharmacopœia, by F. H. WILLIAMS, M.D. London: Macmillan & Co., 1885.

good, or better, is a sovereign or half-sovereign placed between the lips and teeth. Patients are thus forced to keep the mouth shut in order to prevent it from falling out, and its value makes them careful about losing it." The book is furnished with three very copious indices; over a hundred and thirty pages are devoted to them. It is also fully illustrated with diagrams and illustrations of somewhat unequal merit; those in the Pharmacological portion of the work are excellent; those in the *Materia Medica* are apt to be misleading from the absence of scales indicating the size of the specimens. In a work of this magnitude repetition is frequently necessary, and perhaps inevitable, but in certain instances it is rather too marked, *e.g.*, on p. 490 and p. 544 the elimination of iodine, and the mode of production of iodism, are to all intents and purposes repeated at length in the same words. It seems ungracious to refer to misprints, but they are frequent. One which will doubtless surprise all who value Dr. Brunton's work occurs on p. 708, where a wrong formula is given for nitrite of amyl.

### LITZMANN ON LABOUR WITH CONTRACTED PELVIS.<sup>1</sup>

THIS great work fills us with admiration of the patient labour and accurate and minute observation by which it has been produced. The branch of medical science to which it is a splendid contribution has not of late been so much studied in the English-speaking countries as it ought to be. Gynæcology, more lucrative and less laborious, has diverted the attention of most of those by whom midwifery ought to be advanced. In midwifery, exactness of diagnosis and soundness in practice, are too often their own only reward. But it must not be forgotten, that research in midwifery in England is carried on under greater difficulties than is the case in Germany. Just as other branches of medicine and surgery owe their advance to the opportunities afforded by the aggregation of disease in our great hospitals, so it is to the bringing together of midwifery cases under circumstances favourable to observation that we must look for progress there. In Germany the numerous lying-in hospitals, well officered and equipped, fulfil this condition: and the result is seen in the grand strides in our knowledge of the science of obstetrics proper which we owe to that country.

The book before us is composed of three parts. The first, which occupies 158 pages, consists of four lectures on labour with contracted pelvis. The first is on the diagnosis of pelvic contraction in the living; the second, on the influence of contraction of the pelvis upon labour, considered generally; the third, on the influence of particular forms of contracted pelvis upon the process of labour; and the last, on the treatment of labour with pelvic contraction. With regard to these lectures, it is scarcely too much to say that to one who is only acquainted with the subject from reading English text-books, they open up what is almost a new world of thought. They show the reign of law in what was previously nothing but confusion. They give interest to, and bring practical uses from, the observation of small points in which, unilluminated by the light of science, the student of midwifery sees little value except perhaps as a help to the cultivation of his sense of touch. The mechanism of labour and the deviations from it, considered by too many students we fear as a sort of barren scholastic exercise, become full of interest, and are seen to

abound in lessons of direct practical utility. It is a book which we hope may, some day, be seen in an English dress; in any case its teaching is sure to permeate the text-books of the future.

The second part of the work consists of three lectures on the history of labour with narrow pelvises. These are very interesting, although they have no direct bearing upon the practical business of the accoucheur. They fill 88 pages. The remainder of the volume consists of the cases upon which the didactic teaching of the 2nd, 3rd, and 4th lectures is based. They are cases of labour reported with a fulness and minuteness and precision of detail to which, taken as a whole, English obstetric literature affords no parallel; and, if we seek here and there in English monographs for cases to compare with Litzmann's elaborate reports, we shall find but few that come up to even an average case out of this collection. As a summary of our judgment we can only repeat what we have already said, that no obstetric teacher ought to omit the careful study of this book, and that it must largely colour the teaching and practice of the future. We are sorry to say anything which may lessen the desire of our readers to get the book, but truth compels us to add that Prof. Litzmann's style is cumbersome and involved, his sentences lengthy and complicated—indeed, for an English reader, it seems to us as difficult German to translate as is to be found in medical literature.

*A Practical Treatise on Urinary and Renal Diseases;* by WILLIAM ROBERTS, M.D. Fourth edition. London: Smith, Elder & Co., 1885.—In the preparation of this edition, which has long been looked for, Dr. Roberts has been assisted by Dr. Maguire, and he acknowledges his indebtedness by placing the name of the latter on the title page with a generosity which unfortunately is not very common. So much has been said in regard to albuminuria in the ten years that have elapsed since the last edition, that Dr. Roberts found it desirable to re-write the section dealing with this important subject. As regards the tests, he declares for two only, *viz.*: the old methods of boiling and nitric acid. All the new tests he has found untrustworthy, including his own brine test, and all for the same defect, *viz.*: that they give a reaction with mucin and other substances which cannot be distinguished from that indicative of albumen. To the list of pathological states in which albumen is liable to be found, the author now adds functional albuminuria, including especially the physiological albuminuria of adolescents; he inclines to accept Sir William Gull's hypothesis that it is due to atony of the vessels and nerves of the kidney. A long note is appended on the pathology of albuminuria, in which he accepts the following general conditions:—1. Alterations in the composition of the blood. 2. Alterations in the circulation of the blood through the kidneys. 3. Alterations in the structure of the kidney. The section on bacteruria has also been re-written, and contains a most interesting and detailed account of a case in which he found micrococcus chains in the perfectly fresh urine; he succeeded in obtaining a pure cultivation of the organism, but is not able to throw any light upon the nature of the case; the patient eventually died with polypoid growths in the bladder. As to the oneness of the two forms of Bright's disease, the author's views remain unchanged; he still holds, with the great majority of writers in this country, that though the large white kidney may atrophy, it can never be converted into the granular kidney. The recent work of Manson and others in reference to the *filaria sanguinis hominis* has been duly incorporated in the present edition, but we cannot say that the section on the *Bilharzia hæmatobia* has been brought up to date at all, and it is evident that the editors have not seen Dr. Guillemard's little monograph on the disease which appeared some three or four years ago. With this single exception we believe that the work is fully up to date, and it cannot fail to maintain its great and well-earned popularity.

<sup>1</sup> Die Geburt bei engem Becken, nach eigenen Beobachtungen und Untersuchungen, von Dr. Carl Conrad Theodor Litzmann, Professor der Gynäkologie an der Universität Kiel. Leipzig: Breitkopf and Härtel, 1884. S. 738.

*Lectures on Diseases of the Nervous System, especially in Women*; by S. WEIR MITCHELL, M.D., Second edition. London: J. & A. Churchill, 1885.—We feel sure that the new edition of Dr. Mitchell's admirable lectures will be received on this side of the Atlantic with more than ordinary attention. His subject, the nervous disorders of women, is one that interests every practitioner, and his views on treatment are gradually receiving general acceptance. The new matter in the present edition deals with hysterical affections of the joints, of the alimentary canal, and rectum especially, and of the relation of hysteria to organic disease of the spine. Under this latter head a most remarkable case is narrated, tending to upset some accepted views in regard to disease of the spinal cord. We have been accustomed to believe that when any group of muscles presented the "reaction of degeneration" there was hopeless disease in the corresponding area of the spinal cord. Dr. Mitchell's case, however, shows that this is not universally the case. The symptoms in the case of the young lady in question were of so extreme a character, that nothing short of her complete recovery would have sufficed to satisfy us that there was not organic disease of the cord; the patient was blind, her mental faculties were impaired, her limbs were contracted in an extreme degree, the contraction not giving way under an anæsthetic, and the muscles of the leg presented the degenerative reaction, and yet she got quite well. Dr. Mitchell says that the clinical history of acute hysteria has yet to be written, but it appears to us that he has contributed at any rate the preliminary chapters, and if, as he says, we still know nothing of the physical basis of hysteria, we would reply that, thanks to him, we are at any rate in a better position to recognise and treat it than we were.

*Injuries of the Spine and Spinal Cord, without apparent Mechanical Lesion, and Nervous Shock, in their Surgical and Medico-Legal Aspects*; by H. W. PAGE, M.A., M.C., Cantab. Second edition. London: J. & A. Churchill, pp. 397.—Mr. Page's now standard work appears after thorough revision, in its second edition. The author candidly tells us that he has been unable to make such additions to it as he had wished and contemplated, but otherwise, so good and so full of valuable information is the book, that we should never have discovered that additions were either possible or necessary. The work throughout is full of plain common-sense argument, and testifies to an unbiassed, yet critical mind at work in an old field, but entirely on new lines. Though great prominence was given to the work by what we may call a regrettable mistake, its popularity and success in no sense rest on such an accident, but rather on the admirable reasoning and sound conclusions drawn from a very large experience in the particular class of cases under discussion.

*Frozen Sections of a Child*; by THOMAS DWIGHT, M.D.; Fifteen drawings from Nature, by H. P. QUINCY, M.D. New York: William Wood & Co., 1881. This useful atlas, prepared under the direction of the Parkman Professor of Anatomy at Harvard University, appeared some years ago, but it has never been noticed in these columns, and we gladly take the opportunity of drawing our readers' attention to it. The study of sections and plates of sections, which is now becoming so popular, can never replace careful dissections as an anatomical training, but it is a very excellent supplement to the ordinary course of anatomy, and indeed it may be almost said to be necessary to a full and clear idea of the architecture of the human body. The present volume exemplifies this in a remarkable degree, for it deals with the body at an age which, anatomically, has received little attention, the subject of the sections having been the body of a girl of three years of age. To the increasing number of practitioners who are devoting their attention to the diseases of childhood, it will give important aid; to such practitioners an accurate knowledge of anatomy is essential, as their diagnosis must necessarily be formed almost exclusively on the study of objective facts, and any means which facilitates this study and renders accuracy in it more possible will be heartily welcomed. The plates are accompanied by explanatory chapters, in which the in-

ferences to be drawn from them are noticed, and many points omitted in the ordinary text books are emphasized. The peculiarities due to the age of the subject are pointed out, and the appearances contrasted with those met with in adult sections. In his preface Professor Dwight gives directions for making frozen sections, a process which, owing to the colder winters of the author's city, is evidently much easier there than in our own temperate climate. The book is one which should be constantly in the hand of every surgeon or physician who has to deal with the disorders of childhood.

*Micro-Chemistry of Poisons*; by THEODORE G. WORMLEY, M.D. Second Edition. Philadelphia and London: J. B. Lippincott Company, 1885.—It would be difficult if not impossible to speak in terms of too high praise of this beautiful work. The arrangement is systematic, the author's style clear, and the whole subject is minutely and thoroughly treated. The plates, sixteen in number, all from steel engravings, are without exception admirably executed, and constitute a most important feature in a work which even without them would have made its mark. The new matter in this edition consists mainly in a chapter on gelsemine and an appendix on the examination of blood and the detection of blood stains. In both these articles the author shows himself to be fully abreast of current medical opinion on these important subjects.

## ABSTRACTS AND EXTRACTS.

### THE TRANSMISSION OF PHTHISIS.

IN a recent clinical lecture on the transmission of phthisis between husband and wife, M. Potain (*Revue de Médecine*, June) briefly records a case in which there was reason to suppose that a woman who had died under his care from phthisis had contracted the disease from nursing her husband, who died of the same malady. He then proceeds to study the general evidence bearing upon the question. The old popular belief in the contagious character of phthisis was shared by Hippocrates and Galen, and in later times Sennert, Morton, Valsalva, Morgagni and many others had held the same opinion. In the middle ages, especially in Italy, phthisis was regarded by the law as a contagious disease, sufferers from it were isolated, and the notification of the sick was compulsory. Gradually with the advance of pathological anatomy the notion of its contagiousity became lost, at any rate so far as the medical profession was concerned, for in many places the popular belief in its contagiousness lingered on. Laennec, who believed in the inoculability of phthisis, did not admit its contagiousity, and he was followed by Portal, Andral and Requin, who all shared his views. Finally, the histological researches of Virchow and his school afforded a fresh support to the opponents of the contagion theory. Many practitioners, notwithstanding all these facts, were led to share the popular belief, and to still think that tuberculosis might be contagious. It was chiefly in the army that the facts of transmission were most striking, and the frequent occurrence of tuberculosis in young men, healthy for the most part, but living together, was a strong argument in favour of the contagious nature of the disease. It was a French Army physician who first undertook to demonstrate scientifically what his every-day experience taught him to presume to be the case. To M. Villemin belonged the honour of having been the first to prove experimentally the virulence of tuberculosis. His first work in this direction dated back to 1865, and at that date he had already arrived at the opinion that tubercle was an infectious zymotic disease. Naturally his views at first met with much opposition. In 1877, Klebs announced the discovery of bacteria in the sputa of phthisical persons. In 1882, Koch succeeded in demonstrating conclusively the bacillus of tubercle by the aid of new methods of preparing and staining, Toussaint having failed the year before in his cultivation

experiments. M. Potain then briefly recounted some instances in which contagion from wife to husband had taken place, as well as some in which it had been from husband to wife. In all these cases it was observed that the contracted disease ran a rapid course, more rapid in fact than in that in the person from whom it was contracted. Sometimes tuberculosis might be transmitted to successive husbands or wives as the case might be, and sometimes a husband having contracted phthisis from his wife, and after her death having married again, had been known to transmit the disease to the second wife. It was noted that in the majority of cases where a wife became phthisical through contagion, she had already borne children, and it was already recognised that pregnancy was a weakening cause, predisposing to phthisis, but cases were cited where the transmission of the disease had taken place in the absence of pregnancy, so that this was not an essential; nor did it by any means follow that phthisis always proved contagious between married persons. Wherever individuals lived together in common, as in monasteries, barracks, &c., the transmission of phthisis was of frequent occurrence. The mortality from phthisis in barracks had been shown to be higher than in the civil population, but with the army in the country this was not the case. The marked difference which existed between town and country in the matter of the frequency of tuberculosis showed the danger of over crowding, and afforded a proof of the contagious nature of the disease. These facts seem to indicate that the danger of contagion ought to be great in hospitals, but as a rule the stay of the patient was not sufficiently long to enable the influence of the contagion to take effect. As regarded hospital nurses it had not been clearly shown that phthisis was more frequent amongst them than in the rest of the public. Thus, then, the lecturer urged, the contagiousness of phthisis could no longer be disputed. The infecting agent penetrated into the organism either in the form of a bacillus or in the form of zooglœa, which as M. Malassez had shown was only a special form of the parasite. But what was the mode of transmission? Some had thought that it took place by means of the perspiration, but this was open to numerous objections: phthisis had often been contracted by persons who had not been exposed to its influence. It had been thought that the expired air might contain the infective agent. This could not be proved. Undoubtedly the most frequent mode of transmission was the absorption of dust coming from dried sputa. The sputa therefore were the chief source of danger, and all efforts at prophylaxis should be in the direction of keeping the sputa from becoming dried until such time as they could be effectually destroyed.

**TREATMENT OF PULMONARY CONSUMPTION.**—Dr. T. J. Mayo writes as follows on this subject in the *Therapeutic Gazette* for June: All individuals belonging to the consumptive class possess two prominent characteristics,—(1) a capricious appetite depending upon a facile derangement of the digestive and assimilative apparatus, and (2) a lack of constitutional resistance against unfavourable conditions. The strength and sustenance which they derive from their daily physiological income is barely sufficient to meet the daily demands incurred by carrying on the normal expenditures; hence, the reserve capital is but small, and leaves the body in but an unstable equilibrium, unfit to react against the contingencies of disease which may be encountered at any time. It is evident, therefore, that the physician's attention is promptly demanded to rectify the digestive and assimilative difficulties in this disease, and his success or failure in the treatment of it is measurably due to his ability or inability to permanently restore these impaired functions. In order to succeed it is necessary to discriminate rigidly between those foods which agree with the patient and those which do not. As far as the force-producing value of foods is concerned, there can be no doubt that cod-liver oil and the fatty and saccharine foods stand at the head of the list; but it is also true, on the other hand, that many patients have a marked aversion to all fatty substances, and oftentimes when cod-liver oil does agree, it diminishes

the capacity of the stomach for other kinds of food. Again it is well known that in these cases there is a constant tendency to sourness of the stomach after eating, caused by excessive fermentative changes of the fatty and sugary foods; hence, with all the redeeming features of the non-nitrogenous foods, it would be madness to persist in their use when they are so plainly contraindicated. When they are well borne, stimulate the appetite, and make flesh, they are invaluable. Among the non-nitrogenous foods which are least prone to undergo fermentation are alcohol and butter, and the dietetic value of these articles, if they agree, increases in proportion as it becomes necessary to exclude the other non-nitrogenous foods from the dietary list. The nitrogenous foods which are employed to greatest advantage in this disease are beef, mutton, eggs, oysters, lobsters, milk, either raw or cooked, cheese, bread, beans, peas, &c. These foods, by entirely obviating the constant tendency to fermentative changes in the stomach, furnish a desideratum which cannot possibly be supplied by the non-nitrogenous class. In the management of the dietetics it is of the utmost importance to have these patients under constant and entire control of either a nurse or an assistant, and to have them pursue a rigid and systematic course in regard to everything that pertains to their welfare. Each patient should have a programme laid down as to what to do in relation to eating, drinking, sleeping, exercising, amusements, application and administration of remedies for the whole twenty-four hours. No half-way measures will answer in the treatment of this malady. The great object to be gained is to economise the energy of the stomach and the body, in order to secure the greatest amount of work with the least expenditure of vital force. The first can undoubtedly be best achieved by allowing the patient to take small and oft-repeated meals. Five or six meals a day at regular intervals, slowly and thoroughly masticated and swallowed, will furnish a sufficient amount of nutritive material to the patient. Dinner taken between one and two o'clock should be the heaviest meal, and the last one at night should be the lightest one in the day. Upon a most dexterous cook depends the task of serving a variety of foods, and of rendering the bill of fare tempting and enticing to the patient's appetite. No appetite is as fastidious as that of the consumptive, and he should never know in advance what the table has in store for him, so that he is not allowed sufficient time to manufacture excuses for not eating certain kinds of foods. He always eats best when he is surprised by some new and inviting dish; but, on the other hand, nothing should be denied to him unless it is known to be positively injurious. In regard to medicinal treatment which is calculated to arouse the digestive apparatus, much can often be done. A pressure and fulness in the gastric region, associated with sour cructations after eating, is very often relieved by eight or ten drops of dilute phosphoric or of dilute nitro-muriatic acid in a tumblerful of hot water after meals, and, if necessary, a combination of compound tincture of cinchona, gentian, and eardamoms before meals. A brisk massaging over the gastric region for ten or fifteen minutes has a very beneficial effect in these digestive disorders.

**KRAUROSIS VULVÆ.**—Professor Breisky, of Prague, describes under this term a little-noticed form of atrophy of the mucocutaneous covering of the female pudendum. He has observed twelve cases, of which the following were the characteristics:—Apparent deficiency of the nymphæ, the integument from the mous veneris to the meatus urinarius passing smoothly over the clitoris without folds. Sometimes a cicatricial line is seen in the middle line of the vestibule. The glans clitoridis is either quite concealed by the shrunken teguments, or lies underneath a small round depression in them. On separating the labia majora, the mucous membrane below the urethra is stretched, and projects as a transverse fold. An effect of the atrophic process is a "*stenosis vestibularis*," together with which the tissues become unyielding, and readily tear. In consequence, after labour, extensive lacerations are often seen, and even by coitus much fissuring may be produced. At the places of greatest atrophy, the integument is whitish and dry, sometimes covered with a thick somewhat rough

epidermis, while the neighbouring parts are shining and dry and of a pale greyish-red. The sebaceous glands of the pudendal folds generally appear remarkably few. Breisky has made a microscopical examination in one case, and found a cicatrix-like appearance; the connective tissue being sclerosed, nearly homogenous, the fibres running in a few nearly parallel bands, instead of having the usual undulating appearance. The papillæ were of unequal sizes, mostly small, the rete malpighii strikingly thin. No sebaceous glands could be seen, and only remnants of sweat glands. As to the ætiology of the disease, the author can only say that in 4 cases much pruritus preceded it; only 3 patients suffered from leucorrhœa; syphilis was not demonstrable in any; none had suffered from eczema or any exanthem; nor could difficult labours, parturient injuries or puerperal inflammation be pointed to as ætiological factors. Sugar was not present in the urine of any. The affection has not been hitherto described, and its characters are not those of the condition of the vulva which is known to commonly follow severe pruritus. Neither does it correspond to any form of eutaneous or mucous atrophy hitherto described. Therefore the author has given it the name of "kraurosis" ("schrumpfung"—shrinking) "vulvæ." As to its course and termination nothing is known. Treatment as yet has proved ineffectual. We take the above from the *Centralblatt für Gynäkologie*, June 6th, 1885.

**EPIDEMIC AND SPORADIC CHOLERA.**—Dr. Alexander Harkin, who can lay claim to having witnessed every epidemic of cholera that has taken place in Belfast, in a paper read before the Ulster Medical Society, after discussing the modern views with regard to the bacillary origin of the disease, proceeds to consider the influence of the part played by the nervous system. The vomiting and purging are apparently due to an abnormal or excited condition of the nervous supply to the stomach and bowels; the choleraic voice, the vertigo, the spasms and cramps, and the tremors all own the same cause; the symptoms of collapse in the algid stage are due to the irritation and hypertrophy of the sympathetic system; whilst the depression of the functions of circulation and respiration point to affection of the vaso-motor system. The treatment should be directed to exerting some control over the sympathetic nervous system. For the general treatment rest in bed between blankets is essential; turpentine and mustard stupes may be applied to the abdomen; beef tea, milk and whey and iced water ad libitum may be given. Dilute sulphuric acid with opium has proved as beneficial as any other internal remedy, but Dr. Harkin lays no stress on internal medication at all, and urges the application of some blistering fluid behind the ear extending along the course of the pneumogastric nerve, as far as the angle of the jaw. As a rule he only applies it on the right side, but if necessary it also may be applied to the left side. The reason for choosing the right side is that the right pneumogastric nerve is distributed to the whole of the small intestines. He has tried this remedy in all stages of cholera and recommends it for all. It has appeared to him to control and almost paralyse the sympathetic in the stomach and intestines, and to stop at once the inordinate secretions due to its agency. The violent contraction and palpitation of the heart are controlled, the dilating power of its walls and cavities especially of the left side is restored, and the congestion of the pulmonary and arterial systems is put an end to.—*Dublin Journal of Medical Science*, June 1885.

**THE ELECTRICAL EXCITABILITY OF THE UTERUS.**—Dr. E. Bumm, of Würzburg, writes in the *Archiv. für Gynäkologie* (Band XXIV., Heft 1) on electricity as applied to the uterus, a subject to which some attention has been drawn lately. The following are his conclusions. In the majority of cases electrical stimulation does not influence the uterus sufficiently to be of use in practice. We cannot stimulate the uterus through its nerves, therefore the electricity must be applied directly to the muscle itself. The uterus being a large flat muscle and the excitability of smooth muscular fibre low, it is necessary that the current should be applied in the manner by which the greatest possible effect can be produced. This condition is not fulfilled either by applying the electrodes externally, or by bringing one pole in contact with the vaginal portion. A

powerful effect is only to be produced by putting one conductor in the uterine cavity itself, and so bringing the muscle directly between the electrodes. This can only be done when the uterus is empty. It follows therefore that the only rational use of electricity in midwifery is to combat relaxation of the uterus with hæmorrhage in the third stage of labour, and this only when the non-contraction of the organ is due to simple atony, and not to mechanical causes. Dr. Bumm states that he has never observed any bad effect, either on mother or child. As electricity has been recommended as a means of inducing premature labour, we may mention further that Dr. Bumm has applied it in ten pregnant women, without any effect. Out of 40 women in labour, in only five was there a marked effect, and in 20 no effect whatever could be perceived. We may add that the paper contains an exhaustive survey of the literature of the subject.

**CARBOHYDRATES IN THE HUMAN LIVER.**—The *post-mortem* formation of sugar goes on in the liver, according to Kratsehmer in the *Chem. Cent.*, from a healthy or diseased subject up to a certain extent, and quite independently of the amount of glycogen present at the time. Since the glycogen remains intact for a time, the sugar must come from other sources. The degree of fullness of the alimentary canal does not in general influence the result. Cases occur in which, with considerable amounts of sugar, no trace of glycogen occurs, whilst in other cases, in the liver of the lower animals as well as of the human subject, the glycogen has not been attacked. In pathological cases, both sugar and glycogen may completely disappear from the liver. The livers of both men and animals afford a substance containing both nitrogen and sulphur, which has not yet been described. When a liver free from sugar and glycogen is de-albuminised by treatment with hydrochloric acid and potassium mercury iodide, and the clear filtrate is mixed with 5 or 6 times its amount of 90 per cent. alcohol, a small snow-white flocculent precipitate is obtained, in appearance exactly like glycogen. This shrinks to gum-like floes on the filter, is largely dissolved by water, and can be reprecipitated by alcohol. Neither saliva nor mineral acids convert it into sugar; it contains nitrogen and sulphur, is not precipitated by phosphotungstic acid, but is precipitated by potassium mercury iodide, and is distinguished by this and other reactions from albumin, peptone, mucin, and gluten. It also occurs in livers which contain sugar and glycogen.—*Journ. Chem. Soc.*, June, 1885.

**KOLA.**—Dr. Leon Monnet, in a paper on the physiological and therapeutical action of Kola in the *Therapeutic Gazette*, No. 4, arrives at the following conclusions:—(1) Kola, by the caffeine and theobromine which it contains, is a tonic of the heart, whose pulsations it accelerates, while it increases their power and regulates their contractions. (2) In the second phase of its action, it becomes, like digitalis, a regulator to the pulse, whose energy it raises; under its influence the pulsations become more ample and less numerous. (3) As a result of its effect on the vascular tension, diuresis augments, and this fact renders it valuable in affections of the heart with dropsy. (4) It seems to result from my observations that kola, while energizing the cardiac contractions and promoting the contractility of the muscles of organic life, has, nevertheless, a paralyzing influence on the striped muscle when employed in toxic doses. (5) It is a waste restrainer, diminishing the losses of the economy from the combustion of the azotized compounds; probably from a special action on the nervous system. (6) It is a powerful tonic by the principles which it contains, and its employment is indicated in anæmia, in chronic affections of debilitating character, and in convalescence from grave fevers. (7) It favors digestion, probably by augmenting the secretion of gastric juice (eupeptic influence), and by acting on the unstriated muscles of the stomach which it tonifies. Under its influence anorexia disappears, and the digestive functions become more regular. (8) Lastly, it is an anti-diarrhœic medication of great value, and as such has rendered good service in chronic diarrhœa, and in certain cases of sporadic cholera, although its action in these instances may not as yet be clearly explained.

## SPECIAL CORRESPONDENCE.

## INDIA.

(From Our Bombay Correspondent.)

*Paid v. Honorary Hospital Surgeons—Cholera in the Bolan Pass—The Insanitary Condition of Quettah and the advisability of its abandonment as a Military Station.*

June 9th.

In a previous letter I commented on the subject of the employment of honorary assistant surgeons to the Goculdas Tejpal Hospital of Bombay, and stated that the experiment having proved to be a failure, the Government had appointed paid assistants from the grade of assistant-surgeons in the service. It would appear that a memorial from the friends and supporters of the honorary assistants whose services were dispensed with, has since been submitted to Government, who, after referring the matter to the civil Surgeon-General, Mr. Moore, have re-affirmed their former verdict. On the subject of these appointments, I would observe that it would doubtless be still better in every respect were the Government to employ junior members of the covenanted Indian Medical Service, in place of assistant surgeons.

It has been reported in the Indian journals that cholera is prevailing in the Bolan Pass, and rapidly spreading in the directions of communication and traffic. I gather that it was carried there from Rindli in Sind by *human intercourse*, because it was raging there first, and because there has been *human intercourse* between Rindli in Sind and the Bolan Pass, and further because there was no cholera in the latter parts or communication with any other cholera-infected place. A Bombay contemporary writes that "A telegram from Rindli says that cholera at Pirchowki is increasing. According to the official report, three or four cases occur daily, but private information puts the number of cases down at more than double that estimate. The people, says the telegram, are deserting the place, and the bulk of the *coolies* (labourers) are being sent up the Pass. Cholera continues at Rindli in a moderate degree." Later news to hand, as I write, informs me that orders have been issued for the evacuation of Rindli as far as the Commissariat and Transport Departments are concerned, in preparation for the war with Russia. It would appear that among the labourers working on the Quettah Railway, there occurred 75 cases up to the 30th ultimo; of this number, it is said, 32 proved fatal. The sanitary arrangements of these parts, including Quettah (the soil of which is sodden with sewage), are, indeed, in a very unsatisfactory condition, and most decidedly call for remedial measures to be adopted with promptitude and energy. Indeed, if the sanitary arrangements of this district are to be placed on anything approaching a satisfactory footing, the abandonment of Quettah as a military station is an absolute necessity. But I fear very much that, however sound this advice of mine may be, it is not likely to be followed for political, financial, and other reasons, leaving out of consideration the pressure and influence which are not unlikely to be brought to bear against any such proposition by those interested personally in the present state of affairs.

At the present time, the heat in most parts of India is very great, and people are, as a matter of course, anxiously awaiting the advent of what is called the *monsoon*, the setting in of the rains, in about a week or fortnight, according to the geographical situation.

**DIABETIC COMA.**—An Italian observer whose observations are recorded in the Naples *Giorn. Internazionale delle Scienze Mediche*, disbelieves the ordinary theory that acetone in the blood is the cause of diabetic coma. He says that acetone is not particularly poisonous, less so indeed than ethylic alcohol. He finds that aceto-acetic ether does not produce diabetic coma, but that it produces albuminuria and hæmoglobinuria, and is itself voided in the urine unchanged. Crotonic aldehyde is very poisonous, causing in a rabbit a train of symptoms comparable to those described by Kussmaul as characteristic of the coma of diabetes.

## GENERAL CORRESPONDENCE.

## THE FIRST APPENDIX TO THE "MEDICAL DIGEST."

[To the Editor of the Medical Times.]

SIR,—Considering that during the past four years so much has been written on Medical Science, it has been suggested that it would be acceptable to many if the first appendix to the "Medical Digest" were to be issued at the end of 1885, instead of at the close of 1886, as originally proposed. I wish, upon this point, to elicit the opinion of yourself and, through your journal, that of those interested in the subject. A post card addressed to myself, or to the publishers, Messrs. Ledger, Smith, and Co., St. Mary Axe, E.C., expressive of such opinions, and noting, at the same time, any needed corrections in the edition of 1882, will oblige.

I am, Sir, yours, &amp;c.,

RICHARD NEALE, M.D. Lond.

60, Boundary Road, South Hampstead, N.W.

June 26th, 1885.

## MEDICAL CONSULTATIONS.

## NO. XV.—THE TITLE OF DOCTOR.

SCENE.—*A medical book-club dinner at Lancelton-on-Sea.*

## DRAMATIS PERSONÆ.

STAVESACRE.—*A brand new Brussels M.D.*COWHAGE.—*M.R.C.S., L.S.A.*BROOM.—*M.D. Cantab., from a neighbouring town.*

*Several other practitioners, deeply engaged in conversation—mostly of guns, and drugs, and wounds, &c.*

COWHAGE.—(*Glass in hand.*) Well, here's to your new door-plate, *Doctor Stavesacre!* May its lustre never grow dim.

STAVESACRE. Thanks, Cowhage; but you count too much on the diligence of surgery-boys.

BROOM. Eh?

STAVESACRE. O, Cowhage is pleased to be facetious. Between ourselves, he grudges me my promotion a little. But really I could not help it. My friends were always worrying me; patients kept saying, "How strange a successful man like you should be only *Mr. Stavesacre!*" and then young Liverwort over there drops down on us brandishing his Scotch M.D.; so the end of it was, I ran over to Brussels. I did not covet the title myself, don't you know, but really the competition in these watering-places is so brisk, that one cannot afford to ride the high horse. I am sure my old diplomas were as good as half the M.D.'s about, but then the public somehow thinks otherwise. Besides, you must admit it's very convenient to be called "Dr." It is less shabby, don't you know? It enables one to drop the "surgeon and accoucheur" for instance. A plain "Mr." on a door-plate may be a piano-tuner for all the world knows.

BROOM. Nay, to my thinking, the "Dr." is the more shabby. You never shake it off. You are always in uniform. It goes with you everywhere, sticks to you like a burr.

STAVESACRE. It is not an unprofitable burr in a place like this, I can assure you. You go out to dinner, say, as

plain "Mr.," and very likely unless you tell it her, the old dowager you take down never guesses your profession; whereas "Dr." illumines her at once, and if you only play your cards well, ten to one before dessert she has made up her mind to call you in to her next colic.

BROOM. I question whether dowagers so won are worth winning.

COWHAGE. I am sure they are not. They are apt, you know—with all deference to my colleague's social charms—to find dinner-party impressions illusory. A man looks nicer through a champagne glass than through a medicine phial.

BROOM. No doubt. When I go out to enjoy myself I like to leave the stethoscope behind, to get into mufti, as they call it. I detest advertising my business to all and sundry, and having always the look of touting for patients. That's one advantage I get from calling myself "Mr." Besides, the more one respects the title of "doctor" and all it ought to imply, the more one hesitates as to one's worthiness to wear it. Take my case, for instance. I am not a learned man in any sense, but only a simple country practitioner who by good fortune rather than desert, has had conferred on him a title that was meant to imply erudition. As I cannot pretend to be erudite, "Mr." is quite good enough for me.

COWHAGE. Why, for that matter, "Mr." is good enough for any of us. But we are governed by custom and not by philology. You will no more prevent a word widening out by refusing to use it for yourself, than you will prevent a river reaching the sea by damming it out of your garden. Philology gives you just as good a claim to the title of "doctor" as to that of "esquire," by which you expect your correspondents to address you. Historically "Mr." is good enough for anyone, but practically it classes you with the first drunken chimney-sweep, who is not even *master* of himself, let alone anyone else. It is of no use fighting against this diffusion, or, if you like it better, this degradation of titles. Depend on it, we shall live to see every practitioner calling himself "Dr." whatever you or I may do. As for your denying yourself a title to which you have a perfect right, I should be inclined to call it a piece of false humility, implying a contempt for the University that gave it you. Surely if they thought you learned, it does not lie in your mouth to reiterate that you are not.

BROOM. (*Quietly.*) We can only judge for ourselves what best meets our self-respect.

COWHAGE. O, of course!

BROOM. For my part I think so highly of the title of "doctor" that to be worthy of it I feel one should continue to deserve it. A learned man of thirty years ago is not necessarily learned now. What chance have you, or I, or any other busy general practitioner of keeping learned? Why, then, should we scramble for a title that Sydenham and Harvey made honourable by their use of it?

STAVESACRE. Really, I can't soar so high as that, Mr. Broom, though like you I deprecate the vulgarisation of the title. This outcry for its general use is to my mind nothing but a bit of trades-unionism. Those who have it are not jealous of those who have, and so want to reduce us all to one dull level of uniformity.

COWHAGE. Ah, Brussels, Brussels, what a change is here! Why, last year, Stavesacre, you were quite of my way of thinking. It was not trades-unionism then. And in your heart you know it is not now. Why, none of us are jealous of a man who can show that he is really more learned and skilful than we are. What I object to, and

what you also objected to a twelvemonth ago, is a conventional and accidental standard of superiority. Take young Liverwort now. He is not a bit more worthy to be called "Dr." than you or I or half a dozen fellows down the table. But his father chanced to have more money or more "nous" than either of ours, and so sent him to a school where he could get a title. It is monstrously unfair. What an indignity, for instance, to a successful man like you to be sent back to cram-books again, and driven across the water for a degree!

STAVESACRE. Pray forget me for a minute, Cowlage, if you can, and think of the general good. If you bring down the M.D. to the lowest level, you at once deprive every man of more than common talents of his best incentive to use them, as well as of his due reward for them and their good use. What will it profit a man to work hard and spend five or six years on his education, if he gets no advantage from it over one who has sauntered through the common curriculum, and passed College and Hall by the skin of his teeth?

COWHAGE. You can easily make too much of that argument. For instance, it gives a man no greater credit with the public to have taken an honours' degree, and yet men strive for honours. Medals go into a drawer after a short spell of fingering, and yet men compete for medals. You can't make it plain on your doorplate that you have been house-surgeon to this hospital and house-physician to that, and yet every vacancy of the sort finds competitors. If the London Colleges were to give every pass-man the title of "Dr." to-morrow, I doubt whether it would diminish the entries for the London M.B. You see, your argument will not hold water. In fact, I am not at all sure that the system you champion does not do the student more harm than good. The less you encourage men to run after flashy titles, the more I believe will you drive them to the studies and the work which will enlarge their practical efficiency. There is a great deal too much competing for honours amongst students now-a-days. If a man hopes to be able to flaunt an M.D. as a visible token of superiority, he has the less incentive to make good his superiority in more solid and practical ways.

STAVESACRE. Then you come to nearly the same point as Broom. You would divorce erudition from the practice of medicine, while he believes the two divorced already. But whereas he is logical enough to drop the title when erudition lapses, you would give the title to every one, erudite or not.

COWHAGE. Simply as a convention. It is mere pedantry to be dominated by language. To the public "Dr." means not a pundit, but a practitioner. Call yourself "Mr." as much as you will, to your patients you are still the "Doctor." Naturally, they cannot grasp the logic of an arrangement which gives you a handle to your name and me only a tail, which makes you Doctor Stavesacre and me only Cowlage, Doctor.

STAVESACRE. They may not grasp the logic, but they grasp the fact. Don't be too confident in your generalizations about the public. Their eyes are much wider open than we suspect. They know very well that there is some difference between a "Dr." and a "Mr." They know that the one mostly implies a longer training, or, at any rate, a higher degree of medical culture than the other.

COWHAGE. But you will admit that very often it does not. How is the poor public to distinguish between a Brussels and a Brummagem M.D.? People assume that a "Dr." is a better practitioner than a "Mr.," whereas

the fact may be that he is only a better chemist, or botanist, or section cutter.

**BROOM.** My good friends, it seems to me you are wrangling about the shells and letting the oyster drop. Those patients that choose their doctor by his doorplate are infinitesimally few, and, to my thinking, little worth having. The best patients are those who judge the pudding by its taste, and not by the elegance of its recipe; who come to you because of the good report their friends give of you, and not because of any university imprimatur. The public thinks itself, and perhaps wisely, a much better judge of a doctor's practical efficiency than any university can be. Chance patients, who only know of you through the plate-engraver, are always suspicious of you and difficult to deal with, and for my part I would rather they passed me by. No, let us each stand on our own bottom, and despise such fortuitous and rickety elevations as diplomas and degrees. If we work so as to win confidence in our own efficiency, throwing off all pretence to be what we are not, why then we shall earn, not perhaps fame and fortune, but our own and others' respect, which, considering all things, is the best reward a poor practitioner can look for. Trust me, we shall be happier and more genuinely successful if our patients learn to know us as good and kind and true men, than if we had all the titles and diplomas and distinctions that any university can give without those virtues.

**COWHAGE.** 'Tis the voice of success. Nevertheless, here's to your new doorplate, Stavesacre.

**STAVESACRE.** And here's to your lamp, Cowhage. May it never cease to throw its warm light on the pallid wayfarer, and tempt her within your doors.

## MEDICAL NEWS.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE election of Fellows to serve on the Council of the Royal College of Surgeons took place on Thursday last, and caused considerable excitement, not among the aspirants only, but also among the voters at large. Rumours were abroad that a certain well-known surgeon, who has shown himself an uncompromising enemy to all schemes of reform, and who was seeking re-election, would not meet with that support which his undoubted abilities, and strength of character, no less than his professional standing gave him the right to expect, especially as his re-election practically meant succeeding at no long interval to the Presidency of the College. We are pleased to see that these rumours have proved unfounded, and that Mr. Savory, to whom they alluded, has come in at the head of the poll, a long interval separating him from the next on the list. It would have been very regrettable if one who has proved himself so able an administrator, who has served the College so faithfully, and who has taken such a prominent part in medical education during the last 30 years or more, had been passed over on this occasion, and thus deprived not only of his seat on the Council, but of the highest position which the College has at its disposal. For, however desirable it is to introduce changes into college management—and we hold that it is very desirable to do so—such changes must be brought about gradually, and only after mature consideration. Nothing would be so detrimental to the college interests as any sudden alteration in the *modus vivendi*, and a sudden substitution of a new and untried system of working and

governing the institution, such as would probably follow on a too rapid change in the *personnel* of the council. For these reasons, over and above Mr. Savory's personal claims, which even his opponents will admit to be pre-eminent claims, we rejoice at his re-election. Not less pleased are we that Mr. Pemberton, as representing the provincial Fellows, has this time been elected. Besides this claim, he has always taken great interest in the affairs of the Association of Fellows, and he enters the Council practically pledged to support their views and help on the cause of Reform which the Association advocates. Mr. Maenamara, who stands third on the list, is also known as an active advocate of reform; the manner in which he has devoted himself during his year of presidency to the management of the affairs of the Metropolitan Counties' Branch of the British Medical Association gives an earnest of administrative ability, and of his fitness for the duties which will now devolve upon him. We can only hope that these last-named gentlemen will not, like some of their predecessors, forget their pledges, and allow the pleasures of office to blind them to the reforms which as independent Fellows they strove to accomplish. Mr. Gant, Mr. Cowell, and Mr. Mason came next on the list, but with a long interval between them and Mr. Maenamara; Mr. Rouse came last, with a modest 41 votes, including one plumper.

It is not possible to give the exact number of Fellows who voted at the Election; but there was a more than average attendance, especially of provincial Fellows, among whom may be mentioned Messrs. Lund, Baker, Pearce, Simpson, Reginald Harrison, Bartleet, Vincent Bell, Manby, Crosse, Cadge, Bennett, May, Bowering, Brookhouse, Richardson, Crosse, Anderson, and many others. One of the features of the voting was the large number of plumpers recorded for Mr. Savory, showing unmistakably the feeling, of some at least, of his supporters.

The following is the poll-list:—

	Votes.		Plumpers.
1. W. S. Savory	182	including	42
2. Oliver Pemberton	140	„	12
3. Maenamara	127	„	4
4. Gant	73	„	3
5. Cowell	54	„	16
6. Mason	52	„	3
7. Rouse	41	„	1

**UNIVERSITY OF DUBLIN.**—At the Trinity Term Examination for the Degree of Bachelor of Medicine (M.B.), held on Monday, June 8, 1885, and following days, the successful candidates passed in the undermentioned order of merit:—

William S. Dobbin; William Leah; George T. Revington; Arthur E. Switzer; Edgar Hogben; William P. Morgan; Walter C. Poole; Augustus E. Dixon; Alexander S. Patton; Cathcart Garner, Henry I. Hadden, æq.; John D. Wynne; John M. Day; Edward W. A. Gray; Alexander Findlater, Whitley B. Stokes, æq.; William A. Ardagh; Frederick A. G. Davis; Robert L. Donaldson; Thomas Du B. Whaite; John I. Russell; William I. Donaldson; William V. MacMahon; Edwin G. Newell.

At the corresponding examination for the Degree of Bachelor in Surgery (B.Ch.), held on Monday, June 15, 1885, and subsequent days, the successful candidates were arranged in order of merit as follows:—

Alexander Stoney Patton; Edgar Hogben; Arthur E. Switzer; Robert K. Johnston; Walter C. Poole; William P. Morgan; William A. Ardagh; Cathcart Garner; John T. Bouchier-Hayes; Robert L. Donaldson; John M. Day; Edward I. Farmer; George Revington; John I. Russell, John D. Wynne, æq.; Thomas Du B. Whaite; Daniel Conway, Miriam M. Faulkner, æq.; Alexander I. Boyd, Robert I. Montgomery, George Hilliard, æq.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentlemen passed their examination in the Science and

Practice of Medicine, and received certificates to practise, on Thursday, June 25th, 1885:—

Parounag-Jean Baronoff, 46, Guildford Street, Russell Square;  
William Grimshaw Bigger, M.R.C.S., Riverview, Londonderry;  
Procter Selby Hutchinson, M.R.C.S., 15, Cavendish Square, W.

On the same day

Vincent John Rigg, White House, Fillougley, Coventry, passed his examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise.

UNIVERSITY OF EDINBURGH—*Medical Degrees Examinations*.—The following gentlemen have passed the final examinations for graduation in Medicine:—

Arthur Russell Aldridge, Robert Thomas Allen, James Anderson, John A. Ashcroft, John Mackintosh Balfour (with distinction), Robert Beveridge, John Wilson Black, Robert Bone, George Lindsay Bonnar, Louis Jules Henry Bouchet, Edward Kemp Bourne, Reginald Bowman, Herbert Brooks, Harbit Brown, Walter Burns, William Johnstone Cameron, Edward Chamberlayne, Clifton Charleton (with distinction), Reginald Chetham Strode, Richard Davidson, M.A.; David Middleton Greig, Joseph Griffiths, Samuel Hughes, George Francis Johnston, John Charles Lamont (with distinction), Edward Leonard Lees, William Robert M'Kinnell, Charles Henderson Melville, Edwin Morton, Edward Joseph B. du Moulin (with distinction), Ernest Robertson, Herbert Shelmerdine, William Henry George Stephen, Caleb Terrey, William James Thomas, Henry Alexis Thomson, John Warnock, Fitzgerald George Westerra, Henry Worsley.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.—The distribution of prizes to the students will take place at the Medical School, Chandos Street, on Friday, July 3rd, 1885, at half-past three o'clock, Sir Richard Temple, Bart., in the chair.

ROYAL INFIRMARY, EDINBURGH.—The Edinburgh Football Association has handed 60*l.* to the Infirmary from "gate" money received.

THE ST. JOHN AMBULANCE ASSOCIATION.—A centre has been opened in the Canterbury district, New Zealand; 104 persons, the result of two meetings held at Christchurch in May, entered their names as members.

SANITARY INSTITUTE OF GREAT BRITAIN.—The ninth Anniversary Meeting will be held in the Lecture Theatre of the Royal Institution, on Thursday, July 9th, at 3 p.m., Sir John Lubbock, Bart., in the chair. An address will be delivered by Prof. Corfield, on "The Water Supply of Ancient Roman Cities," and the Medals and Certificates awarded to the successful Exhibitors at the Exhibition held at Dublin, in 1884, will be presented.

CHARITABLE BEQUESTS.—The late Mr. James Alexander, of Avening House, Hampstead, bequeaths 1,000*l.* to the Royal Hospital for Incurables, Putney; 500*l.* to the Hospital for Women, Soho Square; 100*l.* each to the National Hospital for the Paralysed and Epileptic, Queen's Square, Bloomsbury; the Surgical Aid Society; and the Samaritan Free Hospital, for Women and Children.

MILK DISTRIBUTION FROM A HOUSE IN WHICH WERE CASES OF SCARLATINA.—A Dutch milkman who had scarlatina in his family, having been warned that it would be illegal for him to continue his sale of milk, sought to evade the law by driving his cows into the country, and entrusting a boy with the distribution of milk from his house. The law was fortunately equal to the occasion, and the ingenious milkman was fined.

THE CAUCASIAN MEDICAL SOCIETY.—This society now comprises 433 members, including 41 honorary members and 31 corresponding members. A subsidy of 2,300 roubles is received yearly from the Government. What would the Chancellor of the Exchequer say if the Clinical Society were to apply for a Government subsidy?

FURTHER USES OF COCAIN.—Dr. Trileski has employed cocaine locally in vomiting and for the pains of labour. The effect in both cases was satisfactory. No effect was produced on the course of the labour.

UNIVERSITY OF KHARKOV.—Prof. N. N. Beketov, having just celebrated his jubilee, the St. Petersburg Academy has in honour of the occasion elected him one of its honorary members.

PROFESSOR JÄGER AND HIS PILL.—Professor Gustavus Jäger, well known in Europe as the apostle of woollen

clothing, lately patented a pill, which contained, as he said, a distillation of the liquid which exists in human hair, and advertised his pill in a learned-looking pamphlet as a sovereign cure for many internal disorders. The Austrian Minister of the Interior was inquisitive enough to have these pills analyzed, and finding them to contain nothing but sugar of milk, has forbidden them to be sold.

ROYAL HOSPITAL FOR SICK CHILDREN, EDINBURGH.—It has been announced that from and after July 1st, no infectious cases will be received into the hospital. On the other hand, no such cases already in the hospital will be dismissed until they are entirely cured. This may take a period of from six weeks to two months. Thereafter, the fever wards, which are the finest in the hospital, will be thoroughly disinfected and prepared for the reception of general cases. This will afford an immense benefit to the city, as from thirty-five to forty beds will be rendered available for such cases; and, as it is understood that adequate and suitable accommodation for children suffering from fever has been provided in the new Fever Hospital, the result as a whole, particularly when it is to lead to the opening of an additional ward in the Infirmary, must be a very great gain to the city.

CHOLERA AT ARANJUEZ.—The Madrid Correspondent of the *Standard*, whose telegrams have contained by far the best intelligence of the cholera epidemic in Spain, telegraphing at midnight on Wednesday says that the latest intelligence from Aranjuez is quite distressing. "The number of cases to-day increased over two hundred and fifty, and the deaths were more than one hundred and twenty-five. All the telegraph clerks are ill of cholera. Numerous cases have occurred in the Regiments of the Line and the Hussars. The Civil Governor of Madrid has been to Aranjuez, where he found four bodies lying unburied near the station, and many others in various parts of the town. He has asked for the services of medical men and Sisters of Charity from the convents, and for help to bury the dead. He says that five thousand out of the nine thousand inhabitants have fled."

VOLUNTEER MEDICAL STAFF CORPS.—It is officially announced that Surgeon-Commandant Cantlie, and Surgeon Hall (adjutant) have been attached to the Training School, Medical Staff Corps.

GLASGOW WESTERN INFIRMARY has benefited to the extent of seven guineas by the temporary addition to the spirit duties. Two publicans have forwarded part of the sums returned to them by the Government. This is an example deserving of being followed. In a letter to the papers acknowledging receipt of the money, the secretary of the Infirmary speaks of it being "in urgent need of funds."

HEALTH OF GLASGOW.—The vital statistics of Glasgow for the fortnight ending 20th June show a death-rate of 23.4 per 1,000, as against 25 the previous fortnight, the diminution being in zymotic diseases. Two cases of small-pox were registered and removed to the hospital. The first was that of a fireman on board a steamer sailing from Calcutta to London. He was unvaccinated and died in a few days. The other case was that of the fireman's bed-fellow who, along with three other persons, lived in the same house and were all unvaccinated. On the discovery of the disease they were all promptly vaccinated, but the operation failed with the sailor's bed-fellow. For the week ending June 27th the death-rate was 24 per 1,000.

CONVERSAZIONE AT THE MIDDLESEX HOSPITAL.—A very successful conversazione, organised by the President and Officers of the Students' Medical Society, was held at the Middlesex Hospital on Thursday, the 25th ultimo. At least two thousand guests collected within the precincts of the hospital, and enjoyed to the full the various artistic and scientific amusements provided. The Board-room and New Out-patient Department were decorated for the reception of the guests and for the exhibition of the various objects of scientific interest. But the special feature of the evening was the illumination of the spacious gardens of the hospital. A musical entertainment was provided in the school, to which Mr. W. H. Cummings and others

lent their assistance; and in the anatomical theatre, which was filled to overflowing, Dr. Benjamin Ward Richardson delivered an interesting address on "Medical Poets." No profession, he said, had produced so many poets as phys'c. Of what might be called Prose Poets, brilliant examples were such men as William Harvey, Arbuthnot, William Hunter, Sir Thomas Watson, John Fernandes Clarke, Mr. Stephens, of Finchley, and others. Among poets of fame who had been more or less connected with the practice of Medicine, he instanced Sir Thomas Browne, the author of the *Religio Medici*, Sir Richard Blackmore, Sir Samuel Garth, Mark Akenside, John Armstrong, Oliver Goldsmith, Erasmus Darwin, Nathaniel Coltar, George Crabbe, David Muir, and John Keats. From each of these authors Dr. Richardson gave extracts, and at the conclusion of the address a hearty vote of thanks was accorded to him.

**ST. MARK'S HOSPITAL.**—In aid of the cost of the recent extension of the hospital, a festival dinner was held on the 24th ultimo, at the Langham Hotel, Mr. George Palmer, M.P., presiding. It appeared from the small endowment and from subscriptions 6,000*l.* was raised, but the annual expenditure was 13,000*l.* The deficit of 7,000*l.* was made up by constant appeals to the generosity of friends and others. The new wing was empty for the want of funds to furnish it, albeit there were numbers of patients ready to be admitted to the hospital. The evening's subscriptions amounted to 2,200*l.*

**ST. PETER'S HOSPITAL, HENRIETTA STREET, COVENT GARDEN.**—The annual report just issued, shows that the in-patients for the year were 232—an increase of 38 on any previous year. In the out-patients' department there were 3,964 new cases, and 29,089 attendances, exhibiting a considerable addition. The income was 2,520*l.* and the outlay 2,300*l.*, leaving a balance of about 200*l.* The debt on the building fund had been reduced to 700*l.*, an incumbrance of which the Committee desire to be freed, to begin a maintenance fund.

**THE HYPODERMIC INJECTION OF OILS.**—At the recent meeting of the American Medical Association (*New York Medical Journal*, May 23rd), Dr. Shoemaker, of Philadelphia, communicated the results of his observations, carried on now for some years, on the effects of the hypodermic injection of oils. Not only have rapid and satisfactorily purgative results been demonstrated, but their utility in debility, dyspepsia, scrofula, tuberculosis, and certain diseases of the skin and nervous system has been amply proved. It is the quickest and best method of introducing oil into the system, especially when more nutrition is required, or when the patient is unable to swallow oil or this does not become easily assimilated in the alimentary canal. Oil is also a valuable menstruum for suspending other drugs for hypodermic use, and it may be used with suitable diet or with other medication by the mouth. For purgative action, one or two drams of castor oil usually suffice; and for nutritive purposes the same quantity of cod-liver or olive oil may be administered two or three times a day. In the event of alimentation depending wholly upon this injection, they should be given about every two hours. A large syringe, provided with a needle of good calibre and with a capacity of from two to eight drams, should be employed; and the injection may be made in any part of the body well provided with subcutaneous cellular tissue, into which the oil should be thoroughly deposited. About the same amount of irritation is caused as by any other hypodermic injection, and sometimes a nodular elevation is produced which usually disappears in from twelve to forty-eight hours. No inflammation or induration follows, provided the proper precautions are taken in using the syringe properly, and the tissues are in their normal condition. Dr. Shoemaker has injected oils in very many cases (occasionally as much as half-an-ounce being used at a time), without any unfavourable effect being caused; and the results obtained demonstrate that certain conditions and diseases can be controlled, relieved, or cured. It is, indeed, an invaluable method, on which full dependence may be placed, especially when the alimentary canal can no longer absorb and assimilate medicines, particularly oil.

**THE CITY OF LONDON DISPENSARY AND SURGICAL APPLIANCE ASSOCIATION.**—It appears, from the Secretary's statement, at a dinner held at the Holborn Restaurant last week, in connection with this institution, that it was not yet, as had been anticipated, self supporting. There had been 21,710 attendances at the Hospital, and 1,532 at patients' houses, since the Dispensary had been opened, and the modest sum of 300*l.* or 400*l.* would free the institution from debt—an amount which, in consideration of the benefits derived from it, we should hope will be forthcoming.

**LONDON SCHOOL OF MEDICINE FOR WOMEN.**—The prizes and certificates won by the pupils of this school were distributed by Professor Gladstone, on Tuesday last. The report for the past year stated that there had been a larger entry of pupils than in any previous year. Fifteen pupils had joined last October, and two more in the summer. Five had passed the first professional examination of the King and Queen's College of Physicians, Ireland, and four the final examination. Two had passed the M.B. examination of the University of London, and seven students who had taken their diplomas have been studying in the large hospitals in Vienna. The experiment that had been tried of providing female medical officers for the female clerks in Government offices had worked well in Liverpool, London, and Manchester. The financial statement showed that although there was still money in hand from previous balances more subscriptions were required.

**BOROUGH OF HUDDERSFIELD.**—Dr. Spottiswoode Cameron's report for the year 1884 has just reached us, from which we gather that the public health has been unusually good during the year, the general death-rate having been 19.5 per 1,000, showing a marked diminution on any previous year. Whooping cough proved exceedingly fatal during the year, no less than 61 deaths being attributed to this cause, giving a death-rate during the first half of the year of 1.19, whilst 1.77 represents the death-rate of all the zymotic diseases. The death-rate from autumnal diarrhoea was relatively high, and this Dr. Cameron attributes in great measure to the high temperature and the scanty rainfall. He believes, however, that the deaths under this head would have been much more numerous had it not been for the persistent and regular flushing of the drains, which had been systematically carried on. The Notification of Infectious Diseases clause has been found to work smoothly, and by this means information was received of 239 cases.

**DR. WARLOMONT.**—In the *Presse Médicale Belge* of June 21, Dr. Warlomont, the distinguished Brussels Ophthalmologist, who is also so well known in this country by the active part he has taken in the vaccination question, details the circumstance of his arbitrary dismissal from the post of Director of the Ophthalmological Institute. Other causes than the one specified must surely be in the background, but the only one mentioned is the circumstance of his health having necessitated during the last year or two a visit abroad for a few months, for which he obtained the necessary authorisation from the authorities. During his 30 years of service, he has never before been a week at a time away from his post. Without calling upon him for any defence or explanation, the managers of the Institute superseded him by abolishing his office. On his seeking for the pension that was due to him, he was informed that this could only be gained by a person who had attained 65 years of age, and had served the Institute for 30 years. His service of 32 years fulfilled one of these conditions, but he had yet 282 more days to live to attain the necessary age. The abrupt and hasty way in which the dismissal was brought about had all the appearance of an intentional deprivation of this acknowledgment of services rendered.

**CHOLERA PREVENTION ON THE CONTINENT.**—A fortnight ago the Austro-Hungarian Government requested the Governments of Germany, Switzerland, Italy, and France to supply information as to the measures taken in their respective countries to prevent the spread of the choleraic infection. Answers were returned immediately, and a circular has now been sent to all the municipal authorities in Austria and Hungary, calling their attention to some of

the precautions recommended. The sanitary condition of both Vienna and Pesth is at present excellent. Disinfectants are largely used in the watering of the streets, and especially of markets, hospital wards, cabstands, and railway stations. Precautions continue to be taken in Russia against an outbreak of cholera. All officers and soldiers have received printed instructions on the subject, and cholera sections have been prepared in the military lazarettos of St. Petersburg, with beds for 60 officers and 775 privates. In the St. Petersburg military district, cholera stations have been established for accommodating 3,067 privates and 252 officers.

**A CIRCULAR HOSPITAL.**—Compelled by exigencies of space to discard the commonly accepted pavilion plan for a new infirmary which they were compelled to erect at New End, close to the heath, the Hampstead Board of Guardians have just finished a building on the new circular ward system, and the structure was opened for the first time on the 25th ult. to the inspection of the public. The Hampstead Board is the first parochial authority in Great Britain which has adopted this plan, the only other example in working operation being a small private one at Greenwich. It has, however, been used on a very large scale by the municipality of Antwerp, although it is believed that the building at Hampstead will compare very favourably, especially in the important matter of ventilation, with the foreign institution. The circle is fifty feet in diameter, and contains seventy-two beds on three floors—twenty-four on each—arranged around the walls. In the centre of the building a ventilation shaft is carried from the foundation to the roof, and a balcony has been placed round each ward.

**THE FEVER HOSPITAL ARRANGEMENTS AT EDINBURGH.**—It is understood that, pending permanent arrangement, the Town Council are to endeavour to secure the services of the whole of the present medical and nursing staff of the Fever Hospital, the management of which they take over at once. It is not anticipated that there will be any difficulty in coming to a temporary arrangement with the hospital staff until the Town Council have finally determined how the management of the Fever Hospital is to be conducted. As stated before, the feeling in the Council is that the management should be under the direct control of the Corporation. As a consequence of the Infirmary managers being relieved of the expenses of the Fever Hospital, they intend, it is understood, to equip and open immediately another ward in the Infirmary; so that what the public lose in one way they will gain in another.

**ST. VINCENT'S HOSPITAL, DUBLIN.**—Surgeon-Major Tobin, F.R.C.S.I., of the Army Medical Department, an old student and resident assistant at the hospital, has been appointed to the additional assistant surgeoncy recently created. Mr. Tobin was appointed in 1879 Assistant Professor of Military Surgery to the Army Medical School, and put in charge of the Surgical Division of the Royal Victoria Hospital, Netley. Last year he spent several months in the schools and hospitals of Paris, Vienna and Berlin, and subsequently he went out to the Soudan as "field-surgeon" to General Graham's expeditionary force. His period of office at Netley having expired, he retires to civil life on the twenty years' service pension. He will prove a great addition to the teaching power of the St. Vincent's Hospital staff.

**MEN AS NURSES.**—An association has been formed for the purpose of training men as nurses. The promoters believe that many men would rather be attended in illness by their own sex than by women. Bachelors and widowers residing in chambers and some men in families would, it is thought, employ properly trained men. In the army and navy men have been found to possess all the qualities for making good nurses, and many military and naval surgeons have testified to the superiority of men as nurses for soldiers and sailors. The new association proposes to train suitable men for nurses in civil life. The idea was originated by Miss Jane Hamilton, a near relative of the late Dr. Billing, F.R.S., and the committee is submitting a plan to one or more of the large hospitals with a view of establishing an efficient training school for men.

**MUNICIPAL AND SANITARY ENGINEERS ASSOCIATION.**—The annual meeting was held at Westminster, on the 25th ultimo. The report was satisfactory both in respect to the financial position of the Association, and the increase of its membership. The President-elect, Mr. R. Vawser, of Manchester, read an address in which he dwelt on the failure of sewage purification schemes being traceable to projects for utilisation of the products, instead of the primary proper duty of the purification of the effluent water. Two papers were read and discussed: one by Mr. Crimp on the recent electric lighting trials at Wimbledon; the other on sanitary gas-making, by Professor Wanklyn. The proceedings of the yearly meeting were brought to a conclusion on the Friday following, when papers were read on the "Ventilation of Sewers," "Highgate Hill Steep Grade Tramway," and on "Dangerous Structures." About eighty of the members were subsequently entertained at luncheon by the Lord Mayor, at the Mansion House, who in proposing the toast of his guests spoke of them as the practical executive of the municipal and sanitary authorities of the kingdom. After the luncheon, several visits were paid to places of engineering interest in the city.

**HYDROCHINON, THE NEW ANTIPYRETIC.**—In an article in the *New York Medical Record* (May 30), Dr. Kinnicut, as the results of the trials of this substance at the St. Luke's Hospital, New York, arrives at the following conclusions:—1. That in hydrochinon (known to chemists as dihydroxybenzole) we possess a new and most efficient antipyretic. 2. Its use is apparently unattended with any injurious effects. 3. The antipyretic effect of single doses is comparatively temporary, resembling in this respect that of kairin, thallin, and antipyrin; but the maintenance of moderate temperatures in hyperpyretic conditions can be safely obtained by repeated doses. 4. While apparently without effect in arresting a specific disease process, its employment is conservative, and productive of a marked amelioration of many of the symptoms incident to high temperatures. 5. With our as yet limited experience of the drug, it should be given prudently, and its effects carefully observed. (From 15 to 20 grains were the standard single doses employed.)

**IMAGINARY UTERINE DISEASE.**—Prof. Goodell observes that the crying medical error of the day is the mistaking nerve disease for womb disease. From this wide-spread delusion it has come to pass that no organ in the human body is so over-treated, and consequently so maltreated, as the uterus.—*New York Medical Record*.

**ORTHOGRAPHICAL ERRORS.**—The *Boston Medical Journal*, while indicating an error by which Dr. Milner Fothergill's name is transformed into "Milner Sathergell" as an example of the "strange masquerading which English names undergo in French and German journals," amusingly commits a far more serious mistake by quoting the sinning periodical as the *Lyons Médicale* instead of the *Lyon Médical*. In point of fact, all medical journalists quote names much more correctly than they used to do, and we should make some considerable allowance for the faulty copying of our uncouth Anglo-Saxon denominations.

**COSMETICS.**—M. P. Vigier observes in the *Gazette Hebdomadaire* that the mineral acids which constitute the base of some well-known cosmetics are objectionable, and that tartaric acid in the proportion of 1 to 20 of the glycerole of starch is very preferable in acne and redness of the face. This, however, is a medicinal application only to be used on occasions; but he proposes a cosmetic that may be continued for an indefinite period, and must be regarded rather as a preservative than a remedy. It is composed of boric acid, 1 part to 100 parts of rose-water with 5 drops of English honey water. The face is to be moistened morning and evening with this lotion, which is but another application of that substance, boric acid, that is so useful in therapeutics.

**THE COST OF CHOLERA IN FRANCE LAST YEAR.**—The French administration has just published (*Revue de Thérapeutique*, June 15th) an account of the expenses that have been incurred for the arrest of the progress of cholera

during its short visit of last year. Together, these amount to 1,050,000 francs, distributed in sums varying from 280,000 francs in Algeria to 100 francs at Arrière. There are also charges of 90,000 francs put down for medical inspection at railway stations and at the frontier; 7,000 francs for mission expenses; 10,000 francs for quarantine on the coasts; 30,000 francs for deterioration of material lent by the war office; 10,000 francs for medals; and 100,000 francs for miscellaneous expenses.

**ACTION OF DYNAMITE ON THE NERVOUS SYSTEM.**—Attention has lately been called to an injurious effect produced by handling dynamite (independently of the danger from its explosion), as manifested by headache, tinnitus, and palpitation. One recent writer believes it to be due to small amounts of nitro-glycerine swallowed, stating that a man, who formerly had the habit of tasting his fingers to ascertain if the dynamite was washed off, recovered from these symptoms on discontinuing the habit and wearing gloves; others claim that the "dynamite headache" is due to inhalation, and is similar to that caused by nitrite of amyl, and that it is inseparable from the use of dynamite, unless immunity be obtained by idiosyncrasy or prolonged habit.—*Boston Medical Journal*, June 1.

**GRAFTING MUSCLE FROM A DOG.**—The *Louisville Medical News*, of May 16, gives an account of the first instance of muscle-grafting that has been executed in the United States. A laundress, 23 years of age, had her arm crushed in a mangle, and although no bones were broken, there was deep laceration just below the elbow joint, the muscles also being badly torn at the elbow, and much tissue being lost. Several weeks were required for the healing, and she was able only to move the arm with great difficulty, and had practically lost the use of her fingers. She entered Bellevue Hospital, New York, and it was determined to employ muscle-grafting, the execution of which occupied half-an-hour. Alongside of the operating-table a dog was laid upon another table, and an anæsthetic having been administered to both subjects, an incision was made into the arm at the seat of injury, a raw fresh surface being secured by cutting off the ends of the contracted and paralysed muscles. By a rapid stroke of the scalpel, the thigh of the dog was laid open, and muscular substance 4 inches in length and 2 in width, was instantly transplanted to the opened arm. The wound was sewn up and bandaged, neither patient nor dog having suffered any pain from the operations that had been performed. The experiment was quite successful, for in little more than three weeks the young woman was able to move her arm with little difficulty. It is a trifle less limp than before the accident. She has also regained the use of her fingers.

**PAPER-BOTTLES** are now being made on a large scale in Austria and Germany. The paper must be well-sized, and is composed of 10 parts of rags, 40 of straw, and 50 of brown wood-pulp. It is impregnated or coated on either side with 60 parts of defibrinated blood, 35 of lime powder, and 5 of sulphide of alumina. After drying, 10 or 12 rolled leaves are coated again, placed over each other and then put into heated moulds. The albumen of the blood forms a combination, on pressure, with the lime, which is perfectly impermeable to spirituous liquids. The bottles are made in two pieces which are joined afterwards.

**PROFESSOR TYNDALL AND SCIENCE IN AMERICA.**—Professor Tyndall has directed that the receipts from his lectures in the United States in 1872, amounting to some 6,000*l.*, shall be equally divided between the Universities of Columbia, Harvard and Pennsylvania, with the view of founding science fellowships for men who wish to devote their lives to original research.

#### APPOINTMENTS.

**AWDRY, WALTER, R.**, M.B. Dub., M.R.C.S. Eng.—Medical Officer to the Berkeley District, Thornbury Union, *vice* Mr. J. T. Bridgman, deceased.  
**BAILEY, W. H.**, M.R.C.S., L.S.A.—House Surgeon and Secretary to the Newark Hospital and Dispensary.  
**BAMBER, HARRY, M.B.** and C.M. Glasg.—Assistant Medical Superintendent and Dispenser to the Infirmary, Fulham Union, *vice* Mr. F. J. Ingoldby, resigned.

**BARTON, GEORGE HENRY, M.R.C.S. Eng.**, L.R.C.P. Edin.—Medical Officer to the Market Rasen District, Caistor Union, *vice* Mr. H. Turnour, deceased.  
**BROWN, JOHN TAYLOR, M.B.** and C.M. Glasg.—Medical Officer to the Trelleck District, Monmouth Union, *vice* Mr. G. Mayon.  
**DILLON, J. T.**, M.D.—Medical Officer to the Listowel Dispensary of the Union, *vice* U. Fitzmaurice, M.D., deceased.  
**ELLIOTT, W.**, L.D.S. Edin. and Dub., F.C.S.—Professor of Dental Mechanics in Queen's College, Birmingham.  
**HOWARD, HERBERT, L.R.C.P. Lond.**, M.R.C.S. Eng.—Medical Officer to the First District, Guiltecross Union, *vice* Mr. Horace F. Howard, deceased.  
**LACEY, THOMAS S.**, L.R.C.P. Edin., L.R.C.S. Ire.—Medical Officer to the Second District, Oldham Union, *vice* Mr. W. F. Chadwick, deceased.  
**LEWIS, JAMES KING, M.R.C.S. Eng.**, L.S.A. Lond.—Medical Officer to the Thorverton District, Tiverton Union, *vice* Mr. Henry Robinson, resigned.  
**LONGMAN, GEORGE P.**, L.R.C.P. Edin., M.R.C.S. Eng.—Medical Officer to the Donhead District, Tisbury Union, *vice* Mr. W. H. Reed, resigned.  
**MEDCALF, ERNEST S.**, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A.—Medical Officer to the First District, Steyning Union, *vice* Mr. J. Dixon, deceased.  
**MCMURRAY, JOHN, M.D.**, M.Ch., L.M. Ire.—Assistant Medical Officer to the Brownlow Hill Workhouse of the Parish of Liverpool, *vice* Mr. J. G. Barns, resigned.  
**MORRIS, C. A.**, M.A., M.B., B.C. Cantab., M.R.C.S.—Resident Medical Officer to the Liverpool Royal Infirmary.  
**O'CALLAGHAN, R. T. A.**, L.R.C.S.—Surgeon to the County Infirmary, Carlow.  
**ROYDS, W. A. S.**, L.R.C.P., M.R.C.S., L.S.A.—Surgeon to the Royal Berkshire Hospital.  
**TOBIN, R. F.**, F.R.C.S.I.—Assistant Surgeon to St. Vincent's Hospital, Dublin.  
**VAUDREY, E.**, M.B.—Resident Assistant House Surgeon to the Derbyshire General Infirmary.  
**WOLFHAGEN, J. E.**, M.B.—Assistant House Surgeon to the Royal Albert Hospital, Devonport.

#### VACANCIES.

**BANBURY UNION.**—Medical Officer for the Middleton Cheney District, in succession to Mr. T. C. Lawson, resigned. Area, 6,428 acres. Population, 2,241. Salary, £53 per annum.  
**CHESEA HOSPITAL FOR WOMEN, FULHAM ROAD, S.W.**—Resident Medical Officer. Salary £60 per year, with board and residence. Candidates must be duly registered. Further particulars may be obtained of the Secretary, to whom applications must be sent by July 6th.  
**DEWSBURY UNION.**—Medical Officer for the Dewsbury District, in succession to Mr. W. F. Watts, resigned. Area, 1,335 acres. Population, 21,617. Salary, £55 per annum.  
**EAST LONDON HOSPITAL FOR CHILDREN, AND DISPENSARY FOR WOMEN, SHADWELL, E.**—Assistant Physician. (*For particulars see Advertisement.*)  
**HANTS COUNTY ASYLUM.**—Junior Assistant Medical Officer. Salary, £100 per annum, with furnished apartments, board, washing, and attendance. Candidates must be doubly qualified and registered, unmarried, and not above 27 years of age. Applications with copies of testimonials to be addressed to the Committee of Visitors, Knowle, Fareham, not later than July 8th.  
**MADELEY UNION.**—Medical Officer for the Workhouse, in succession to Mr. J. Procter, resigned. Salary, £26 per annum.  
**MANCHESTER ROYAL INFIRMARY, DISPENSARY AND LUNATIC HOSPITAL, ETC.**—Honorary Obstetric Physician. (*For particulars see Advertisement.*)  
**NORTHALLERTON UNION.**—Medical Officer for the Osmotherley District, in succession to Mr. Cumine, resigned. Area, 11,327 acres. Population, 1,874. Salary, £35 per annum.  
**ROYAL CORNWALL INFIRMARY.**—Honorary Physician. Candidates must be medical graduates of the University of Oxford, Cambridge, Dublin, Edinburgh, Glasgow, or London, or Members or Fellows of the Royal College of Physicians of London, and must not be connected in partnership with any person who practises Surgery, Pharmacy, or Midwifery. Diplomas or other qualifications and testimonials, to be sent to the Secretary, on or before July 8th.  
**SALOP AND MONTGOMERY COUNTIES LUNATIC ASYLUM, SHREWSBURY.**—Junior Assistant Medical Officer. Salary, £100 per annum and £8 in lieu of beer, with board, lodging, and washing. Candidates must be registered, and not over 27 years of age. Applications with not more than six recent testimonials, to be addressed to the Medical Superintendent, on or before July 8th.  
**WESTERN GENERAL DISPENSARY, MARYLEBONE ROAD.**—Honorary Surgeon. Candidates must be Fellows of the Royal College of Surgeons of England. Full particulars as to duties, etc., can be obtained of the Secretary. Candidates must forward their applications, with testimonials, on or before July 10th, and attend at the Dispensary on Monday evening, July 13th, at seven o'clock. —Also, Junior House Surgeon. (*For particulars see Advertisement.*)

#### DEATHS.

**HOWARD, Edward**, Deputy Inspector-General of Hospitals, A.M.D. at Mindenwolfe, Bedford, on June 28th, aged 69.  
**HOWE, JOHN ERNEST, B.A.**, M.B., M.R.C.S., at Knowle Vicarage, Warwickshire, on June 28th, aged 27.  
**PRAER, HORATIO, M.D.**, of 7, Edwards Square, Kensington, at 28, Devonshire Street, on June 20th, in his 80th year.  
**SAMPSON, G. E. GREEN, M.R.C.S.**, at St. Matthews, Ipswich, on June 27th, aged 81.

## NOTES, QUERIES, AND REPLIES.

## THE CAUSATION OF LABOUR.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—On looking down the Index of the *Medical Times* of to-day's date, I see no mention of my letter to you "On the Causation of Labour," published in your issue of January 10th last. It is a theory of a physiological act not previously explained, and which I hope you will not permit to be lost sight of.

I am, Sir yours &amp;c.

WM. ELLIOTT PORTER.

Lindfield, Sussex, June 27th, 1885.

## COMMUNICATIONS RECEIVED—

Prof. GAIRDNER, F.R.S., Glasgow; Dr. STURGES, London; Dr. BRISTOWE, F.R.S., London; OUR PARIS CORRESPONDENT; Dr. MAXWELL, Woolwich; Dr. SHELLY, Hertford; Mr. E. NETTLESHIP, London; Mr. W. E. PORTER, Lindfield; Dr. JAMES OLIVER, London; Mr. E. S. GUNN, London; Dr. R. NEALE, London; THE SECRETARY OF THE SOCIETY OF APOTHECARIES, London; Mr. CLARK BELL, New York; Messrs. BRAND & Co., London; Dr. CLIFFORD BEALE, London; THE REGISTRAR-GENERAL FOR ENGLAND, London; THE SECRETARY OF THE ROYAL INSTITUTION, London; Dr. GUILLEMARD, Cambridge; Dr. W. WILSON, Florence; Dr. PROSSER JAMES, London; THE SECRETARY OF THE SANITARY INSTITUTE OF GREAT BRITAIN, London; Mr. TRENDLELL, London; Mr. H. F. PORTER, Cambridge; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; THE SECRETARY OF THE CHARING CROSS HOSPITAL SCHOOL, London; THE EDITOR OF THE LIVERPOOL JOURNAL OF COMMERCE; MESSRS. STREET, BROS., London; THE SECRETARY OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION, London; Mr. D. W. THOMPSON, Dundee; THE SECRETARY OF THE MEDICAL BOARD, University of Cambridge.

## BOOKS RECEIVED—

Our Recent Debts to Vivisection, by W. W. Keen, A.M., M.D.—Proceedings of the Society for the Study and Cure of Inebriety—Endometritis Fungosa, by J. B. Hunter, M.D.—Announcement of Trinity Medical School, Toronto—The Encyclopædic Dictionary, Part 18—Foreign Bodies left in the Abdomen after Laparotomy, by H. P. C. Wilson, A.M., M.D.—Case of Brachial Monoplegia, due to Lesion of the Internal Capsule, by A. H. Bennett, M.D., and C. M. Campbell, M.D.—Pathological Mycology, by G. Sims Woodhead, M.D., etc., and Arthur W. Hare, M.B., C.M.—Suicide, by W. Wynn Westcott, M.B. Lond.—Contributions to the Surgical Treatment of Tumours of the Abdomen, by Thomas Keith, M.D., LL.D. Edin.—Handbook for the Instruction of Attendants on the Insane—Lectures on Diseases of Children, by Robert J. Lee, M.A., M.D.

## PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Révue Médicale—Gazette Hebdomadaire—Nature—Boston Medical and Surgical Journal—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medizin—Philadelphia Medical News—Louisville Medical News—Weekblad—The Philadelphia Medical Times—Le Progrès Médical—Berliner Klinische Wochenschrift—Centralblatt für die Medicinischen Wissenschaften—Deutsche Medicinische Wochenschrift—The New York Medical Journal—The Hospital Gazette—Revista de Medicina—The Therapeutic Gazette—The Polyclinic—The British Gynecological Journal—The Monthly Homœopathic Review—The Journal of Mental Science—The Edinburgh Medical Journal—The Medical Temperance Journal—The Veterinarian—Archives Generales de Medecin.

## HOSPITAL OPERATING DAYS.

Monday.—Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopedic, 2 p.m.

Tuesday.—Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.

Wednesday.—Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopedic, Great Portland Street, 10 a.m.

Thursday.—St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.; Chelsea Hospital for Women, 2 p.m.

Friday.—St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday.—King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

## ON NATURAL GROUPS OF SKIN DISEASES.

A STUDENT'S LECTURE

By JONATHAN HUTCHINSON, F.R.S.,

Emeritus Professor of Surgery in the London Hospital College.

GENTLEMEN,—To continue our subject, the common Chilblain will give us another good type-form from which to construct a family group. Let us define a chilblain to be an inflammation produced by direct exposure to alterations of temperature, commonly, but not exclusively to cold. If the cold has been extreme, and gangrene is produced, we call it frost-bite, but it would be very difficult to draw an abrupt line of demarcation between frost-bite and chilblain. Unquestionably, personal peculiarities as regards force of circulation very materially influence the individual liability to frost-bite. There are many frost-bites which do not end in gangrene, but which produce a chronic condition of inflammation scarcely distinguishable from chilblains. Many forms of chilblain, however, by no means require exposure to severe cold for their production. Those who are very liable to them get chilblains at all times of the year, if they are in the least exposed to wind or wet. In a few instances the cause is not cold at all, but rather heat, and we may have what we may appro-

priately call the sun-blain and fire-blain. In order that chilblains should occur it is necessary that the solid tissues, and not alone the vascular ones, should possess a sort of inborn susceptibility which renders them liable to inflame when exposed to changes of temperature. Note that it is not mere feebleness of circulation; chilblains are by no means constantly associated with cold extremities. Those who habitually have red, cold hands and feet, and in whom the capillary circulation is at its weakest, are precisely those who never get chilblains. Their tissues do not resent the influence of cold, and do not inflame when it is removed. On the contrary, those who suffer much from chilblains have not infrequently a rather active circulation, the susceptibility being in the tissues themselves, or possibly in the vaso-motor system. We will class everything which can be proved to be in direct relation with slight changes as regards cold and heat, as of the nature of chilblain, and you must not imagine that they always present the same features. The commonest form is perhaps an ill-defined swelling of the skin, red sometimes, livid at others, which itches and burns, and which is very liable to crack and become sore on the surface. In other cases the part is permanently livid; there is but little burning and no tendency to crack. In some the inflammation is very superficial, a mere erythema; in others it is deep, and leaving the skin, it may affect the subcutaneous cellular tissues, or even the periosteum. Sometimes a whole finger is involved in swelling, not unfrequently chil-

blains implicate the nails, and sometimes, but in rare instances, they affect the joints and ligaments. I keep to my definition: a chilblain is anything that results from exposure to slight alternations of heat and cold. We must not restrict it to any particular tissue. For obvious reasons chilblains occur chiefly in certain definite positions—to wit, on the extreme periphery of the body. The fingers, the toes, the heels, the nose, the ears, and the lips, are the parts most liable to suffer, and about in the order in which I have mentioned them. The part affected will of course vary with the kind of exposure to which the individual has been subjected. Inborn peculiarity of tissue is obviously the main predisposing cause. They are common in certain families and perhaps in certain races. Youthfulness of tissue is also almost essential; as we advance in years our tissues become, as a rule, less and less irritable under exciting causes of the kind mentioned. The liability to chilblains sometimes constitutes an important complication of other diseases, more especially of hereditary gout, and some of the forms of what is known as Raynaud's symmetrical gangrene of the extremities and the condition which I have myself described as "Last Joint Arthritis" are closely connected with them. The relationship of chilblains to lupus erythematosus is exceedingly close—so close, indeed, that it is sometimes impossible to distinguish them from each other.

Close to the chilblain family, but not in it, we may place a small and unimportant group of affections in which derangements of nutrition of the skin occur in connection simply with senility. I do not refer to such affections as senile gangrene, which is, of course, not a skin disease, but to certain forms of palmar psoriasis, chronic eczema of the hands and disease of the nails, which, so far as I can tell, seem to be associated rather with senile degradation of tissue than with anything else. In this category ought to be placed senile blanching of the hair and loss of hair, unless, indeed, we regard them rather as physiological processes than as disease.

It is a very great mistake to count the peeling and cracking of the palms which has received the unsuitable name of psoriasis palmaris as being always of a specific nature. In a large proportion of cases I feel sure that it is chiefly senile, the result of degeneration in the nervous and vascular systems, with the addition perhaps of some slight local cause of the nature of pressure, such, for instance, as the use of tools. The skin has got old, and ceases to wear well and to repair itself easily. The palms of the hands are far less frequently affected in this way than the soles of the feet, and for an obvious reason: they are far less used. Possibly even in a majority of elderly persons who are obliged to stand much we should find evidences of impaired nutrition in the integument of the soles. If there be any tendency to disease of the spinal cord, any defective sensation or slight form of ataxy, the risk of these senile changes is very greatly increased. These affections induce, indeed, a sort of premature local senility. The chief importance of recognising this group of maladies is negative, that we may avoid attributing them to causes which have really nothing to do with them.

Erythema multiforme and Erythema nodosum may suitably form the central figures of an ill-defined and, as yet, ill-understood group. They are types of forms of skin disease, in which the phenomena are always systematically placed on the halves of the body, or rather the two sets of limbs, and are, therefore, obviously due to some general influence, probably, but not quite certainly, a blood cause. Something very like them may occasionally be produced by the iodides and bromides, and it is possible that they are sometimes of drug and diet origin. This, however, is by no means certain, and more frequently they appear to depend upon

causes of the same nature as those which produce acute rheumatism. These symmetrically placed forms of papular or nodose erythema are always transitory and not usually recurrent. They disappear without regard to treatment, and possibly without any influence from it. As their name implies, they may vary very considerably in the precise type of outward manifestation, but they are almost always restricted as regards location, affecting the limbs only.

The conditions to which the term Purpura is applied, and of which scattered extravasation of blood, or thrombosis of blood vessels, are the distinguishing feature, are so various as regards their causes, that it is perhaps scarcely right to group them in one family. Purpura is usually a mere symptom, and a symptom which by no means always acknowledges causes of the same class. Often it is the result of the use of some drug or article of food, as, for instance, the over-consumption of table salt or the administration of iodides or bromides. In other cases it follows on impediment to the circulation. In a remaining group, however, which comprises the more typical examples of what is known as purpura hæmorrhagica, we are as yet quite unable to assign its cause, and cannot venture to place it in alliance with any other malady. It may be that in these there lurks an unsuspected idiosyncrasy as regards some drug or article of diet. It is possible that sometimes the very thing which has caused it is prescribed as a means of treatment. Further investigation may very likely show that a purpura group is by no means necessary to a complete classification, and that the cases in which this symptom is present may be properly relegated to their appropriate families, in each of which something is known as regards the cause. It would be premature, however, to attempt to do that now.

We may take Erysipelas as the type-form for another family. We know quite well how to describe this malady. It is an erythematous inflammation of the skin, attended with œdema, with a red edge that rapidly spreads and a surface which usually vesicates. Professional opinion, however, is not quite so well agreed as to its definition. Many would say that it is a specific fever and always depends upon a specific virus which has been introduced into the blood. For my own part, I am concerned to deny this with emphasis, and to say that it is a non-specific inflammation of the skin, which such influences as cold, wind, wounds, &c., can originate, and which itself causes the fever which accompanies it. It is only by accepting this definition that we shall succeed in constructing the group which I now desire to sketch.

The essence of the erysipelatous process is probably inflammation of the lymphatic spaces, for from their implication comes the œdema and the rapid spreading which are so characteristic. We have two chief forms in which we encounter erysipelas: one the terror of the surgeon, the traumatic variety, which occurs in connection with wounds; and the other the medical form, which affects almost exclusively the face and head, and which is often in recognised association with exposure to cold or heat. The surgical form gives no immunity as regards second attacks, and the medical one is well recognised as involving a very decided liability to recurrence. Remembering these facts, we are, I think, in a position to recognise the true position of certain other maladies closely related to erysipelas. There is what is called the vesicating erythema of the cheeks: a form of disease which occurs perhaps twice a year to those who are liable to it, but which differs from common erythema, medical erysipelas, in showing no tendency to spread at the edge, and in being of very brief duration. Of this disease the first attack is almost invariably the most severe and the most like common erysipelas. This remark applies also to

another form in which there are no vesications, but in which recurring attacks of œdema occur, sometimes so frequently that the part never wholly recovers itself. This chiefly affects the eyelids, cheeks, and lips, and may easily lead to permanent deformity, a sort of elephantoid hypertrophy of the features. In close connection with this we must mention true elephantiasis, the Barbadoes Boucnemia or the elephantiasis Arabum. This affection, if we would rightly place it, is, I believe, simply hypertrophy consequent on manifold attacks of erysipelatous œdema. Its beginning is usually some slight injury leading to acute œdema, and occurring in a dependent part which cannot easily recover itself. The position rendering the œdema permanent, repeated slight attacks of erysipelas in the damaged part leave each behind it its special increment. Thus, by slow degrees, a mixed condition of solid œdema and true hypertrophy of the cutaneous and subcutaneous elements results, and in a few cases grotesque deformities ensue. There is no mystery about the disease, its stages are in their explanation as simple as possible. The varieties which it assumes are in connection with the part affected, the habits, nationality, the state of the health of the patient and the climate in which he lives.

We may constitute another group of those maladies which are definitely in association with the Nervous system. It is possible indeed that they are, from beginning to end, diseases of the nervous system—that is, of those parts of the nervous systems which are located in the skin. It is perhaps not correct to speak of such a disease as herpes zoster as being induced by the nerves, for we should possibly be nearer the truth if we were to name it as a form of cutaneous neuritis, and to recognise that its result is the disorganisation of the end-organs and ultimate nerve structures. In this group of neurotic skin affections we place definitely two, but it may easily be true that there are several others. The two which I will name, herpes and morphœa, are of extreme interest, but I must not venture now to enter upon any detail, as they are both very large subjects. I must be content to say respecting them both, that in their most typical forms they are distributed in the most definite manner according to the known anatomical arrangement of the cutaneous nerves. The disturbances in the skin which are induced are always limited to the part first affected. This statement is equivalent to saying that their inflammatory products are not infective. This is a most remarkable feature, and with it is correlated another which probably depends upon it—that, namely, of the invariable spontaneous subsidence of the process. This spontaneous cure takes place very quickly in herpes, but very slowly though not less surely in morphœa. The forms of skin inflammation induced in these two diseases are very different. In herpes it is vesicular, or now and then gangrenous; in morphœa it is first erythematous, and then a sort of sclerosis. In herpes it is clearly the sensory filaments which are involved, as denoted by the pain which attends the process and the numbness which follows it; whilst in morphœa the absence of disturbances in sensation, and the great amount of derangement of nutrition which results, warrant a plausible conjecture that it is the vaso-motor filaments which are implicated. In neither disease, so far as we know, has the general health of the patient anything to do with the malady. Neither of them ever happen to infants. Herpes zoster must be definitely placed amongst the drug and diet diseases, as well as in the group which we now constitute, for there is no doubt that it is often produced in severe typical forms by the administration of arsenic.

I have spoken hitherto of herpes *zoster* exclusively, but there is another form of herpes, the symptomatic herpes labialis, in the main a herpes, which differs a

good deal from zoster, more especially in the fact it is liable to occur over and over again in the same individual. It is associated chiefly with vaso-motor disturbance causing rigor or horripilatio, but in some instances would appear to be a wholly local malady. Curiously enough, arsenic which will cause herpes zoster very seldom causes symptomatic herpes, and usually prevents its recurrence.

Although in the groups which we have named we should be able, I think, to comprise almost the whole of what we know as skin diseases—whether mere symptoms of other maladies or substantiated in themselves—yet there would remain a small number which will present considerable difficulty. The only way out of this difficulty that I can see will be to create a number of small and comparatively unimportant groups, most of which it would be impossible to name, as we have hitherto tried to do, by reference to supposed cause, since of many the cause is complex or possibly as yet unknown. I allude to such diseases as acne, sycosis, frambesia, and the like. Concerning most of these I am sure that we may hold that the convenience neither of the student nor the practitioner would be helped by our attempting to place them in artificial association with other maladies which may bear a superficial resemblance to them as regards the local lesion. We had better let erysipelas stand as erysipelas simply, than class it with *bullæ* because it frequently vesicates, and we shall understand acne quite as well if we make of it a family to itself instead of classing it with *pastula*. I would propose, then, to take a type-form for each of these smaller groups, to use the name which is in common employment for it as the name of the group, and then to see how many cognate maladies will cluster round it. It will easily be understood that no very abrupt lines of demarcation can be drawn between groups constructed on this principle; and that we shall not unfrequently find it necessary to mention the same disease under two headings, or perhaps more. That this should be the case, necessarily follows from our having attempted a natural classification. It is a difficulty which assails the naturalist in every field of investigation. Neither the geologist nor the botanist can escape it entirely, or if they do it is only by arbitrary methods. It is a difficulty, however, which from the nature of his materials the investigator of disease must encounter much oftener than they do. We encounter connecting links and mixed forms on every hand, and we should inflict a great and very foolish injury to truth if we were to try to make them bend to conventional rules of classification. It should, indeed, be one of the foremost precepts which we keep in view, that the causes which we have to study are capable of endless and diverse mixtures and combinations. The problem before us is, how best to express these combinations in our nomenclature. The plan which is the simplest will, I believe, be found to be the best. If we are careful to give clear definitions to the names which we have in common use, it will not, I think, be difficult to combine those names in such a manner that they shall express with tolerable exactness what we mean. For myself, I very much prefer the plan of joining together two well-understood substantives rather than that of constructing a new and possibly very unwieldy adjective to be applied to one of them. For instance, I prefer the word treason-felony to that of felonious treason as expressing with less ambiguity what is meant. I prefer also the word lupus-acne when I mean a real admixture of the two conditions to the invention of an adjective which, at the best, would imply only resemblance. With these explanations, we will proceed with our task of attempting to group the forms of skin disease which have not as yet been included.

I will take then as our next group the Lupus family. The type-form of common lupus is well known, and so also is that known as lupus-erythematosus. Whilst these two present very remarkable differences so important that not a few have suggested that they ought not to be placed together, they yet possess such features of resemblance that it would be, I think, most unwise to separate them. We will claim the name lupus for every form of inflammation of the skin which begins at a point, spreads slowly, but steadily at its edge, is attended by cell infiltration or more properly by cell growth, which growth undergoes after a time retrogressive changes, and leaves the skin more or less disorganised. A spreading or serpiginous edge; and the final result a scar, are then the almost distinctive features of this process. They, like all other forms of skin disease, may be closely imitated in those whose tissues have been affected by syphilis. When this happens, we simply prefix the adjective syphilitic, well recognising that in so doing our diagnosis, prognosis and treatment all of them undergo a complete change. By the substantive we denote here the character of the pathological change, by the adjective its cause, and it is the cause which is all important. No more inconvenience can result from our speaking of a syphilitic-lupus than of a syphilitic lichen or psoriasis, for in each instance we clearly recognise that the malady is totally different from the non-specific prototype which lends it its name.

To return, then, to common lupus, we find it occurring under two chief forms. In both of them the process is locally infective, and tends to self multiplication; but there is the great difference that in one the disease begins symmetrically on the two halves of the body, whilst in the other it is never symmetrical except by accident. This difference is, I admit, a most important one, and were it not that there are connecting links it might seem sufficient to detach lupus-erythematosus from lupus vulgaris.

It is to be admitted, however, that there are cases of lupus erythematosus which are not symmetrical, and in which it is exceedingly difficult to distinguish the local process from that which occurs in common lupus; whilst there are instances of the latter in which the disease becomes generalised, and approaches in distribution closely to that of the erythematous form. It would appear that lupus erythematosus has a very close alliance as regards its exciting causes with chilblains. It is caused by exposure to sun and to cold, and it occurs almost invariably first, and often exclusively, to the parts which are most exposed to those influences. It does not, however, like chilblains, come to an end on removal of the cause, but proves its relationship to common lupus by spreading like it at its edge indefinitely and over large areas, and leaving the skin when it comes to an end in the condition of scar. In the lupus family, in addition to these two chief forms, we have several other more rare ones, some of them exceedingly rare. Thus we have a sebaceous lupus, a variety of the erythematous in which there is often little or no erythema, but the skin becomes rough and pitted like a piece of orange peel. We have also a lupus lymphaticus, in which the lymphatic trunks are involved after the same manner as the blood vessels in the erythematous kinds. Further, there is an acne-lupus, an eczema lupus, and a peculiar form to which it is difficult to give any appropriate name, which occurs only on the hands and feet.

The lupus family has affinities less or more strong in its different forms with scrofula, with chilblains, with psoriasis, and with cancer. Not very unfrequently in persons past middle life the lupus scar takes on malignant processes. A most interesting form of family disease has within the last ten years been observed by Hebra and Kaposi in Vienna, and studied

with enthusiasm by dermatologists in all parts of the world, which appears to be a form of erythematous lupus, but which occurs in several members of the same family, begins in very early life, and leads in not a few instances to malignant growths even in those who have not yet passed childhood.

We will allow the disease known as Sycosis to stand as the type-form for another group. In this affection hair follicles are involved; a suppurative inflammation of the follicle loosens the hair and destroys the bulb, leaving a small scar. The sycosis process, like that of lupus, is infective, and like it, may sometimes begin symmetrically and sometimes not so. It usually spreads gradually, unless arrested by art, over large areas, permanently destroying all the hairs, and leaving the skin in a condition of scar. It occurs to just the same class of patients as those who get lupus, and both the constitution and the local measures are *mutatis mutandis* very similar. Clearly sycosis is a near congener of lupus. It is a great mistake to imagine that sycosis is confined to the male sex and to the whiskers and beard. It is true that it shows its most characteristic features on these parts, but for the simple reason that there the hairs are the largest and most closely set. The ophthalmia tarsi which so often destroys the eye-lashes of delicate children is, if we would regard real affinities, a sycosis. In some cases the eyebrows also are attacked, not unfrequently the axillæ, and now and then the hairy scalp. It may sometimes affect the hairs of the body generally, and produce an eruption which will probably get the name of impetigo. In yet rarer cases we have a true sycosis unguium in which all the nails of the fingers and the toes are affected, inflame, suppurate and are exfoliated. The nails, as you know, are only modified hairs. You will observe that I put wholly aside that form of sycosis which is due to a vegetable parasite. It is quite true that this is the form which produces the most characteristic conditions, and which has furnished some of the best portraits of sycosis in our atlases. Its cause, however, is totally distinct from that of the sycosis which I have been describing. If we met with it on the scalp of a child in association with ringworm, as we frequently do, we should call it kerion, and as such cure it. It is exactly the same disease when it occurs on the bearded chin of an adult, and it is curable by exactly the same treatment. Surely it is better that we should call it kerion there also, and not jumble matters up by calling it a parasitic sycosis. It belongs of course to our first groups—that of the tineæ or diseases due to vegetable parasites. It has no relation to the health of the individual, and may be cured in as many weeks as sycosis will take months or even years.

Our next group is the Acne family. In acne we encounter the inflammation more or less acute or chronic of the sebaceous follicles. The tissues surrounding them are always involved, sometimes becoming very erythematous, and at others hypertrophic. In some cases the contents of the follicle accumulate within it, and consolidate, forming a comedo. In others suppuration takes place around the follicle, and a pustule results. Thus we may have different forms of acne, the comedo form, the common pustular form, an acne rosacea or erythematosus, an acne tuberosum and an acne-lichen. Many interesting features of peculiarity might be mentioned as regards these and other types of acne. Of all the varieties a few general statements will be found to be true. In all it will be found that the blood supply to the skin is liable to disturbance in connection with the derangement of what is known as tone. It does not matter what the precise cause of this disturbance of tone is, whether the patient has been lowered artificially by the administration of iodides or bromides, or whether

he brought it upon himself by any one of the many various possible irregularities of life, whatever has lowered his tone will place him in danger of acne. And the precise form which it will assume will depend upon the original endowments of his skin. If he have a thick coarse skin with large follicles he will get the comedo, the pustule, the follicular abscess, and possibly in the end tuberosus hypertrophy of his nose. If his skin be fine and thin the tendency will be to erythematous acne. Acne is the disease to which, for the most part, and with the exception of the erythematous and tuberosus varieties, young persons only are liable to. Its pustules invariably leave small scars; it is probably in some low degree infective, that is—one pustule may cause others; it has probably a slight alliance with sycosis, and also with that state of health which leads to boils. I am sure, however, that I have told you what is true, in saying that it is mainly dependent upon derangements of tone when they occur to young people.

## AN ADDRESS ON MEDICAL EDUCATION.<sup>1</sup>

By W. T. GAIRDNER, M.D., LL.D.,

Professor of Medicine in the University of Glasgow.

(Continued from page 5.)

I AM no enemy, as all my friends here and elsewhere know, to the scientific side of medical education. I have rather been a supporter of the scientific branches in the broadest possible way in my own University during the whole course of my connection with it. But, nevertheless, looking at medical education as a practical whole, I cannot but confess that there is a possible danger—all the greater now that the immense and daily increasing number of details becomes more and more overwhelming to the young mind, or to any mind—in the scientific branches being so developed that it will be impossible to teach the practical branches in an adequate way. Only last night I happened to be in the company of a very old friend of my own, an excellent practitioner, whose son is at the University of Glasgow. He is a very clever young fellow, and has got immensely attracted by the study of biology. He is occupied all the day in the way Professor D'Arcy Thompson showed me in his laboratory to-day, making sections and studying microscopic forms. He is proud of the work. He is wholly absorbed in it, and says "I don't want to go beyond this. This is the sort of thing I wish to live by." In my own much earlier experience I had in my class a young man who was a very good linguist. He was a thoughtful man, with varied accomplishments, and endowed with a truly scientific brain. He came to my class and mastered everything that I had to teach him. Everything, by some kind of instinct, seemed to arrange itself in his mind in such a way that in the very first year he beat all the senior pupils in practice of medicine, with all their hospital experience (of which he had literally none at this time), in the easiest possible way. It came very naturally to me to say to that man, I should like to take you into the hospital as my assistant. But no; it would not do; nothing would induce him, after all his success in my class, to do a single day's turn in practical work. From that time to this he has hardly ever entered an hospital; or if so, only as a governor. I was utterly unsuccessful in bringing him face to face with true practical medical work, because the

scientific instinct was so strong in him, that it overcame every other instinct. That man is now Professor of Chemistry in one of the old Scotch Universities, and he is a very distinguished Professor. This, indeed, is an exception; but what is to come of the mass of the men who may be thus attracted by the earlier subjects, and who are induced in one way or another to prolong the association, so that in four years there is literally no time for us to teach the other important branches? We do our best, we clinical teachers. But what if the students come to us unprepared? What if they come to get their eyes and their ears educated for the first time as to things they should have been educated in long ago? Observe the difficulty, for it is a very serious difficulty. The practical training and discipline is, as it were, shunted into a corner, and so made impossible; and this is more especially the case with the medical training which, coming in the order of time necessarily after the surgical, and yet being much wider and more complicated in its scope, is too apt to be run entirely into the fourth year of study, and not half done even then, simply because the man, with all his previous training, is not half ready for it.

Now to meet this difficulty, which we all acknowledge is a serious one, I have heard of two different kinds of proposals. One is to throw back a considerable portion of the early scientific training from the Colleges into the schools; to demand of the schools the teaching of elementary physics, chemistry, and biology. Well, perhaps many of those here who know the schools and the school system of Scotland much better than I do will be able to say whether that be desirable or not. It is plain we are not ripe for it just now. The schools have not the apparatus—have not the means of giving anything more than a mere knowledge by rote; and knowledge by rote is worse than no knowledge at all. Unless the schools can teach these things, as Professor D'Arcy Thompson and the other professors teach them here, they need not begin. Therefore, for a long time to come that plan may be considered as practically out of the question. A second proposal is to extend the curriculum to five years. Well, speaking for myself, I have no objection to that. The matter has been discussed and argued in the Medical Council without any decided conclusion being arrived at. At present you may regard it as settled that the medical curriculum will not be altered generally to five years in all probability, for some time at any rate. But, suppose it were, I have so much belief in the attractive power of these early scientific branches—I feel so much myself the attraction they have for the mind—that I am convinced that the same difficulty would still occur. The risk would be that a considerable number would still have their whole attention monopolised by these early branches, and that those branches which it is absolutely necessary for them to acquire as practitioners would be, to some extent, apt to be shunted out of the course. There is only one remaining way, and that is a way I ventured to propose more than a quarter of a century ago, but which is regarded by several of my colleagues as rank heresy. It remains for us to see whether we can inoculate Dundee with this idea, and whether this College, beginning with new men, and not hampered by old prejudices, can give a medical training in the way I propose, and so develop a new type of medical teaching, having all the advantages of the old apprentice system, and superadded to these a considerable portion of valuable scientific training.

What I propose is that the scientific and practical training shall be carried on together throughout the medical student's education, so that he does not at any period of it lose touch either with the one or the other. Is it possible to teach the early scientific branches

<sup>1</sup> Delivered at University College, Dundee, June 27th, 1885

without monopolising a man's mind? The view adopted by Oxford and Cambridge is that they should take the man for two or three years to teach him the science only; and then turn him over into the London hospitals to teach him the practice. I venture to say that if that is the scheme of medical education that is to be adopted, not four years, not five years, not six years perhaps will be sufficient, and this education will ever remain the education of the few; and at least it is safe to say that this never can be the education of the great mass of medical practitioners; and remember, the studies of the great mass of the medical practitioners are what chiefly interest the public. Therefore, although the Oxford and Cambridge idea may be suitable for these great universities and the great hospital centres of London, and is therefore by no means to be discouraged, I maintain that for the medical student as I know him, as I esteem him, and as I have a life-long knowledge of him, that method is quite out of the question. I think there might be in a medical school an organisation such that at every stage of the student's training an illustration could be sought out of the field of disease. He should be brought more or less face to face with the business of his life all through his course, so as at no time to lose touch with it altogether, and yet be in a position to apprehend the relation to it of thorough and genuine scientific work. I may illustrate what I mean by one or two examples. A great deal of what is called stethoscopy—the science of auscultation, which rests, in the main, upon a basis of pure physics, and might therefore be advantageously taught at the very commencement of a medical career, in connection almost with preliminary training; a great deal of this and of the most elementary principles of it, has actually to be taught during the last year of a student's course. It is during the fourth year only that I can count absolutely upon his being brought into connection with me at all; although, in point of fact, many students begin in their third year to think it worth while to know something of what the practice of medicine is. The difficulty I meet with is that the man has at this advanced period to be taught for the first time really and personally what is normal, what is healthy, and it may take months before his ear, not to speak of his mind, is educated so that he can be made to draw a single correct inference. Now, why learn all that on the diseased subject when it could be learned so much more easily and satisfactorily on the healthy subject? There are scores of instances of matters of this kind that could be taught casually and incidentally during the progress of the scientific training. Illustrative cases which happen to present themselves at the hospital could be made good use of according to the stage of progress of the student at the time. The same method could be followed in the learning of physics, chemistry, and the whole realm of graphic physiology. There are facts in connection with all these sciences which could be explained in the lecture and illustrated at the hospital. But in the event of a School of Medicine being founded in Dundee, should it, it has been asked, take the Oxford and Cambridge method, or go on a model of its own? If Dundee goes on the Oxford and Cambridge method, and makes itself purely a scientific school, and sends its pupils thereafter to Glasgow or Edinburgh, as a matter of course, and of necessity, it is losing practically half its advantage. It is giving up the game. It needs no prophet to see that in a poor country like Scotland a system by which the scientific training by itself is to be developed in this alarming way will not at all suit the purses of the students or the time they have at their disposal.

Now, what I have to suggest is that you might manage to interest my friend, Dr. M'Cosh (the medical superintendent of the Dundee Royal Infirmary), in this

matter. He is an old student of my own, and I know how good a man he is in the practical department, and how much he feels the whole value of a medical training. If we could manage to get Dr. M'Cosh to support himself by one or two well-paid hospital tutors, young men recently off the irons, thoroughly well-trained both in the practical and theoretical side; and if the few students of your nascent medical school were paternally supervised by these tutors, who would follow them up in the lectures, learn what they were getting in the chemistry class, what in the biology class, and take them into the hospital for an hour or an hour-and-a-half every day, and teach them what the hospital affords in connection with disease, and explain such things as may bring the lectures into relation with the clinical side of medical training, you would make these students feel their profession all along, and you would add a new interest to their scientific training. I shall be told that this is impracticable. Well, in Glasgow and Edinburgh, with our large number of students, with all our old traditions, with certain interests involved, and with ways which have become fixed and stereotyped, it is impracticable. But to my mind it is not impracticable in a new school. If this were done in a new school it would, in my opinion, come to modify beneficially the whole course of medical training not only of the older schools of Scotland, but also of the hospitals and schools of England. I will not absolutely say that the student should go very much into the hospital from the first moment he enters the classes, but I do think he should be led into the hospital soon, and be led under the tuition of a man who would make it his business to lighten his mind with ideas tending to forward him in his vocation, and at the same time to give an interest to his scientific study by showing its bearing upon his future vocation. This might occupy two years, this joint system of scientific and practical training. Then I may engage to say that in the third and fourth year the clinical training would begin at an immense advantage, and we clinical teachers—I am supposing myself for a moment in Dundee—would find our men with their ears and eyes educated, their senses trained, and their minds qualified to a certain extent much more accurately and really to appreciate the facts of disease, as we are obliged to study them and lay them down, from a practical point of view.

But I am afraid that in this long disquisition we are losing sight of one of the main objects of this assembly. We are losing sight of you, my young friends, and I may say here I have written this, the only previously written part of this address, without properly appreciating the number of the fairer and gentler sex that were to be present on this occasion. We are losing sight of you who have launched out already in your several careers of study, and are here to obtain the prizes which you have so well earned. For you, too, I have one word of warning and one word of encouragement. The word of warning I shall not give in my own words, but in the words of Mark Pattison. In his very pungent, but unmistakably sincere, book recently published (his memoirs), the late Rector of Lincoln says—and I may observe that the most remarkable thing about this passage (otherwise I should not be quoting it here), is that it is not a criticism on his opponents, but a severe, if just, commentary on the results produced by the reforming movement supported by himself and by his friends—“The young Oxford, which our present system tends to turn out, is a mental form which cannot be regarded with complacency by any one who judges an education not by its programme, but by its *élèves*. Our young men are not trained; they are only filled with propositions of which they have never learned the inductive basis. From showy lectures, from manuals, from

attractive periodicals, the youth is put in possession of ready-made opinion on every conceivable subject: a crude mass of matter which he is taught to regard as real knowledge. Swollen with this puffy and unwholesome diet, he goes forth into the world regarding himself, like the infant in the nursery, as the centre of all things, the measure of the universe. He thinks he can evince his superiority by freely distributing sneers and scoffs upon all that does not agree with the set of opinions which he happens to have adopted from imitation, from fashion, or from chance. Having no root in itself, such a type of character is liable to become an easy prey to any popular charlatanism or current fanaticism." The word of encouragement shall be taken from one of my own old addresses; in which I have endeavoured to show forth as regards the medical art, but in terms, I think, applicable equally to every other, the principle that underlies all sound teaching and learning. It is this: "The first lesson to be learned in order to make all other lessons possible is, in my opinion, this — to deal very largely with things and not with mere words; to realise as much as you can all your instruction by making it your own through personal observation; to suffer nothing, if it can possibly be avoided, to lie in the mind as a dead weight of vocables, oppressing the memory and dwarfing the intellect, but to bring everything into the living light of fact and of nature, and thereby at once to assure to yourself the truth and exactness of your knowledge, while at the same time you are stamping it down upon the memory by the most sure and lasting of all technical methods. This is essentially the modern spirit of scientific inquiry, in virtue of which alone you can rise out of the dogmatism and orthodoxies of the past to make secure and beneficial progress in the knowledge of your profession." I do not for a moment suppose that any of the able and accomplished men whom I see around me will differ from me in respect of the words I have just cited, or will think that they are aimed contemptuously at scholarship or the study of languages, or especially of the Greek and Latin languages when studied in the spirit of Mark Pattison, or of the best representatives of such studies in Oxford or Cambridge. To speak such words in the presence of Principal Peterson would in that case be an outrage on propriety which I could not bring myself to commit. But I appeal to the general context of these three published addresses of mine, which, however, I will not inflict upon you, in proof that I do not personally at all undervalue linguistic studies; and you will perhaps take it as an additional proof of my sincerity in this, that, as a matter of fact, having lost sight of almost all the little Greek I had in my school days during the absorbing claims of the medical curriculum, and the after days of practice and scientific studies, I took pains to recover a little of it by renewed studies long after I had become deeply engaged in the business of life. But even in the study of languages there is a right way and a wrong way, and the principle here is the same—to keep close to nature and the facts—to make them, in short, a living study and not a dead one. The unamiable and self-sufficient type described by Mark Pattison grows everywhere, as well as in Oxford, out of want of thoroughness in doing the work in hand, whatever it be, or out of want of a right direction in that work. The best training in humility and truthfulness that can possibly be supplied, short of the highest Christian exemplar, and the moral and religious element which grows only out of that, is to be found in the study, the large and reverent study, of nature. Who that is once confronted—really confronted, I mean, and not merely verbally confronted—with a single realm, however apparently trivial or remote, of natural science, can

avoid applying to himself the well-worn expression ascribed to Newton, of standing on the brink of an illimitable ocean of unknown truth, of which only the merest margin can be surveyed by mortal ken? What man of the present day, in all that belongs to the essence even of the Christian idea of humility and reverence, devotion to truth, and freedom from self-seeking, is greater and nobler than Charles Darwin, whom some would call (wrongly, as I believe) an Agnostic or an Atheist?

Now, in a College which, by its very constitution, is wholly divorced from theological opinion and teaching, you may require to be warned of a danger springing from this source. How far this is or may be so, I am not here to say. But I am here to say what I know from an experience of many years as a teacher, a student, and a man of active and practical life—that there is no natural tendency in science and learning in themselves, and certainly no tendency in medical science or practice, to make men proud, overbearing, and self-sufficient. When science is simply crammed out of books, indeed, and with a view to examinations and to prizes, there is, it may be admitted, some such risk, because then you are placing yourselves in relation, not with the illimitable majesty of nature and the overwhelming dominion of law, but with some little smattering of knowledge set aside for you to get up by rote, in which you are comparing your little paltry self, not with the whole field of knowledge, but with so much of it as has been "got up" by some other man. But to him who comes really face to face with nature, whether in the physical, vegetable, or animal world, whether in health or disease, who makes thoroughness his aim from the first in everything he does and thinks, and who is not to be diverted from this aim either by lucre or popular applause, or even by the desire to excel others—to such a man (and such men I hope your training here will make some or most of you) reverence and humility of character come as a matter of right, indeed of necessity, because they know and feel, even if they fail thus to formulate their convictions, that all nature is the temple of the living God, glorious and immense, and unspeakably great above all the possible conceptions of any finite mind. Those who enter this temple may well put their shoes from off their feet, and understand that the place whereon they are standing is holy ground. But they will only adopt this attitude of mind when they cease to compare their own puny efforts with those of their neighbours, and learn to contrast them with the enormous sum of human effort that has already, during all these centuries, taken the same direction; and finally with the illimitable ocean of the unknown, over which, if I mistake not, the Holy Spirit still broods, as of yore, and, if you are thus wise and reverent, will reveal Himself to every one of you.

---

THE annual meeting and dinner of the Cambridge Medical Graduates Club will be held at the Holborn Restaurant on Wednesday next, July 15th, at 7.30 p.m., when Dr. W. H. Dickinson will be in the Chair. Any graduate who has received and not answered an invitation to join the Club may become a member by applying to either of the Honorary Secretaries: Dr. J. R. Fowler, 35, Clarges Street, Mayfair, W., or Dr. W. E. Steavenson, 39, Welbeck Street, W.

## CLINICAL LECTURES

ON

DISEASES OF THE URINARY TRACT  
IN THE YOUNG.DELIVERED AT THE HOSPITAL FOR SICK CHILDREN,  
GREAT ORMOND STREET.By JOHN H. MORGAN, M.A. Oxon., F.R.C.S.,  
Assistant Surgeon to the Hospital.

## LECTURE I.

It is, I presume, the legitimate function of Clinical Lectures to supply in greater detail the results of observation on cases or on classes of cases which do not generally find mention in the ordinary text-books, or are alluded to only in such a manner as will supply the general features of the subject, and it is of advantage that they should be illustrated, as far as possible, by the presentation of cases or by the demonstration of specimens so as to allow a closer examination of the matter in hand. It might well be expected that this institution should be able to add in this manner much towards the knowledge of the diseases of children, and such indeed was one of the primary objects of its foundation. But such has been the prolific nature of this parent, that in the course of the last twenty years, children's hospitals have sprung up in numbers, not only in this metropolis, which already counts some eight or ten, but also in every large town throughout the country as well as in many rural districts. It is a necessary result that while humanity gains science is bound to suffer. Speaking only from my own experience of the out-patient room during the last fifteen years, since I first began to work there under Mr. Thomas Smith, the number of cases of any rarity or of any unusual interest has diminished in a very marked proportion. Formerly, the cases were not few that were sent to this hospital for an opinion, many of them coming from long distances and being often of exceptional interest and rarity. At the present moment, although the hospital stands foremost in the country among such institutions, the number of rare and exceptional cases which come for advice are necessarily very much fewer, since they naturally seek advice nearer home, and are eagerly seized on by the medical officers of such smaller institutions, who gain a local reputation for skill in the treatment of children's maladies, but have not leisure in all the harass of general practice to give to the world the results of their experience.

Thus, you will understand that in our out-patient rooms a very large amount of monotonous work has to be done, with only occasional relief of meeting with cases of unusual interest, whilst to pursue a search into any particular subject requires a much longer period of observation and enquiry.

The subject which I propose to consider in the present course of lectures is that of the surgical affections of the urinary tract in the young; it is one to which for many years I have given particular attention. My endeavour will be to treat the subject as fully as possible, but avoiding those portions of it which are amply dealt with in the text-books of surgery or in the more special treatises upon diseases of children, and I shall hope to illustrate what I have to say by cases which have come under observation in the out-patient room or in the wards, as well as by specimens and drawings from the museum.

Commencing at the end of the tract, and dealing first with the deformities of the urethra, it is of some interest to note that, as compared with the intestinal tube which not infrequently has no external opening,

there is but one case so far as I can ascertain in which congenital absence of the urethra is recorded. This is described by M. Peliteau in *Gaz. Hebd. de Med. et Chir.*, Jan. 30, 1864, though some other cases are there said to have been mentioned by French authors. As this was remedied by operation, it is to be presumed that the deficiency was limited to the anterior portion of the urethra. The condition of epispadias, when the urethra opens upon the dorsal surface of the penis, is exceedingly rare, that is to say, when unaccompanied by extroversion of the bladder. I have notes of only one case, in which the opening was situated just behind the glans, and was complicated by division of the prepuce and by non-descent of the testis on both sides. A case of this deformity is found recorded by Mr. Partridge in the "Transactions Pathological Society," vol. xvi. p. 192, and reference is there given to two other specimens. Another case of which I am unable to find the notes is represented in the drawing which I here show. In it the penis appears to be diminished in size, and the urethra opens above its base just in front of the symphysis pubis. It would appear to represent a case which has fallen short of the ordinary condition seen in ectopia vesicæ, and is of peculiar interest on that account as well as for its extreme rarity.

Of hypospadias, where the opening is placed upon the under surface, we see very many examples in which the opening of the canal may be situate in any position from the centre of the perinæum to the point at which the frænum is attached to the body of the penis. This is by far the most usual situation for the opening, and it is frequently so small as to escape any but the most minute search. More than once cases have been brought to me in which it has been declared that no opening of the urethra existed, a condition which, as I have said, is almost unknown. Probably, in these cases the examination has been confined to the glans penis only, when there is invariably to be found a depression for the meatus at the usual spot, the actual orifice lying further back. In many instances the smallness of this opening has been the cause of so much distress that it has required enlarging, and this I have always done in the same manner as when, after amputation of the penis, the orifice having been slit up the edges are drawn apart and attached by a horsehair stitch to the tissue on each side. As instances of what may happen from this condition, a boy was brought here with this deformity in whom the mucus and dirt had so obstructed the passage as to cause painful and delayed micturition, and in the case of a youth the same causes had led to a gleet discharge. Thus, it will be seen that it is of the greatest importance minutely to examine the under surface of the penis, scrotum and perinæum in all cases of the deformity, and the question which is invariably asked regarding them, and to which a careful answer must be given, is as to the power which a male thus formed has of begetting offspring. To this the reply must mainly depend upon the position of the orifice in the case under consideration, but, on the whole, the instances are few even where the opening of the urethra is situated very far back, in which ejection of semen cannot take place.

An interesting enquiry connected with this subject, and one which confirms the above remark, is as to the hereditary nature of this deformity; and in a most instructive article in the *Lancet*, April 19, 1884, Mr. Lingard gives an instance in which this deformity was traced through six generations, and relates a case in which it was transmitted by the widow of a hypospadian to four sons by a second husband who had no deformity. I have in several cases been able to trace an hereditary transmission of the condition.

I once was witness to an attempt to increase the

procreative possibilities of a child whose urethra opened behind the scrotum, by making a channel through the scrotum and forming a passage beneath the penis. This was done by dissecting off and turning over flaps of the scrotum, which were united in the middle line so as to form a channel by which the fluids which passed along the urethra might be conducted. The operation was performed by many stages, and the result was not at all satisfactory. In those cases in which the penis is bound down to the scrotum, and is therefore incapable of becoming properly erected, some operation may be called for, and under such circumstances any proceeding that is undertaken requires to be somewhat freely performed. An ingenious method of operating has been described by Mr. Pick, by which the malformed prepuce with the tissues of the penis and scrotum are made to form the floor of a channel by which the fluids discharged from the abnormal orifice of the urethra may be conducted. How far this was of practical utility was not ascertained, and I have personally much doubt as to the efficacy of any interference. On the contrary, cases are quoted in which the urethral orifice has been very far back, in which procreation has been effected.

I do not touch here upon those extreme cases of hypospadias in which the urethra is open along the greater part of its length, and the external organs are so ill-developed as to leave some doubt to which sex the patient may be said to belong. These cases are more properly discussed under the subject of hermaphroditism, because together with the deformity of the urethra there is also considerable deviation from the normal of the sexual organs which may resemble analogous parts in either sex. Here I show a sketch which I had an opportunity of making from a recent specimen which was exhibited lately at the Pathological Society. But short of these extreme cases there are many in which this condition exists with some other abnormal state, as in the boy before you, who, with a moderate condition of hypospadias, has an ill-developed scrotum, and in whom neither testis has descended; or in this other boy who has nearly the same condition of urethra, but has no testis in the scrotum on the right side, whilst on the left it has descended, and is followed by a congenital hernia. These are two examples of very usual complications of this condition. Before leaving the subject of these deformities, I may mention one or two anomalies which I have met with, such as a curious instance of congenital penile fistula in which a probe passed in at the meatus issued at an orifice midway along the under surface of the organ, micturition being performed through both openings; and another in which the depression for the meatus, which was impervious, lay upon the left side of the glans, and the urethra opened upon the left side of the corona.

In this preparation is a specimen of cyst of the prepuce which corresponds in size, nature and situation with another which was under my care. They resemble the mucous cysts of the lips, &c., and require nothing but evacuation for their obliteration. Trivial as so slight an imperfection may seem, there can be no doubt that a long prepuce, especially when its orifice is narrow, is the cause of very many ailments of youth. To its presence has been ascribed the existence of talipes, and even of paralysis, whilst a well-known surgeon has seen in it one of the provocations of hip-joint disease. How far it may influence the origin of these affections I will not argue, but there can be no doubt that by reason of the obstruction to the ready flow of urine it produces effects directly upon the bladder. "I have seen," says Mr. Bryant, "this simple condition of the penis produce every degree of

irritability of the bladder even to hæmaturia, also retention from the same cause, also priapism." Sir James Paget, speaking of the hypertrophy of muscle, says (*Surgical Pathology*, p. 57): "Action of muscle, if it be at once frequent and forcible, may produce hypertrophy, even though the action be unhealthy." This appears to be the case with the bladder of some children who suffer from frequent and very painful micturition, and nearly all the signs of calculus, but in whom no calculus exists. The bladder in such children is found exceedingly hypertrophied, and there may be no other disease whatever of the urinary organs. Dr. Golding Bird has shown that phimosis, by obstructing the free exit of urine, may give rise to these signs and to extreme hypertrophy of the bladder. If confirmation of these observations be wanted it is to be found in the cases which occur almost daily in our practice here of children who, having all the symptoms of calculus, with the exception perhaps of hæmaturia, are permanently relieved by removal of the prepuce. Hence it has become my invariable practice, when a child in these circumstances is brought to me, to place it under the influence of an anæsthetic, and having ascertained the absence of stone to perform circumcision. Prominent among the consequences of this condition hernia, especially inguinal, is in very many instances induced, owing to the frequent and extreme tension to which the abdominal muscles are brought in order to overcome the resistance to the flow of urine, and the pressure which is in consequence exerted upon the contents of the abdomen. Mr. Kempe, lately house-surgeon to this hospital, published the result of observation on 50 consecutive cases of congenital phimosis (*Lancet*, July, 1878), and found that of these 31 had rupture, in 5 there was double inguinal hernia, and in many of these there was umbilical hernia as well (umbilical hernia alone was not counted). In none of these cases was the rupture noticed at birth, the earliest was observed at three weeks, the latest at two-years-and-a-half. The adhesions which are so often found to exist are small bands of cicatricial tissue passing between the prepuce and the glans, and bear a close analogy to the bands which so frequently are found to unite the edges of the labia in fat and healthy female children. There would seem to be some sort of congenital tendency to their formation, for I have known them to occur in several brothers, and in one case they had existed in the male members of three generations at least. At an early age they are easily torn, and leave only a slightly excoriated surface of mucous membrane, but if allowed to persist into adult life they may cause serious trouble, not only by the irritation caused by the smegma secreted from the glands of the corona, but also from the hæmorrhage which follows any attempt to break them down. The later effects of this condition, such as the greater liability to venereal affections, and the induction of cancer of the penis, need only be alluded to here as having weight in deciding upon the advisability of operating. Let me add one caution regarding the operation: do not be satisfied with less than its complete performance. Twice during last year I was called upon to repair the results of too sparing a hand, which by reason of only partially removing the prepuce had caused a contraction of the parts which was more serious than the original condition, and necessitated a second and complete circumcision.

Stricture of the urethra in children occurs only as the result of wounding, and is therefore necessarily very rarely met with, although for the same reason it is a very serious condition. I have seen two cases. one was in a boy who had tied a piece of string so tightly round the penis that it had caused ulceration of the parts, and a cicatrix in the lower part of the

urethra which, so long as he was under observation, did not cause serious inconvenience. The other case was that of a lad who when very young had ruptured the urethra by falling astride of a rail, and who ultimately died of the effects of the stricture, which was so obstinate that no urine could be passed without the aid of a catheter, and he had more than once to undergo the operation of perineal section.

Passing on to the bladder, we need not concern ourselves with those abnormalities which are only discovered after death, and which present neither symptoms nor inconvenience during life, such as an entire or partial division of the cavity, but we will proceed to discuss that occasional deformity which goes by the name of extroversion of the bladder, *ectopia vesicæ*, and for which Mr. Holmes aptly proposes the term congenital hiatus of the bladder, as indicating what is a very important feature, viz., that a great part of the bladder is positively absent. This condition arises through deficient development of the anterior wall of the abdomen as well as of the bladder itself, and in consequence the posterior wall of the viscus is seen in the middle line, and is united at the edges by a cicatricial margin to the healthy skin of the abdominal parietes. Some have endeavoured to account for the deformity as due to inflammatory processes taking place *in utero*, and like most other things obscure in surgery the ægis of syphilis has been extended over it in explanation. But occurring as it does in the middle line, and often in conjunction with other errors of development happening in the same individual, there is no doubt that it is due to an arrest of development which, from what is known of the progress in development of the allantois from which the bladder is formed, must necessarily take place before the third week of embryonic life, a fact which of itself silences the suggestion of being induced by maternal impression. In common with other deficiencies in the median line which are found upon the anterior surface of the body, it is more frequent in males than in the opposite sex, and in confirmation of this I have met with only two cases in females during the last ten years. The first was the offspring of healthy parents, and there were two elder children perfectly well formed. She presented the usual mass of granulation-covered mucous membrane above the pubes, which were not united by bone in the median line, a condition found usually to co-exist with this deformity. At the lower part of this mass were two symmetrically-placed eminences of florid granulations which marked the orifices of the ureters, and from which the urine could be seen to issue, occasionally mixed with blood from the granulations. In each groin was a fulness covered by ordinary skin, not in any part resembling that of a scrotum, and containing no hernia nor any body which might be ovary or testis. From below the pubes in the middle line the parts were divided by a fissure, bounded by prominences which might represent the labia, but the state of the vagina, uterus, &c., could not be ascertained. The second case which I here show you comes of healthy parents who have three elder and one younger child, all of whom are normally developed, and the condition is very nearly identical. In a somewhat similar case, of which a dissection was made by Dr. Champneys and described in the St. Bartholomew's Hospital Reports, the uterus and appendages were normal, and it is stated that cases of pregnancy and of parturition have occurred in subjects of this deformity. The anus was placed rather more anteriorly than normally, and this is said to be the usual condition, and was noticed in both my cases, whilst other parts of the intestine are often found to be abnormal in their situation and relations. The ureters are nearly always tortuous and dilated, as are also the pelves of the kidneys, and the former may open into

the vagina, the urethra or the rectum. As the drawings which I exhibit will show, it is in male subjects of this deformity that epispadias is met with, and the floor of the urethra may in some of them be seen lying open along the whole length of the short and ill-developed penis.

The general health of these children is, as a rule, very good, and notwithstanding the results of the deformity they grow up into healthy and well-nourished adults. Sometimes the bleeding from the granulations, when they are pushed forwards against the clothes, causes a drain upon their strength, and besides the urinous smell which surrounds them, and which might be expected to interfere with health, the parts in the neighbourhood occasionally suffer severely from eczematous eruption. Besides this the urine frequently deposits phosphatic matter which, forming crusts in the edges and folds about the lower part of the abdomen, gives rise to sores which do not readily heal. These results may be combated by careful management, by cleanliness, and by the use of appropriate ointments, and the adjustment of a well-made apparatus to catch the urine, and prevent it from running over the surrounding parts. The difficulty, on the one hand, and the expense on the other, of providing instruments seem to point to the desirability of performing, an operation to remedy this defect. Two surgical measures have been performed with this object which, described briefly, are as follows:—

1st.—To divert the course of the urine so that it may be passed per rectum, as proposed and unsuccessfully attempted by Mr. Simon.

Or, 2ndly, by means of a series of plastic operations to cover the exposed mucous membrane, and so allow the more perfect adaptation of an instrument for reception of the urine.

This subject is ably discussed by Mr. Holmes in his work on the Surgical Treatment of Children's Diseases, and he there states that as far as our present experience goes the danger and difficulty of Mr. Simon's operation appear to outweigh its probable advantages. The second method has been successfully carried out by Mr. Holmes, and more frequently by Mr. Wood. To the writings on the subject by these gentlemen, I would refer those who are inclined to perform the operation; but for my own part, seeing the risk to the patient which cannot be considered small, and looking to the protracted period during which healing must take place, to the large extent of cicatricial tissue which results, and the comparatively small advantage gained, I prefer to trust to the careful adaptation of an instrument, notwithstanding its inconvenience and expense.

In the specimen here shown from our museum you will see the parts removed from a boy who died of brain-disease, and who had been operated on for the remedy of this deformity, and in this child which I exhibit you will be able to compare the results of operation with the condition in the other subject of the deformity which is before you.

[At the conclusion of the lecture a number of cases which had been collected for the purpose were shown to those present, and the remarks above given were then illustrated.]

---

EDUCATIONAL OVER-PRESSURE.—Messrs. Macmillan & Co. will publish immediately a translation of Dr. Hertel's work on over-pressure in Danish high schools, with an introduction by Dr. Crichton-Browne, who considers it an eminently careful and scientific treatise, placing in a clear light the dangers and difficulties which beset educational enterprise in the present day.

## SOME CASES OF INTEREST.

By JOHN GASON, F.K.Q.C.P.I., Rome.

At the present time I have under treatment in the Protestant Italian Hospital in Rome an interesting case of keloid. The subject is a woman 75 years of age, on whom I operated thirteen months since for the removal of scirrhus of the entire left breast. In November last I visited her at her home. She complained of an eruption resembling urticaria, accompanied by much irritation and fever, close to, but not on the cicatrix, which was completely healed. This eruption took place on both sides of the transverse incision. There were then ten or eleven of these raised wheals or button-like eruptions. When they first appeared they were of a light red colour, convex on the upper surface, firm and smooth to the touch, no pain on pressure, but attended with considerable irritation. At the present time there are eleven of these buttons of keloid existing on both sides of the transverse incision for the removal of the cancer, but not in contact with it, though some of them run into the others. They are of a round shape with well-defined margins except where they join with the others, of a firm consistence, much raised, some about an eighth-of-an-inch above the adjoining skin. The centre of each button of keloid is much darker than the exterior. They resemble very much in their appearance large buttons. She complains at times of irritation in this eruption. She has no fever, but since their appearance she has not been quite well. Her tongue very foul. Appetite bad. She sleeps well. Within the last week there is a considerable diminution in their size. They continue to be very hard, and are much flatter than they were. She is at present taking 10 minims of Fowler's solution of arsenic three times a day.

I have also at present under my care two cases of hypertrophy of the labia majora. They are both in married women. They think that they had syphilis, but when I first saw them I could not ascertain such to be the case. There was slight ulceration at the junction of the labia majora with the external skin. The health of both patients is good. The labia, particularly in one case, were very large. Under antiseptic treatment I removed both labia, and drew the cut edges together by means of silver wire. Both patients were completely well in ten days, and were able to leave their beds. One has already left the hospital quite cured, and the second will leave in a few days quite well.

This hypertrophy of the labia majora was so great in both cases that it caused them considerable inconvenience. They are both young. In removing them, no vessel required to be secured; the hæmorrhage was slight and soon ceased.

Operation for the removal of a large cervical gland in a girl 17 years of age:—Anungiata Tofani, æt. 17 years, has had a large cervical gland extending from the lobe of the left ear downwards since childhood. In its removal by dissection it was requisite to proceed very cautiously, as its attachments were closely connected with the adjoining parts. In its removal it was necessary to secure two vessels by torsion and one by ligature. It was done under antiseptic precautions. The edges of the wound were united by silver wire ligature. There was no fever, and the incision was quite healed in 15 days. Her general health improved very much, and she left the hospital quite well.

REPORTS OF  
HOSPITAL PRACTICE IN MEDICINE  
AND SURGERY.

## ROYAL FREE HOSPITAL.

HÆMORRHAGE INTO PONS LEADING BY  
RUPTURE TO EXTENSIVE SUPERFICIAL  
EXTRAVASATION.

By SAMUEL WEST, M.D., F.R.C.P.,

Physician to the Hospital, &amp;c.

JAMES C. was brought into the Royal Free Hospital unconscious and paralysed, and died two hours later. He had been seen to fall suddenly in the street. The pupils were equal, but minutely contracted.

It transpired that he had had an injury to the head two years before, and since then had had pains in the head for which he had been two months in the Doncaster Infirmary. On *post mortem* examination, the convolutions of the brain were found flattened on both sides. The vessels at the base were very atheromatous. The pons and upper part of the medulla were covered with blood; this extended under the pia mater, over the upper part of the cerebellum, corpus callosum, and crown, all of which parts were softer than natural, but otherwise normal; the ventricles contained a little clear serous fluid. In the middle of the pons on the right side the tissue was discoloured, and a long transverse slit was found infiltrated with blood, from which hæmorrhage proceeded. The right side of the cerebellum was remarkably soft, and on section a cavity was found, containing recently extravasated blood, from which the finger could be passed into the cavity corresponding with the slit described. This was not the source of the hæmorrhage, but a laceration produced by the blood as it passed from the pons. The aorta was slightly atheromatous, the left ventricle slightly hypertrophied, but the valves healthy. The kidneys were large (right =  $6\frac{1}{2}$  ozs., left =  $5\frac{1}{2}$  ozs.), and the liver firm, weighing  $3\frac{1}{2}$  lbs.

A hæmorrhage in the pons which leads to rupture and large superficial extravasation is very uncommon.

## ABERDEEN CHILDREN'S HOSPITAL.

GLIOMA OF RETINA—THREE CASES IN A  
FAMILY OF FIVE.

By Dr. ALEXANDER MACGREGOR.

JOHN F., 4 years old, was admitted into the Aberdeen Hospital for Sick Children, suffering from a large tumour of the right eye. The following is shortly the history of the family:—He was one of a family of five, whose father is living and in good health; and whose mother died at the age of 34 of "disease of the liver and heart." The left eye of the eldest child was removed when he was two years old. The tumour recurred in the stump, and also affected the right eye. In the case of the second child, the left eye was removed when the child was three months old. Nine months afterwards the right eye became affected, with a fatal result in a few months. The third child has escaped, is six years old, and in good health. The fifth child is fifteen months old, and so far, has shown no symptoms of the malady that has played such havoc among the members of this unfortunate family.

The fourth child is the one that came under my care. In his case the left eye was removed when he was seventeen months old. Nearly two years afterwards the right eye became affected, the sight was lost, the eyeball protruded, and became more and more involved until, *on admission*, the orbit was completely filled with a red fleshy pulsating tumour, which protruded more than an inch beyond the margin of the orbit. He died a few days after admission, apparently from exhaustion.

## APPOINTMENTS FOR THE WEEK.

---

Thursday, July 16.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 6 p.m.—  
Annual General Meeting at Holborn Restaurant.

---

# Medical Times and Gazette.

SATURDAY, JULY 11, 1885.

---

THE Council of the Royal College of Surgeons, at their Meeting on Thursday afternoon, elected Mr. Savory President of the College, and Mr. John Wood and Mr. Henry Power Vice-Presidents. The College has seldom been so well officered.

CONVOCAION of the London University met on Tuesday last to elect a representative on the Senate, and advantage was taken of the opportunity by various members to move resolutions, only one of which, however, was of medical interest. The result of the voting for the three names which have to be submitted to Her Majesty when a representative of Convocation is to be elected, was that Mr. Carey Foster was returned, as the French say, "on the first line" with 397 votes; Dr. R. F. Weymouth "on the second line" with 276 votes; and Mr. Philip Magnus last with 179 votes. The fact that 156 voting papers, or more than one in six, were rejected, provides a curious commentary on the stupidity and carelessness of even London University graduates.

A COMPARATIVELY small number of medical graduates were on the spot when Dr. W. J. Collins moved his resolution:—"That this House desires to express its approval of the resolve of the Senate, as intimated by the Vice-Chancellor, to maintain the standard and scientific character of the medical degrees of this University;" but decidedly more were present than when at the commencement of the business an attempt was made to obtain precedence for the motion. Dr. Collins made a lucid and able speech in support of his motion. He said that he was acting after consultation with many graduates, and specially quoted Mr. Savory, who had requested him to say that he would strenuously oppose any attempt to make the degrees *common*. There had been an agitation initiated by the Metropolitan Counties Branch of the

British Medical Association, and taken up by the medical journals, to diminish the severity of matriculation, to facilitate the acquirement of degrees, and to enable practitioners who had gone through the curriculum to take degrees without being obliged to again pursue the same course. In Convocation last February, Lord Justice Fry and Sir J. Lister had argued to the effect that the standard must be lowered and teaching improved; and finally the Colleges of Physicians and Surgeons were inclined to enquire if they could not obtain powers to grant a doctorate. The whole question seemed to lie in this, whether the standard should be lowered, or candidates screwed up to the present requirements. The demand to lighten the degrees came ill from medical students, who were far more favourably situated than students in other faculties, for they had a special curriculum marked out for them. The Senate had so far yielded as to give up Logic in the M.D. examination in favour of Mental Physiology, and had allowed the Preliminary Scientific and Intermediate M.B. to be taken piecemeal; a policy which might culminate in the granting of an M.D. "in monthly parts." He contended that facilities *for* taking degrees had been mistaken for facilities *in* taking them, and he was especially severe upon Dr. Bristowe, whom he taxed with ingratitude to his alma mater. Dr. Collins denied that in moving this resolution he was at all actuated by "vested interests," and averred that the movement against the University emanated from the teachers of the London schools, who desired to prevent the exodus of students to Scotland. The Senate through its Vice-Chancellor had shown itself determined to maintain the standard, and he trusted that Convocation by passing the motion would strengthen the Senate in this resolve. Dr. E. W. Roughton seconded the motion, which, without further debate, was carried with but two dissentients.

AT the annual meeting of the Ophthalmological Society on Friday last, the following were elected as the Officers and Council for the year 1885-6, viz.:—  
*President*, Jonathan Hutchinson, F.R.S. *Vice-Presidents*: Sir William Bowmau, Bart., F.R.S.; \*George Johnson, M.D., F.R.S.; Thomas Reid, M.D. (Glasgow); \*T. Sympson (Lincoln); T. Shadford Walker (Liverpool); J. C. Wordsworth. *Treasurer*, J. F. Streatfeild. *Secretaries*: \*Seymour Sharkey, M.B.; W. A. Brailey, M.D. *Other Members of the Council*: \*John Abercrombie, M.D.; \*Sidney Coupland, M.D.; George Cowell; G. A. Critchett; \*Walter Edmunds; \*W. Adams Frost; E. Nettleship; Priestley Smith (Birmingham); Simeon Snell (Sheffield); \*J. B. Story (Dublin); John Tweedy; W. Spencer Watson. Those whose names are marked with an asterisk (\*) were not in the Council, or did not hold the same office, during the preceding year. The appointment of a librarian was decided upon, and a well-deserved compliment was paid to Mr. James E. Adams in his unanimous election as a life member of the Society.

THE time of the Society up to the commencement of the annual meeting was mainly occupied in discussing a paper read by the President at a former meeting, on

that knottiest of ophthalmic subjects, viz., the nature of sympathetic, or, as he called it, reflex ophthalmitis. Mr. Hutchinson had propounded a theory (partly new) that the disease was conveyed from one eye to the other by the blood; to this theory, however, none of those who spoke found themselves able to subscribe. Mr. Nettleship showed how it could account for some of the phenomena, and also how it failed to satisfy other conditions often observed; and Dr. Brailey contrasted it with the better known theory of direct transmission, pointing out that on the whole the latter more nearly met the various requirements which must be fulfilled; but he, in common with all who took part in the debate, was careful not to accept any theory as altogether satisfactory. Mr. Spencer Watson asked why other organs did not suffer from the effects of sympathetic inflammation, instancing the joints as the only ones in which it was probable that this took place; and Mr. Power observed that the great length of time that sometimes elapsed before the sympathetic effects were manifested was very difficult of explanation on the hypothesis of blood transmission; whilst Dr. Mules regarded this fact of the variability in the date of onset of the disease as clearly in favour of the theory of a bacillary origin. Dr. Noyes, in an interesting speech, passed in review very briefly all the theories that had been advanced, without accepting any of them; and the President, in reply, disclaimed any intention of tying himself down to the hypothesis he had advanced, though none of the speeches that he had listened to had convinced him that it was untenable.

THE cholera is still raging in Spain, as many as ten thousand cases and nearly five thousand deaths having been officially recorded since we last wrote on the subject. The disease is still mainly confined to the four maritime provinces of Valencia, Castellon, Murcia, and Alicante, and to the four inland provinces of Saragossa, Cuenca, Toledo, and Madrid, though scattered cases in fugitives have occurred in the provinces of Salamanca, Tarragona, and Zamora. The infected territory may be roughly represented by a triangle, with its base occupying the middle two fourths of the eastern seaboard, and its apex situated at Madrid. Of towns, Valencia and Aranjuez have been most severely visited. In the former, a city of some 110,000 inhabitants, 1,500 cases and 870 deaths have been recorded in the last week. At Aranjuez there has been a regular stampede of the inhabitants, even the chemists and tavern keepers have closed their shops, and the only people moving about its beautiful alleys, it is said, are priests, doctors, and men with carts removing the dead or the sick. The king made a secret visit to Aranjuez on Thursday week, and was received with enthusiasm, but his example does not appear to have infected the inhabitants. Later accounts, however, state that the scare is subsiding with the arrival of abundant supplies, army surgeons, and sisters of charity. The epidemic is evidently of a most virulent character judging from the mortality. M. Gibier, a French doctor, who went to Spain to see Dr. Ferrán's inoculations, says he never saw cholera in a more terrible form than in

the Spanish hospitals and improvised infirmaries. The filth there is inconceivable to one used to French establishments of the same kind. He has not the slightest belief in Dr. Ferrán's vaccine, and thinks one might as well prevent violent colds by inoculating with catarrh mucus as deadly cholera with Dr. Koch's bacilli. The following are the daily official returns of cases and deaths during the first week of the present month:—

	Cases.	Deaths.
1st .....	1,487	692
2nd .....	1,354	664
3rd .....	1,424	668
4th .....	1,639	825
5th .....	1,467	660
6th .....	1,701	797
7th ....	1,109	628
Totals ....	10,181	4,934

OUR Paris Correspondent writes:—The pilgrimage of Professor Brouardel and his companions to the feet of the great Western Sage, who professes to stamp out the most formidable of modern epidemics, has produced the most startling and unexpected results. Dr. Ferrán positively refused to make known his method of preparing the fluid, the inoculation of which, he claims, preserves from cholera. He would not allow the French Commission to carry off even a single tube of vaccine matter for the purpose of examining it under the microscope, and refused to sanction any experiment outside of his "laboratory." The place dignified with that high-sounding name possesses none of the modern appliances of science, not even an apparatus for regulating the temperature of the stove in which the cholera virus is cultivated for attenuation. The single microscope available within its precincts only possesses a magnifying power of 700 diameters, while in all modern laboratories of bacteriology magnifying powers of 1,200 or 1,400 diameters are considered indispensable. We must admire the genius of investigation which led Dr. Ferrán, with such imperfect means, to achieve such portentous discoveries; but we cannot laud the spirit in which he told the French Commissioners that he could not surrender his secret without "a guarantee." The meaning of this expression was clearly indicated by the Doctor himself, in a letter officially addressed to the (French) Minister of Trade, in which, after deploring the indifference of his native country, which, unlike France and Germany, grants no pecuniary reward to its men of science, he openly says, "All the fame in the world would not preserve my children from poverty if death should overtake me."

It seems fair that before granting Dr. Ferrán a "substantial" reward, the Spanish Government should make sure that there exists a "substantial" discovery. The French Commission could not solve the problem, as the doctor had no microscopical preparations to show them, and would not grant them permission to make any of their own. They had therefore no means of controlling Dr. Ferrán's startling announcements as to the mode of reproduction of the cholera bacillus, nor of making experiments upon living

animals. All they could do was to attend the doctor in some of his "vaccinations" and to examine the statistical data which seem to plead in favour of his system. Dr. Ferrán inoculated, in presence of the Commissioners, a certain number of Sisters of Charity. He injects the contents of a full syringe (one cubic centimetre) into the back part of each arm. No antiseptic precautions are taken, and the air contained in the syringe is not even expelled before the injection takes place. The results are a slight malaise with lowering of the temperature, no fever, no vomiting, or diarrhoea. It must be allowed that, on the whole, no bad effects seem to follow the injection. The blood of persons inoculated contains no abnormal elements.

THE statistical data, which at first sight appear to confirm Dr. Ferrán's statements, are upon further investigation found to be altogether unreliable. The population of Spanish towns is always understated, in order to avoid taxation; the number of deaths is also understated, especially in times of cholera, in order to avoid the much-dreaded sanitary "cordon." No reliance, therefore, can be placed upon the figures, which seem to prove that vaccinated and revaccinated subjects are less liable to infection than others. Besides, it is well known that in all countries cholera is less frequent among the more prosperous classes of society than among the poor. Now, the poor are properly not to be reckoned among vaccinated subjects, since Dr. Ferrán's charges vary from four to ten shillings. As the doctor is said to vaccinate from 500 to 600 persons daily, the operation would not seem to be altogether unprofitable, and the "guarantee" which Government refuses is evidently drawn from the public. It may, therefore, safely be concluded, as Professor Brouardel remarks, that Dr. Ferrán has far too hastily stepped out of the scientific and experimental period into the period of what he calls "practice." Compare with his rashness the extreme prudence of Pasteur! Yet the French physiologist operated upon cattle, and not upon man.

It is stated that a British Commission is about to proceed to Spain in order to examine into the still doubtful question of the relation between germs and cholera, and as to the treatment of that disease. This Commission—which is composed of Professor C. S. Roy, of Cambridge University; Dr. Graham Brown, Edinburgh; and Mr. C. S. Sherrington (George Henry Lewis Scholar)—goes to Spain under the auspices of the Royal Society, and of the Association for the Advancement of Medicine by Research.

IN answer to Lord C. Hamilton, who asked for information as to the steps being taken by Government to prevent the importation of cholera, Mr. A. Balfour told the House of Commons on Tuesday that the more extended inspection undertaken during the present year by six Government medical inspectors is now almost complete as regards the port and riparian districts of England, and is being pursued in other districts which there is reason to suppose would be

most likely to suffer from cholera in the event of its introduction into this country. As a part of this inspection sanitary authorities are met and counsel taken with them, and their more immediate duty of preparation against cholera, as well as their general sanitary duties, are impressed on them by the Board's inspectors. The regulations which were in force during the prevalence of cholera in France and Italy are still in operation. As regards rags, an order has been issued prohibiting until the 1st of November next the importation of rags from Spain.

A BRIEF discussion arose in the House of Commons on Tuesday as to the Lunacy Bill of the late Government, but though Sir Henry Holland admitted that the new Government were fully alive to the gravity of the question, and Mr. Stuart Wortley stated that his department was strongly in favour of the Bill, very little light was thrown on the intentions of the Cabinet regarding it. At present the Government appears to fight shy of the magisterial intervention, and to more or less identify itself with Lord Shaftesbury's views on that proposal. Lord Salisbury, however, has admitted in the House of Lords that there is every disposition on the part of the Government to proceed with the Bill, and it is stated that its remaining stages in the Upper House will be got through this week.

THE deaths last week in London numbered 1,366, which, though 118 below the average for the week, caused the death-rate to rise from 16.3 to 17.5. Of the

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past eleven weeks.

zymotic diseases, whooping cough, diarrhoea and small-pox showed a marked rise over the record of last week, the two former causing 59 and 51 deaths respectively,

whilst the latter counted 39 victims. There were, however, only 94 fresh cases of small-pox, representing a diminution of 100 when compared with the return a fortnight previously. The deaths from measles fell from 90 to 80 and scarlet fever caused 9 deaths. Enteric fever was fatal in 9 cases, and diphtheria in double this number. There were 192 deaths under the head of diseases of the respiratory system. In the chief provincial towns, Liverpool alone maintained the high death-rate from measles that has prevailed during past few weeks with 20 deaths, Manchester having 11 and Sheffield 7 fatal cases. The highest general death-rate recorded, viz., 27·6, was at Halifax, and the lowest, viz., 12·8, at Birmingham.

THREE Reports to the Local Government Board relating to outbreaks of diphtheria have lately reached us. The first of these is Dr. Simpson's report on the prevalence of diphtheria in the Urban and Rural Sanitary districts of Shaftesbury in Dorsetshire. The inspection was rendered necessary by the large number of cases that occurred in 1884, 102 cases with 18 deaths having been recorded. The disease first made its appearance in October 1883, and as usual seems to have been disseminated in great measure through the medium of the school. The exact way in which the disease had been first introduced could not be traced owing to the time that had elapsed before the enquiry was commenced. The defective arrangements, however, in regard to the disposal of sewage, and the great prevalence of pigstyes in close proximity to the houses, constitute insanitary conditions favourable for creating a predisposition to such diseases as diphtheria. The Urban and Rural Sanitary districts of Wellington in Somerset, which have also been reported upon by Dr. Simpson, do not seem to be in better plight as regards sewage disposal, for the report says that the soil is saturated with sewage and the water supply polluted. The two main streets of Wellington are said to be well planned, but the courts and alleys leading out of them are in many instances unfit for human habitation, the general health of the inhabitants is far from good, the children are pale, and cases of "blood poisoning," abscesses, &c., are said to be common. Diphtheria was shown to have been prevalent and fatal from the middle of 1882, but the first case was traced back to December 1881, when it was introduced to the factory by a girl whose father worked at the Poole brickworks. Further enquiry revealed the fact that sore throat had been common amongst the workmen at Poole for some months previously, but Dr. Simpson was unable to assign the cause of the presence of the disease there to any particular factor. He believes that both at Wellington and Poole the dampness of the soil had much to do with the spread of the disease. The Rural district of Spilsby in the Fen district of Lincolnshire has been the subject of a report by Mr. John Spear. Two of its parishes, viz., Stickford and Friskney, suffered severely from diphtheria in the autumn of 1883 and the spring of 1884. In the former there were 37 cases with 10 deaths, and in the latter 79 cases with 30 deaths. Mr. Spear reports that the land is habitually damp, that the houses are ill-kept and dirty,

and that there is no proper provision for the removal of excreta. The water supply is mainly derived from the rain water, that from the dykes being occasionally called into requisition. In all these outbreaks the readiness with which the disease is transmitted from one person to another constituted a marked feature.

THE Guardians of the City of London Union appear to be dissatisfied with the system of management pursued at the City of London Asylum. The charges brought forward at the recent meeting of the Guardians were not very definite, nor perhaps very well sustained, but they were widely supported by the members present, and it is evident that a strong feeling of dissatisfaction prevails. That such a feeling should exist is not to be wondered at, when it is considered how large a share of the cost of maintaining an asylum is contributed by the Union, and how completely powerless the Guardians of the Union are to control or guide in any way, the expenditure of the money which they contribute. The obvious and proper remedy for such dissatisfaction as found expression at the meeting in question, is to give those who find the money the control of its distribution.

IN London, owing to the numerous opportunities of obtaining medical advice gratis, the provident dispensary system has a hard and up-hill fight, but some tangible progress appears to have been made since 1881, when the Metropolitan Provident Medical Association began its operations. This Association has now eleven branches, four of which are financially independent, and managed by a local Committee of *bonâ fide* members in conjunction with representatives of the medical staff. It is estimated that some 25,000 persons belong to these dispensaries, the annual income derived from whom amounts to over three thousand pounds. The Association believes that at least fifty more branches are necessary to supply the needs of the Metropolis, and we can well believe it but at present it only asks for one thousand pounds to enable it to carry on its work till the end of 1886. Seriously we know of no way in which philanthropists may do so much good at so small an expenditure. The Association, if it is determined to persevere, has a big work before it, of which it has as yet only touched the fringe. There are at least half-a-million of persons in London who ought to belong to provident dispensaries.

THE Paris Academy of Medicine has terminated a prolonged discussion on the contagion of erysipelas by adopting at its meeting on June 22 the following resolutions, drawn up by Professors Verneuil and Tillaux:—"The discussion which has engaged the attention of the Academy for so long a period, has demonstrated that erysipelas is eminently contagious; and that antiseptic treatment has certainly diminished its frequency and gravity, but is unable to always prevent either patients who come from without infecting the wards of hospitals, or patients who quit the hospital from creating epidemic centres outside. So that every year a certain number of deaths take place exclusively due to this importation and this reciprocal infection and the in-

definite persistence of the disease. To remedy this state of things, the Academy believes that it is indispensable to have within the hospitals special wards in which the isolation of erysipelas patients may be effectually practised. The Academy, therefore, makes the formal demand for such facilities at the hands of the authorities, who now that they are duly warned, will not desire to assume any longer responsibility for the existing state of things."

On the 8th inst., the Academy elected Dr. Vallin, an eminent military physician, to fill the place of the late lamented Dr. Fauvel, in the section of hygiene.

M. PAUL VIGIER, writing in the *Gazette Hebdomadaire* (July 3), states that on the occasion of a former communication of his, at the beginning of the year, the druggists of Lima were seized with such a spirit of speculation that the exportation of Peruvian coca assumed extraordinary proportions. The only object of mercantile attention was the obtaining of bales of the miraculous leaf, and as soon as the orders for every morsel of it that could be got arrived, a kind of delirium seized all concerned, nobody having any doubt that this precious shrub would lead to the resurrection of Peru. Forthwith, anything that could be regarded as coca was at once shipped without any selection being made, the most faded and yellow leaves brought three times the price of the green leaf of other days, and all the old stocks of the warehouses were in demand. The result is that care must now be taken in making purchases of the leaf, it only being bought, indeed, after ascertaining what quantity of cocaine it will yield. According to its state of preservation the amount varies from zero to 4 grammes per kilogramme, and the assay of this substance is just as important as that of opium. At present we must be satisfied with a yield of 2 grammes per kilo. A large arrival at Havre has just terminated a crisis in the trade, which had continued for six months; cocaine now only costs 10 francs per gramme, and M. Vigier is of opinion that the usual price will soon be 5 or 6 francs. In his former communication he suggested that the chemists of Peru should themselves manufacture cocaine, which is done with great ease, and which would at once reduce the price of the article by saving the freight of the leaves. A kilogramme of cocaine could be conveyed by the parcel-post at a small charge from Callao in a month, while 50 kilos of coca, which would furnish this amount, would be dear in transport, and would require two months to arrive. M. Vigier describes a new and simple procedure for extracting the alkaloid, and his advice is no doubt likely to be taken by the Peruvian chemists.

LAST week some forty representatives of the medical profession in Belgium assembled at the country house of Professor Boddaert near Ghent, to present him with a testimonial on the completion of his hundredth case of ovariectomy. The testimonial consisted of an artistic bronze, with an appropriate inscription. Subsequently, M. Boddaert entertained the testimonialists at dinner, when his health was proposed by Professor Du Moulin, of the University of Ghent, and received with acclama-

tion. The operation of ovariectomy has recently made great progress in Belgium, mainly through the efforts of Professor Boddaert. Twenty years ago a successful ovariectomy had never taken place in Belgium. Sir Spencer Wells operated with success at Ghent in 1871, and encouraged by his teaching and practice which he had followed in London, Boddaert began his series, and in fourteen years completed his first century of cases, seventeen of which proved fatal. At first, before the use of antiseptics, the mortality was discouraging, nine deaths having taken place to twelve recoveries. Since antiseptic precautions have been introduced, however, Boddaert has operated 75 times with only 7 deaths. Of four cases of removal of cysts of the broad ligament, three recovered. The Belgian doctors are to be congratulated on their readiness to honour this pioneer of abdominal surgery in their country, considering, to quote the journal which brings us intelligence of the event, that "fraternal effusiveness is not much in vogue with the medical profession."

THERE is a very unfortunate discussion going on at present in professional circles in America, which, it is quite possible may turn out disastrously for the International Medical Congress which it has been decided to hold at Washington in 1887. It will be remembered that a small Committee of the American Medical Association was nominated by the executive of the Copenhagen Congress, with full power to add to their number, and to act on behalf of their professional brethren. Carrying out their mission they chose as colleagues twenty-eight leading American practitioners, especially selected on account of their standing in the profession, and drew up the programme which has already been published. Subsequently, when the Committee reported to the meeting of the American Medical Association at New Orleans, exception was taken to their proceedings on the plea that they had exceeded their powers, and had no commission to act on behalf of the Association. The jealousies that had been roused amongst those who had been passed over in the co-optative selection were worked upon by two or three pushing wire-pullers, and, in the end, resolutions were passed, revising the work of the Committee, and substituting a Committee of 38 men selected from the different States and Territories for those added to their number by the original Committee. At a subsequent meeting, the results of which we are daily expecting to hear, the subject was again to come under consideration, and we learn that it was the intention of all the leading practitioners in the States to withdraw from the Congress, if the decisions of the original Committee were not treated with more respect. We sincerely hope that the profession in America will strenuously support their recognised leaders; otherwise they will make an exhibition of themselves to the world, and besides imperilling the future success of those international gatherings which have hitherto been conducted with so much harmony, will distinctly lower the respect in which the profession is held throughout the world.

THE American Laryngological Association, whose proud motto is "lux et veritas," recently held its seventh annual Congress at Detroit, Michigan, and got

through a lengthy programme of what it quaintly terms "exercises." The President, Dr. E. L. Shurley, of Detroit, led off with an address, and followed it up by a paper on the use of galvanism in pharyngeal affections. As many as nineteen other papers were set down for reading, a considerable proportion of which dealt with disorders of the nose. The last paper on the list was by Dr. J. Solis-Cohen, "On the Efficacy of Mild Measures in the treatment of so-called Naso- and Naso-pharyngeal Catarrh," which, from its title, looks as if it contained a protest against the violent treatment so commonly practised. The Congress concluded its labours with a "boat-ride" on the river.

DR. J. C. EVERS, writing in the *Weekblad* as a consultant retired from practice, gives several instances of the value of consultations where either himself or some other practitioner had overlooked some important physical sign which would have enabled a true diagnosis to be made. A gross case of military surgeons' carelessness came under his notice. He was asked to see a soldier who had been sent to prison for insubordination, *i.e.*, for having failed to perform his duty satisfactorily. He was looked upon by the medical officers as hypochondriacal, but was found by the writer to be suffering from cyanosis, and general anasarca with stenosis of the pulmonary artery. This diagnosis was confirmed shortly afterwards by the autopsy, which likewise revealed a patent condition of the ductus arteriosus and foramen ovale. Equally serious cases have come under Dr. Evers's notice more than once where men suffering from serious organic mischief have been compelled to perform duties in the public services for which they were physically unfit. He mentions also the case of a woman who had suffered for some months with pains in the epigastrium and vomiting. Nothing was made out by the student who took the case, and the acting physician instead of examining for himself accepted the student's statement that there were no objective physical signs. Dr. Evers, however, discovered a small tumour above the umbilicus, which was in fact a small hernia, probably through a small arterial foramen in or near the linea alba. Again, a general officer who had recently returned from India, complained of pains in the abdomen and about the cardiac region with nausea, and an ulcer of the stomach was suspected; the practitioner who brought the patient mentioned that there was a hydrocele which he had wanted to tap, but which the patient refused to allow to be operated on. Dr. Evers will not soon forget his look of distress when the "hydrocele," on being percussed, gave a clear tympanic note. A truss quickly cured all the old gentleman's troubles.

THE inventive genius who devised the first perambulator certainly deserved the gratitude of mothers and of nursemaids. Whether the infant himself had always reason to be equally grateful, may well be questioned. The springs were often far from comfortable and easy in their action; the child was placed upon an unyielding seat with a rigid back for an hour or two together, at an age when it would not have been expected or allowed to sit up for the same length of time under any other conditions, until gravity, weariness,

and weakness compelled it to assume a huddled-up semi-recumbent posture combining all varieties of spinal curvature. The vehicle itself possessed an unfortunate facility for turning sharply and suddenly in a small circle, to the serious disturbance of its occupant, and frequent and disquieting jolts were inevitable under any but the most careful management. Too often the nursemaid seemed to think that the child, once consigned to its perambulator, was satisfactorily disposed of without any need for further attention from her: *quis custodiet custodes?* But later improvements have rectified many of these disadvantages, and have combined to make the modern perambulator not merely a luxurious baby-carriage, but one which is, as nearly as possible, automatically safe. Two pairs of bicycle wheels with rubber tyres reduce jarring to a minimum; the bassinet form allows the child to recline at full length; while cunningly devised canopies and a reversible carriage have been contrived, to shield it from excess of wind and sunlight. But amid all these good reasons for satisfaction, we have lately noticed with amazed astonishment the latest enterprise of some perambulator-builder gone mad. It takes the form of a single perambulator in which the child sits beneath a leathern hood closed in front with a glass window that fits closely down to the apron. It is, in fact, a miniature reproduction of that form of bath chair in which elderly invalids occasionally appear out of doors, but carefully excluded from the outer air. The observant pedestrian will have noticed as a not insignificant fact that the infants whom he sees enclosed in this manner are always somnolent. The sun may be blazing in upon them through that sheet of glass which limits their small air-chamber, converting it into a sort of super-heated hot-house, but still they remain, in nursery parlance, "good"; while the observer feels that they are slumbering on in that narcotic sleep induced by the continuous re-breathing of their self-polluted atmosphere. It is curious to think that the affectionate mother, who would shudder at the notion of exhibiting her baby to admiring visitors tightly corked up in a large glass bottle, should have no hesitation in sending it out of doors to be asphyxiated in a machine contrived on the same principle, just because this happens to run upon wheels and is called a perambulator.

IN an address to the Graduates at the Women's Medical College of Pennsylvania, Dr. W. W. Keen, the Professor of Surgery to the College, recently took the opportunity to point out a few of the benefits of vivisection. Starting from the position that in the future medicine must either grow worse, stand still, or grow better, he showed that in order to do the latter, we must try new methods, give new drugs, perform new operations, or perform the old ones in new ways—in short, we must make experiments. These experiments must be tried on some living body, as experiments on the dead body can never do more than conduce to manual dexterity. As experiments on our fellow beings can never be right or justifiable, it follows that if medicine is to progress it must be by means of experiments on animals. Amongst the drugs now in con-

stant use whose action had been previously ascertained by careful experiments on animals, he mentioned cocaine, chloral hydrate, eucalyptus, nitro-glycerine, calabar bean, jaborandi, salicylic acid, and nitrite of amyl. America had been accused of having contributed very little to the progress of medicine by means of vivisection, but this Dr. Keen contended was a strong argument for its more extended employment. Amongst the more important results of vivisection in America, the work of Parkes in relation to gunshot wounds of the abdomen was mentioned, as also Dr. H. C. Wood's well-known researches on the intimate nature of heat-stroke, and the more recent labours of Drs. Wood and Formad on the nature of diphtheria. After a brief reference to the brilliant results obtained by Sir Spencer Wells, and the recent cases of cerebral surgery published by Dr. Hughes Bennett and Mr. Macewen, Dr. Keen concluded his admirable address with a few sentences in praise of Lister and the antiseptic system which has proved so great a boon all over the world.

#### A PLEA FOR VARIETY.

THE profession has before it two remarkable expressions of professorial opinion on the important question of medical education, the one contained in that portion of Prof. Gairdner's Dundee Address which we print this week, the other in a characteristic letter of Prof. Ray Lankester in the last issue of the *British Medical Journal*. We would strongly advise every one who is seriously interested in the training of the medical practitioner to carefully read these articles side by side; but for those who have not the time or opportunity to do so, we give their "leading motives" side by side.

##### PROFESSOR GAIRDNER.

I am no enemy to the scientific side of medical education. \* \* But nevertheless, looking at medical education as a practical whole, I cannot but confess that there is a possible danger in the scientific branches being so developed that it will be impossible to teach the practical branches in an adequate way. \* \* \* The view adopted by Oxford and Cambridge is that they should take a man for two or three years to teach him the science only; and then turn him over to the London Hospitals to teach him the practice. I venture to say that if that is the scheme of medical education that is to be adopted, not four years, not five years, not six years perhaps will be sufficient, and this education will remain the education of the few, and never can be the education of the great mass of medical practitioners; and remember the studies of the great mass of medical practitioners are what chiefly interest the public."

##### PROFESSOR LANKESTER.

It would seem ridiculous, were it not deplorable, that it should be necessary at the present day to insist on the value to a medical man of a fair knowledge of the range of organisation of the lower animals and of plants. Not merely the advantage but the necessity of such knowledge is admitted by the whole of Europe outside London. \* \* \* The opinion of a majority of the medical profession as to the proper subjects of medical education, though extremely valuable, cannot be regarded as decisive. \* \* The general complaint to the effect that the medical student of the present day cannot give sufficient time to the acquirement of strictly professional knowledge, owing to the large amount of time which he is induced to give to preliminary subjects, is not a reasonable one. The preliminary and accessory subjects should be, and as a matter of fact are, no more extensive than is absolutely reasonable and therefore necessary."

The above sentences no doubt suffer somewhat for being torn from their context, but with context or without it we do not think there is much room for doubt as to which view the majority of our readers will incline to. Their opinion may perhaps weigh little with Prof. Lankester, as he not obscurely hints, but if we may say so without unpardonable rudeness, we should be disposed to attach greater importance to the views of any cultured medical practitioner, let alone so distinguished an authority as Prof. Gairdner, than to those of the teacher of an isolated and accessory branch of medical education. One of the great difficulties in the way of obtaining a really practical and commonsense education for the medical student lies in the invincible tendency of all teachers of special subjects to regard their own science as the most important in the curriculum, and to make demands on the student's time and energy which would only be reasonable on the supposition that he was to be made an expert in that subject. The hatred of half knowledge which is at the bottom of this tendency is one with which we can heartily sympathise, but it is obvious that the medical student, let him give to his preliminary studies what time he may, can never hope to be more than an amateur in them, if he is to be an expert in those subjects, the practical application of which will be the work of his life and the source of his income. If he is led to become an expert in biology, or in chemistry, or in physics, as the professors of each of those sciences seem to wish, there is a risk—and not merely a hypothetical risk, but one which is repeatedly being demonstrated by individual instances—of his being frightened or tempted away from the study of medicine, and so robbing our profession of the very class of mind of which we stand so greatly in need.

We should be the last to affirm that—apart from this risk—a thorough training in biology is not an admirable prelude to medical study. But the same may be said—and is said by different professors—with an almost equal amount of truth, of chemistry and physics. It must be remembered, however, that in each case the value of the training depends on the scientific method which it teaches, rather than on the facts which it imparts. To Prof. Lankester's contention that a fair knowledge of the range of organization of the lower animals and of plants is necessary to a medical man, we are almost inclined to return a categorical denial. Such knowledge is scarcely more necessary or more valuable than the fair knowledge of the anatomy of a steam-engine, or of the combinations of tungsten and rubidium which the teachers of physics and chemistry respectively demand of him. What is necessary and valuable is the training in observation and reasoning in a more or less exact science as a prelude to his study of sciences which are not exact, and in which, therefore, strictness of method and accuracy of observation are all the more necessary. If we do not take care we may wake some morning to find that we have spent generations in shaking ourselves free from classical shackles only to put ourselves under the yoke of biology which, under incompetent teachers, may conceivably become quite as much a dead language as any that schoolboy was ever birched for.

The assumption which appears to us to vitiate most of these discussions on the training of medical students, and from which we rejoice to see that Prof. Gairdner has broken free, is that all medical education must be of one pattern. Men argue that because this system has been adopted in Germany, therefore we must introduce it in England; that because Oxford swears by this curriculum, therefore we must swear by it here in London; that because Edinburgh teaches in this way, we must follow her example in order to ensure her success. Such arguments are those of doctrinaires. The two things to be striven for are that whatever is taught shall be taught well, and that no practitioner shall be admitted to the Register who has not a thorough knowledge of his practical subjects. But we hold that the greatest variety should be encouraged at different schools and hospitals as to what preliminary subjects shall be studied, and how the practical branches shall be taught. We cordially re-echo Prof. Lankester's demand for "Lehrfreiheit" and "Lernfreiheit," but we would demand them in a somewhat less restricted form than he appears to do. We see no reason for instance, except the risk pointed out above, why the student's preliminary training should not be in physics alone, or in chemistry alone, or in biology alone, for it is pretty clear that if the teachers' demands continue to increase at their present rate, it will soon be utterly beyond the student's powers to take up all three. And as for set lectures in his professional subjects, we would let each school retain or abolish them at its own will. The German and Scottish methods are no doubt admirable in their way, especially for Germans and Scotsmen, but the English system, as Dr. Gairdner admits, has merits of its own, which we ought to be careful not to throw away in our eagerness for theoretical and symmetrical perfection. Prof. Gairdner has shown how a new school may take advantage of its newness to inaugurate a new method of medical teaching, and we sincerely hope that the interesting experiment he has sketched may be fairly tried; we also trust that advantage may be taken of the new birth which we all hope is before the University of London, to establish a reasonable and well balanced system of education which, without servile imitation of foreign models, and with sufficient elasticity to meet the views and methods of different schools, shall place clinical excellence in the very front of its requirements, and shall regard the preliminary sciences rather as the means than as the end of culture. It is perfectly possible to agree with the view stated so ably by Dr. Collins and endorsed by Convocation on Tuesday, that the University of London ought to maintain the standard and scientific character of its medical degrees, and yet to ardently desire to see them taken by at least half our London students. There are few medical graduates of the University, we venture to say, who would wish to see their degree depending for its value mainly on arbitrary and irrational restrictions.

## THE PARLIAMENTARY REPRESENTATION OF THE SCOTTISH UNIVERSITIES.

IT is now an open secret that the distinguished medical practitioner of whom we have heard during the last two or three weeks as a probable candidate for the representation of the Universities of Glasgow and Aberdeen in the new Parliament, is none other than the eminent surgeon, Mr. Erichsen. It appears, however, that Mr. Erichsen has been in the flattering, if somewhat distracting position of being solicited by two University constituencies, and that Glasgow and Aberdeen have had a serious, and it is now stated a successful rival in Edinburgh and St. Andrew's. The Edinburgh Liberals seem to have been quite knocked out of time, to use a vulgar phrase, by the decision of Sir Lyon Playfair to withdraw from the seat which he has held for so many years, and there is therefore a certain excuse for the somewhat scant consideration which they have shown their fellow Liberals of Glasgow and Aberdeen in stepping in and carrying off the candidate of their choice. But that is a matter which we may leave to the rival wooers for Mr. Erichsen's hand themselves. What will concern and interest the profession at large is that one of their number so highly respected as Mr. Erichsen should stand for some constituency at all events, and preferably for that in which he has the best prospect of success. Sir Lyon Playfair's services will not be lost, though he becomes the representative of hand- rather than brain-labour, for his voice on behalf of science in all its departments will no doubt continue to be heard and respected as much in the future as in the past, whatever and wherever be his seat. But the opportunity which his change of seat gives of reinforcing the ludicrously small contingent of science in the House of Commons ought not to be neglected. The Edinburgh graduates will not be doing justice to themselves, or to the sciences whose successful culture has made their University what it is, if they prefer a man of the law, however eminent in his profession, to a man of science. Still, for all that they ought not to have spoilt Mr. Erichsen's chances of becoming the representative of Glasgow and Aberdeen if they cannot hold out to him an equally good prospect of success, and it is not yet too late to give careful consideration to the question which seat promises best. We are sure that every member of the profession, to whatever party he may belong, would regret to see Mr. Erichsen falling between two stools. On the whole, he would make a very good Parliamentary representative of the medical profession. He has a robust common-sense, a self-reliance, and a practical directness which would perhaps be more likely to commend themselves to Parliament as the characteristics of his profession than the philosophical deliberation and distrust of active interference, which might be claimed as equally peculiar to the medically-trained mind. Mr. Erichsen, too, enjoys a position and has enjoyed an experience which would render him an exceptionally good representative. If elected, he would occupy such a position in Parliament as never within the present generation has been held by a member of the medical profession in London.

---

DENTAL HOSPITAL MEDICAL SCHOOL.—The Annual Distribution of Prizes of this School will take place on Friday, July 24th, at 5 o'clock at the Hospital, 40, Leicester Square. Sir J. Risdon Bennett has kindly consented to take the chair.

To return to the question of probabilities, it is at all times difficult to form an opinion as to the movements of political opinion in constituencies, the voters of which are so widely scattered over the kingdom as is the case with University graduates. We know this, however, that the Liberal section of the younger generation of Glasgow graduates are very anxious for a contest on the ground that the Conservative majority in the Council has of late been steadily diminishing. Since 1869, when the majority of the Conservative candidate was 504, Mr. Asher is the first Liberal who has obtained a majority in one University. In Glasgow, too, the Rectorial elections have been uniformly in favour of the Liberals by large majorities since 1877, when Mr. Gladstone was elected by a majority of 544, though it must be admitted that only six years previously Mr. Disraeli obtained the Rectorship by a majority of 304. The feeling therefore among the younger graduates of Glasgow is that the large Liberal element that has existed for some years among the students has by this time invaded the Council to such an extent as to render the prospect of a sufficient Liberal majority extremely favourable. On the other hand, the University of Edinburgh seems steadily lapsing into Conservatism. Sir Lyon Playfair's majority, which in 1868 was 255, had fallen in 1880 to 74. For the Lord Rectorship Lord Hartington had in 1877 a majority of 248, whereas in 1880 Lord Rosebery's majority was only 39, and in 1883 the Conservatives succeeded in polling for Sir Stafford Northcote 52 more votes than the Liberals polled for Mr. Trevelyan. On the whole, Glasgow and Aberdeen would seem to offer Mr. Erichsen the better chance of success, though there may be other considerations which we do not know of that have determined his choice.

#### A MONOCOTYLEDONOUS UNIVERSITY.

THE author or authors of the scheme for reorganising the University of London would seem to have been deeply infected with the cult of the lily. They swear by threes and multiples of threes. The flower of their toil is as remarkable for its ternary arrangement as any monocotyledonous bloom that bursts from the earth to herald the coming warmth of spring. They are of one kidney with the monthly nurse who pins her whole faith on the special and undeniable virtue which exists in the third numeral. We have much to thank them for. Their love of symmetry renders it all the more easy to grasp and remember the details of their proposals, just as the monocotyledonous orders tax the memory far less than the arbitrary peculiarities of the dicotyledones. Thus they place the University which they are attempting to reorganise under three main bodies—the Senate, the Faculties, and the Boards of Studies, Convocation becoming in their hands a degenerate and obsolete organ of little more than historical interest. Their Senate, again, is composed of multiples of three. At its head we have the official trio—Chancellor, Vice-Chancellor, and Chairman of Convocation, a sort of triple stigma. Then come thirty ordinary members, of whom six are

to be elected by the Crown, six by Convocation, six by the Constituent Colleges, and three by each of the four Faculties. The last arrangement is no doubt a blot on the scheme, which, however, could be easily repaired. The Faculty of Laws, for instance, might well have been thrown into the Faculty of Arts, which is henceforth to become the refuge of destitute subjects fathered by no other Faculty. The lawyers would possibly object, but surely some sacrifice might be expected of them in the interests of symmetry. The retirement of Senators is also subject to the ternary law. One third of each group of six is to retire every year, and each Senator therefore would sit for three years. Coming to the constituent Colleges, we find them arranged in groups of three: (1) Colleges occupying the entire time of the student; (2) Colleges giving lectures of the most advanced kind; (3) Colleges giving evening lectures, or otherwise not falling under one of the two preceding groups. We may add that the Constituent Colleges are to consist of bodies in or near London which are either named in a schedule settled by a joint Committee of the Senate and Convocation, or are admitted by the Senate with the concurrence of the Faculty or Faculties interested. The institutions from which the University receives certificates for degrees in medicine—in other words, the recognised medical institutions—are to retain their right of granting certificates whether they become Constituent Colleges or not.

The Faculties again are to consist of *three* groups of members: (a) Such teachers in the corresponding Faculty of the Constituent Colleges as have been admitted to the Faculty by the Joint Committee or the Senate; (b) Examiners in that Faculty during their period of office and *three* years subsequently; (c) Eminent persons, not more than *six* in number, elected by the Faculty. The duties of each Faculty would be to elect three members of the Senate, to nominate a Board of Studies, and to advise both the Senate and the Board of Studies on the subjects connected with the Faculty. Coming to the Boards of Studies, we find that the members of each Board are to number some multiple of three, not less than six, and not more than twenty-one, with one representative of Convocation added. One third of the representatives of the Faculty are to retire each year, and the representative of Convocation is to sit for three years. The main duties of the Boards of Studies would be to advise the Senate with regard to the regulations and examinations in their respective Faculties, the Senate being forbidden to act without such advice having been given; to advise the examiners; to receive the recommendations of the Faculties, to report to them, and to summon them for discussion when necessary.

The scheme, which is practically the work of Lord Justice Fry advised by a small sub-committee, has been ratified with very little alteration by the Committee of Convocation appointed to deal with the subject, and will be submitted to an extraordinary meeting of Convocation to be held on the 28th instant, the earliest day on which that very common property, the theatre of the University, is available. The proposals will no doubt be most hotly discussed in Convocation, and if they ever reach the Senate may count

on meeting with a still warmer reception there. We may prophecy without hesitation that very many members of Convocation will strenuously object to so much power being given to the Faculties and Boards of Studies, composed as they will largely be of teachers who are not graduates of the University. The scheme professes indeed to leave Convocation itself unchanged, but practically it reduces it to a cipher, a proposal not likely to commend itself to a body whose chief characteristic has always been its determination to get and keep as much power in the University as possible. But if Convocation is shorn of its importance by the scheme, the Senate is shorn much more closely. Theoretically, it is allowed to remain the governing body of the University, but practically its powers are divided and distributed amongst the Boards of Studies, which are obviously intended by the authors of the scheme to be strong bodies to whose representations the Senate will be almost obliged to defer, and without which, indeed, it cannot act.

## ESSAYS ON MEDICAL CLASSICS.

---

### VII.—HEBERDEN.

WILLIAM HEBERDEN was born in London in 1710. He entered St. John's College, Cambridge, at the age of 14, took the degree of B.A. in 1728, and that of M.A. in 1732, and became a Fellow of his College in 1730. He subsequently studied medicine both at Cambridge and in London, and graduated as M.D. in 1739. For ten years he practised physic at the University, lectured annually on *Materia Medica*, and made a valuable collection of specimens, which he presented to his College shortly after he removed to London to practise in 1749. He had been made a Fellow of the Royal College of Physicians in 1746, and in 1749 he was elected a Fellow of the Royal Society. Before long he acquired a very large London practice, and gained a high character as an eminent and liberal-minded physician as well as a learned and accomplished scholar. In 1766 he laid before the College of Physicians a design for publishing a series of "Medical Transactions." The scheme was adopted, and several of the most learned and distinguished physicians contributed papers, but Heberden's were the most numerous and prominent; three volumes of these "Transactions" appeared, in 1768, 1772, and 1785. He delivered the *Gulstonian Lectures* in 1749, the *Harveian Oration* in 1750, and the *Croonian Lectures* in 1760. Some of his papers were contributed to the Royal Society and published in the *Philosophical Transactions*, among them one on Fevers, especially the Plague, and another on the influence of Cold on the inhabitants of London. His chief works, to which he owes his lasting fame, were published separately. Of these, the "*Antitheriaca*," a short treatise written while at Cambridge, is a close and judicious enquiry into the knowledge of drugs and poisons possessed by the ancients, with the special intention of exploding the superstitious belief in the wonderful potency of the poison of *Mithridates*. But his principal work, a really glorious production, is

the "*Commentaries on the History and Cure of Diseases*," which appeared in 1802, at first in Latin, but afterwards in English; from it we obtain most of our knowledge of Heberden as a classical writer, and it forms the main source of the account which follows. Heberden practised actively in London for thirty years, and though after that he gradually lightened his labours, he did not altogether retire from practice until within a few years of his death, which happened in the first year of the present century at the ripe age of 91. There is abundant testimony extant to the excellence of his personal character. No physician was more highly esteemed. He was thoroughly virtuous and honourable; candid, sincere, and unselfish in mind, and modest and dignified in manner, he carried his varied and extensive learning without bringing down on himself the envy of his contemporaries, and used it to the best benefit of those who placed their confidence in him.

The book of *Commentaries* was written late in life. As he says of himself, he divided his life, like that of a vestal virgin, into three periods, in the first to learn, in the second to practise, and in the third to teach, by communicating to others the results of his own experience. The volume was compiled from "notes taken in the chamber of the sick, or from their attendants, and read over every month, and all points were collected thence that threw light on the history of disease or the effects of a remedy." The notes were thus put down at the time the observations were made; and so anxious was he to avoid wilful or unintentional errors, that when he had not notes at hand on which to depend, he would not trust to his memory to supply a description. For instance, he had lost the records of most of his cases of small-pox, and therefore he does not attempt to give a full history of the disease. The papers thus compiled he left at his death, "to any of his sons who may choose the profession of physic," and they came accordingly into the hands of his eldest son, who published them in 1802, a year after his father's decease. They soon became known, and were greatly appreciated, both in Britain and on the Continent, as a scientific contribution of the highest class. They are by no means a collection of merely unique and marvellous cases; the fact, indeed, that the greatest amount of attention and space is given to those diseases which are most commonly met with, testifies to Heberden's anxiety to gain an *intimate* knowledge of those single symptoms which seem of the greatest importance to the patient as well as the physician and provide the chief indications for treatment. Nor is there so much speculation on the nature and causes of disease as the title might lead us to expect; what purely scientific opinions the author might hold are rather implied than expressed. His search after causes is limited to what may be known with certainty by a shrewd and unprejudiced observer; and no conclusion is put down by him until it has been well weighed and revolved over and over again in his mind. He evidently has a great horror and contempt of mere unsubstantial or unpractical theories; he says of such, "all this appeared much more plausible when taught in the schools of physic, than probable when I attended to fact and experience," from which we may gather

that he found he had a good deal to unlearn. He is equally averse to any undue tendency towards rationalism on the one hand and superstition on the other. A good example of the former is to be found in Chap. 97 (*Ventriculi morbi*). "If we were to reason upon chemical principles, nothing seems more practicable than to neutralise and subdue an acid, to which we can immediately add whatever we think proper; but the animating principle makes so much difference between a living stomach and an inanimate vessel, that this, which appears easy in theory, has been found difficult in practice." Of the latter there are abundant examples; it is to be noticed that he always makes his attack on popular superstitions by adducing his own telling experience to the contrary, even in such a case as the influence of the moon upon insanity, rather than by *a priori* arguments. He has no ambition to construct any new system or even to offer a new classification of diseases, but accepts the nomenclature usually adopted from of old, and thus arranges his subjects alphabetically according to their Latin names. He is quite content to hold current and traditional opinions until he has tried and proved them well by experience. He does not even attempt to frame a definition, unless there was previous confusion about a term.

His aim was simply to give as clear and precise an account as possible of the natural history of each disease, and to form a reliable estimate of the value in each complaint of the remedies ordinarily employed. He was always more anxious to determine the powers and uses of familiar drugs than to abandon them in search of novelties, with the hope of finding some panacea; indeed, his experience often led him to discard many remedies which had been recommended, and that to an extent that has given him a certain reputation for scepticism. The very withholding of all the ordinary literary expedients which men employ to enforce attention is in reality the most striking feature of his book; for it helps one vividly to realise the great extent and accuracy of his observations, his weighty common-sense, and the maturity of his experience; for such qualities, indeed, the extreme plainness and simplicity of his style form the most appropriate setting. There is, in Heberden's writings, an easy flow of language, but no show of literary art; no space is wasted in straining after oratorical effect, or in dissertations on the right method to pursue. He scarcely ever indulges in any play of humour; but his descriptions are always cool, serious, sound and practical, with occasionally a very slight burst of enthusiasm. His observations are genuine and original, and his judgments independent; moreover, he always shows just the proper amount of concern in the malady, and attaches the right value to particular symptoms, without being engrossed by trifles or neglectful of anything that is serious or of importance. Hence we feel implicit confidence in him as a guide, and look on his sketches as being quite as faithful as they are attractive. His carefulness is rather amusingly witnessed where he expresses his disbelief in the occurrence of yellow vision in jaundice; "all his patients denied it except two women, whose evidence was very suspicious." A good idea of his mode of thinking and

acting is given in the opening chapter. Among the first considerations in the cure of a disease are:—  
 1. Whether it require any evacuation, according to the general belief of practical authors. 2. Whether any specific or certain remedy has been found out for it. 3. Vomiting, purging, pain and urgent symptoms may demand immediate relief. 4. In long and obstinate diseases, in which no particular remedy is found to have succeeded, it is often advisable to have recourse to the general means of strongly affecting and making considerable changes in the state of the body; in hopes by this shock of dislodging the cause of the disease. 5. Where there is no room for anything else, it is the duty of the physician to exert himself as much as possible to support the powers of life, by strengthening the natural functions of the body. He is no martinet with regard to diet: he says, "I never met yet with any person of common sense (except in an acute illness) whom I did not think much fitter to choose for himself than I was to determine for him;" "the too strict attention to fixed rules of diet and regimen hath often hurt them that are well, and added unnecessarily to the distresses of the sick." He is opposed to starvation in fevers, giving, contrary to contemporary custom, a free diet of eggs, milk, broth and jellies; he admits that for the stomach to lose all its powers so that the patient is averse to taking food is an alarming symptom; for "this death of the stomach never fails to be soon succeeded by universal loss of life." To sound practice he united sound philosophy; "some have pretended to have known too much about it (the vital principle), and been guided by their own fancies and speculations; others have overlooked the laws and powers of animal life and endeavoured to solve all difficulties by the common mechanical powers. Whatever animation be, experience has undoubtedly acquainted us with several means both of deadening and invigorating its operation. Though always trying to remove present inconveniences, the chief efforts must be made against the tendency of the disease to destroy life."

Of the contents of the book, some subjects are of especial interest—principally because the author was the first to notice or throw light upon them. Perhaps the most noteworthy are the chapters on *Angina Pectoris*, *Gout*, *Digitorum Nodi*, and *Varicella*. That on *Angina Pectoris* should be familiar to every physician, as with the exception of a slight reference to it by one of the ancients, it is the first description of the complaint, and one that it would be scarcely possible to improve upon even now. Under the heading "*Pectoris Dolor*," after mentioning the ordinary pains about the chest, he says, "But there is a disorder of the breast marked with strong and peculiar symptoms, considerable for the kind of danger belonging to it, and not extremely rare (he had seen nearly 100 cases), which deserves to be mentioned more at length. The seat of it, and sense of strangling and anxiety with which it is attended, may make it not improperly be called *Angina Pectoris*." He then describes its phenomena and its tendency to end in sudden death, and gives a series of excellent reasons, displaying sound pathology, for ranking it among the spasmodic and not the inflammatory diseases.

Under "Arthritis" there is a complete account of gout—perhaps surpassed only by that of Sydenham; for whereas Heberden holds the mirror up to nature and gives a good picture of the exterior, Sydenham gives an insight into the causes and actual process and reveals nature itself. There is a fair discussion of the question whether it is of service in removing other complaints; and there is some dry humour in his remarks about the anxiety of some people to suffer from it. Chap. 28 on "Digitum Nodi" is brief, but of historical interest, as being the first notice of Rheumatoid Arthritis. It begins, "What are those little hard knobs, about the size of a small pea, which are frequently seen upon the fingers, particularly a little below the top, near the joint? They have no connexion with gout . . . are rather unsightly than inconvenient," &c. Heberden was the first to point out distinctly the difference between chicken-pox and small-pox; the former had previously been overlooked as a trivial skin disease, or regarded as a mild attack of small-pox, and persons who had had it considered themselves, though wrongly, exempt from taking the latter. He had evidently made a careful study of paralysis, and had distinguished aphasia, which is "not due to paralysis of the organs of speech, but to the utter loss of the knowledge of language and letters." The remarks on chorea and epilepsy are also good, especially the description of attacks of *petit mal*. He was extremely judicious in his treatment of intestinal obstruction by opium. We might select many more illustrations of his clinical sagacity, his acquaintance with morbid anatomy (the application of which he did not strain), and his therapeutical resources, but for these we must refer the reader to the work itself.

N. H.

## REVIEWS AND NOTICES OF BOOKS.

*The Inhalation Treatment of Diseases of the Organs of Respiration, including Consumption*; by A. H. HASSALL, M.D. Lond.; London: Longmans & Co., 1885, pp. 367. The subject dealt with in this work has hitherto been somewhat neglected by scientific workers in this country. In America and in Germany it has been fully discussed by Solis Cohen and by Oertel, but no writer of repute has given proof of serious study of the question in any English treatise. A natural repugnance to the adoption of anything like a formulated "system" of treatment, coupled with the fact that the method of inhalation has been made use of for their own purposes by persons whose professional status has not entitled them to respect, may be looked upon as the reason for this apparent neglect. In the work which he has now brought before the profession, Dr. Hassall discusses the question in considerable detail, and emphasizes throughout the opening statement of his preface, in which he declares that much error prevails upon the laws and principles which govern inhalation. On perusal of the whole work we venture to think that the reader will conclude that there is even yet much to be learnt upon the subject. But to unlearn error is a necessary process before the truth can be arrived at, and the author does good service in directing attention to the more glaring absurdities that are perpetrated at the present time, even if his own propositions for their amendment do not meet with universal approval. In his earlier chapters he discusses at some length the mode of entrance of medicaments into the organs of respiration and the principles concerned in the volatilisation and

inhalation of these medicaments. He shows by experimental evidence that inhalation of certain drugs, such as creasote and conium, when carried out according to the official pharmacopœial directions, has no effect upon the lung tissue for the simple reason that the drugs in question never reach the lower air passages at all. They are indeed but little exhausted by the process of inhalation, as much remaining in the inhaler at the end of the sitting as at the beginning. Of steam and hot and cold spray inhalations and of the common oro-nasal inhalers he only speaks in disparaging terms in so far as lung diseases are concerned, but it ought to be borne in mind that in the vast majority of cases such remedies are only employed in the treatment of disease in the pharynx and larynx. A series of experiments undertaken to prove that volatilisation of certain substances takes place more rapidly when they are spread over a large surface and at a high temperature, are quoted in detail, and it is upon the results so obtained that the author grounds his own views as to the most effective means of inhalation. Before entering upon the description of inhalation chambers, he devotes a chapter to an account of the many and various kinds of inhaler that have been devised of late years, giving a decided preference to those which most nearly fulfil the conditions mentioned above, as favouring volatilization. It is to the advantages of complete inhalation chambers, however, that the author draws especial attention, and it is probable that the introduction of this subject forms the principal *raison d'être* of the work before us. By placing his patient in an enclosed space in which the air is charged with a definite and known quantity of medicated vapour, the medical practitioner may satisfy himself that a certain proportion of such medicament does find its way into the affected lungs. In what manner the air is best charged and to what extent such inhalation should be permitted will be found fully set forth in Dr. Hassall's work. Some important hints are given as to the use of inhalation in general, whether through small or great appliances. There can be no doubt that the apparent failure of inhalation is, in many cases, to be attributed to the manifest neglect of ordinary precautions in its use, and it would add to the value of a practical work on the subject if these precautions were even more prominently stated. From his description of the apparatus the author turns to that of the various drugs, solid, liquid or gaseous, which can be by any means introduced by inhalation into the respiratory passages. Of these he presents a list extending over 120 pages, a short account being given of the properties, composition, doses, and mode of administration of each in a style which will be familiar to students of the handbooks of therapeutics, but which does not impress the reader with the idea that its author is writing from his own experience of the drugs in question. The final section of the work deals with the various morbid conditions, upon the treatment of which inhalation could by any conceivable ingenuity be brought to bear. So various indeed would seem the resources of inhalation, that a student might well be led to wonder that any other form of treatment could be necessary in such cases. The practitioner, however, might be inclined to ask upon what kind of evidence Dr. Hassall founds his genuine belief in its value. If we may venture to answer the question from the impression left by perusal of his work, we should reply that it rests mainly upon the evidence afforded by the statements published from time to time by Dr. Ringer and his pupils, and upon the casual contributions to the medical journals of many other writers less known to the world than they. We look in vain for the indications of Dr. Hassall's own labours upon the subject. If he could tell us that he had used, say, three drugs, in a really large number of cases of phthisis under similar conditions, and had obtained definite and distinct results which he could explain on a scientific basis, we venture to think that such a contribution to medical knowledge would be of far greater value than the long and rather wearisome collection of scrappy information over which he has undoubtedly expended much hard work and attention. But as a work of reference the general practitioner will possibly find it useful, containing as it does a fund of information which is capable of practical application. We will express a hope, in conclusion, that the resources of the work will not

lead him to forget the curative influences of a form of inhalation which receives but little notice from the author, that of pure atmospheric air, medicated, compressed or rarefied only as Nature wills it.

*Surgical Operations, Part I., The Ligatures of Arteries;* by SIR WILLIAM MACCORMAC. Smith, Elder & Co., 1885.—This book forms the first part of a compendium of operative surgery. The author tells us that his object is to give a brief, but he hopes accurate statement of the manner in which the several operations may be performed, and in this object a large measure of success has been attained. The work consists of an introduction treating of the various methods of ligature, the indications for and against the procedure, the method of performing the operation, and the effect of the ligature upon the vessel. This is followed by a systematic description of the mode of operation in the case of the different arteries. The introductory section, is clearly and succinctly written, providing the student with the necessary information in as short a compass as could well be managed; the description of the operation and dressings being given, as their importance demands, with some degree of minuteness. The engravings to this section, as well as those illustrating the action of the ligature on the vessel, are exceedingly good. The author is disposed to view the double ligature and division of the vessel with little favour, unless in exceptional cases. The special part is to be regarded as exhaustive from a practical point of view, since it contains directions for the application of the ligature in every feasible position. Each artery is treated of separately, and its anatomy, the indications for its ligature, the mode of operation, and the results obtainable are detailed. The anatomical guides and relations are given with due accuracy, and the tables of collateral circulation are likely to be of special use to the student, while the sections devoted to the history, indications and results not only make the volume of use to the surgeon, but have the virtue of rendering it a real manual of operative surgery, rather than a description of operations on the dead body. The author and publishers are to be congratulated on the get up and appearance of the book. The illustrations throughout are of high excellence and utility, besides being extremely numerous. The anatomical ones are very completely explained, and many are quite original in execution. No pains have evidently been spared upon the volume, while its price puts it within the reach of every student.

*The Transactions of the Edinburgh Obstetrical Society;* Vol. IX. Sessions 1883-84. Edinburgh: Oliver & Boyd, 1884. Pp. 222.—We are glad to be able again to call attention to this volume as containing some excellent work. We do not know any obstetrical or gynaecological society that at present produces better work than that of Edinburgh. Space does not permit us to mention every article in the volume, and therefore we must restrict our remarks to the more prominent. Mr. R. W. Felkin contributes an interesting ethnographical paper on labour in Central Africa. Dr. Robert Bell writes on the treatment of uterine displacement by medicated tampons, a method of treatment which, though apparently successful in Dr. Bell's hands in relieving the patient, is yet open to the objection that it is very prolonged, and involves much local manipulation. The great paper of the volume—of which it is not too much to say that it is one of the most important contributions to obstetric knowledge that have been published for some years—is on the anatomy and relations of the uterus during the third stage of labour and the first days of the puerperium, by Dr. A. H. Freeland Barbour. Its object is more especially to ascertain the mode of detachment of the placenta and membranes, a point as to which Dr. Barbour remarks we are still quite in the dark. In this, as well as in many other matters, those who practice obstetrics and gynaecology labour under great difficulties, in that so little of the pathology of that department of medicine is based upon the actual dissection of the dead body. Dr. Barbour's paper is an account of an examination more thorough than any similar investigation that

has been made before, of puerperal uteri. It throws light upon so many points in the puerperal process that we cannot adequately represent its purport in the short space now at our disposal, but must be content with recommending it to the careful study of our readers. The volume contains three contributions from Dr. Angus Macdonald; the first, on extra-uterine foetation, containing a full account of two cases, the second on lupus of the ano-vulval region, also consisting of well described cases. The subject of this essay is further illustrated by a paper from the pen of Dr. Matthews Duncan, "On hæmorrhagic lupus of the female genital organs," and both Dr. Macdonald's and Dr. Duncan's papers are made additionally valuable by chromo-lithographs representing the morbid condition. Dr. Macdonald's third paper is a record of cases treated by him in the Royal Infirmary during six months. The idea of giving some such complete account of all the practice in this department of the hospital is an excellent one, but it is not carried out in the manner in which, from the good work Dr. Macdonald has done in the past, we should have expected. To take one point on which information is much needed at present—the effect of trachelorrhaphy. Dr. Macdonald gives five cases, but in not one of them is anything said as to the history of the patient after the operation. That the split cervix can be repaired there is no doubt; the question is, whether the patient is any the better for having this done. Dr. Macdonald's cases throw no light on this, and we are surprised that he should not see that this is the essential point, and that cases without the after-history are worthless. We find in the volume, moreover, an unpretending but valuable paper, by Mr. Skene Keith, on Emmet's operation, and a discussion thereon, in which we find that Mr. Keith and the speakers on his paper recognised the great importance of following up the cases. The general tenour of the debate was to show that the operation is of far more limited utility than some of our American brethren would have us believe. Dr. J. W. Ballantyne contributes an interesting paper, giving an account of some cases under Professor Simpson's care: a case of pyo-salpinx, and a case in which, to relieve ovarian pain, a ligature was put through the broad ligament and so tied on each side of the ovary as to constrict its vascular supply. The result was improvement in the patient's health; but as some three months afterwards she had an attack of pelvic peritonitis, the case does not tell us whether the proceeding adopted is capable of doing permanent good. We have not exhausted the volume, but as our space is limited, we must here stop. We congratulate the Society upon its production, and thank them for it.

*Osteotomy and Osteoclasia, for Deformities of the Lower Extremities;* by Dr. C. T. POORE. New York: Appleton & Co., 1884.—The author tells us that he has had considerable experience both in the mechanical and in the operative treatment of deformities, and he has no doubt of the want of a concise treatise on the subject, one in which the methods of operating and the management of the wound and limb after operation are considered in detail. The work before us is intended to supply this want and the details in question. The book is rather unequally divided between osteotomy and osteoclasia, the former receiving the lion's share, perhaps because the author considers osteotomy the better operation, and prefers this method of recording his opinion to any more definite or direct statement of his views. We must acknowledge that the subject is worked out in a comprehensive manner, which testifies to diligent study; all noteworthy cases and authorities are duly cited; so much is this the case, indeed, that the author's own individuality and experience rather sink into the background. As regards methods of procedure, we find little to criticise, provided it be right to operate at all. Whether, however, osteotomy should be performed on young children is a point open to discussion. The author gives as a criterion the amount of sclerosis, as tested by manipulation rather than age: "If, by the use of moderate force (and by moderate is meant *not* enough to cause any pain) the bone is felt to yield or spring, it is safe to conclude that the bone has not become hard. . . . If the bone does not yield, the sclerosis has advanced so far that

mechanical treatment will fail." Osteotomy is indicated, he thinks, when the bones have become hard, and in certain cases also which have become partially sclerosed. We have no doubt that many cases of rickety deformity right themselves slowly long after sclerosis, as measured by our author's test, has set in, and we have been led to adopt this view by carefully watching cases for many months, even for years, in which an operation has been refused by the child's friends, and we have seen both genu valgum and bow legs gradually straighten, without even the use of splints or other mechanical apparatus, after expressing an opinion that an operation was necessary. The reason why parents are often so indifferent to deformities of the legs in their children may be distinctly traced to the popular tradition that "they grow out of it in time." Our author himself lays stress on the frequent association of relaxed ligaments, and, strangely enough, regards this condition as indicating osteotomy. We agree with him "that the practice of compelling children to wear mechanical appliances for the relief of knock-knee for years is cruel." Our own reason and his probably do not accord. He considers them useless, we consider them needless. Better than either osteotomy or mechanical appliances is good general treatment—internally, good diet and cod liver oil; externally, manipulation and shampooing. If the social status of the patient permits it, a sojourn at the seaside will often work marvels for young children under five or six years. In saying this, we do not condemn the practice of osteotomy—quite the contrary; for young adults, even for elder children, it is an operation of the greatest value, and one we have practised many times during the past eight or nine years. With osteoclasia, however, despite its antiquity, we have little or no sympathy; we have seen complicated instruments giving immense leverage fail completely to break the bone even in children, and for deformities of this kind osteotomy on every ground appears to us to be preferable to it. For deformities arising from ankylosis of joints, we equally prefer osteotomy, for after *redressement brusque*, especially of the hip or knee joints, serious constitutional disturbance, ending fatally, has been not infrequently reported. Osteoclasia may answer well enough in some cases of badly-united fracture, but, as a rule, a small subcutaneous osteotomy allowing the surgeon to attack the deformity in the most advantageous manner, and requiring neither force, nor bruising of soft parts, is for all reasons to be commended. The work is well published, and illustrated with neat drawings.

*A Practical Treatise on Fractures and Dislocations*; by F. H. HAMILTON, M.D. 7th edition. Illustrated with 379 woodcuts. London: Smith, Elder & Co., 1884, pp. 1,005.—Since the first edition of this work appeared in 1859, it has rapidly advanced in public estimation, and has long been considered as the most exhaustive and most reliable work on the subjects of which it treats. The first two-thirds of the book are devoted to fractures, and here every possible variety is considered seriatim. Frequent references to recorded cases are made in each of the chapters, in which the reader gets not only the author's own experience and views, but a *resumé* of those of other authorities also. The last chapter is especially devoted to gunshot fractures. Possibly from the fact that it is very short, the author has been obliged to be rather dogmatic, and on this account it is less thorough and less good than many of its predecessors. Drawings of the vertebra, showing the course of the bullet which caused President Garfield's death a few years ago, are given in this new edition, as well as an account of the autopsy. The same thoroughness is displayed in the second part, in which dislocations are treated. The first chapter deals with general considerations—nomenclature, causes, symptoms, pathology, prognosis, and treatment. Then follow chapters on the individual joints; that on dislocations of the hip joint being specially worthy of perusal. It is in this subject that we are specially beholden to American surgeons for the most important advances that have been made, and when the subject is read side by side with the older teaching, and the past and present methods of treatment are contrasted, the immense superiority of the latter over the former—

persuasion instead of force—becomes at once evident. The last chapter deals very thoroughly with the interesting but obscure subject of congenital dislocations. The work is well printed, and embellished with many drawings, which add greatly to its teaching value.

## ABSTRACTS AND EXTRACTS.

### KRAUROSIS VULVÆ.

MR. LAWSON TAIT writes to us as follows with regard to a paragraph which appeared in this department of the journal last week:—The disease which Professor Breisky has described under this term is not one which, as he imagines, has not been previously described, nor is his statement true that as to its course and termination nothing is known. If you will kindly reproduce in your columns the following account of the disease, which I have given at p. 43 in the first edition of my book on "Diseases of Women," published so long ago as 1877, you will, I think, see that I have not only described it, but have also included many facts which Dr. Breisky seems to have missed. The termination of the disease is always in spontaneous cure, and is arrived at simply by the traversing, over the whole surface of the nymphæ, of the disease which I have described. The disease may be relieved in many ways temporarily, but time alone effects the cure.

"The nymphæ are also subject to a peculiar degenerative and atrophic change, which occurs only at or after the climacteric period. It is a very distressing complaint, and one of the most intractable with which we ever have to deal. It is very often, but by no means always, associated with vascular caruncle of the urethra, of which I shall speak further on. This affection has been alluded to by Simpson, and various other authors, but no description which I have seen includes all the facts that may be observed in connection with it. It is always confined, in my experience, to the mucous membrane on the inner surfaces of the nymphæ, and is never met with in the labia majora, or in the vagina higher than the vestibule. It is a very frequent cause of the total suspension of marital intercourse, and is the real disease existing in a large number of cases of so-called vaginismus, a term which is widely used as a cloak to cover ignorance and carelessness. A patient suffering from this disease will nearly always be found to be over 40 years of age, and she will state that she has a slight yellow discharge, a good deal of scalding when she passes water, and that she suffers excruciating agony on any attempt at intercourse. This latter is always the first symptom in date; and when a case comes under the notice of the gynæcologist it will generally be found that intercourse has been discontinued for many months, if not for several years. The misery is very great, and a great deal of the climacteric drunkenness, too common among women, is due to this disease. When the labia are separated and an inspection made, one or two spots of redness on the mucous surface of the nymphæ will be observed, varying in colour from a palish brick-red to a bright purple; and if these be touched they will be found to be exquisitely tender. If very carefully observed in a chronic case, these spots will be found to be very slightly below the level of the normal mucous membrane. If a case be watched for a long time, it will be found that the spots are transitory and spreading, that after lasting for some months, the red colouring either entirely disappears from the spot observed, and comes out at another, or extends serpigginously, disappearing from the old site as it progresses towards the new. This process is very slow, but it explains the intractable nature of the disease, which is seldom content until it has passed over the whole mucous surface of the nymphæ. During its progress, the vestibule of the vagina slowly contracts, until as in the case of a widow lady now under my care, it may be so reduced as barely to admit a finger, even though the

patient has borne several children. In her case the disease has been going on for nearly six years.

"In one instance I was enabled to remove a fragment of mucous membrane, containing a patch of this vascular change, and I found enough to display the pathology of this mysterious disease. I placed the fresh fragment in my freezing leptotome, and having stained the sections by hæmatoxylin, silver lactate, gold perchloride, and carmine, I found that at the site of the spot all the textures had been removed save a few fibres, the walls of the capillaries, and the superficial epithelium, under which the loops of capillaries with thinned and dilated walls lay almost unprotected. The gold staining also showed nerve fibres, which lay amongst the capillaries almost as unprotected. These observations explain the three chief clinical facts of the disease, the great pain, the abnormal vascularity of the spots and their tendency to bleed when touched, and the contraction of the surface in the third stage. It is, in fact, a progressive atrophy of the mucous membrane, the last textures affected being the blood-vessels and nerves; for when the process has been completed the pain ceases, the redness disappears, and nothing remains but a vestibulum vaginae so narrow that incredulity may be excused when the patient states that she has borne children. I have been fortunate enough in two cases, one of which furnished the specimen described, to watch the complete course of the disease, almost from its commencement to its perfect recovery, and I have seen all the stages described. This experience is rare, because the patients suffer so much, and they see so little prospect of cure, that they generally wander about from one gynaecologist to another, until the degenerative process works its own cure. Great relief is obtained, though only temporary, by the application of strong carbolic acid to the red spots. The acid is a powerful local anæsthetic, and it never fails to mitigate the tenderness for a time. The application of a plug of cotton-wool, soaked in a saturated solution of neutral acetate of lead in glycerine, placed between the nymphæ at bedtime, is also generally successful in procuring some relief. The patient should always be informed that the progress of her disease will extend over years, that it will certainly get well in time, but that treatment from time to time will give her relief. She seldom retains this belief for any length of time, for it is the misfortune of gynaecologists that the diseases they treat are generally so chronic in the courses they run, that the patients wander about and rarely give any one practitioner a very prolonged trial."

#### POISONING OF AN INFANT THROUGH THE MILK OF ITS MOTHER.

PROF. BROUARDEL has recently (*Revue de Thérapeutique*, July 1) communicated the following interesting case to the Society of Legal Medicine. A man was charged with poisoning, by means of arsenic, his wife and his infant, whom she was then suckling. The child had died with the symptoms of cholera some days after its mother had herself manifested analogous symptoms. As this occurred during hot weather, the occurrence did not arouse suspicion until November, when the woman and her mother, who lived with her (and whose money the man was charged with endeavouring to obtain by forgery), were both attacked with choleraform symptoms. A paper containing white arsenic was also found in the pocket of the accused. As the death of the infant was now canvassed, Prof. Brouardel caused its coffin to be brought to Paris about six months after its burial. The body having been entirely converted into fatty matter, so that isolation of the viscera was impossible, it was submitted to analysis *en bloc*. Weighing about two-and-a-half kilogrammes, it yielded five milligrammes of arsenic, which certainly did not proceed from the linen in which the body was wrapped, or the soil by which the coffin was surrounded. The question now arose, whether the arsenic was eliminated by the mother's milk; and as the possibility of this had never been sufficiently investigated, Dr. Pouchet undertook some very conclusive experiments. He administered to some of the nursing mothers in the St. Louis Hospital, who had diseases of the skin, from six to twelve drops of Fowler's solution,

and found that their milk always exhibited a relatively considerable quantity of arsenic. For example, the milk of a nurse who had taken eight milligrammes of arsenic for six days, was found to contain one milligramme in 100 grammes of milk. In such doses neither the nurses or the infants exhibited any symptoms. But it does not follow that the same result would have followed had the arsenic been exhibited in a single considerable dose. The endeavour to ascertain this by experiment on sucking animals did not furnish any conclusive results, owing to the great difference in susceptibility to the action of arsenic, so that no conclusion obtained could be applied to the human subject. At all events these investigations show that the lacteal secretion is a predilectory channel of elimination for arsenic, and that it is imprudent to administer it to nursing women. The man was sentenced to 20 years hard labour.

#### VALUE OF ICE IN CONGESTIVE CHILL.

No one, writes Dr. L. B. Anderson, doubts the value of ice, externally applied, in active congestion of the brain, various hæmorrhagic states, and in local inflammations. But its value in congestive chill seems to have escaped the observation of the profession. A fully developed congestive chill is as insidious as it is alarming, and when improperly treated, fatal. The whole surface, with an occasional exception of the chest and epigastrium, is as cold as death, and bathed in a profuse perspiration. The pulse soon ceases to beat at the wrist, and the pulsations of the heart are frequent and feeble. The respiration is short and hurried, with an occasional sigh. Sometimes both the respiration and pulse are slow and feeble. The surface becomes mottled with the irregular accumulation of dark venous blood in the cuticular capillaries. The countenance is variable: sometimes it is calm and serene, the eye expressive of no emotion, and the patient sinks into the sleep of death, as if falling into a calm repose; at other times, great restlessness, anxiety, and suffering may exist. Often one who is reduced to the verge of dissolution and recovers, is perfectly oblivious of what happened during all this period of congestion, though he seemed to be perfectly conscious all the while. Accompanying the congestion there is, sometimes, a diarrhœa (always very unfavourable), at others, nausea, and occasionally, when the lungs are peculiarly implicated, pulmonary hæmorrhage. Whatever agent may produce a chill—and there are hundreds which may under favourable atmospheric and hygienic influences—there is always a suspension of the functions of the organic nerve-centres, whereby secretion is suspended, the circulation is impeded, and there is an accumulation of an abnormal amount of blood in the vessels of the internal organs, and a diminution in those of the surface. The vital processes being suspended by a torpid condition of the nerve-centres which preside over these functions, the various constituents of the blood are massed in a heterogeneous conglomeration, and chemical forces come into vigorous exercise, generating every conceivable morbid product, from the simplest salt or acid to the most deadly ptomaine. In the meantime the evolution of heat from these rapid chemical changes increases the centripetal action, and hastens the march to a profound congestion. The use of stimulants, anodynes, or narcotics is calculated to increase the trouble and lessen the chances of recovery. Ice poured into the great central reservoir, the stomach, rapidly absorbs and renders latent the superfluous heat, gives tone to the exhausted nervous centres, sets free the pent-up nervous forces, puts in motion the torpid vessels, restores the vital forces, and thus equalizes the circulation.—*Therapeutic Gazette*, June.

#### DISEASES OF CHILDREN.

SCURVY IN A CHILD.—Dr. Jones Bateman, in the *Birmingham Medical Review* for July, records a case of infantile scurvy. The patient was a female child, aged six, who had always been delicate. Her habitual diet had always been bread and butter and tea for breakfast and tea, and bacon and bread for dinner except on Sunday, when she had

meat for dinner, though sometimes in the shape of salt meat; she never had fruit or fresh vegetables. On admission she was noted to be small for her age, and presented signs of past rickets. Her gums were red, spongy, and bled on the slightest touch; there was an ulcer on the inner side of her cheek and another on one tonsil. Her arms were much swollen about the elbow joints, the skin being tense and presenting the characters of a recent bruise. A somewhat similar condition was found in the popliteal spaces, a few petechiæ were scattered over the body, and her eyelids were much swollen. She improved for the first four days, but she then became very quiet, and would not take her food, and her temperature sank in a remarkable way, being at one time as low as 93.4°; this condition lasted about twenty-four hours, she then passed two motions slightly stained with blood and began to improve. After this she had an attack of cancrum oris of the lower lip, which was checked by three applications of strong nitric acid; the ulceration of her gums was not finally cured until she had had fourteen teeth extracted. A tonic line of treatment was adopted throughout, but the only thing that seemed of much service was alcohol. At no time was any blood or albumen present in the urine. The author thinks the diagnosis of scurvy justified by the absence of serious hæmorrhages, and by the fact that the diet had been entirely wanting in potatoes and milk.

**THE TREATMENT OF CHOREA.**—In a clinical lecture on the treatment of chorea recently published in the *Progrès Médical* (No. 24), M. Joffroy strongly advocates the use of hydrate of chloral. His first experience of it was not satisfactory; he treated two children suffering from severe chorea with large and repeated doses for four or five days keeping them in a deep sleep during nearly the whole time, but without any material benefit. He then took to giving it methodically three times a day, in regular doses, and considers that he has obtained excellent results by this method. For children over ten, the daily dose should be sixty grains; for those under that age this should not exceed forty-five grains. Seeing that he speaks of having continued the drug sometimes even for two months, and that he admits that in the severest cases the drug has proved of no service, it is evident that even in his hands chloral has not shown itself to be of more service than the thousand and one drugs which have already been recommended for this disease. In the severest cases M. Joffroy has found wet packing of great service.

**ACUTE GASTRO-INTESTINAL INDIGESTION.**—When an infant who has previously appeared to be in good health shows symptoms of indigestion, it must be determined whether these symptoms are due to a catarrh or other affection of the alimentary canal, or merely to some error of diet. The latter is the cause, according to Dr. J. M. Keating (*Archives of Pediatrics*, May), when the child's tongue is perfectly clean, and there is no stomatitis and no fever. On the other hand, if there is fever and the tongue is coated, the bowels being distended and the motions offensive and slimy, change of diet will not suffice to restore health. Something must be done in addition to this. The quantity of food may, with advantage, be lessened, the feet may be put into hot water, and the gums lanced when there is any indication, but the main object of treatment is to evacuate the contents of the alimentary canal; this is effected by small doses of calomel, and especially by promoting vomiting, for which purpose nothing is better than to encourage the child to drink plentifully of warm water. A spice poultice to the abdomen is strongly recommended, and if any sedative is necessary Dr. Keating thinks that there is nothing superior to one or two drops of sweet spirits of nitre. In the after treatment pepsin is found useful in some form or other as well as cinchona and nuxvomica, and in older children arsenic is thought highly of.

**THE KEEPING WARM OF PREMATURELY-BORN CHILDREN.**—Credé, of Leipzig, describes in the *Archiv für Gynäkologie* (Band xxiv., Heft 1) a warming cradle or box, in which premature children can be kept and their heat maintained. It is a sort of miniature bath, made of copper, with double sides and bottom; and between the two walls is a space for hot water, which is poured in

above, and let run off by a tap below. The hot water is renewed every four hours. This machine has been in use in the Leipzig Lying-in Institution for more than twenty years. Every child weighing less, or only a little more, than 2,500 grammes (about 5 lbs.) has been put into it. The result has been, that out of 677 children so treated (excluding 24, who weighed less than 1,500 grammes), only 97 have died, or 15 per cent. The average mortality of children in the same class in other institutions, where no warming apparatus was used, Credé estimates at 65 or 66 per cent. This was the mortality at Paris. Now, in the Paris Maternité and Cochin Hospitals, Auvard's couveuse is used, and children under 2,000 grammes put into it. The mortality has fallen to 38 per cent. Credé's mortality, for children under 2,000 grammes, with his warming box, is 36 per cent.

**THE RELATION BETWEEN GONORRHOEA AND OPHTHALMIA NEONATORUM.**—Drs. Leopold and Wessel, contribute to the *Archiv für Gynäkologie* (Band xxiv., Heft 1) a paper which, if the facts contained in it are confirmed by other observers, is a very important one. That the ophthalmia of the new-born is due to inoculation of purulent discharge from the mother's vagina is commonly accepted. It is also commonly believed that it is next to impossible to be positive whether a purulent vaginal discharge is gonorrhœal or not. Leopold and Wessel have not been content to rest in this inexactness. In 18 cases of pregnant women with purulent vaginal discharge they examined this secretion for the gonococcus of Neisser. In 17 of them none were present; no precautions were taken to prevent the infants of these 17 from getting ophthalmia, but none of them suffered from it. In one case Neisser's gonococci were found without doubt; the child of this woman on the fourth day had ophthalmia. These researches go to show that we have in the gonococcus of Neisser a certain test of gonorrhœa; and that gonorrhœa is the actual and true cause of ophthalmia neonatorum: two general propositions, which, if corroborated, are distinct strides in our knowledge.

**OPHTHALMIA NEONATORUM.**—In a paper on this subject read before the Staffordshire Branch of the British Medical Association (*vide Ophthalmic Review*, June), Mr. Vose Solomon proposes that the mother should be supplied prior to her confinement with the materials for an eye-lotion, with all needful directions for its use. Every order for the parish midwife should be accompanied by a packet containing sixty grains of alum, and bearing the following label: "LOTION POWDER FOR THE BABY'S EYES.—Directions.—Dissolve this powder in a pint of clean water. Directly you see matter come from the baby's eye, clean it away every two hours with a bit of wool or rag, and then thoroughly wash the inside of the lids with the lotion. If the eye looks weak and does not matter, use the lotion every four hours. Get a doctor as soon as possible. Eyes that matter, if neglected, often go stone blind." He thinks that by this plan public attention would be drawn to the disease, and thus this preventible malady might ultimately be stamped out.

---

## REPORTS OF SOCIETIES.

---

### OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

FRIDAY, JULY 3RD, 1885.

JONATHAN HUTCHINSON, F.R.S., President, in the Chair.

#### *Living Specimens.*

MR. MARCUS GUNN showed a patient with symmetrical enlargement of the upper half of the face, with proptosis, optic atrophy, and anosmia. The patient was a female, aged 22, married. About 11 months previously, neuralgia in both temples and vomiting set in, when she was two

months pregnant with her first child. The neuralgia continued. The sight of the left eye began to get dim two months before her confinement in February last. Two days before the birth of the baby, she became quite blind in the left eye, and remained so for one month, when the vision gradually improved until June 5th, when she again became suddenly blind in this eye. The day after the birth of the baby, she became suddenly blind in the right eye, and continued so for a fortnight, when the vision of that eye steadily improved. Two months before confinement, the face became slightly swollen, and the eyeballs prominent; these symptoms considerably increased. The patient had objected to see anything of a blue colour. There was no history of fits or syphilis. She was very pale and puffy, with considerable prominence of both eyeballs, and swelling of the upper part of the face, very marked in the eyelids. The deformity of the face was bilaterally symmetrical. There was apparently some thickening, and marked tenderness over the whole of both superior maxillary bones, and over the ramus of the jaw on both sides, and especially near to the zygomatic processes. There was complete anosmia. Pupils of medium size, right active to light, left barely so. Both optic discs atrophied; the veins large and rather tortuous. No albuminuria. Patella-tendon reflex was normal. Facial paralysis had set in suddenly that day (July 3rd). Antisyphilitic treatment had been of no avail.

Mr. LANG showed a mother and son in both of whom the iris on both sides was totally deficient; both patients had lateral nystagmus; the mother had a lamellar cataract in the right eye; the right eye had been cataractous, and had been operated on unsuccessfully; the child had striæ in both eyes. The mother had had two other children; the second had aniridia; the boy shown was the third.

Mr. LANG also showed a child who had first come under his care when 16 months old in March 1882; the right eye was then excised for glioma; the left appeared healthy, but, in January, 1884, the patient was again brought with a growth in the left eye in the front part of the retina at the inner side; a secondary growth subsequently developed in the episternal notch.

Mr. LAWFORD exhibited microscopical preparations of a tubercular deposit in the choroid, obtained from the right eye of a child, aged 5 years. The growth had been observed with the ophthalmoscope during life, as a yellow patch surrounded by a grey halo in the yellow spot region, and a sketch made of it. The child died of tubercular meningitis; and at the necropsy, miliary tuberculosis of the lungs, heart, and liver was found. Microscopically, the nodule in the choroid presented all the evidences of tubercle, except the presence of the bacillus tuberculosis, which, though carefully looked for, was not proved to be present. Bacilli were easily obtained in specimens of the meninges taken from the base of the brain of the same patient.

#### *Reflex Ophthalmitis.*

The PRESIDENT, before inviting discussion of his paper, read on May 14th, briefly recapitulated the chief theories which had been put forward:—1. That there was a disturbance of a hypothetical trophic centre for the eyes. 2. That there was a progressive neuritis advancing from one eye to the other along the optic or ciliary nerves or their sheaths (or the lymph-spaces). 3. That the infective agent was transferred by the blood-circulation and became active in the eye either because it was arrested by the small size of the capillaries and the favouring influence of light (Berlin), or because the infective elements found a suitable nidus in the tissues of precisely similar character in the fellow organ. Professor Berlin's theory predicated the existence of germs, his own did not.

Mr. HENRY POWER, after dwelling on the great interest and importance of the subject raised by the President's paper, criticised the views put forward in it, on the ground that many facts were left unexplained. How were the greater frequency and rapidity of the disease in children than in adults to be accounted for? Wounds of the ciliary region were much more apt to produce sympathetic ophthalmia in children than in adults; he had been accustomed to attribute this to their restlessness, the wanton removal of bandages, and the difficulty of keeping young

children in a dark room for many weeks. He thought that there was strong evidence that sympathetic ophthalmitis was an extension from the original disease. It was true that a very considerable interval might elapse; this was a difficulty on either theory. He quoted one case of foreign body in the eye (a rivet impacted in the optic nerve), where, for twelve years, frequent attacks of inflammation occurred. How was it that this patient could go about for so long without suffering from more than slight sympathetic ophthalmia? He also referred to cases of relapse after apparent recovery from sympathetic ophthalmia. These occurrences appeared to be explicable upon the theory that the inflammation travelled along nervous tracts better than by the theory advanced by Mr. Hutchinson.

Mr. SPENCER WATSON thought that an objection to the theory was, that other sense-organs did not suffer from sympathetic inflammation. The only example of sympathetic inflammation occurring elsewhere than in the eye, was the occasional occurrence of inflammation sympathetically in joints. The eye was the only sense-organ where the anatomical arrangements afforded a ready channel for the transference of inflammation by continuity of tissue. He did not agree with Mr. Power that sympathetic ophthalmia was more common in children than in adults; children, he thought, bore wounds of the ciliary region better than adults.

Dr. NOYES (New York) observed that the active theory of the day was the theory of propagation by bacilli. All the theories fell under one of three categories: the spread of the disease was set down to the agency either of nerves, of lymph-channels, or of bacilli. All these theories were so wanting in any sound scientific basis, that he was not ashamed to say that he had not arrived at any final opinion. It was necessary to recognise that sympathetic ophthalmia occurred under various conditions, and to distinguish clearly between sympathetic irritation and true sympathetic inflammation. The theory which attributed sympathetic inflammation to the agency of bacilli, taught that if the first eye were septicly infected, the second eye if it became affected became the seat of sympathetic inflammation; whereas, if the first eye were not affected by a septic inflammation, then the second eye suffered sympathetic irritation. He referred to cases of trigeminal neuralgia accompanied by herpes zoster ophthalmicus, where the eye of the affected side was lost with subsequent sympathetic affection of the other eye. An objection to the nervous theory was that wounds of the ciliary region were not invariably followed by sympathetic affection. He quoted a case in which a foreign body had remained in front of the iris for nineteen years, and referred to other similar cases; but, as a contrast, he mentioned a case in which a piece of percussion cap was impacted in the iris. After some years of quiescence, atrophy of the lens occurred, and coincidentally neurotic irritation of the other eye. In other cases, the bony shells found in damaged eyes set up neurotic irritation; the removal of the shell was followed by recovery. A shrunken eyeball might be very sensitive, and yet no neurotic irritation might ever be produced. He had observed two cases in which the removal of the cicatricial tissue at the apex of the orbit was followed by a relief of the sympathetic symptoms of the other eye. It was true that excision of a portion of the optic nerve was not always successful, but V. Graefe used to perform subcleral division of the ciliary nerve with success. He especially desired to urge that, before resorting indiscriminately to excision of the eye, the possibility of saving the eye with useful vision should be fully discussed. He felt that he hesitated much more now than he formerly did in advising excision.

Mr. NETLESHIP said that of all the theories that of blood infection accounted for some of the phenomena of the disease more easily than any other, e.g., the simultaneous appearance of changes, such as neuro-retinitis or iritis in widely different parts of the eyeball. The difficulties in the way of accepting the theory were, that upon it was hard to understand how the incubation period could ever be so long as it sometimes actually was, or why the disease should break out in the sympathising eye at a considerable interval after the removal of the infecting eye. Two other questions might be asked which would perhaps tell as much against as for the theory under consideration. How could ex-

ceptional but well attested cases be explained in which parts outside the eye, such as the eyelashes, underwent organic change in the course of sympathetic inflammation? and how was it that the exciting eye might be but slightly damaged though the sympathising eye suffered profoundly, even to total blindness? The severity in the sympathising eye must depend upon the number of germs which it contained; if these were bred in the exciting eye, why did it not suffer in proportion? On the other hand, if they were not simply carried by the blood, but multiplied in it, how did the other tissues of the body escape serious change? As regarded the transmission theory, there were difficulties in regard to all the paths along which the disease had been thought to travel. Deutschmann's view that septic inflammation was conducted along the optic nerves met with a certain amount of support from clinical facts. Failure of sight, papillitis, or papillo-retinitis were, for instance, among the earliest phenomena of the disease, and in cases of traumatic inflammation of the eyeball it had been proved that inflammation could travel up the optic nerve. But iritis or keratitis punctata had been present in all cases, or nearly all, which had shown early retinal or neural changes, and all these phenomena might be accounted for upon the supposition of inflammation of the choroid. The clinical proofs that were required in support of this theory were that the changes should appear at the disc some time before they were seen in other parts of the eye, and that failure of vision should precede the other visible alterations. Again, according to the transmission theory, basic meningitis ought sometimes to be seen as a sequel. In mild cases too, on the optic nerve theory, the disease should sometimes be confined to the optic nerve, but except, possibly in a case of Dr. Brailey's, this was hitherto unknown. Again, in retrobulbar neuritis there was no evidence that the inflammation ever spread upwards to the other eye, though it went downwards to the disc on the same side. The chief objection to the theory of transmission along the filaments of the fifth or sympathetic nerves was that the path would be so very long and narrow; the nerve twigs were so very difficult to examine that it was easily to be believed that inflammatory changes in them might escape detection.

Dr. MILES thought that sympathetic irritation and inflammation, though they had some symptoms in common, ought to be separated. The connection between them was that the former dilated the lymph-spaces, and so allowed the more easy transit of infective elements. As to the difficulty raised with regard to the long interval between the injury and the sympathetic inflammation, he did not think that that was conclusive against the bacterial theory. It was not known how long a period might be necessary for their passage along the lymph-spaces. He was unable to say whether the micro-organisms must be invariably introduced from without.

Dr. BRAILEY compared the evidence in favour of the President's view with that which seemed to support one of the most recent and plausible of the other views, the theory of direct transmission along the substance of the optic nerve or the sheath space around it. In favour of the former was the fact that cells from a choroidal sarcoma were transmitted through the blood to other organs, such as the liver. But, on the other hand, he knew of no instance in which they had lodged, and produced a sarcoma in the choroid of the opposite side. Similarly, a purulent ophthalmitis might produce a purulent meningitis without any direct continuity, but it did not produce a purulent choroiditis of the opposite side. Again, there was some little physical evidence in favour of direct transmission, namely, the finding of inflammatory cells after enucleation in the loose tissue between the nerve-sheaths; there was also the case recorded by Snellen, where an injury to one eye resulted not only in sympathetic disease of the other, but also in total deafness, with every symptom of acute meningitis; and, finally, the experiments of Deutschmann, who produced papillitis of the one eye by injections into the vitreous of the other eye.

The PRESIDENT said that the arguments used had not convinced him that his theory was untenable, though he was not prepared to adopt it strongly. It was a theory that was applicable to other diseases, such as multiple periostitis. He agreed with Dr. Noyes that excision of the injured eye after the development of sympathetic inflam-

mation did no good, and ought not to be performed if there was any hope of useful vision in the injured eye. The occurrence of relapses was not conclusive against the theory, for inflammation in any situation might recur when an organ recovering from inflammation was again exposed to irritation. With regard to the argument used by Dr. Brailey, it was to be noted that occasionally a malignant growth of one eye did recur in the other. The sequence of the development of secondary growths in cases of malignant disease was very irregular; the intervals were sometimes very long; further, it was not safe to argue from the behaviour of one class of morbid element what would be the behaviour of another, for instance, from the behaviour of malignant elements to that of inflammatory elements. His own experience did not lead him to agree with Mr. Spencer Watson that children were less liable than adults to sympathetic inflammation.

As this was the last meeting of the session, two papers, one by Mr. Critchett, on a case of Extreme Retinal Irritability; and the other by Dr. Walter Edmunds and Mr. Lawford, on the Pathological Anatomy of Optic Neuritis, were taken as read.

#### *Annual General Meeting.*

The business of the Annual Meeting was then proceeded with.

The Secretary read the following Report of the Council:—

"The Council have again to congratulate the Society upon its continued prosperity. During the Session eighteen new members have been elected, so that the total number is now 202, including 25 non-resident members.

"Since the last annual meeting the Society has lost two members by death, viz., Drs. Buchanan Baxter and F. A. Mahomed. One resident and three non-resident members have ceased to belong.

"The Council recall with satisfaction that early in the Session Sir William Bowman was elected unanimously an honorary member of the Society.

"The first Bowman lecture was delivered by the President in November, and at the request of the Council Dr. Hughlings Jackson, F.R.S., has consented to deliver the second lecture.

"The Library now contains considerably more than a hundred volumes, nearly all of which have been presented to the Society. The Council recommend the appointment of a special officer as librarian to take charge of it in the future.

"A deputation of the Society, consisting of the President, Sir William Bowman, Bart., F.R.S., Mr. John Tweedy, Dr. D. McKeown, Dr. Brailey and Dr. Abercrombie waited on Mr. G. Russell, M.P., at the Local Government Board office on May 8th, to urge upon that Board the necessity for adopting some measures for the prevention of blindness from ophthalmia neonatorum. The deputation was very well received, and though no action has as yet been taken, there is reason to believe that some good may result.

"During the Session a considerable number of papers have been communicated, and the meetings have been well attended.

"The Committee appointed to consider some points in connection with sympathetic ophthalmia has sifted a large mass of evidence, and it hopes shortly to be in a position to present a report."

The Treasurer then presented the balance sheet duly signed and audited. The income of the Society had amounted to 256*l.* 17*s.* 0*d.*, exclusive of Sir Wm. Bowman's gift, and a balance of 379*l.* 13*s.* 1*d.* had been carried forward.

The adoption of the report and balance sheet was carried *nem. con.*

The following resolution was then proposed from the Chair:—"The Council has had under consideration the peculiar and much regretted circumstances under which Mr. James Adams's active connection with the Society has come to an end. Remembering Mr. Adams's great services to the Society in the past, the Council recommends that he now be elected a Life Member without any payment of Composition Fee,"—and carried by acclamation.

The alterations in the Rules proposed by the Council were unanimously accepted.

The list of officers and Council elected for the Session 1885-6 will be found on another page.

## GENERAL CORRESPONDENCE.

### "HOW IS IT WITH THE PROFESSION?"

[To the Editor of the Medical Times.]

SIR,—Your article of July 4th must have been warmly welcomed by many a country practitioner. It is seldom an attempt is made to feel the professional pulse throughout the land.

For London's physicians and leading men it would seem to be enough that the great heart of medical science beats with constantly renewing vigour, that the stream of knowledge and reform is for ever flowing *somewhere*. Whether the tide ever reaches the distal vessels or not would appear to be a matter of little consequence.

To those who have been many years in country practice, this indifference respecting provincial doctors may pass by unheeded; but the younger members of the profession feel that it is rather hard to be so severely let alone. For my part, I think we need not seek far to find a reason for the apparent callousness of the profession concerning this neglect. We are indeed impotent because so little noticed. We went to the Hospital crude and unformed; we left it useful scientific men. But there our connection with the great centre is at an end. We are the creations of a governing body, not members of a self-ruling fraternity. We trusted to Medical Councils to form us in the past; we must leave them uninterrupted power to rule us in the future. And so, finding our bucolic ideas are not wanted, we turn back to our work—work that is often worse than drudgery. Yet our burden might be somewhat lightened if we could know and feel that our own voices could influence our own welfare—that our affairs were no longer in the hands of those who, however anxious to raise the standard of medical education, are leaving a large and useful section of the profession out in the cold.

I am, Sir, yours, &c.,

G. P.

## INVENTIONS AND IMPROVEMENTS.

### NEW SOUND DEADENER.

By J. WARD COUSINS, M.D. Lond., F.R.C.S.

THE little instrument devised for this purpose consists of an elastic air cushion, and is made in several sizes, to suit the varying capacity of different ears. As a sound deadener it powerfully modifies and reduces the intensity of sonorous vibrations, but it does not altogether suspend the sense of hearing. It can be instantly introduced into the aural orifice, and the deadening power can be regulated by the degree of firmness with which it is put in. It is very neatly made in flesh-coloured vulcanite by Messrs. Maw, Son & Thompson. The Sound Deadener has proved an excellent ear protector for artizans and other persons exposed to the injurious effects of sound. It is a matter of common observation that deafness is intimately associated with noisy occupations, and although individuals placed under the same conditions exhibit very different aural susceptibilities, still, as a general rule, persons who are exposed for a long period to loud and harsh sounds are sure to suffer more or less injury. At the present time, about three hundred men are employed as boiler-makers and riveters at the Royal Naval Yard, Portsmouth, and out of this number very few can be found in possession of normal hearing power. As a general rule the men appear remarkably indifferent about their aural insensibility, and some even regard their deafness with satisfaction, as it reduces the distress caused by the constant concussion on the tympanic membranes. The Sound Deadener is also an excellent ear protector for swimmers and divers, and for all who suffer from aural

disturbance after bathing. It forms a shield which effectually prevents the entrance of water into the ear, and, when used for this purpose, it has proved invaluable to many patients labouring under aural delicacy and chronic disease. It has also been worn with great comfort by many suffering from abnormal aural sensibility, associated with general nervous depression and debility; and by railway travellers and other persons unable to sleep in consequence of the disturbance and confusion produced by continual noise. It can be used as an ear protector during exposure to the blast of explosives, or severe cold or wind; and it forms an elegant substitute for the old-fashioned and unsightly plug of cotton-wool.

## MEDICAL NEWS.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Thursday, July 9th. The minutes of the Extraordinary Council of the 3rd instant were read and confirmed. Mr. Savory, having been introduced, resumed his seat as a Member of Council. The name of Mr. Francis Goold was ordered to be removed from the list of members. Mr. Clarkson's name was also erased, in consequence of his refusal to withdraw certain advertisements to which the Council objected. It was decided to inform Mr. Alabone that the Council accepted his explanation, and had decided to take no further action, provided that he withdrew all the copies of his work which contained the objectionable passage, and that he submitted to the Council for inspection any new edition which he might intend to publish. The Report of the Joint Building Committee of the two Colleges was submitted. The negotiations with the agent of the Duke of Bedford having fallen through, the committee recommended that the two Colleges should jointly lease for 99 years a piece of land facing the Embankment, at a ground-rent of 2,200*l.* per annum. The Examiners in Medicine and in Midwifery were re-appointed. Messrs. Power and Cadge were appointed Professors of Surgery and Pathology. Messrs. Stewart, Brailey, Hill and Treves were appointed Professors of Comparative Anatomy and Physiology. Mr. Wooldridge was appointed Lecturer on Anatomy and Physiology, and Mr. J. B. Sutton Erasmus Wilson Professor.

Mr. Savory was unanimously elected President, and Messrs. Wood and Power, Vice-Presidents for the ensuing year. Mr. Macnamara and Mr. Pemberton having subscribed the By-Laws took their seats at the Council. A special vote of thanks, proposed by Sir Spencer Wells, and seconded by Mr. Marshall, was voted to Sir James Paget in connection with the completion of the new Pathological Catalogue of the Museum. Mr. Marshall then gave notice of motion—the terms to be afterwards determined upon—that some permanent record of Sir James Paget's long and valuable services be erected in the College. The Council then adjourned until the *first* Thursday in August.

UNIVERSITY OF EDINBURGH — MEDICAL DEGREES EXAMINATIONS.—The following candidates have passed the final examination for Graduation in Medicine, those marked with an asterisk having passed with distinction:—

Robert Blair, Pulicet Parthasaradhi Chetti, Edmund Wearne Clark, B.Sc.; Frank Gerard Clemow, Frederick William Collinson, John Cram, M.A.; James Henry Dawe, Jules Delepine, Henry George Dickman, \*Kenneth M'Kinnon Douglas, William Oliphant Dow, Walter Musgrave Eaton, William Elder, George Graves Eyre, B.A.; William Cooke Faulkner, Lewis Gordon Fischer, Alexander Fisher, M.A.; H. S. R. Freeborn, Edwin Sargood Fry, \*John Garvie, John Edward Gemmell, John Glegg, James Gray Glover, A. E. Lambton Gray, C. W. Monroe Grier, Thomas Howard Griffith, William B. Thompson Gubbin, John Scott Haldane, M.A.; Stuart Pennington Hallows, John Thomas Harvey, John Hunter Helm, \*Thomas Arthur Helme, Walter Croft Helme, Frank William Hennessy, George Vickerman Hewland, John Ramsay Hill, Herbert Hirst, Joshua Jacobus Hoffman, William Edward Home, B.Sc.; Archibald Hood, Reginald Ernest Horsley, Alfred William Hughes; James Hunter, M.A.; Ernest Cory Kingdon, John Richards.

ROYAL COLLEGE OF PHYSICIANS.—The following candidates have passed their final examination, and have been licensed to practise:—

Thomas Pagan Lowe, Bath; James Donaldson, Lochmaben; Alfred William Robson, Birmingham; John Henry Booth, Chesterfield; Alexander Cook, Rutherglen; John Francis Hall Edwards, Birmingham; Henry Ernest Purdon Wright, St. Helens, Lancashire; Robert Charles Gordon Dill, Burgess Hill, Sussex; Thomas Cardwell, Reading; John O'Callaghan, Cappamore, County Limerick, Ireland; and William M'Manus, Athlone, County Westmeath, Ireland.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, July 2nd, 1885:—

James Harry Ernest Brock, M.R.C.S., 30, Bartholomew Road, N.W.; Thomas Rushbrook, M.R.C.S., 22, Rutland Street, Hampstead Road, N.W.; Samuel Gordon Smith, M.R.C.S., 76, Barnsbury Road, N.

ROYAL COLLEGE OF PHYSICIANS.—At an extraordinary meeting of the College held on Thursday, July 2nd, a communication was received from the British Association respecting the proposal to hold an International Scientific Congress in 1888. A report was read from the Committee on the Croonian Trust and adopted. The Report of the Committee on the Lunacy Act Amendment Bill was read, and the President was requested to transmit a copy of it to the Earl of Shaftesbury.

EDINBURGH UNIVERSITY—NEW EXAMINATION HALL.—Alterations involving a cost of about 1,000*l.* are at present being made at the north-west corner of the University buildings. The octagonal room, which was formerly the principal part of the anatomical museum, with the apartments to the east and south of that structure, are being converted into a large examination hall by the removal of the intervening walls, the superstructure being supported by strong iron beams and pillars. The floor space which will be afforded under the new arrangement will give accommodation for some 240 students at a time, when engaged at written examinations. The work is being rapidly proceeded with, and will be completed by the beginning of the ensuing winter session. The contractors are Messrs. John Mitchell and Son. Mr. R. Morham, City Superintendent of Works, prepared the plans for the alterations.

UNIVERSITY OF GLASGOW.—The summer session at Glasgow University closes on Friday, the 10th instant, and the Final Examinations for medical degrees begin on the following Monday and last three days. The subjects included in the examination are: Materia Medica, Forensic Medicine, Practice of Medicine, Pathology, Surgery and Midwifery. For some years the subjects of Materia Medica and Therapeutics were separated and taken at different examinations. Now the old arrangements are restored, whereby both subjects are included in the same examination. The number of candidates is 115. The graduation takes place at the end of the month.

THE REPRESENTATION OF THE UNIVERSITIES OF EDINBURGH AND ST. ANDREW'S.—At a meeting of the Edinburgh and St. Andrew's Universities Liberal Association held on Friday last, it was resolved to request Mr. Eriehsen to become a candidate for the Universities, in the Liberal interest, at the general election. The invitation, we are informed, has been accepted. Mr. Eriehsen was one of those who received honorary degrees last summer on the occasion of the Tercentenary of Edinburgh University. The *Scotsman*, commenting on Mr. Eriehsen's candidature says that it will be strange if his high professional standing, his scientific attainments, and his undoubted culture do not commend him to the Universities as a more suitable representative than the Lord Advocate. Mr. Eriehsen has made his mark in the scientific world, and he comes forward at the desire of those who wish to see the Universities represented as becomes their character.

THE ROYAL SOCIETY OF EDINBURGH.—The fifteenth ordinary meeting of the Royal Society was held on Monday, when several interesting papers were read. The vital relations of micro-organisms to tissue elements formed the subject of a paper by Dr. G. S. Woodhead and Dr. A. W. Hare, and Dr. Woodhead, in communicating the results of

their investigations, mentioned that Edinburgh was now thoroughly equipped for bacteriological investigation. In the University there were complete apparatus and arrangements for carrying on the work in the Pathological, Surgical, and Practice of Physic departments. Professor Turner described a specimen of Sowerby's whale (*mesoplodon bidens*), which he recently obtained from Shetland. This species was looked upon as very rare. Since 1870 he had been fortunate enough to obtain three specimens. They came from the north of Shetland, and were characterised by having very sharp snouts. In 1881 he got a specimen which was first recognised from one east ashore in 1806 near Elgin. From that date up to 1881 no other specimen of this particular whale had been obtained anywhere on the Scottish coast, although one or two had been got on the Irish coast. One peculiarity about it was that the food had to pass through globular compartments, eight in number, before it reached the stomach, which was very like the human stomach, and might be said to be of two compartments.

SIR GUYER HUNTER.—It is stated that Sir Guyer Hunter has been selected as the Conservative candidate for the representation of the Central Division of Hackney in the new Parliament. His special experience would, no doubt, render him an extremely valuable addition to the House of Commons.

APPOINTMENTS.—His Excellency the Earl of Carnarvon, Lord Lieutenant of Ireland, has up to the present made the following professional appointments in the Vice-regal household: Surgeon-in-Ordinary, Edward Hamilton, M.D.; Surgeon-Oculist-in-Ordinary, Archibald Hamilton Jacob, M.D.

THE CHOLERA IN SPAIN.—The Belgian Government has despatched Dr. van Emerghen, the author of *La Microbe du Choléra*, on a mission to Spain, in order to investigate the cholera there prevailing, as well as Dr. Ferrán's inoculations.

THE CHAIR OF HYGIENE AT THE PARIS FACULTY OF MEDICINE.—For the Chair of Hygiene, which has become vacant by the resignation of Prof. Bouehardat, the Faculty has sent in to the Minister of Public Instruction the names of Dr. Proust on the first line, and Dr. Landouzy on the second line.

TYPHOID FEVER AT SWANSEA.—There are said to be no fewer than 400 cases of typhoid fever in Swansea, and quite a scare prevails among the inhabitants. The outbreak is said to be due to sewage matter being allowed to run from surrounding farms into the reservoirs.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual general meeting, for the purpose of receiving the reports of the council and honorary officers, and electing the office bearers for next session, will take place at the Holborn Restaurant, on Thursday next, at 6 p.m. The members and their friends will subsequently dine together. Professor Corfield has been nominated as the new President of the Society.

ST. ANDREW'S GRADUATES ASSOCIATION.—The annual meeting was held on the 30th of June, at 11, Chandos Street, Cavendish Square. The following office-bearers were re-elected:—Dr. B. W. Richardson, President; Dr. J. H. Paul, Hon. Treasurer, and J. M. Menzies, M.A., Hon. Secretary. The report of the Hon. Treasurer showed a balance of upwards of 90*l.* in favour of the association. A committee was elected to report to the council on legislation as bearing upon the Scottish Universities and upon the University of St. Andrew's in particular.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The Annual General Meeting will be held in the Examination Hall, Queen's College, Cork, on Tuesday, August 4, 1885, under the presidency of J. A. Eames, M.D., F.R.C.S.I. In the morning the officers for the ensuing year will be appointed, general business will be got through, and a recommendation of the Council in regard to the granting Certificates in Psychological Medicine by the Association will be brought forward. At the afternoon meeting, held at 2 p.m., Dr. Eames will deliver an address, and Dr. Haek Tuke will read a paper on "A Case of Moral Insanity." The Members of the Association will dine together after the meeting.

**THE PREVENTION OF CHOLERA.**—With a view to preventing the introduction of cholera from the Continent, the Town Council of Dover decided at their recent meeting to adopt very strict precautionary measures with regard to importation of rags, &c., from Spain. In case of any such imports being landed they are to be at once destroyed. The Swausea Port Sanitary Authority have issued stringent instructions to the pilots that no vessels having cases of sickness on board are to be admitted into the docks until examined by the medical officer. The customs authorities have adopted the most stringent quarantine precautions.

**FORFARSHIRE MEDICAL ASSOCIATION.**—Dr. Keith Anderson presided at the annual meeting held at Arbroath, on the 2nd instant. The financial position of the Association was satisfactory. The office-bearers for the year ensuing were elected, as also a Council, and local secretaries for the several towns in the county. A paper was read by the President, which led to some discussion, on Neuralgia and Hydrothorax occurring in his practice. In Montrose the next meeting of the Association was appointed to be held.

**THE FIFE LUNACY BOARD.**—It is somewhat refreshing now-a-days to hear of such an exceptionally prosperous career as that of this Board. According to an announcement made by the clerk at a meeting of the Board, held at Cupar, on the 30th ultimo, 6,693*l.* was the credit balance at the Board's bankers, notwithstanding the discussions and efforts made to reduce it, covering a period of several years. The balance at one time exceeded 7,000*l.*, and, as will be seen, it has not been appreciably affected by the renewal of the deliberations upon the subject.

**THE ALBANY MEMORIAL HOSPITAL.**—On Saturday last the Albany Memorial wing of the National Hospital for the Paralysed and Epileptic, was declared open by the Prince of Wales. Towards the close of the ceremony, the Princess of Wales received a number of purses in support of the building fund. A concert was held in the evening. The collection of the day, including the sum of the presentation purses, amounted to upwards of 1,000*l.*

**CONVALESCENT HOME FOR SCARLET FEVER, STANMORE.**—Miss Mary Wardell, on the approaching first anniversary (the 14th inst.) of the opening of her home, at Stanmore, appeals to the public to commemorate the anniversary by "Birthday presents" to the home, of annual subscriptions, donations, or articles of furniture, toys, games, &c., especially anything for outdoor use. It appears 5,000*l.* is required to complete the home for its full complement of patients, and to carry it on an annual income of subscriptions of 500*l.*, in addition to the receipts derived from patients' payments.

**FEVER AND SMALL-POX IN THE METROPOLIS.**—At the meeting of the Asylums Board on Saturday, the returns of fever cases in the Board's asylums showed that there were 244 cases under treatment, as against 245 a fortnight ago. In regard to small-pox, 233 cases had been admitted during the fortnight, as against 378 a fortnight ago, and there were 852 in the asylums and camp as against 1,145 at the date of the last report.

**DISFRANCHISEMENT FOR MEDICAL RELIEF.**—It is stated that immediately after the Chancellor of the Exchequer on Tuesday night intimated a disposition to offer facilities to Mr. Jesse Collings to forward the Medical Relief Bill, Mr. J. G. Talbot blocked the measure. Mr. Jesse Collings, M.P., replying to a resolution of the Leicester Liberal Association, strongly condemning the proposed disfranchisement by medical relief, and referring to his own measure on the subject, writes:—"I shall lose no opportunity of pressing the matter forward, and I trust we shall be able to bring such pressure to bear on the Government that the measure will become law even at this period of the session, and the monstrous injustice involved in the amendment of the House of Lords be remedied. It cannot be endured that poverty should be made a crime to be punished by loss of the rights of citizenship." The Earl of Kimberley, in replying to the same resolution, says: "I beg leave to say that I voted in favour of the clause in the Registration Bill rejected by the House of Lords, and shall continue to support the

removal of the disqualification of voters by the receipt of medical relief."

**AN IRISH VIEW OF THE LAST MEDICAL BILL.**—At the election of Parliamentary representatives of the Dublin University on the 30th ultimo, Dr. Edward H. Bennett, who supported the candidature of Mr. Plunkett, took occasion to say that, "Every one familiar with medical topics knew well the distress that the medical profession had recently been in—that, in fact, it had only just floated above water. But this they had to congratulate themselves upon, that in the coming session they should have the support, and perhaps more influential support in consequence of their present positions, of their two last representatives in maintaining the status of the corporations in the profession, and putting aside what they could characterise as an attempt at legislation by destruction. The last efforts, as far as they were proposed, were merely proposals to destroy everything good in the profession for the purpose of seeing what good would come out of the ruin. He thought they might safely say that David Plunkett, and the Lord Chancellor in his position as Cabinet Minister, would help to avert such ruin as that, and he thanked them on the part of the medical profession for their constant attention to its interests."

**THE REUBEN HARVEY MEMORIAL PRIZE.**—The first triennial award of this prize has just been made. The prize was founded by subscription in 1882 in memory of Dr. Reuben J. Harvey, a Doctor of Medicine of the University of Dublin and a Fellow of the King and Queen's College of Physicians in Ireland, who died of typhus fever caught in the discharge of his duties as one of the physicians of Cork Street Fever Hospital, Dublin, on the 28th of December, 1881, in the thirty-sixth year of his age. Dr. Harvey was rapidly making a reputation as a physiologist at the time of his death, and the prize was established with the two-fold object of perpetuating his memory and of encouraging original research in the department of physiology. It is to be awarded once in every three years to the writer of the best essay on a subject selected by the candidate, evidencing original research in animal physiology, including pathology, the essay to be illustrated by drawings or preparations. On the present occasion only one essay was sent in, by an author under the *nom de plume*, "*In cute curanda plus æquo operata juvenus.*" The subject selected by him was "The Changes occurring in the Skin in some forms of Disease." The examiners for the Prize—Dr. Walter G. Smith, acting on behalf of the President of the King and Queen's College of Physicians, and Mr. Phineas S. Abraham, acting on behalf of the President of the Royal College of Surgeons in Ireland—reported most favourably of the essay, which was illustrated by 59 microscopical sections and several original sketches. Accordingly the Presidents of the Colleges awarded the prize, the value of which is 20*l.*, to Mr. Henry T. Bewley, Bachelor of Medicine and Bachelor of Surgery of the University of Dublin, who proved to be the writer of the essay.

**THERAPEUTIC PROGRESS.**—In his presidential address, at the annual meeting of the Birmingham and Midland Counties Branch of the British Medical Association, Dr. Sawyer (*vide Birmingham Medical Review* for July), after pointing out the difficulties that beset therapeutic progress and the conditions necessary for its attainment, concluded as follows: "There is another condition of our work in the treatment of disease about which there has been much misconception, but about which we can scarcely miss agreement if we weigh the case carefully. It is this: whether we like it or not we must be mainly empirics in our practice. We must not be above being empirics. I do not mean empiricism in any bad sense of the word. I do not mean that there is any real opposition between true empiricism and scientific practice. The great bulk of our therapeutic knowledge is as yet empirical, and as empirics, though as rational and scientific ones, we must administer it. By this empiricism I mean, and mean only, a knowledge which is founded upon experience. I mean a knowledge which grows from and with experience, and which is in this sense empiric, however scientifically it be

applied. In much of our therapeutic work it is experience which prompts our action whilst experience alone can test our results. Much of what we do we cannot explain, in the scientific meaning of the word explanation, so we lean upon experience, and trust with an empiric faith much that we know to be true though we cannot understand it. We expect much of further gain to our art from the discoveries and developments of physiological research into the actions of medicines, and such research has already given us some valuable remedies, which an *a priori* reasoning has applied in practice and which experience has confirmed. . . . Progress has two sides. It advances with a double front, by the discovery of the unknown and by the perfection of the known. What the unknown has in store for us we cannot say, but a mine of therapeutic progress lies ready at our hands in the perfection of the remedies we already know. At the perfection of the known we can all work and none shall miss his prize. The discovery of the unknown bears fruit late, seldom, never, and splendid; the perfection of the known bears fruit at once, always, continuously and in bushels.

**CHARING CROSS HOSPITAL MEDICAL SCHOOL.**—On Friday last (July 3) Sir Richard Temple presided at the distribution of medals, prizes, and certificates gained during the summer and winter sessions by the students of the Medical School connected with the Charing Cross Hospital. The ceremony took place in the lecture theatre of the institution in Chandos Street. From the dean's report it appeared that 60 new students were admitted last year, as compared with 50 during the previous twelve months, whilst the total number now on the roll was 180. The Llewellyn scholarship was awarded to W. J. Colborne, who also won the governor's clinical gold medal and the Pereira prize; and the Golding Scholarship was obtained by R. E. Fasnacht. Sir Richard Temple commented upon the general efficiency of the Charing Cross Hospital and School, and remarked that it must be satisfactory to every true-hearted philanthropist.

**THE ADELAIDE HOSPITAL, DUBLIN.**—The annual meeting at the close of the summer session was held last week in the theatre of the hospital, when the prizes were awarded to the successful candidates. The chair was taken by Lord James Butler. The closing address of the season was delivered by Dr. Purefoy, who called attention especially to the antiseptic method of treating wounds which was now so fully carried out in the surgical department of the hospital, and which had yielded brilliant results. In the Adelaide Hospital they had now the means of manufacturing the materials and solution used for the carrying out of the antiseptic method, and since they had done so they had obtained even better results than formerly. The prizes distributed included the Hudson Scholarship (gold medal and 30*l.*), awarded to Mr. George T. Revington, B.A., and the Hudson Prize (silver medal and 10*l.*), to Mr. J. Darley Wynne, B.A.

**THE GREAT ORMOND STREET HOSPITAL.**—Subject to the deduction of some small amount for expenses, a sum of 842*l.*, the result of the concert given by Madame Cellini, on the 25th ult., on behalf of the Hospital for Sick Children, Great Ormond Street, has been handed to the committee of the hospital.

**POOR LAW MEDICAL OFFICERS' ASSOCIATION.**—A meeting of the Association will be held at Cardiff during the meeting of the British Medical Association, to which all Poor Law Medical Officers and others interested in the subject are earnestly invited to attend, as matters of great importance in reference to the future of Poor Law Medical Officers will be discussed. Mr. Wickham Barnes, the Honorary Secretary of the Association, has announced that he would feel obliged if, prior to the meeting, every Poor Law Medical Officer throughout the Kingdom would send him a post-card stating "Yes" or "No," as regards their approval of the Lords' amendment in reference to Poor Law Medical Relief.

**ERRATUM.**—In *Medical Times* for July 4th, 1885, page 31, line 17 in first column, for "St. Mark's" read "St. Mary's Hospital."

## APPOINTMENTS.

- BARROW, FREDERICK, M.R.C.S. Eng., L.S.A. Lond.**—Medical Officer to the Rothbury West District, Rothbury Union, *vice* Mr. John Todd.
- BRAMWELL, H., M.B.**—House Surgeon to the Newcastle-on-Tyne Infirmary, *vice* J. Waldy, M.R.C.S., L.R.C.P., who has been promoted to the Office of House Physician.
- CHADWICK, GEORGE FREDERICK, L.R.C.S. and L.R.C.P. Edin.**—Medical Officer to the Codford St. Peter District, Warminster Union, *vice* Mr. Isaac Flower, resigned.
- GARSTANG, E. M., M.R.C.S., L.R.C.P.**—Honorary Surgeon to the Bolton Infirmary and Dispensary.
- LANE, JOHN WILLIAM, M.D. St. Andr., L.R.C.S. Ire.**—Medical Officer to the Workhouse, Clun Union, *vice* Dr. Lemon, resigned.
- LEEMING, ROBERT W., M.R.C.S. Eng., M.B. Camb., L.S.A. Lond.**—Medical Officer to the Kendal District and to the Workhouse, Kendal Union, *vice* Mr. R. T. Leeming, deceased.
- MAWBAY, WILLIAM GEORGE, L.R.C.P. and L.R.C.S. Edin.**—Medical Officer to the Blisworth District, Towcester Union, *vice* Mr. William T. Poplewell, resigned.
- O'MEARA, JOHN BRETT JOHNSTONE, L.R.C.P., L.R.C.S., and L.M. Edin.**—Medical Officer to the Sutton Bridge District, Holbeach Union.
- ROYLE, JOHN FREDERICK S., M.B., C.M. Aberd.**—Medical Officer to the Polesworth District, Atherstone Union, *vice* Mr. Mark Hales, resigned.
- THORP CHARLES WILLIAM, F.R.C.S. and L.K.Q.C.P. Ire.**—Medical Officer to the Workhouse, Todmorden Union, *vice* Dr. W. Thompson, deceased.
- THURSTON, EGAR, L.R.C.P., L.S.A.**—Superintendent of the Presidential Museum, Madras.

## VACANCIES.

- ERPINGHAM UNION.**—Medical Officer for the Cromer District, in succession to Mr. R. McKelvie, resigned. Area, 8,818 acres. Population, 4,090. Salary, £66 per annum.
- HENDON UNION.**—Medical Officers. (*For particular see Advertisement.*)
- HOLBEACH UNION.**—Medical Officer for the Lutton District, in succession to Mr. J. E. Smith, resigned. Area, 14,642 acres. Population, 2,675. Salary, £37 10*s.* per annum.
- HUNTINGDON COUNTY HOSPITAL.**—House Surgeon. Salary, £60 with rations. Candidates must be qualified in Medicine and Surgery. Testimonials to the Hon. Secretary, on or before July 13th.
- MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.**—Medical Officer. Salary, £40 per annum, with board, apartments, and washing. Candidates must be qualified and registered. Applications, with copies of testimonials, to be sent on or before July 31st.
- MANCHESTER ROYAL INFIRMARY, DISPENSARY AND LUNATIC HOSPITAL, ETC.**—Honorary Obstetric Physician. (*For particulars see Advertisement.*)
- RUGBY UNION.**—Medical Officer for the Rugby District and the Workhouse, in succession to Mr. G. J. Sadd, deceased. Area, 10,030 acres. Population, 12,492. Salary, £50 per annum. Salary for Workhouse, £50.

## DEATHS.

- BARKWAY, F. T., M.R.C.S., L.S.A.,** at Grove House, Lavenham Suffolk, on July 5, aged 59.
- CHEPMELL, E. C., M.D.,** at Florence, on June 24th, aged 65.
- DALE, GEORGE THOMAS, L.S.A.,** at 8, Pembridge Place, Bayswater, W., on July 6, in his 86th year.
- DEMPSTER, CHARLES CARROLL,** Deputy Surgeon-General, Army Medical Department, at Tramore, County Waterford, on June 20th, aged 51.
- HIND, G. W., F.R.C.S.,** at 184, Euston Road, on July 4th, in his 84th year.
- KEMP, GEORGE, M.D.,** at Ivy Cottage, Pilton, Barnstaple, on June 28th, aged 77.
- MANBY, F., F.R.C.S.,** at East Reedham, Norfolk, on June 30th, aged 74.
- SKEEN, ANDREW,** Surgeon-Major, at Kassauli, Punjaub, India, on June 10.
- WOOD, ARTHUR, M.D.,** at 12, Philbeach Gardens, Earl's Court, on July 7, in his 80th year.

## NOTES, QUERIES, AND REPLIES.

### A PHYSICIAN WANTED.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—The city of Truro is in the centre of the population of the county of Cornwall, which population numbers about 330,000 persons. The city of Truro itself contains 11,000 persons, and within a few miles there is a population not far short of 80,000 souls. For many years Truro always had *three* physicians resident therein, but of late two only. Of these two, one has recently died, greatly respected, at the ripe old age of 80 years, and the last surviving physician is now 70 years of age. He has just retired, in consequence of advancing age, from the post he has long held with so much credit to himself as the honorary physician of the Royal Cornwall Infirmary. This noble institution is therefore at the present time *without a physician*, although there are probably 50 or 60 in-patients in the house,

to say nothing of the out-patients, which far outnumber those maintained within the walls. I may add that the income of the Infirmary was never greater than it is at the present moment. The office of physician and surgeon of the Royal Cornwall Infirmary has always been an honourable, and hitherto much-coveted office, and it does therefore appear inexplicable that no one has applied for the office known to be vacant. No one will deny that the position of a physician is a highly honourable one. Men skilled in the art of healing, whether physicians or surgeons, have always, in this and other countries, been held in high estimation. The study of physic is one sure to command respect, and, speaking for myself and many others, I can confidently state that a physician of good acquirements, with good tact and comely presence, combined with a sincere desire to do good in his generation, would command and receive a kindly greeting in the good city of Truro. I may add that within my own knowledge fees of £10, £15, £25 and even £50 have been paid of late to have the opinion of men of good position supposed to be well versed in the healing art.

I am, Sir, yours, &c.,

Truro, July 4th, 1885.

A FATHER OF A FAMILY.

## LECTURES ON SOME OF THE DISTINCTIVE CHARACTERS OF DISEASE IN EARLY LIFE.

GIVEN AT THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

By OCTAVIUS STURGES, M.D., F.R.C.P.,

Physician to the Hospital.

LECTURE IV.

*Tuberculosis.*

HAVING spoken of infantile spasm and convulsion, it would have been of interest next to compare the nervous disorders of infancy with those of childhood; to notice how, along with the development of mental and bodily activity, new forms of functional disease appear, taking shape and colour from the natural characteristics of their subjects, until, little by little as life advances, the affections of childhood get transformed into the more abiding but strictly analagous affections of men and women. But time gives no opportunity for this, and in dismissing the subject

of nervous disorders in early life, and turning to the consideration of tuberculosis, I would only ask you to bear in mind how vast and varied is the field which they occupy, and how dim, partial and insufficient the light which morbid anatomy affords.

Tuberculosis, as I have more than once reminded you, is the central feature of children's disease. Amongst the poor, at least, it is the great enemy of child-life. No one, therefore, who attempts to speak, however cursorily, of the distinctive characters of disease in early life can afford to pass it by. Yet the subject is so encompassed with difficulty, and just at present, the particular point which is attracting attention—the relation of tubercle to micro-organisms—is (or ought to be) so entirely in the hands of a few trained observers, that it is impossible to approach it without apology. In what I have to say to-day I shall confine myself to the clinical aspects of the affection, to its comparison with the tubercular development of later life, and to certain considerations in reference to the cause, distribution and symptoms of tubercle which cannot but be important factors in determining its pathology and directing its treatment.

It is in early life that tubercular development shows its greatest activity and widest extension. The earlier the life the more generalised the tubercle, and the less its association with destructive changes. As time goes on tubercle more and more tends to the lungs, its nervous symptoms become less prominent, and its

exciting causes less obscure.<sup>1</sup> Infantile tuberculosis, moreover, exhibits along with its generalness (in what precise relation to the tubercular development is matter for question), that which is, in a measure peculiar to it. I mean enlargement and cheese-like degeneration of the lymphatic glands, a condition which, although mostly out of sight, may be safely predicted whenever tubercle itself can be predicted.

In its typical completeness tuberculosis invades every tissue and organ of the body, being co-extensive with those adenoid bodies which are supposed to pervade the connective tissue skeleton, and whose hyperplasia is the hypothetic structural basis of the disease. Yet, clinically speaking, the chief seats of activity of tubercle—the places, I mean, where the occurrence of inflammation is apt to indicate it during life—are the brain, the lungs, the peritonæum and the small intestine. Thus tuberculosis comes to resemble certain general diseases which have some particular local manifestation, and like them, it will often display symptoms which call off the attention from the prime source and origin of mischief, and fix it upon some single seat of trouble. Just as we may mistake a pneumonic consolidation, which is in fact part of enteric fever, for a simple pneumonia; or pulmonary œdema, which is part of a general dropsy, for simple bronchitis; just so, only much more easily and excusably, may we mistake tubercular for simple inflammation. Herein lies the main difficulty of tuberculosis from the diagnostic point of view. It is a general disease; it shows as a local inflammation. Hence it is that, mindful of the extreme liability to tubercle in early life,<sup>2</sup> we are always on the look-out for it, knowing that it may be lurking behind the commonest affections. If infantile bronchitis be prolonged, if diarrhœa, or vomiting, or night-fever persist, or the child without obvious cause lose cheerfulness or appetite, in all such cases, notwithstanding that such ailments are common with all children, we begin to make enquiry for some of the special signs of tubercle development, wasting or sweating or grinding the teeth in sleep, and so forth.

Perhaps the best illustration of the diagnostic difficulties of tuberculosis, as well as of its varieties at different periods of life, is to be found in its near resemblance, both in childhood and in youth, to enteric fever. In the child enteric ulceration is one of the commonest associations of acute tuberculosis, and in the abdominal distension, indefinite mode of onset and general languor, its likeness to typhoid is intimate. There is besides the same tongue, the same splenic enlargement, even it may be the spots and the characteristic typhoid evacuations. It is true that the bodily heat in tuberculosis is less than is commonly found in typhoid, and that the course of the temperature is less definite. But such differences are not constant or reliable, and at the outset an indefinite typhoid in a young child can never be certainly known as not tuberculosis, a regrettable perplexity, since the one is almost certain to recover and the other to die.

And in youth as well as childhood tuberculosis may closely resemble enteric fever, but not quite in the

same way, for the tuberculosis of adolescence has already begun to contract its area and to tend towards the lung. Hence it will not be by abdominal symptoms that the resemblance will be made, nor yet of necessity by pulmonary, for disseminated miliary tubercle in the lungs may give no physical sign whatever, but rather by the pyrexia and daily increasing prostration. And inasmuch as acute tuberculosis after childhood is a comparative rarity, the liability to error is here far greater than in the former case, and the actual fact is that such attacks are very commonly misapprehended up to the time of death.

But, in the case of children, this obscurity seldom lasts to the end. The earlier symptoms may have been abdominal or pulmonary, indistinguishable from enteric fever or from simple broncho-pneumonia; but the time presently comes when, by their endurance and by the wasting of the body and night-sweats, we are assured that the inflammation has a tubercular basis. Not only so, but however little there may have been of such symptoms during the illness, it is but seldom that the end comes without signs of cerebral disturbance, sickness, or vomiting, or convulsion, or coma or any of these. Thus a disease which may be absolutely undiscernable at the outset becomes obvious enough when there is no longer any use in recognising it.

It is remarkable that the extreme liability to general tuberculosis concerns the very same age that is most exposed to spasm and general convulsion from trivial and unexplained causes, altogether apart from tubercle. There is a time of life somewhere between four and five which marks abruptly the period at which tubercular development undergoes a marked abatement. At this hospital the children dying of tuberculosis under five years old are to those so dying above that age in the proportion of nine to two; a calculation, it must be remembered, which without doubt understates the actual infant mortality of the disease owing to our very sparing admission of infants. In a large majority, as I have before mentioned, there is no tubercular parentage to account for this large death-rate.<sup>3</sup> Yet from their very early decline, from the deaths of many who are but a few weeks old, it would seem as though the tubercular process—whatever that may be in its early stage of development—were called into activity at the very commencement of extra-uterine life.

It is difficult, of course, to estimate the share in this high and early mortality which is due to neglect and ill living and other circumstances of poverty. There is urgent need of accurate statistics upon this point as regards the well-to-do. Still, with whatever difference between classes, it is but too certain that the infant mortality from tuberculosis in this country is prodigious, and that inheritance is quite insufficient to account for it. Large numbers are born to die. The conditions of independent existence, such atmospheric exposure and such functional activity as life implies, become at once sources of injury and irrita-

<sup>1</sup> One hundred and four tubercular children taken in succession, give 24 over 5 years old; 5 of these are examples of induced tubercle following caries and suppuration; in 6 peritonitis was the chief local affection, and in 1, ulceration of the ileum; in 6, the lungs were most concerned, 2 of these being cases of phthisis. In 1 case of meningitis, tubercle was confined to the brain; and in another there was evidence of old as well as new inflammation. There was besides a case of "tubercular kidney." Only 3 of the 24 were examples of general tuberculosis dying with cerebral symptoms after the manner which is so characteristic in the younger children.

<sup>2</sup> In 1,420 deaths at the Hospital for Sick Children, taken without selection and mostly consecutive, there are 434 who died with tubercle, *i.e.*, over 30 per cent. The proportion is very unequal for the several years computed, but, taking these large numbers, the tubercular proportion would seem to be between a third and fourth of the total mortality.

<sup>3</sup> As regards *age*, 133 consecutive cases of tubercular deaths yield 109 under 5 and 24 above that age. A similar proportion prevails throughout. As regards *inheritance*, in a series of 95 consecutive deaths of tubercular children (Vol. ii., P.M. and Case Book) no family history could be obtained in 34. Of the remaining 61, the father was phthisical in 3, the mother in 6, both parents in only 1, there was phthisis in the father's family in 9, in the mother's family in 6, both parents were healthy in 28; the remaining 8 were uncertain. In a second series (Vol. iii.), 30 children dying of tuberculosis have one parent phthisical (father or mother) in 5 instances, and phthisis in the family of one parent in 4 instances, there are 21 with no phthisis whether parental or otherwise. In a third series (Vols. iv. and v.), where doubtful cases and cases of distant phthisis are neglected, 113 children dying of tuberculosis have one parent with phthisis in 21 instances and both parents ascertained to be healthy in 58. There are many causes to militate against the perfect accuracy of such statistics, but allowing full margin for error, it may yet be asserted that inheritance is but a small factor in the large mortality of young children from tuberculosis.

tion. These children are in precisely similar plight with those whose inspiratory efforts are too feeble to keep the lungs inflated, or those, again, whose reflex excitability is so extreme that common sensation is converted into spasm. We have here, in the language of Niemeyer, as applied by him to the lungs, the utmost degree of "vulnerability." The children are doomed at birth, and they set about the process of tubercle development so soon as they are separated from the parent.

And, under the same figure and with the same authority, we recognise lesser degrees of vulnerability; and we recognise, moreover, the lessening of susceptibility in this respect (be it more or less) as life goes on, which is a law of nature. There is the child of capricious appetite and eager, variable temper, easily upset, often feverish and restless at night, and apt to sweat about the scalp, and to grind its teeth in sleep. With them the continuance of life is largely dependent on the intelligent vigilance of those who can interpret such signs and discern from time to time the particular direction whence danger threatens. To these children the common incidents of life, pressing now from this quarter and now from that, are all perilous. They have to face in turn the troubles of teething, the effort and excitement of mental training and the deteriorating influence of certain childish affections, notably of measles and whooping-cough.<sup>4</sup> With care and good fortune these dangers are successively overcome. The morbid susceptibility both lessens and narrows. It is less easily aroused, and it concerns fewer organs; until presently the age is reached when for the first time life becomes secure. Yet there is no period of absolute immunity from tubercle. The long continuance of empyema or other suppuration, the occurrence of measles or whooping-cough, or even of typhoid fever, these and other accidents may induce tuberculosis which would not otherwise have occurred. Thus we are all under the possibility of tubercle; some will only succumb to it under extra and special inducement; some only with care escape; and a large number are fore-doomed, be the circumstances what they may.

Owing to the manner of its distribution, tuberculosis comes naturally to be regarded as a child's disease. Yet the law that throughout I have been insisting on still holds good, that there is nothing in childhood which may not be repeated in after life. The age does no more than to shape expectation. Thus, anyone observing a child in convulsion or coma would at once be reminded of tubercle, whereas no such thought would occur on seeing an adult in like condition. And yet men and women may have general tuberculosis as well as children, and, like them, its active development may be cerebral and not pulmonary.

I have before me a striking example of this kind. It is that of a young woman of 19 who was admitted into the Westminster Hospital, under my care, some three years ago. She was then unconscious, had strabismus, and unequal pupils, and what little nourishment she could be got to swallow was not retained. She had been acutely ill for only ten days, sickness being the most prominent symptom. There was no wasting about the body or other indication of long illness. She quickly died without recovering consciousness. *Post-mortem* miliary tubercle was found occupy-

<sup>4</sup> The injurious influence of measles is especially worthy of notice, and comes out in strong relief on perusing a large number of cases consecutively. It is very common to find children, who up to the time of an attack of measles have been strong and healthy, dating their tubercular decline from that event or from the bronchitis which succeeds it. Numerical computations upon this subject are not easy, because the examples cannot be taken consecutively owing to the common practice of leaving negative facts unrecorded. Yet the circumstances are such as would lead me to lay special stress, in the many cases of doubt, upon the absence from the patient's history of three of the great factors of tuberculosis—measles, whooping-cough, and tubercular inheritance.

ing the lungs,<sup>5</sup> peritonæum, and spleen, while the ileum was acutely inflamed and had two small ulcers near the ileo-cæcal valve. The condition, remarkable at her age, was, in fact, precisely that which is so common in children, and from the symptoms it would have been immediately suspected had the patient been ten years younger. As regards the brain, however, it was observed that, although the pia mater was markedly injected, no tubercle was discovered in this situation. In the substance of the pons varolii, however, two roundish bodies were found, something smaller than hemp-seed, which, on examination, presented all the microscopic characters of tubercle.

In such ways, whether from the age of the patient or the misleading character of the symptoms, we may encounter tubercle without suspecting it. But so ever-present to the minds of those who have to deal with children is the presence and insidiousness of tuberculosis that we are perhaps more exposed to the opposite error: to suspect tubercle where there is none. Especially is this the case when the occurrence of cerebral symptoms in childhood suggests the most common and characteristic of all the modes of tuberculosis. And hence arises this strange dilemma: the more elaborate and comprehensive our descriptions, the more fully we seek to warn the student against overlooking the earliest evidences of meningeal tubercle, the more are we compelled to dwell upon ambiguous symptoms, upon what is sometimes tubercle indication and sometimes not, attributing here or there a significance which is more express and definite than the facts warrant.

There is no more graphic description of acute hydrocephalus than that of Dr. West, who divides it into three stages, and enters with much minuteness into those earlier nervous symptoms which are apt to be overlooked. But the difficulty is to fit the symptoms to the anatomy of the disease, to say what condition of brain or of membranes coincides with each of these stages respectively. What are the life signs of actual tubercular development, what of hyperæmia or of inflammatory exudation, and what is the relationship and order of procession of these several phenomena? All that we know is that a child may fulfil the symptoms of the first stage, and even of the second, and then recover; and that, fulfilling all the stages and dying, it by no means follows that any tubercular growth, or even that recent inflammation shall be found *post-mortem*. In fact, no more is signified for certain, even by the later symptoms, such as retraction of head, strabismus and repeated convulsion, than a condition of cerebral irritation, to which it is clear, both from the fact of recovery in some instances and the fact of death without either tubercle or new inflammation in others, no more precise definition can be given.<sup>6</sup>

We have, in fact, ample authority (derived from the

<sup>5</sup> Anatomically there is practical equality of tubercular invasion in early life between the brain and lungs, the peritonæum being far behind. But it is to be noticed that while the brain is sometimes free, and sometimes meningitis is found but no tubercle, it is very rarely indeed that the lung escapes altogether; where there is no tubercle there will be pneumouia and enlarged, perhaps caseating, glands. I find but one out of 65 consecutive cases of tubercle where the lungs are natural. It is one of peritonitis, presumably tubercular. (No. 82, Vol. v., P.M. and Case Book.) Thus, the liability of the lung in tuberculosis, which is so obvious a fact with the adult, is true of the child also, although less apparent clinically than anatomically.

<sup>6</sup> A child, aged 4, had daily convulsions and vomiting with retracted abdomen and progressive wasting. Later, strabismus and unequal pupils were superadded. After about 6 weeks of such symptoms, which were now better and now worse, the child began to mend, and two months after the first seizure all cerebral symptoms had disappeared. The patient, now recovering, caught measles, and of an intercurrent attack of bronchitis connected therewith, died less than a fortnight after the disappearance of the nervous symptoms and without any return of them. *Post-mortem* there was no tubercle either in the brain or elsewhere, and no sign of inflammation past or present. (Vol. i., p. 649, P.M. and Case-Book.)

records of this hospital for the last 25 years) for saying, first, that children with symptoms taken for tuberculosis—and the statement need not be limited to the brain alone—will sometimes recover, contrary to expectation and contrary to their common rule, and sometimes they will recover from a first and die in a second and precisely similar attack; secondly, that children with symptoms taken for tuberculosis during life, and dying just as the tubercular do, will sometimes fail to exhibit any grey granulations whatever, while sometimes (as in the case just related), although granulations appear elsewhere, there will be none at the seat of active inflammation, the place, that is, to which the symptoms pointed, the organ through whose disorder the patient died.

Now, as a way out of this difficulty, in so far as it concerns hydrocephalus, it is maintained by some high authorities that there is a spurious as well as a real hydrocephalus, an affection to which Dr. Marshall Hall gave the name "hydrocephaloid disease," which arises from different and, indeed, quite opposite causes, which needs a perfectly different treatment, yet which the nicest discrimination hardly enables us to separate from the condition it simulates.

I would ask you on every ground, both logical and pathological, to reject this "spurious hydrocephalus" as an unreal shelter. There is no room for it either in physiology or therapeutics, and in morbid anatomy it does not even claim a place. The old notions of the overfed and actively inflamed brain, and the underfed and anæmic brain—of "depletion," curative up to a certain point, and injurious afterwards—all this has ceased to be. Modern treatment in discarding altogether the depletion of little children suffering meningitis by means of bleeding and mercury has taken away whatever appearance of reality "spurious hydrocephalus" ever possessed. And if all similar phraseology were banished along with it—"spurious croup," "spurious whooping-cough," "bastard pneumonia" and the like—we should all be the gainers. Acute hydrocephalus is acute meningitis, and where it is wrongly attributed owing to the misinterpretation of clinical signs it is not the inflammation that is to be blamed, but our own narrow and insufficient definition of its symptoms.

What other solution is possible? When I observe symptoms like meningitis accumulating day by day, symptoms which I have seen and followed to the *post-mortem* room many times, and which books describe to me as the signs of tubercular meningitis, what am I to say of those exceptional examples—of the one case in twenty that recovers? There are but two answers. One is simple meningitis, which is recoverable, is indistinguishable from the tubercular. The other is tubercular meningitis, is itself recoverable in its earlier stages.<sup>7</sup> The whole question, as it seems to me, resolves itself into this: What is the period, and what, if any, are the signs of tubercular development, *when does the tubercle itself come*, and how are the local inflammatory signs (and I would even add the general constitutional signs) related to that event? Keeping to our illustration in acute hydrocephalus, if tubercle be the *cause* of inflammation, then tubercular meningitis must be always and

necessarily fatal; and we err, from time to time, in prognosis from not knowing its proper signs. But if tubercle is a result or part consequence or occasional associate of meningitis, then there is a period in every case of the kind when the inflammation being pretubercular is not necessarily fatal, but sometimes recovers, and sometimes causes death at that early stage.

Shall we say, then, tubercular manifestations, both local and general, precede and herald the actual advent of tubercle; tubercular inflammation may precede tubercular development; the local symptoms, like the constitutional, are at the first but warnings of a tubercular irruption which appropriate treatment, whether by climate, diet or drugs<sup>8</sup> may in certain instances arrest? The statement is one which obviously can receive no direct sanction from morbid anatomy, inasmuch as the cases which it contemplates are precisely those which are removed from that field of observation. Yet it may be true, nevertheless. Let us leave the children for awhile and enquire of older people. Youth may be taken as well as childhood to illustrate the ways of tubercle, and especially of pulmonary tubercle, where there is less of doubt and obscurity than in the case of acute hydrocephalus. A young Englishman born in New Zealand came over to this country to study for the bar. Very soon he began to show tubercular symptoms, cough and wasting and night sweats, with now and again some localized bronchitis. These symptoms persisting, he took alarm and advice, and returned, as he hoped, temporarily to his birth place. Back in New Zealand, leading an outdoor farming life, he got stout and robust, and presently returned to his chambers and student life in Lincoln's Inn. Thereupon, again, comes the wasting and cough and the rest of it, and this time his condition is so grave as to threaten very speedy death. But he is carried on board ship, sails from the country which he is now persuaded is not liveable for him, and once more becomes a strong and healthy man. Here is but one case out of many. It can hardly be doubted that this young man so long as he lived in London was making for tubercle; it can hardly be doubted that he came very near to actual tubercle development; yet it is certain that he managed to escape that final stage, and that sea air and his native climate twice saved his life.

It is the same, I am persuaded, with children and with hydrocephalus. But here the fact is obscured, partly because, until quite recently, meningeal inflammation was so fiercely attacked by bleeding and mercury that the chances of recovery were reduced to a minimum, and partly because the term "spurious hydrocephalus" was applied to those that survived that treatment. Pulmonary tubercle is not put to the same penalty, nor has anyone as yet proposed to call symptoms like those I have just quoted "tuberculoïd," and so the truth is more apparent in the case of the lungs than of the brain. But a more rational treatment, aided or not by the use of drugs, is coming to the rescue of these unhappy babies who are threatened with tuberculosis, and already there are signs that the subjects of meningeal inflammation recover in larger proportion than heretofore.

I have taken acute hydrocephalus for the purpose of illustration as being the most characteristic as well as the commonest form of tuberculosis in young children. But, as you have seen, the symptoms of meningeal inflammation are dubious and equivocal to a degree even beyond what we are in the habit of admitting. The case is much plainer in tubercular peritonitis, for the signs of this inflammation are within

<sup>7</sup> The point at issue concerns the relationship of meningitis to tubercle, a question which is not affected by the observation that the diagnosis of meningitis itself, whether tubercular or not, is not absolutely infallible. Yet in proof not only of the general correctness of diagnosis, but also of the recoverability of meningitis, it is not rare to find *post-mortem* the signs of old meningeal inflammation corresponding to a distinct clinical history of a past attack. I would commend to notice Dr. Goodhart's remarks on this subject: "No doubt," he says, "some of the less severe cases of simple meningitis get well," and he adds an opinion that the error has been "not in the diagnosis, but the too rigid application of the more general rule that meningitis is generally fatal." The same writer is, I believe, equally in the right in declining to assign any precise diagnostic value at present to optic neuritis. "Diseases of Children," p. 395, &c.

<sup>8</sup> I include drugs tentatively in the growing belief that tubercular inflammation in children is sometimes favourably influenced by the employment of the hypophosphite of soda in doses much larger than those which are now official.

sight and touch. In children who are markedly "tubercular," the abdomen will become distended, sometimes it will give signs of fluid, the patients will waste and sweat and have continued pyrexia, and yet a certain proportion of them eventually recover. The name "tubercular peritonitis" is habitually attached to such symptoms; and, in the event of recovery, it is less readily withdrawn than in the other case. For of the inflammation there has been physical evidence, and to speak of simple or idiopathic peritonitis is almost meaningless. Moreover, unlike what happens in meningitis, the several steps in the morbid process are here traceable, from the early hyperplasia of lymphatic glands which is its first starting point. We recognise throughout the structural basis of the affection, and can even define anatomically the precise stage at which recovery becomes impossible.

But upon this branch of the subject—the part played by the lymphatic glands in the so-called tubercular diseases of childhood—there is no room to enter. Had time permitted it could have been shown how the several forms of tubercular phthisis in children, whether thoracic or abdominal, owe some of their distinctive characters to the behaviour of these glands; and especially how empyema, which in early life is sometimes only a form of phthisis, takes its shape in consequence of the intimate histological likeness between pleura and lymphatic glands.

In conclusion, I would direct your main attention to two considerations of the highest practical importance, arising out of the great and difficult subject which has been so inadequately discussed this afternoon. One is the possibility, nay, the probability, that the mortality from tuberculosis in children here in London is in large degree preventable. The other is the uncertainty which must always attend the early diagnosis of tuberculosis, more especially in that cerebral form which is its commonest manifestation in infants, an uncertainty which is not removed by the recovery of the patient.

The enormous mortality of poor children in London concerns chiefly, as I have said, those who are under five years of age; and it is not to be accounted for by inheritance. For a certain proportion of this high death-rate is probable that the health deterioration produced by measles and whooping cough is responsible, and for a further proportion the conditions of London life among the poor. What we want to ascertain is the relative action of these several factors. Considering that many of the circumstances of poverty—such, for instance, as concern food, clothing, and exposure—are much the same both in town and country, it is at least plausible to maintain that one chief agent of tuberculosis, and part cause of the intolerable fatality of the disease in London, is overcrowding and dwelling underground away from the light and the sun—such conditions of living, in a word, as are known to cause tuberculosis in rabbits and guinea pigs. That is the first point; and the second is that when tuberculosis seems already in possession, be the signs those of meningitis, peritonitis, or broncho-pneumonia, a fatal termination is not to be regarded as inevitable. Not only is there a premonition of danger in certain well-known constitutional signs, there is besides a pre-tubercular stage of inflammation capable of recovery, and it may be within reach of drugs, a stage which, so far as acute hydrocephalus is concerned, has hitherto been so hardly dealt with by "antiphlogistics" and "depletion" that the natural tendency to recover (be it more or less) has been under-estimated.

NAVAL MEDICAL SUPPLEMENTAL FUND.—At the quarterly meeting of the Directors of this Fund, held on the 14th instant, Sir W. R. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of 62*l.* was distributed among the several applicants.

## THE USE OF HOMATROPINE AS A SUBSTITUTE FOR ATROPINE IN ESTIMATING LESIONS OF REFRACTION OF THE EYE.

By W. LANG, F.R.C.S. Eng.,

Ophthalmic Surgeon to the Middlesex Hospital; and Assistant Surgeon to the Royal London Ophthalmic Hospital,

AND

JAMES W. BARRETT, M.B.,

Demonstrator of Physiology in King's College and Clinical Assistant to the Royal London Ophthalmic Hospital.

THE great inconvenience which patients experience from the prolonged paralysis of accommodation and mydriasis, which follow the application to the eyes of atropine for the purpose of ascertaining lesions of refraction, has stimulated us to make investigation with a view of ascertaining whether any other agent would answer the purpose equally well, and at the same time minimize the attendant inconveniences.

This preliminary communication is based upon the first set of experiments conducted by us, and as both the primary and check experiments have been uniform in their results, we now feel justified in publishing the results depending on them.

The objection to the use of atropine for the purpose mentioned is, that the accommodation usually remains paralysed after its application for from seven to ten days, and sometimes even longer, so that the determination of a lesion of refraction involves paralysis of the accommodation for seven to fourteen days.

It was required, then, to find an agent which would effect the necessary paralysis in a short time, and the effects of which would rapidly pass off, so that the examination for the purpose of finding the lesion of refraction could be made very shortly after the patient was seen for the first time.

There are, probably, several agents which will effect this purpose, but the one which, from a variety of considerations, appeared to us to be the best is homatropine, which was first introduced to the notice of the English profession by Mr. Tweedy some years since. With respect to the necessity for applying any agent in estimating lesions of refraction we can refer to some experiments made by Mr. A. S. Morton and Mr. J. W. Barrett,\* which show that, without the use of some such agent, retinoscopy gives very unreliable and variable results.

Fifty eyes have been experimented on by us with the view of ascertaining whether this agent is equal to atropine for the purpose mentioned. The notes of the examination of 31 of these are attached. Notes of the remaining 19, which were of the nature of check observations, are not here inserted.

The method of experiment adopted was as follows:—After noting the vision, a solution of homatropine (2 per cent.) was freely applied to the eye, the lids being held apart and the eye bathed in the solution for about half-a-minute. For the majority of cases, after an hour's interval, this proceeding was repeated, but in a smaller number of cases this was not done.

Not less than 15 minutes after the second application (when it was made), retinoscopy was practised at the macula lutea in the usual manner. After this a solution of atropine 0.4 per cent. was applied to the eyes three times a day for four days, and at the end of this time retinoscopy was again practised.

The results given in the two cases were then compared and the vision ascertained whilst the patient was under the influence of atropine.

A consideration of the following tables shows that

\* Paper on Retinoscopy in Press.

very much the same result was given when the 2 per cent. homatropine solution was applied once or twice, and also in the isolated cases where an 8 per cent. solution was used.

The object of the second application was to prevent error which might occur from the washing of the atropine out of the eye in the first application by the tears.

To obviate this washing out we have used a 2 per cent. solution of pure homatropine in castor oil. This we find answers perfectly, as it does not give rise to oil globules on the cornea like the vaseline ointment, or preparation of homatropine, and at the same time does not leave the conjunctiva so soon as a watery solution. As a rule, too, but one application is required.

Of the 31 eyes the notes of the examination of which are stated above, 14 were myopic, and 17 hypermetropic. Of the 14 myopic eyes, the astigmatism indicated under the two conditions did not differ by more than 0.25 D. In 4 (Nos. 3, 17, 18, and 30) the lesion of refraction indicated was exactly the same in both eyes. In 9 (Nos. 1, 2, 8, 4, 21, 22, 23, 24, and 29), the myopia indicated was less under atropine than under homatropine by from 0.25 D. to 0.5 D., whilst only in 2 (Nos. 5 and 6) was there a difference of as much as—1 D. and this in very myopic eyes, in which very accurate retinoscopy was impossible.

Of the 17 hypermetropic eyes, the results given were much the same under the two conditions. The astigmatism indicated under the two conditions did not differ by more than 0.5 D. In five cases (Nos. 7, 8, 16, 25 and 26), the results given under the two conditions were identical. In ten cases (Nos. 9, 10, 11, 12, 15, 19, 20, 27, 28, 31), the hypermetropia indicated under atropine was greater than that indicated under homatropine by from 0.25 D. to 0.5 D. Whilst in two cases (Nos. 13 and 14), the hypermetropia indicated under atropine was less than that indicated under homatropine by 0.25 D. So that the general result of the experiments was that under the influence of homatropine the myopia indicated was less than, and the hypermetropia greater than, that indicated under atropine and that the difference averaged about 0.25 D. in only two cases being more than 0.5 D. In these cases (Nos. 5 and 6), the condition of the eye explains the error.

Making every allowance for possible errors in working, the result shows that, at all events in the majority of cases, homatropine may be used in the manner indicated for the purpose of estimating lesion of refraction. In ordering the glasses it will simply be necessary to deduct or add less than the amount usually allowed for the atropine, the difference being something under 0.5 D. There are, however, some cases of spasm of the accommodation which need the prolonged use of atropine, and cannot be examined in this way.

As to the time taken by the accommodation apparatus to recover after this application, our investigation on this head has been rather of a clinical than a scientific character; since we have assumed the time of return of voluntary control over the apparatus to be the time when hypermetropes, whose accommodation has been paralysed as described, could again read and do their near work accurately, and also by the time when the pupil became of normal size. We have found this period in about twelve hypermetropes to vary from 24 to 48 hours after the final application of homatropine.

Since even this delay in regaining complete control over the apparatus is an objection, we have managed to do away with it altogether by means of the application of a solution of eserine .4 per cent. to the eyes after retinoscopy.

The application of this solution after retinoscopy has been followed, in the cases in which we have tried it, by such a change in the accommodation apparatus that the patient (hypermetropic) in a few minutes ob-

tained fair distant vision and fair near vision, the near vision being Ir. j. at 25 c.m. distance. The effect of the eserine seems in some cases to pass off completely just as the effect of the homatropine is ceasing, whilst in other cases just before the homatropine effect has ended. Still we have found so far that by this use of eserine patients are enabled to continue their daily work without interruption after the retinoscopy is effected. All patients whose eyes we have so treated have been hypermetropes, since such an application is hardly necessary in the case of myopes.

We feel, then, justified in asserting—

(1) That in the majority of cases where it is required to estimate the refractive condition of the eye atropine need not be used, but that a 2 per cent. homatropine ointment or solution applied in the manner indicated will answer equally well.

(2) That the effect will pass off in from one to two days, but that if the patient be hypermetropic or emmetropic, and is desirous of avoiding the period of paresis of accommodation,

(3) One or two applications of .8 per cent. solution of eserine just after the examination is finished will give him fair near vision till the effect of the homatropine is beginning to pass off.

### ON ARTHROPATHIES ASSOCIATED WITH INFANTILE PARALYSIS.

J. A. COUTTS, M.B. (Cantab), M.R.C.P.,

Assistant Physician to the East London Hospital for Children.

THE interest connected with anything concerning the conditions known as Charcot's disease, as evidenced by the late prolonged debate at the Clinical Society, must be my excuse for a crude and somewhat premature paper. In that debate, as reported by the medical journals, most of the speakers confined themselves somewhat rigidly to the question of the connection of the joint lesion with locomotor ataxia, and the whole dispute ranged itself about the point as to the reality of so-called tabetic arthropathy as a distinct disease. Now in thus restricting themselves, it seems to me the speakers missed much of the advantages that might have resulted from the consideration of arthropathies associated with other diseases of the spinal cord. Charcot, although chiefly treating of the disease as associated with *tabes dorsalis*, by no means limited it to the last, and speaks of it as a factor in paraplegia from Pott's disease, tumours occupying the grey spinal substance, progressive muscular atrophy, acute myelitis, &c. His cases on which he most relies to demonstrate the connection between the cord and arthropathies are two in which the disease manifested itself on the paralysed side after severance, by wounds, of one lateral half of the cord.<sup>1</sup> Here the joint troubles occurred almost simultaneously with the motor ones on the paralysed side, affording strong confirmation of the dependence of both on the same injury to the spinal cord. In speaking of the joint phenomena in locomotor ataxy he strongly expresses the opinion that they will be found consecutive to extension of the cord lesion to the motor cells in the anterior cornua, along the internal radicular fasciculi. If his views be correct as to the dependence of the arthropathy on the motor cells in the anterior cornua, then locomotor ataxia with its manifold symptoms and varied lesions, would seem

a most unsuitable example to take for their verification. Search should rather be made in those diseases due to lesions more strictly confined to the motor cells. Of these, at the present time, the two best known are infantile paralysis and progressive muscular atrophy. Of occurrence of arthropathies in the latter disease Charcot has, as I said before, given examples. That he does not instance it in the former would seem to prove, either that he was unacquainted with arthropathies occurring during its course, or else considered them due to causes other than spinal. Now, in infantile paralysis, it would seem to me that we possess every requisite for the manifestation of this much debated disease. In it the lesion is probably irritative in its nature at its commencement, and originates in, or at least very early in its progress involves, the large motor cells in the anterior cornua; any sclerotic changes that may occur in the neuroglia being secondary to the changes in the motor cells. If it can be shown that joint disease occurs here, then strong confirmation would be afforded of Charcot's views as to the part played by the spinal elements in locomotor ataxia and other diseases.

In an admirable paper on rheumatism in children, read before the British Medical Association in August, 1883, by Dr. Barlow, the author calls attention to an affection occurring at the commencement of infantile paralysis, which he warned his hearers should not be confounded with rheumatic manifestations. Since my attention was called to it by this paper I twice chanced to come upon this affection during an investigation as to the frequency of rheumatism in children made at the instigation of Dr. Sturges.<sup>2</sup>

My first case was that of a male child, aged sixteen months, who had been ill for six days when first seen. The mother stated that the child was slightly feverish at the commencement of the attack, but this was never very marked; there had been no convulsions, and the disturbance being attributed merely to teething no medical man was called in. On my first seeing the child, the mother informed me that there had been no movement of the left leg since the commencement of the attack, a circumstance which she ascribed to rheumatism, giving as her reasons for so doing the condition of the ankle joint. This, on examination, presented an obvious swelling, but permitted free handling without pain or discomfort to the child. Although to the touch this ankle-joint seemed of a higher temperature than the unaffected one, the same condition along with a slight hyperæmia obtained in the whole left limb below the knee, and was not localised in the ankle-joint. There was no history of accident, and nothing like bruising of the tissues about the joint. The left leg was flaccid and the knee-jerk unobtainable, while it was readily elicited on the other side. The diagnosis of infantile paralysis was arrived at and borne out by the result. On being seen the next week the condition remained much the same with the exception that the surface temperature on the affected side was the same, or even lower than that on the sound one. At the end of a month the swelling of the ankle-joint was still present, there had been marked wasting of muscles, the circumference of the left leg being nearly an inch less than that of the right, and its temperature much lower; the contrast between the wasted limb and the swollen ankle-joint presented a striking appearance.

My next case was that of a male infant, aged 11 months, and the illness dated from a month previous to the time of my seeing him. Beyond slight feverishness and fretfulness there had been no definite symptoms to mark the commencement of the attack. At his first visit to the hospital there was noted wasting of left

<sup>1</sup> Charcot. "Diseases of the Nervous System." New Sydenham Society's Edition, vol. ii. p. 58.

<sup>2</sup> *Lancet*, Sept. 20th, 1885.

leg, its circumference being nearly half an inch less than its sound fellow, with flaccidity and loss of temperature. There was swelling of the left ankle-joint, which the mother stated had made its appearance a few days after the child had been taken ill. In addition to this condition of the ankle-joint the dorsum of the left foot was puffy and swollen, as if œdematous, but the swelling was firm to the touch, and did not pit on pressure.

These cases, I may add, ran the ordinary course of those of infantile paralysis, the muscles, as usual, most affected being those on the front of the leg. The swelling of the ankle-joints gradually disappeared, and at the end of six weeks from the first commencement, beyond extreme mobility of the joint, left no traces of its former presence.

Besides these two cases where the arthropathy commenced almost simultaneously with the motor troubles, I had the opportunity of seeing the same condition in the right ankle joint of a female child aged three-and-a-half years, who had been the victim of infantile paralysis of the right leg for nearly two years. In her case the swelling was shorter lived, lasting only a fortnight, but as I was unable to connect her joint trouble with any fresh paralytic condition, such as is sometimes seen in the disease,<sup>3</sup> I purposely leave it out of consideration in the views about to be put forward.

Now, as to the nature of these joint-lesions occurring in infantile paralysis? That they were not rheumatic will, I think, be readily granted. The age of the patients, rheumatism in children so young being an extreme rarity, the absence of local tenderness and redness, the course of the disease, the long localisation in the one joint and the absence of complication of others, &c., would all go to negative such a supposition. The most careful enquiries failed to elicit any traumatic cause to account for any such injuries.

There seem to be the following reasons for believing that they were of spinal origin and due to the same exciting cause as the paralysis—(1) They took place on the affected side, and were strictly limited on that side to the region presumably in relation with the same part of the cord as the paralysed muscles. (2) The date of their origin, probably the same as that of the paralysis, coincided with the supposed acute stage of inflammatory changes in the cord. In connection with this I would draw attention to the close resemblance of some points in my first case to some of those detailed by Charcot in his cases of severance of one lateral half of the cord. (3) The progress of the joint affection was the same as that of many others observed during the course of other spinal affections.

No one can be more fully aware than I am of the fallacy attached to reasoning on data so meagre as those which I furnish. The chief reason for my paper is that others may be induced to publish their experience of those arthropathies occurring in infantile paralysis, and their views as to their possible association with the disease known by Charcot's name. That these arthropathies are not very uncommon at the commencement of infantile paralysis will, I believe, be verified by those who search for them. Unfortunately the protean aspect which the disease presents at its commencement must often obscure its diagnosis until the time has passed for the recognition of these possible arthropathies, and our experience at children's hospitals is chiefly limited to cases in which the disease has existed for so long a time as to render the complaint an unmistakeable one. But in many cases one can gather from the parents or friends a history of the existence of a supposed rheumatic affection at the commencement of the attack, and although such testimony is, as a rule, extremely untrustworthy, it may be taken for what it is worth as confirmatory of the

frequency of the arthropathies. It is possible again, that in some of those cases in which extreme mobility of the joint exists, more than is explainable by the state of the muscles, the extra mobility may be a legacy left by the past arthropathy.

In conclusion, it would be interesting to know whether the cases associated with arthropathies differ in any respect in the severity of their progress from those without this accompaniment; whether, as I fancy, muscular wasting is more rapid in them than ordinarily, and also whether recovery is at all influenced by the fact that a joint lesion was a factor at the commencement of the disease.

---

## PERFORATING ULCER OF THE BLADDER.

By JAMES OLIVER, M.B. Edin., M.R.C.P. Lond.

THE type of ulcer I am about to describe as affecting the bladder has hitherto been looked upon as more or less peculiar to the stomach and duodenum. When however, we consider the probable cause of its formation, it is not to be wondered at that other parts of the intestinal canal and even the bladder itself may become the seat of a similar necrotic change. In the *Lancet* of March 7th of this year, I recorded a case in which the ascending colon had been thus perforated, and doubtless careful pathological observation will prove that such are not uncommon.

Perforating ulcer of the bladder is primarily always acute; if, however, there be extensive destruction of tissue, the functions of the organs are likely to be permanently disturbed and the disease become one truly chronic in character. This ulcer is especially apt to recur, a fact strongly in favour of a diathetic tendency or proneness to the affection. It usually develops without signs of inflammation or suppuration, and as in the stomach and other parts of the intestinal tract, apparently results from a plugging of the vessels which run in and nourish the coats of the viscus. If the blood supply to any tissue of the body be suddenly withdrawn—as happens when a vessel becomes occluded—and collateral circulation be not readily established death of the part is inevitable. Embolism and thrombosis are the most frequent causes of softening in the brain and spinal cord, and it is more than likely that these play an important part in the production of perforating ulcer of the bladder. Round ulcers similar to those we are now considering have been produced in the stomachs of animals artificially by the introduction of emboli into the gastric vessels. This form of necrosis is truly analogous with dry gangrene occasionally seen in the extremities of the aged, where the arteries, because of the generative changes in their coats, have become impervious. The embolic theory of chorea is still tenable, and all who see much of this disease remark its frequent association with rheumatism or a rheumatic predisposition. Judging from those cases of perforating ulcer of the bladder which have come under my notice, I am inclined to believe that the rheumatic diathesis augments the tendency to this affection, and favours embolism as a probable cause of its production. In one case the symptoms attributable to perforating ulcer developed during an attack of acute rheumatism, and as the patient died some time after, opportunity was afforded for examining the bladder and verifying the diagnosis. The heart in this case showed no trace of valvular disease. Females, it would appear, are more prone to this affection than males, and especially about the period of puberty. No exciting cause can as yet be suggested.

<sup>3</sup> Charcot. "Diseases of the Nervous System." New Sydenham Society's Edition, vol ii. p. 134.

One or more ulcers may develop according to the number of vessels occluded; some days, however, must necessarily elapse before disintegration is completed. Whether the necrotic changes shall invade the whole thickness of the bladder wall or not depends on the seat of obstruction of the artery, the completeness or incompleteness of the plugging, and the period at which collateral circulation becomes established. Should, however, the destructive process attack all the coats of the bladder, and at a part covered by peritonæum, this coat tends to thicken and form adhesions with neighbouring structures, it may be the small intestine or omentum, thereby preventing rupture of the organ, extravasation of its contents, and death by shock or peritonitis. If the bladder forms adhesions with any part of the intestinal canal, the ulcerative process may extend and invade this organ too; vesico-intestinal fistula, though fortunately rare, may therefore depend upon simple perforation. In such cases even a careful enquiry into the clinical history may fail to reveal the probable starting point.

The symptoms and course of perforating ulcer of the bladder are usually very insidious, and fatal peritonitis may result from destruction of all the coats ere the grave condition has been recognised. Pain more or less constant and referred to the hypogastrium is a frequent symptom—it is aggravated by pressure and any slight distension of the organ. There is frequency in micturition, and the pain as a rule becomes sharp and cutting in character towards the end of the act. The most distressing symptom of all is tenesmus, which results from spasm of the muscular coat, and may continue for some time after the organ has completely emptied itself. Blood usually appears in the urine about the third or fourth day, is small in quantity, and is expelled with the last drops of urine. The treatment is rest and bland food; opiates must be given to relieve pain and the intense bearing down.

**THREE CASES OF PLEURISY WITH EXCESSIVE EFFUSION OF FLUID.**

(Under the care of Dr. JOHNSON.)

(Reported by Mr. T. SYDNEY SHORT, Medical Registrar.)

**CASE I.**—J. C., æt. 15 years, was admitted on Feb. 10th, 1885. He had had no previous chest trouble and gave a history of good health. Ten days before admission he caught cold and had several shivering fits, followed by dyspnoea, pain in the left side, and feverish symptoms. On admission the respirations were 40, the pulse-rate 102 per minute, and he complained of a sharp pain in the left side on taking a deep breath. The left side of the chest measured 1 inch more than the right at the level of the ensiform cartilage and  $\frac{3}{4}$  inch more at the nipple level. The whole of the left side was dull on percussion, with absence of vocal fremitus below the 7th rib; above this vocal fremitus was present, but decreased. The vocal resonance was absent below the level of the 2nd rib and much diminished above, with an ægophonic twang. The heart was pushed over to the right side, and the apex beat most plainly seen in the epigastrium. In three days there was a distinct pleural friction-sound heard most plainly at the 4th left intercostal space syn-

chronous with the heart's impulse. At the end of the week the fluid had much decreased; fremitus could be obtained all over in front, but not at the base behind. The patient improved rapidly, and was sent to the Convalescent Home on March 16th; no evidence of fluid could be detected after the beginning of the month. The temperature during the first week ranged between 99° and 102° F., and during the second between 98° and 101° F., gradually falling to the normal.

*Treatment.*—Nitrate of potash with quassia at first; on the 9th day, iron and quinine; and on the 13th day, cod liver oil in addition.

**CASE II.**—G. E., 47 years, admitted on April 20th, 1885. He had no history of any previous chest disease; was a travelling photographer by trade and much exposed to the weather. Robust-looking man, subject to attacks of gout. Three weeks before admission was out on a cold and damp day, but felt no bad effect from this until a week afterwards, when he had several rigors and a severe pain beneath the left nipple, much dyspnoea, and a short cough. These symptoms continued for a fortnight, the dyspnoea getting worse and the rigors recurring. On admission he was breathing 60 times a minute. The left side of the chest was larger than the right by  $\frac{1}{4}$  inch, the whole of the side was dull to percussion, with absence of vocal resonance and fremitus. Bronchial breathing was heard in the left vertebral groove, heart was pushed over to the right side, no impulse could be seen on the left of the sternum, the apex beat was diffused and visible from the right edge of the sternum to  $\frac{1}{2}$  inch from the right nipple. Temperature 101° F. Paracentesis thoracis was performed on the day of his admission below angle of left scapula, and 98 oz. of clear serum were drawn off. Dyspnoea greatly relieved, and the next morning the respirations were only 18 a minute, the temperature had dropped to 98° F., rising however to 101.4° F. the same evening. On the second day the dulness extended up to the nipple level only, and feeble breathing with frictions were heard above this. The heart was seen now beating just to the left of the sternum. At the end of the week dulness reached as high as the 6th rib on the nipple line, and the 8th in the scapula line; above these the vesicular murmur was present, but feeble, and ægophony was heard below the level given posteriorly. The heart assumed its normal position on the 10th day, and the temperature during this week varied from 98° to 100° F. During the next three weeks the patient steadily improved, the temperature being at about normal, and at the end of this time the vesicular murmur and the vocal resonance and fremitus were equal on both sides, except at the extreme left base where they were still feeble. He got up at the end of the third week, and was discharged on June 10th. No treatment was required beyond that mentioned.

**CASE III.**—E. H. W., aged 15 years, admitted on April 30th, 1885. He was a pale-looking boy, and a "roller" at printing works by occupation. Had had no previous chest trouble. No phthisical history in the family.

He was admitted with dyspnoea, pain in the left side, and slight cough with no expectoration. Said that at about Christmas time he had suffered with pain in the right side of the chest and a cough, but did not lay up with it; he went on with his work and had his chest poulticed at night. The pain passed off, but during the early part of the year he had several recurrences of pain in both sides of the chest. A week before his admission the pain settled in the left side of the chest, and he had several shivering fits with sweats at night time and a short dry cough. For three days he had been laid up in bed. On admission respiration = 36; pulse = 112. Left side of the chest was dull all over front and back, and the intercostal spaces were bulging

outwards; the circumference of the side was larger than that of the right side, with greatly decreased expansion. The heart was pushed over to the right side and the apex beat was seen in the right fifth interspace. Temperature = 100° F., and on the next day 101.4° F., being irregular during the week, but only once rising over 100° F. Linsced meal poultice was applied, and he had Pot. Iod. gr. v. in water three times a day. The first two days he sweated freely, with no cough nor pain: on the fifth day the dulness in front reached the third rib only, and exaggerated breath sounds were heard above this. At the end of the first week the dulness reached the fourth rib in front and the eighth behind, the fremitus above being good, but absent below. The resonance was high pitched on percussion, and frictions could be heard above the level of the fluid. The heart not yet in its normal position. At the end of a fortnight there was no absolute dulness anywhere, and breath sounds could be heard all over, but were feeble at the base. Temperature during the last week was at about the normal. On May 11th he was ordered a quinine mixture; his condition steadily improving he had a belladonna plaster applied on the 21st, and an iron and quinine mixture internally on the 24th. The heart regained its normal position during the second week.

It was found that the right side of the chest was really larger in circumference than the left on account of a lateral spinal curvature, so that the increase in the size of the left side from the collection of fluid was more than a mere measurement would imply.

*Remarks by Dr. JOHNSON.*—While the first and third cases afford good examples of the rapid absorption of an extensive pleuritic effusion, the second case illustrates the immediate relief afforded by paracentesis when the symptoms call for active interference. In the first and third cases, although at the time of admission there was copious effusion in the left pleura with displacement of the heart, there was no distress of any kind, and after a few days it was evident that the effusion was being rapidly absorbed. The friction found to the extreme left of the cardiac region, and synchronous with the heart's systole in the first case, was evidently caused by the impulse of the heart against a pleura roughened by lymph. There was no evidence of a pericardial friction. In the second case there was considerable dyspnoea and distress at the time of admission, and as the man had been three weeks ill, it was probable that there might be a considerable thickness of lymph over the surface of the pleura, which would retard if it did not entirely prevent the absorption of the fluid; the immediate performance of paracentesis was therefore decided upon with a very satisfactory result.

**FEMALE MEDICAL EDUCATION IN AUSTRALIA.**—The Sydney correspondent of the *Times* writes that the annual commemoration of the Sydney University, held on May 2nd, was remarkable as being the first occasion on which ladies had been admitted to the degree of B.A. The number of female students in the University classes has steadily increased, and all the novelty will soon wear off. "Even in our small medical school, which is just making a beginning, we have one lady student who is said to be preparing herself for work connected with the Zenana Mission. Mrs. Garrett-Anderson, who is at present on a visit to Sydney, has expressed herself as surprised and pleased at the opportunities which exist here for female medical education, and she has recommended some who have applied to her for advice by all means to prosecute their studies in Sydney, as they will get there as good a medical education as elsewhere, with freer opportunities of walking the hospitals."

## APPOINTMENTS FOR THE WEEK.

Wednesday, July 22.

MEDICAL OFFICERS OF SCHOOLS' ASSOCIATION, at the rooms of the Medical Society, 3 p.m.—Mr. Noble Smith on "Postures in Schools and their Influence upon the Figure."

## Medical Times and Gazette.

SATURDAY, JULY 18, 1885.

It is a well-known historical fact, that many of our most eminent statesmen, from Pitt and Burke to Palmerston and Lowe, have owed their introduction into, if not also their continuance in Parliament, to the existence of so-called pocket boroughs, the owners of which had the good sense to discover and appreciate talents unrecognised by the mass of electors. These have gone their way unwept, but thanks to Lord Salisbury's determined advocacy of the rights of minorities, we have now one-member districts, often corresponding to the wards of our large towns, where a man has a chance of knowing and being known by a large proportion of the constituency, and where the expenses of a canvass cannot be large. "Big" men will doubtless be returned as before, with or without regard to local considerations; but two other tendencies are already manifesting themselves, one for evil and the other for good: first, the selection of local nobodies or busybodies, noisy vestrymen unknown beyond the wards in which they reside; and secondly, the choice of comparatively poor but able men, men to whom the cost of elections has hitherto been prohibitive, and whose claims on a large constituency have been eclipsed by those of wealth and power, though, if elected, they would bring into Parliament new knowledge and new ideas. We would urge before it is too late that efforts be made, especially in the metropolitan boroughs whose representatives will constitute no small proportion of the House, to bring forward several members of the medical profession from both political parties, men who can speak and who have devoted attention to social and sanitary questions.

IN no European Parliament is our profession at present so feebly represented as in our own; the few medical members being such in little more than name, and having for the most part renounced practice for pursuits in which they presumably took more real interest. But already we see not only Mr. Erichsen invited by all the Scottish Universities at once; but Sir W. Gayer Hunter a candidate for central Hackney, and Dr. Tindal Robertson for Nottingham. Surely, with a little self-denial, others could be induced to come forward. Sir H. Thompson is so well known in all classes of society that he would not have the least difficulty in finding a seat, and as a debater would be an undoubted addition to the House; Dr. B.

W. Richardson would be all that a radical teetotal &c., &c. party could desire; Sir Joseph Fayrer has leisure and knowledge of the world, to say nothing of his special acquaintance with India. If vestry clerks are coming forward, why should not some of our metropolitan medical officers of health, as Dr. Seaton and Dr. Thos. Stevenson. Kensington might find an able representative in Dr. Dudfield; and in a year or two, when he is no longer a paid officer of the State, an educated Conservative constituency would do honour to itself by electing Dr. Crichton Browne, who, we believe, would be not averse to enter on a Parliamentary career, and who as an orator would soon make his mark in the House. If Virchow can find the time, who can not?

THE announcement that Mr. Erichsen has agreed to stand for the representation of Edinburgh and St. Andrew's Universities has, according to our Edinburgh Correspondent, given great satisfaction in Liberal circles. The sincere regret felt at the loss of the present representative could scarcely have been better tempered than by the choice of such a man. In him the Universities have secured a candidate who belongs to a profession the most widely represented in the General Councils, who has achieved an unrivalled position as a teacher and leader in his own department, who has filled one of the most honoured and one of the most important administrative posts connected with the profession, and who is in every way qualified to add weight to the discussion on the great questions of sanitary legislation which will no doubt occupy much of the time of the next Parliament. In Mr. Erichsen the Universities have secured a candidate for their suffrages who is neither an office-hunter nor a party stop-gap, but one who comes forward eminently qualified to deal in a special manner with questions of the highest and most pressing social importance, with which the ordinary Parliamentary intelligence can only deal at second-hand. His qualifications for the position he seeks are primarily academic and scientific. On the other side, we have Mr. Macdonald, who is first an ardent Tory partisan, afterwards an amateur soldier, an amateur physicist, and a lawyer of a somewhat parochial reputation (a type with which Parliament seems always abundantly supplied)—a man, in short, who has about as much claim to the representation of the Universities of Edinburgh and St. Andrew's, as he has to the Moderatorship of the General Assembly. Had Mr. Erichsen's name been brought forward earlier it can scarcely be doubted that many who have already pledged themselves to vote for the Lord Advocate would have supported his rival. Not a few Conservatives who have no great desire to see so ardent a Tory as Mr. Macdonald in a University seat, pledged themselves to vote for him as a result of sheer importunity on the part of his committee. Had these been free to vote now, there is no doubt where their vote would have gone.

THE Medical Relief Disqualification Bill of the Government was introduced in the House of Commons,

on Monday, by Mr. A. Balfour, and was read a first time. It goes farther than did Mr. J. Collings' Bill. The Government consider that if disqualification in the matter of Parliamentary elections on account of medical relief is to be abolished, it will be impossible not at the same time to abolish disqualification in other elections also. Disqualification will, therefore, be also abolished in Municipal elections, School Board elections, and the like. One exception is made, however, to the general principle; no man who receives relief from the funds managed by the parochial guardians is to be allowed to vote in poor law matters. The Bill is also to have a retrospective action; *i.e.*, no man is to be disqualified on account of medical relief received since July last year. The history of this so-called medical relief question has not so far been a creditable one. Each of the two great parties in politics has tried to make political capital out of it, and the new Medical Relief Disqualification Bill is at present the biggest bid made in this direction. But for the time little is heard about the paramount importance of teaching the working man to be thrifty, and provident, and independent. We have been loudly and largely told how wicked it is to entice working men to rely for medical relief on the out-patient departments of our hospitals; how we pauperise and generally demoralise them by such facilities; and how we ought to insist on their learning thrift, and subscribing to provident dispensaries. But, alas, in the clash of politics, the voices of these wise teachers are silent. The Government Bill will not meet with universal approval; it certainly contains contentious matter; it has already been blocked by Mr. Courtney; and it is said that it will be severely handled on both sides of the House. The debate on the second reading was to take place yesterday (Thursday), but too late to enable us to record the result—if any.

THE new Government must expect, we suppose, to be asked questions upon subjects that had been pretty well worn out during the reign of the present opposition. On Thursday week in the House of Commons, Mr. Duckham brought up the old subject of Oleomargarine, and asked the President of the Local Government Board whether he was aware that the refuse fat of animals, formerly sent to the tallow-chandler, was now actually used in the manufacture of oleomargarine; that the fat thus used was often in a very putrid state, and that chemicals of a very deleterious nature were used to deodorise it. Mr. A. Balfour replied, with, we doubt not, a properly grave and official countenance, that the Board had no knowledge of the existence in England of any such manufacture as had been described; and he added, of course, that if the hon. gentleman could inform him where any such manufacture was carried on in this country the Local Government Board would be prepared—to bring the matter under the attention of the local authority!

MR. BALFOUR, in reply to a question put by Mr. Brinton, told the House on the same day, that the Local Government Board has communi-

ated with the guardians of several unions with regard to cases of pauper lunatics at present in county lunatic asylums, but who, the Commissioners in Lunacy had stated, might, in the opinion of the medical superintendents of asylums, be adequately and more economically provided for in the workhouse. The guardians in 84 unions replied that they were willing to receive the patients referred to if they were returned to the workhouse. But from 258 unions replies were received to the effect that, for various reasons, the guardians were not prepared to receive such patients. In 37 other unions the guardians were inclined to receive some of the proposed patients, but not others. In some cases the reason assigned for objecting to receive patients was that they had been returned as dangerous since the report by the medical superintendent was made; and in others that there was no proper accommodation for them.

LAST week 1,412 deaths were registered in London, causing the death-rate to rise to 18·0. The zymotic death-rate rose as will be seen from our chart to 3·6; this rise was due wholly to the increased number of deaths from diarrhœa, 110 having been recorded as against 51 last week; 83 occurred in children under one year old. The deaths from small-pox further declined to 23, and the total number of cases under treatment at the end of the week was 780. There

and 13 deaths respectively. Except in Leicester, where there were 10 deaths from it, diarrhœa did not prove very fatal. Manchester is credited with the highest death-rate, viz. 25·8.

IN the early part of the present week, the cholera epidemic in Spain seemed to show some sign of abatement, but the last returns are as bad as ever, as will be seen from the following official returns:—

	Cases.	Deaths.
July 8th .....	1,453	717
„ 9th .....	1,497	700
„ 10th .....	1,395	720
„ 11th .....	1,533	648
„ 12th .....	1,197	588
„ 13th .....	1,092	473
„ 14th .....	1,668	653

Totals.... 9,835 4,499

Altogether, the number of cases officially declared during the second week of the present month was only 246 less than the numbers of the first week. The second week's deaths, however, were fewer by 435 than the first week's, thus pointing to a certain mitigation in the severity of the epidemic. It still continues to spread, and the last news is that suspicious cases have occurred in Segovia, a mountainous province north-west of Madrid, and undoubted cases in the province of Badajoz, to the south-west of the capital, and close to the confines of Portugal. The daily number of cases appears to be declining in Valencia, Murcia, and Castellon, the three maritime provinces first attacked, as well as at Aranjuez; but to be increasing in the provinces of Alicante, Tarragona, Saragossa, and Toledo. It has been officially stated that the total number of cases of cholera in ten provinces in the seven weeks from May 20th to July 9th was 28,042, of which 12,347 ended fatally. The deaths were in the provinces:—Valencia, 6,801; Murcia, 2,319; Castellon, 1,277; Alicante, 646; Saragossa, 280; Toledo, 206; Cuenca, 40; Tarragona, 19; Teruel, 5; Madrid (including Aranjuez), 753. But in the City of Madrid itself, from May 20th to July 9th, only 191 cases occurred, and 113 deaths, of which 80 per cent. were fugitives and sporadic cases. The mortality ranged from 61·29 per cent. in Tarragona to 38·64 in Murcia; whilst in Madrid it was 59·16 per cent. of the persons attacked.

WHATEVER may have been the attitude, whether of hope, of incredulity, or of suspension of judgment, which scientific men at first assumed with regard to Dr. Ferrán's alleged discoveries of the complete life cycle of Koch's bacillus, and of the immunity conferred by inoculation with it, he has, by his conduct towards the French Commissioners, headed by no less eminent a physician and sanitarian than Dr. Brouardel, completely put himself out of court, and thrown away all claim to the sympathy and support of the profession. If Koch, dazzled by the brilliancy of his previous discovery of the tubercle bacillus, the theoretical and practical importance of which is already recognised by the whole medical world, was somewhat hasty and over-sanguine in the matter of the comma-

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past twelve weeks.

were 73 deaths from measles, all but 2 occurring in children under 5 years, and 51 deaths from whooping-cough. Diphtheria and scarlet fever caused 15 and 12 deaths respectively, and 10 were due to enteric fever. In the provincial towns measles was very fatal in Liverpool, Manchester, and Salford, causing 21, 14,

bacillus of cholera (the essential connection of which with the disease in relations other than those of direct causation has not, however, been disproved), he seeks and indeed challenges the fullest criticism, and has distributed what he believes to be the cholera germ to every laboratory in Europe; whereas Ferrán actually refused to part with a single tube, or even to allow his visitors to examine his cultivations.

THE disease that Ferrán induces in his subjects appears to be identical with, though happily for them milder than, that which Thiersch in his well-known experiments produced in mice, and which is now very properly held to have been a form of septicæmia, and not cholera at all; but that was in the dark ages of microzoic pathology. But even supposing it were possible, as it may yet be found, to induce cholera by the injection of bacilli or their products, there is no ground whatever for imagining that it would confer immunity. It is true that those specific diseases, small-pox, measles, &c., one attack of which as a rule protects against a subsequent infection, and in which, therefore, artificial infection holds out a greater or less probability of a like immunity, do occasionally recur; but we have, considering the high mortality, the irregular distribution and the long intervals elapsing between epidemics of cholera in Europe, a number of instances of persons being again attacked quite sufficient to justify the belief that one attack does not in any way protect against the disease in future, and that *a fortiori*, its inoculation, if practicable, would be utterly inoperative. Without repeating Jenner's experimental inoculations of small-pox after vaccination, persons are continually of necessity and in the path of duty exposed to risks and circumstances under which they must certainly have in many cases contracted the disease had not vaccination conferred protection. But in the case of a disease not contagious in the ordinary sense, as enteric fever or cholera, such conditions do not occur, and direct crucial experiment, as drinking the stools, being obviously inadmissible, it is difficult, if not impossible, to say that even some out of numbers of persons operated on must otherwise have been attacked. Protection, even as Ferrán asserts, for a few weeks is a pure assumption; indeed, the idea of temporary immunity requiring a repetition of the operation is entirely without analogy, and seems a mere device to obtain repeated fees.

THE controversy concerning the preservative inoculation of cholera still rages with great intensity. According to our correspondent in the French capital, Dr. Ferrán has sent telegrams to all the Paris journals contradicting Prof. Brouardel's statements, besides which he has communicated a tolerably long note to the Academy of Sciences, describing in a certain measure his *modus operandi*, and claiming the Bréant prize of 4,000*l.*, which was founded in 1850 by M. Bréant, for the discovery of the "*insect*" which produces cholera, or the means of curing that disease. M. Bréant was, in his day, a fervent admirer of Raspail, who pretended that all diseases were produced by *insects*. (a crude and premature form of the microbial

theory), and professed to cure them by his celebrated elixir (near akin to camphorated alcohol). By the sale of this panacea, he realized a fortune of 160,000*l.*, a very *substantial* result, as Dr. Ferrán would say. But if there is any truth in Dr. Ferrán's statements, the prize ought to be divided with Koch, since *he* discovered the "*insect*," which the later observer only cultivated. In the meantime, M. Guignard, professor of botany at the Faculty of Sciences of Lyons, criticises Dr. Ferrán's attempts at morphological description, stating that some of the forms indicated by him belong to the family of the "*Schizomycetæ*," while others belong to the "*Peronosporæ*," and that the description given is the work of an insufficiently prepared observer, studying with imperfect instruments, and examining imperfectly prepared liquids, which contain not one, but several varieties of germs. Several of the Paris papers have taken up the cudgels in favour of Dr. Ferrán, whom they consider as a victim of official misrepresentation and "*red tape*." It could not be expected that the Spanish *naturalist* would allow his boat to sink without a struggle, but the problem, as far as *he* is concerned, seems to be settled in the eyes of most scientific men.

OUR Edinburgh Correspondent writes:—The Final Examinations at the University came to a conclusion on Saturday, when the last list of successful candidates was posted. The number of failures does not exceed that of last year, and it would seem that the general average of attainment has not fallen. No doubt the report of the Visitors from the General Medical Council will be looked for by the Faculty with some interest. The hope which I ventured to express some weeks ago that their visit would put a stop to the absurd system of "*second trials*" in the case of some of the rejected candidates has, I regret to say, not been realized. A select number of tender but backward plants are to be subjected to the process of "*forcing*" at an early date, with the view of coaxing their stunted blossoms into sufficient, though tardy expansion. The process by which a man who fails, say, in surgery, at the regular examination is enabled to pass an irregular one a week or fortnight later, must be a somewhat intricate one, and is apparently a product of the professorial intelligence. The exact method has not been officially divulged, so far as I am aware, and seems to be one of the mysteries of the professorial craft which nothing short of an executive commission can reveal. There is nothing left for the outsider, then, but to take it for granted that it is all right; but if he is permitted to say nothing, he may be excused if he thinks a great deal.

By another year the months of June and July will be big with fate to many an Edinburgh student. By a new regulation, the October sittings of the First Professional Examination are to be transferred to July, so that all the three examinations for the degree will be held about the same time. The April sittings for the First and Second Professional will continue as formerly. This change of the "*First*" to July is a great boon to candidates. It enables them to appear for the examination fresh from the classes, and will

save them much expense by rendering it unnecessary for them to come up to town some weeks before the examination in October for the purpose of reading for it.

THE question of instituting a Physiological and Pathological Laboratory was considered at a special meeting of the Edinburgh College of Physicians last week, and was received with much favour. The further consideration of the scheme was deferred in the meantime, but there is every reason to believe that the scheme is in a fair way towards accomplishment.

AT the Glasgow Royal Infirmary a contest is going forward for the posts of visiting physician and surgeon, vacant by the retirement of Drs. Scott Orr and Eben. Watson. The retirement is, in each case, rendered necessary by the operation of one of the rules of the Infirmary which limits the period of service to fifteen years. Quite a number of the younger men are candidates for the vacancies. For the post of physician Dr. Samson Gemmell, Dr. C. McVail and Dr. J. W. Anderson are applying, and for the post of surgeon Drs. W. J. Fleming, D. Newman, J. C. Renton, J. Barlow, J. A. Adams, Muir and Shaw. The majority of these are already on the Dispensary Staff of the Royal Infirmary, and others are on the Dispensary Staff of the Western Infirmary. The election takes place on the 3rd of August.

WE learn from our Belfast Correspondent that the Ulster Medical Society and the North of Ireland Branch of the British Medical Association have just held their annual meetings at the close of very successful and interesting sessions. These two organisations number between them some 300 members, and have every reason to congratulate themselves upon the result of the work done during the winter months. Mr. John Fagan, F.R.C.S., was unanimously re-elected President of the Ulster Medical Society, and Dr. Kidd was with equal unanimity elected President of the North of Ireland Branch, in the room of Professor Cuming, who retired, and who is further President of the British Medical Association. It is pleasant to learn that our professional brethren across the Channel are reaping all the benefits of organisations, the objects of which are to advance the science of medicine and surgery, and to promote good feeling and brotherly fellowship amongst the members of the healing art. The summer session at the Belfast Medical School has also come to a close, and, though an improvement upon the previous one, still shows that the school has suffered considerably from the recent unsatisfactory and eminently unsuccessful legislation in connection with the annihilation of the late Queen's University. It is, however, satisfactory to know that the teaching arrangements and clinical facilities afforded by Belfast are in a high state of efficiency and activity, and that further improvements and additions to the teaching powers of the College and Hospital are in contemplation in order to carry out and fully meet the suggestions contained in the recent report of the Royal Commission upon the working of the Royal University.

OUR Paris Correspondent writes:—The bad luck which has so pertinaciously attended the Tonkin expedition, seems to have followed the Reserve Division composed of troops brought home from Indo-China, and numbering between seven and eight thousand men. These forces were intended (nominally at least) to serve as reinforcements when needed, after recuperating health and strength in their native atmosphere. But the "Pas des Lanciers," near Marseilles, where they encamped, turned out to be an inconvenient and insalubrious position. The men complained of all sorts of troubles, and it was soon reported that an epidemic had broken out in their ranks. This epidemic turned out to be typhoid fever of a malignant type, and within a short space of time seven hundred and fifty men were lodged in the hospitals of Marseilles, while others sickened and died in the camp. The latest reports speak of a death-rate of 28 per diem. Several officers of high rank have been taken ill, and Colonel Barry, a very gifted and promising officer, who was on the point of being promoted to the rank of Brigadier-General, has just fallen a victim to the epidemic. This painful state of things has lasted for several weeks, but the usual indecision seems to prevail at head-quarters, and no measures have as yet been taken to remove the men from their obnoxious quarters. It would, of course, be imprudent to scatter the men throughout the various garrison towns of France, thereby sowing the seeds of disease through the Army; but the wisdom of creating a focus and hot-bed of fever at the very gates of a populous city, which was severely scourged only last year by an epidemic of cholera, is at least questionable. Besides, one cannot help pitying these unfortunate young men, who after volunteering to serve their country in the far East (the detachments successively sent to Tonkin were principally composed of volunteers drawn from regiments quartered at home), were condemned to undergo the fatigues of a harassing campaign, a distressing climate, and a long sea-voyage; and who, on reaching their native shores, find themselves sacrificed again to motives of public convenience.

A hot and angry controversy took place last Saturday at the Biological Society of Paris between the renowned M. Paul Bert and the equally well-known physiologist Dr. Laborde. The guillotine which, owing to the peculiar tendencies of President Grévy, had been kept at rest for a long space of time, has suddenly resumed its activity, and experimental science has taken possession of some heads, freshly severed from the body. An atrocious murderer, named Gagny, was executed a short time ago, and experiments were made immediately after the execution by Dr. Laborde, Professor Regnard and M. Loyer. In describing the results observed, Dr. Laborde was led to make the remark that consciousness might possibly not be abolished immediately after decapitation; that, at all events, the functions of the retina were not abolished; since the pupil was seen to contract under the influence of light; and that when the brain was supplied, through the carotids, with arterial blood from the vessels of a dog, the excitability (as proved by muscular contractions) of the cerebral substance lasted

much longer (55 minutes) than when no blood is supplied (22 minutes); and that the heart continues to beat during 14 or 15 minutes. At this stage of the proceedings, M. Paul Bert, who presided, rose to express his opinion as to the *immorality* of these experiments, which he described as "an application of torture after death," stating that if he held power he would prohibit them. Dr. Laborde expressed his astonishment to see M. Paul Bert, the celebrated physiologist, appear for the first time in the light of an obstructionist; he expatiated upon the important scientific results which flow from these experiments, and remarked that if it were proved that sensibility and consciousness persist after death, *that* would be the best of all arguments against capital punishment. An angry reply from the President was followed by a retort from Dr. Laborde, and finally the debate was authoritatively closed by the President, who complained, in vehement terms, that a personal attack had been made upon him. It must be confessed, says our Paris Correspondent in commenting on the dispute, that the Biological Society is quite "incompetent," as we say in France, to discuss a point of this nature, being neither an association of philanthropists, nor a synod of theologians. Its province lies in the appreciation and discussion of certain scientific facts, and vivisection has been hitherto its chief mode of investigation. On the other hand, some of our scientific men are too prone to bring prominently before the public certain scientific facts which, however important and interesting in themselves, are calculated to alarm weak minds, and give a shock to weak nerves, and thereby to injure, in the public mind, the cause of experimental physiology.

THE statue of Pinel, which has been erected in front of the Salpêtrière, was unveiled last Monday, in presence of a large crowd. Speeches were delivered by the Prefect of the Seine, M. Poubelle; by the Vice-President of the Municipal Council; by M. Pichan, one of the Members of the Council General; by Drs. Dagonet, Legrand du Saulle and Ritti. A banquet offered by the Medico-Psychological Society closed the ceremony.

THE appointment of a successor to the late Professor von Frerichs in the Chair of Clinical Medicine in Berlin, has of late given rise to much discussion not only in that city, but in most of the medical schools of Germany. A satisfactory settlement has been arrived at by the establishment of two equal Chairs, occupied respectively by Professors Leyden and Gerhardt. The migration of the latter to Berlin is, or ought to be, a source of extreme satisfaction to the leaders of the faculty in that University. The record of work in the past with which Professor Gerhardt has associated his name, compares favourably with that of the greatest workers in medical science. More especially in connection with diseases of children, and as an exponent of the methods of physical examination, are his labours well known in England, whilst as a fellow-worker and pupil of such men as Bamberger, Griesinger, Laschka, and Czermak, he brings to his new work a vast and varied experience of clinical practice, of which the students in

Berlin, whether native or foreign, will not be slow to avail themselves.

OWING to the numbers who take an interest, pecuniary or Platonic, in the subject of the pre-curricular education of the medical students, discussion on the subject is always ready to break out. It is practically endemic amongst us, and there is such a general susceptibility to the infection, that a week seldom passes without its being heard of in one quarter or another. Recently it has appeared in an acute form both in our pages and those of our contemporaries. The discussion is of by no means such recent origin as some are wont to imagine, and a correspondent has called our attention to some passages in Dr. Latham's well-known lecture on "Subjects connected with Clinical Medicine" (New Sydenham Society's Edition, Vol. II.), which, though written over fifty years ago, are so much to the purpose that we do not hesitate to reproduce them. Dr. Latham says:—

"Let us take care what we are about, and beware how we change the character of the English practitioner of physie. He is sound and unpretending, and full of good sense; what he wants is a little more careful and somewhat larger instruction *in what bears directly upon the practical part* of his profession. Give it him, and he will become more trustworthy and more respected every day. But for all that is beyond this, we may recommend it, but we must not insist upon it; we must leave it for each man to pursue according to his leisure, his opportunities, and his capacity, and not exaggerate it into a matter of necessity for all. Where too much is exacted too little will be learned; excess on the one hand naturally leads to defect on the other. . . . Yet I recommend you to get the best scientific education you can. Let each man according to his time and opportunities pursue that department, or those several departments, to which his mind inclines; but let him take care to feel his ground firmly established beneath his feet as he goes along. For here all *half* knowledge is no knowledge at all. Even homely common sense arrives at much safer conclusions in the things which belong to medicine than any scientific principles half understood and misapplied."

We are ashamed that we had forgotten that passage in submitting our "Plea for Variety" last week. No one has urged it better than Dr. Latham. It is also of interest to recall that the same sound and philosophical writer, in the *British Medical Journal*, February 1860, advocated much the same process for interweaving the student's scientific and practical studies, that Dr. Gairdner recently proposed at Dundee.

THE next general meeting of the Medical Officers of Schools' Association will be held at the rooms of the Medical Society, Chandos Street, on Wednesday next, July 22nd, at 3 p.m. A paper, based upon an enquiry made for the School Board of London, on the subject of "Postures in Schools and their Influence upon the Figure" will be read by Mr. Noble Smith. Each member will, as usual, be allowed to introduce two visitors; and the Council have decided, in view of the general importance of the subject to be brought under discussion, that ladies may be admitted as visitors on this occasion.

DR. W. H. BRADFORD, of Boston, U.S.A., states that the dilatation of the pupil and the paralysis of accommodation, which form the chief drawbacks to the employment of cocaine in ocular surgery, may be entirely obviated by combining it with pilocarpin. He claims to have demonstrated that a mixture containing ten minims of a four per cent. solution of hydrochlorate of pilocarpin in a drachm of a four per cent. cocaine solution is efficient in securing the anæsthetic effect of the cocaine, while leaving the pupil and accommodation absolutely unaffected.

IN the *Journal of Mental Science* for this month is a very interesting examination by Dr. Grey of the story which, under the title of "Mr. H.'s own Narrative," aroused so much excitement five-and-twenty years ago. Dr. Grey considers, and his argument is very persuasive, that Mr. H.'s experiences are a tissue of hallucinations and delusions. We commend his explanation to the consideration of Messrs. Gurney and Myers.

IN view of the possible outbreak of cholera, and on account of his repeated failure to obtain any improvement, Dr. Johnson Martin, Medical Officer of Health for the Bolton Rural Sanitary Authority, has asked the Local Government Board to institute an enquiry into the sanitary condition of his district. His chief grounds of complaint are that the Sanitary Authority refused to make a house-to-house visitation when he requested them to do so, and that when he advised that the state of the streets should be seen to, his recommendations were ignored. Some parts of his district are, he declares, in a most insanitary condition. It is evident that Dr. Martin does not receive from the Sanitary Authority that cordial support which every medical officer of health is entitled to expect.

THE annual meeting of the Cambridge Medical Graduates Club was held on Wednesday evening at the Holborn Restaurant, when Sir Henry Pitman was elected a vice-president in place of the late Dr. Herbert Davies. It was settled that the next annual meeting and dinner should be held at Cambridge, and that if possible the club should hold a *conversazione* or smoking concert every year. Dr. Dickinson presided at the dinner as well as at the meeting, and proved an admirable chairman. In proposing the toast of the evening, viz., success to the club, he took occasion to express a hope that some means would be found to extend the functions of the club from those of mere good fellowship in the direction of expressing an opinion on matters concerning the profession at large, and he instanced the action of the Colleges of Physicians and Surgeons in reference to granting degrees as a matter upon which the Club might very well formulate and give vent to an opinion.

THE *Boston Medical Journal* states that a homœopathic physician recently read before a Worcester County medical society a paper on "Nervous Exhaustion consequent upon Concussion of the Spine," which was published *in extenso* in the medical journal of that persuasion. It was subsequently discovered to have

been copied almost verbatim and without credit from Erichsen's monograph on "Concussion of the Spine." An explanation seemed to be in order, which is thus made by the writer: "The *idea* of nervous exhaustion being dependent upon a shock to the spinal chord was wholly original with me." And he naïvely adds: "Had Erichsen not written on the subject, I should have done so," an explanation which he trusts will be satisfactory. This is like the playwright who maintained that the same idea had occurred to both himself and Shakespeare, but that the latter chanced to have the first opportunity of making use of it.

---

#### THE WASHINGTON CONGRESS IN DANGER.

THOSE who have looked forward to taking part in the next International Medical Congress, and have counted perhaps on making personal experience of that friendliness and hospitality of which every English doctor who has yet crossed the Atlantic has brought back such golden report—yes, and not only those, but every practitioner to whom the reputation of his profession is dear—will have read with intense surprise, if not distress, the intelligence we published last week, that the Washington Congress is in imminent danger of falling through. We are sorry to announce that our worst anticipations are in process of realisation. The leading practitioners of Philadelphia, many of whom were to hold high office in the Congress according to the list distributed by Dr. Billings some months ago, met together on the 29th ultimo, and decided that, as the changes recently effected in the preliminary organisation and rules for the International Medical Congress of 1887 "are inconsistent with the original plan and detrimental to the interests of the medical profession in America, and of the International Medical Congress," they would decline "to hold any office whatsoever in connection with the said Congress as now proposed to be organised." This resolution was signed by thirty of the most distinguished practitioners in Philadelphia, including men like Weir Mitchell, Horatio Wood, Roberts Bartholow, Da Costa, Duhring, Goodell, Minis Hays, Leidy, Pepper, W. Osler, Stillé, Tyson and Yandell. We hear that a similar movement is on foot in Boston, and that it is quite likely that the most distinguished practitioners in that hub of the universe will follow the lead of their Philadelphian *confrères*. And as some of the leading New York men, including Dr. Jacobi and Dr. Lefferts, who were to have presided over sections, have already been deposed from their places, as adherents of the New Code, while Dr. Bowditch, the most respected physician of Massachusetts, has been struck off the list of vice-presidents for his sympathy with that party, it must be admitted that the *New York Medical Journal* is probably right in describing the outlook for the Congress as "gloomy." We can only hope that the sound sense for which our American cousins are so distinguished will prevail, and that the decisive action of the Philadelphia practitioners will rouse the mass of the profession in America to step in and to decide by overwhelming numbers before it is too late that old controversies

shall be sunk, that old ill-feeling shall be buried, and that no one shall be allowed to turn partisan spirit into a ladder for his own elevation at the expense of the reputation and good-fellowship of the profession to which he belongs.

We do not wish, and we hope no one on this side the Atlantic will attempt, to revive the memories of the celebrated dispute on the Codes. We believe that the late Dr. Panum, the lamented President of the Copenhagen Congress, distinctly insisted, when the invitation to America was accepted, that the code question should not be raised; and we feel sure that a very large majority of English and Continental practitioners will refuse to cross the water if this understanding is not rigidly kept to. They will feel, too, that if they go to Washington they can only go as the guests of an undivided profession. A Congress from which the most distinguished representatives of American medicine were excluded or had withdrawn would not be worth going to as a scientific meeting, while the remembrance of the bitterness and heart-burnings which had attended its organisation would rob its social distractions of all their charm. It would be like feasting with a man, while his wife, unjustly divorced, stood in the street watching. We can assure our American readers that in the present case the best English sympathies will be with the wife. The men whom English visitors, if they go, will go to see and hear are the very men who have been elbowed out of the Congress. The scientific success of a Congress does not depend on numbers, but on quality. The profession in America is no doubt rich in numbers, as well as in scientific activity, but it is not so rich that it can afford to play all Europe with only pawns on its side of the board.

We must add a few lines to explain to English readers how the matter lies. The American Medical Association, a body which includes some 3,000 of the 40,000 practitioners in the States, appointed a Committee of seven to go to Copenhagen in order to express the desire of the Association that the Congress of 1887 should be held at Washington. The invitation was given in the name of the whole American profession, the Association acting to this extent as its spokesman. It was accepted, and the Committee were entrusted with full powers to organise and appoint officers of the Congress. They thereupon added to their original numbers some score of the leading practitioners of the States, and issued the programme which has been distributed far and wide. At a recent meeting of the American Medical Association at New Orleans, Dr. Billings reported on behalf of the Committee, but a certain section refused to accept the work done, and claimed that the Association had power to revise it, inasmuch as the Committee derived its commission from that body. They succeeded in getting a majority to endorse this claim, and induced the Association to strike off the names that had been added to the Committee and to replace them by 38 new men, elected with regard rather to their local distribution than to their scientific attainments. The new Committee accordingly, with the exception of the original seven, contains scarcely a name that is familiar to English ears. The question of the competency of the Association to act as it had done was submitted to counsel, with the result

that it was declared to have acted quite within its powers. The members of the original Committee therefore decided to attend the meeting of the enlarged Committee held on June 24th and 25th at Chicago, the reports of which have just reached us.

At this meeting Dr. Beverley Cole, of San Francisco, was elected permanent chairman of the Organising Committee, and Dr. Shoemaker, whose name is familiar to us as the active advocate of the use of the oleates known by his name, its permanent secretary. A Sub-committee was appointed to revise the rules and preliminary organisation of the Congress, published at Washington in 1884, and their report and list of officers was subsequently adopted by the Committee. The rules, however, have not yet been published, and we can only say that the first rule was so amended by the Committee as to guard against the participation of irregular practitioners in the meetings of the Congress. Besides this, the Committee removed from their positions in the Congress some twenty-five men, including Jacobi, Loomis and Lefferts, who have given up the code of the American Medical Association and retired from that body, but who are still met in consultation by the "old-coders," and are members of the New York Academy of Medicine. The Committee also entirely changed the executive *personnel*, substituting for men whose names are household words with us others whose reputation has certainly not yet crossed the Atlantic, whatever it may do in the future. It also removed the chairmen of sections from membership in the Executive Committee, and restricted the Membership of the Congress, so far as regards America, to members of the Association, or of State and County Societies in affiliation with it, and to others nominated by the executive. After these achievements the Committee adjourned to meet in St. Louis just before the next meeting of the Association. The above is a very brief abstract of intelligence derived from the American journals and from our correspondents in the States, and no doubt from its very brevity it will appear somewhat confusing to the English reader. The whole affair will look to him, perhaps, very much like a storm in a teapot. He will perhaps, however, be able to realise the dispute a little more clearly if he can imagine the Committee of Council of the British Medical Association having taken the London Congress of 1881 under its entire control, removed all but a few of the leading London men from any share in organising the meeting, and allowed no one to participate in the Congress but members of Association. But even that comparison would be misleading, for the English Association represents at least 50 per cent. of the English profession, while the American Association only contains some 7 per cent. of American practitioners.

---

#### THE LAY ELEMENT IN UNIVERSITY GOVERNMENT.

PROFESSOR RAY LANKESTER, in the letter to a contemporary on which we commented last week, sighs for the "Lehrfreiheit" and "Lernfreiheit"—the free trade in teaching—of Germany. Here is a curious commentary on his aspirations, taken from an excep-

tionally well-informed article in the current number of the *Athenæum* :—

“There is deep truth in the constant warning of Mr. Thring, that the teacher (and the pupil) must have freedom. But in Germany there is hardly any left, and if, with the vulgar imitation of all things German now prevailing, this bureaucracy is further extended, the education of England, bad as it has been in some respects, may be replaced by something infinitely poorer and worse.”

We could hardly have hoped so soon to meet with an authoritative sanction of the “Plea for Variety” which we put forward in our last issue. We are quite prepared to admit with Professor Lankester, indeed we have all along vigorously contended, that there is too little free trade in medical teaching in London. School competes against school, and that which succeeds in obtaining the best staff as a whole no doubt in the long run obtains an advantage over its less efficient rivals, however weak its teaching may be in individual subjects. But the system of composition-fees effectually prevents any competition between individual teachers, and the student may have perforce to attend the lectures and clinical teaching of comparatively incompetent men, while excellent teachers are lecturing on the same subject to almost empty benches at a neighbouring school. To reform this system, to introduce free competition amongst the teachers, and especially the clinical teachers, of the London medical schools, we need the pressure of some powerful central body, such as the London University or the combined Royal Colleges might become. But there is an evident risk that such a body, while securing individual freedom to the teachers, might reduce all medical education in London to one rigid pattern, demanding of all students the same identical curriculum, crushing all minds into one mould, and allowing no freedom for the growth in one or other direction of exceptional talent.

We cannot sufficiently bear in mind that education has not yet been reduced to a science. In another century perhaps it may be, but as yet it can hardly be said to have passed out of the rule-of-thumb stage. At present, then, those who have the opportunity of testing it by its results are likely to be better judges of its efficiency, and of its suitability to its purpose, than those who merely argue about it on *a priori* grounds, or with a very natural distrust of their own abilities, borrow their conceptions of it from other countries. Thus in medical education a teacher takes his pupils through a rigidly conventional course, and if they succeed in passing an equally conventional examination he is satisfied that he has done all that can be required of him. He estimates himself and is estimated by his rivals according to the percentage of pupils whom he succeeds in drilling up to examination standard, but neither he nor his rivals are able to follow those pupils into their after-life, and to determine their fitness or unfitness for the duties they may be called upon to perform. Many a London teacher is no doubt in the constant habit of meeting his old pupils in consultation, though that only gives him an opportunity of judging of their competence in practice, when placed upon their mettle and exposed to criticism. But many teachers, and

especially those who have to do with the groundwork of medical education, enjoy no such opportunities, and their pupils when they have got through their examinations pass out of their purview for the rest of their natural life. We should like to ask Professor Lankester, for instance, how many of his old pupils in the medical department he is in the habit of encountering in their post-graduate career, and what opportunities he has of discovering how far the science he has taught them has increased their practical efficiency. We even notice that in his letter, before mentioned, he does not rely for the justification of his views on the experience of the teachers of the advanced medical subjects, but only makes his appeal to the teachers of physiology, though of course the vital question is, whether the student gets a better grasp of medicine, surgery and pathology from his knowledge of zoology. But apart from individual instances, we may assume that not one London teacher in ten has any opportunity worth taking into account, of judging of the fruits of his labour as seen in the thought and practice of his pupils when they have once become practitioners.

Yet—and here we come to the main thesis of our article—the latest scheme for reorganising the education of the metropolis—that of the London Convocation Committee—rests upon the principle, that the teachers should have practically an exclusive voice in deciding upon the requirements demanded of the student. Hitherto the London University has had both upon its governing and its consultative chamber a considerable proportion of laymen as distinguished from educational experts. Some of the most influential members of the Senate have been men of high rank and culture, who, however, have never been personally engaged in teaching, and have therefore enjoyed the advantage of looking upon the educational mill from the outside. The same is true of Convocation, with the result that though the minor proceedings of that body, when left mainly to a score or so of convocation-trotters, may have been little worthy of admiration, it has nevertheless always risen to the event, and mostly delivered a really sound and liberal judgment when any vital question of principle has been submitted to it. For on such occasions the general body of graduates has been so largely represented as to entirely swamp the small clique of talkative educationalists and crotcheteers who usually represent or misrepresent the lower house of the London University. Whatever of wisdom or of liberal feeling has attached to the resolutions of a full Convocation has been due, we believe, not to the comparatively small body of teachers, but to the large infusion of the lay element. Now, as we pointed out last week, the scheme of Lord Justice Fry deliberately excludes the lay element from any power in the University worth the having. If the scheme is accepted and carried into practice, Convocation will practically cease, because it will have no reason, to exist, for its work will be absorbed by the Faculties. The Senate, on the other hand, will equally find its occupation gone, for the scheme converts it into a mere ornamental figure-head for registering the decisions of the Boards of Studies. But, such as it would be, the lay element upon it

would be reduced to practical impotence. Of its thirty non-official members, eighteen would be elected directly by the teachers, while of the remaining twelve a considerable proportion of the Convocation representatives would probably be teachers as at present, and some at least of the Crown representatives would no doubt be taken from the same class. As to the Boards of Studies, which are to form the working element in the University, they would be composed almost exclusively of teachers, only one representative of Convocation sitting on each Board.

We may assume of course that it has been the deliberate intention of the authors of the scheme to place the control of the University thus exclusively in the hands of teachers, and to banish the lay element from its management. Our objections to the scheme on this ground are vital. We condemn it on a broad principle, and much as we wish to see the London University reconstituted, we hope that the present scheme will be thrown out by Convocation unless materially modified in the sense we have indicated. We do not think that any reasonable man can deny the truth of our contention, that the governing powers of a national body like the University of London ought to contain a certain element representing the experience of practical life. For instance, a very considerable proportion of the medical graduates of the University are general practitioners in different parts of London and the Provinces, who have nothing to do with teaching. Is it not obvious that these graduates are in as good a position for forming an opinion as to the defects of the University course, regarded as a training for practical life, as teachers cooped up most of their days in laboratories and dissecting rooms? And yet this outside opinion is entirely ignored and excluded by the new scheme. The principle that the man who knows what *is* wanted has quite as good a right to a voice in affairs as the expert who has only considered what *ought* to be wanted, in one so thoroughly admitted in English politics that we are astonished to find it disregarded by the framers of the scheme. The sole excuse, for instance, for admitting two million uneducated voters to the franchise is that they have learnt by hard experience where the shoe pinches them, and are as fully entitled to express an opinion on the subject as the bootmaker or any casual observer. This principle is equally applicable, and has hitherto in the case of the London University been recognised as applicable to University Government, and on this ground we consider the scheme now before Convocation as distinctly retrograde, and therefore unworthy of adoption unless modified in the direction we have indicated.

---

#### THE MYSTERIES OF MODERN BABYLON.

TILL the *British Medical Journal* spoke up with such surprising naïvete on behalf of the *bona fides* and accuracy of the recent repulsive utterances of a now notorious evening paper, that conspiracy of silence on the part of all the leading journals which seems to have entered like iron into the soul of the editor of the paper in question was too admirable to be broken. But now

that one organ of medical opinion has had its say and has thrown its friendly ægis over the authors of the newest and most uncleanly "Romance of the Nineteenth Century," we feel bound to write a few words on the subject. To discuss the probability of truth in most of the statements made by the *Pall Mall Gazette* would be almost to take part in the outrage against decency which that journal has committed. But, granting for the sake of argument, that the writer of these articles believed implicitly, and with good reason, in the accuracy of his statements, the most superficial glance at the headings and style of the paragraphs would lead the vast majority of those who have read them to suppose that the redress of a real social grievance was not the sole object of their publication. We do not hesitate to say that even if a small proportion only of the horrors detailed could be shown to be true, a single article, soberly and strongly worded, would have aroused more true indignation, and constituted a far more practical and successful effort at reform, than this deplorable series of novelettes so adapted to appeal to the salacity of the streets.

We do not think that there could be any justification whatever for the appearance in such a form of literature on this subject, not even if the writer asked for no pledge of secrecy, but courted enquiry into his facts in the full light of day, and prayed for the prosecution of the miscreants whose anonymity he has now pledged himself to preserve. The possibility of the two or three eminent personages who have offered to come forward at the call of the *Pall Mall Gazette* being convinced of the truth of the alleged facts is no excuse whatever for their publication. Nor will the public forgive or forget the indubitable offence and harm that must have been already wrought by the almost forced entry of these detailed obscenities into their houses, and into the hands of thousands of our younger population, both male and female. Much more evidence is wanting to the public of the truth of even a small proportion of the incidents adduced than is offered by such an enquiry as the *Pall Mall Gazette* proposes. If the sagacity of the secret commissioners were by any chance at fault, and their informants were possibly "taking them in," or were, at least, not quite trustworthy—a far from absurd supposition, considering their calling and antecedents—it is not inconceivable that other investigators might be deceived as well, even if taken, to use our medical contemporary's words, "from unsullied witnesses to the purity of domestic life—bishops, prelates, clergymen of all denominations, and members of both Houses of Parliament."

Nothing, in our opinion, short of full proof of all the statements, and conviction of the chief offenders, would even partially atone for the moral harm already done by the publication of these papers; but the first of these requirements is unlikely to be satisfied, and the second is out of the question because of the secrecy of the secret commission. All medical men, we are convinced, will resent the imputation cast on the profession by the suggestion that quite a large number of them are ready to sign certificates for the vilest of purposes. The *Association Journal*, while casting no doubt on the facts of the examinations made and certificates given by medical men, innocently "trusts"

that their participation was entirely in ignorance of the aim of the other parties concerned. This is a strange and mysterious position for a journal to take up which has generally proved itself so ready an advocate for the profession whenever it has been said to sin. We think far more highly of the intelligence of our brethren, and not one whit more lowly of their morality, than our contemporary does; and therefore we entirely refuse to believe on the *ipse dixit* of any number of people that these certificates were signed by regular members of the profession; and all the more so because the letters "M.D." are appended in every instance to the blank signatures of these alleged malefactors! It is a poor defence of doctors to call them fools when they are accused of being knaves. The *Pall Mall Gazette* implies that they are both. Till further evidence is forthcoming it is but right to believe that of these particular kinds at least there are absolutely none.

because the opportunities for such observations are few; and therefore it is possible, and indeed to be hoped, that they may be supplemented and perhaps modified in the future. But the author's care and precision are such that his work is solid and real, and can never lose its value. The book is a credit both to the author and the great school in which he has been trained.

*Transactions of the New York State Medical Association for the year 1884, Vol. I.*; edited by AUSTIN FLINT, Junior, M.D. New York: D. Appleton & Co., 1885. This society, which was formed in the early part of last year, is the outcome of a prolonged struggle against the introduction of the New Code. The National Code of Ethics, as it is called, does not allow any of its members to consult with irregular practitioners; the New Code does away with this, which its upholders look upon as the most vital of its clauses. In the course of 1882, owing to the action of a powerful minority, the New York Society abolished the Old Code and adopted the New. Failing in all their attempts to obtain a restitution of the National Code by gentle means, the disheartened majority resolved to secede and found a new society, which should abide faithfully by the National Code. This they have accordingly done, with a result that, in the first year of its existence, the new society has enrolled 522 Fellows on its list. The present volume therefore contains the report of their first year's work. The papers are many of them of great interest, and deal with a great variety of medical topics; it would be invidious to particularize, and our space does not permit of a notice even of a majority of them. The printing and binding of the volume leave nothing to be desired.

*Bericht der K. K. Krankenanstalt Rudolph-Stiftung in Wien* (Report of the Imperial Royal Rudolph Foundation Hospital in Vienna), 1883, pp. 414.—This is indeed a model report. It were to be wished that all endowed charities were either compelled to publish such a detailed account of their work, or that they did it voluntarily. Prefaced by the simple statement that the report is published for the Ministry of the Interior, by the Directorate of the Hospital, we come upon the names of those who form the directorate, and are pleased to find first and foremost as director a medical man, and that all the medical officers rank before the non-professional staff. Then follow a number of tables giving the usual information as to admissions, discharges, deaths, occupations, districts from which the patients were admitted, and a variety of other information more or less interesting, but very useful, should it be wished at any time to compare figures for any special reasons. There are tables of percentages for the current year, as well as summarised tables of many previous years, from which may be seen at a glance how any particular cause of mortality, or cause of disease, or expenditure, or cost of patient stands at the present time as compared with former years. These tables moreover are worked out in great detail; they are not merely lumped figures which give no sort of information beyond totals, but are, what they should be, an actual report of the subject matter, whatever that happens to be. In the part of the report which deals with expenditure, that of the medical officers stands first, showing the paramount position they hold even in a country like Austria. In the more strictly medical part of the report, we again find the same detail of statement, and amplitude of tables, percentages and averages. The diseases are arranged in systems, and a complete review of all the cases treated is given. Then, in greater detail, follows the complete record of the more interesting and unusual cases and of surgical operations. The pathologist's report is carried out in a similar manner.

## REVIEWS AND NOTICES OF BOOKS.

*Spinal Deformity in relation to Obstetrics*; by A. H. FREELAND BARBOUR, M.A., B.Sc., M.D., F.R.C.P. Ed., Assistant to the Professor of Midwifery in the University of Edinburgh, &c., &c. Edinburgh and London: W. & A. K. Johnston, pp. 35, with 38 plates.—This handsome volume reflects great credit both upon the author and the publishers. It is well printed, and the plates are well executed. The subject is one of a purely scientific kind, and it is treated in a scientific way. The letter-press is made up of careful and accurate observations; there is little speculation, and no padding. The book consists of three parts. First, on the changes in the form of the female pelvis present in spinal deformity. This part is based on exact measurement of 13 pelvis associated with curvature of the vertebral column. Drawings of the pelvis are put before us. The absolute measurements of each pelvis are given in a tabular form, and the same measurements calculated in their proportion to a standard line are arranged in another table so that they can be readily compared. The different pelvis are, moreover, represented by diagrams, in the manner adopted by Breisky and Leopold, so that their peculiarities stand out at once to the eye. So far as we are aware, this is the first work in English in which this most instructive method has been followed, and certainly diagrams of pelvic deformity of such number, size, and clearness, have not yet adorned English literature. The second part is on the displacement of the viscera, and the relations of the pelvic organs post partum in a case of kyphosis. It is a description of frozen sections which the author has made of the body of a woman who died with the condition named. It is illustrated with 12 plates of great beauty and excellence. The third part is on the obstetrics of the kyphotic pelvis. Here the author shows a rare and wise reticence. He collects facts, and does not theorize. He has brought together a larger number of cases of labour with kyphotic pelvis than any previous writer; he summarizes the information they give, and lays down brief and clear rules for practice. In an appendix Dr. Barbour gives descriptions, illustrated with 3 plates, of frozen sections from a case of spinal caries without much kyphosis. We regard the work as one of the greatest value. It is one built upon observation, not upon speculation; and this is the only sure foundation of medical science; for it is not too much to say that the progress of medicine consists chiefly in increasing exactness of observation. The book has lessons to teach as to the formation of the pelvis, in topographical anatomy, and concerning practical obstetrics. The field from which these lessons are drawn is a small one,

*Die Wanderleber und der Hängebauch der Frauen*; von Dr. LEOPOLD LANDAU. Hirschwald: Berlin, 1885, pp. 170 (Floating liver and pendulous belly in women).—In his preface to this work the writer complains that too much attention is paid now-a-days to the microscopic evidences of

disease, and too little to the coarse physical signs which come into notice every day, a complaint which we can cordially endorse. As the result of the attention which he has devoted to the subject of which he writes, Dr. Landau is convinced that the wandering or moveable liver is of sufficiently common occurrence to warrant its removal from the category of pathological curiosities to which it has been hitherto relegated. It must be allowed that he has done ample justice to a subject which would not at first sight appear to contain much that lends itself to profitable study. Every conceivable cause for displacement of the liver is in turn considered and discussed, and numerous illustrative cases and drawings are appended which serve to give a practical aspect to a discussion which of necessity depends to a great extent upon conjecture. That cases of pendulous belly are not unfrequently associated, especially in women, with an abnormally moveable liver is clearly shown by the evidence which the author adduces, but he proves at the same time that a vast number of other conditions are capable of producing this uncomfortable malady, and he gives the most precise instructions for their differential diagnosis. With respect to treatment it cannot be said that he is able to offer any strikingly new methods, but as a complete and thorough treatise on a rather neglected subject the work deserves cordial recognition.

*Traité de Thermométrie Médicale*; par P. REDARD. Paris: J. B. Baillière et Fils, 1885.—When we took up this book it was with a full expectation that it would turn out to be little more than a recapitulation of what Wunderlich had already written. We were, however, agreeably disappointed. The author has treated his subject from an entirely new stand-point. The first part of the book is devoted to central alidity, or lowering of the temperature, and in the 279 pages devoted to the exposition of this part of his subject, the author may fairly claim to have exhausted all that there was to be said about it. The most interesting chapters in this portion are those on the lowering of the temperature in lesions of the nervous system, both central and peripheral. The second portion of the book is devoted to local thermometry, and opens with a full description of all the apparatus which have at one time or another been devised for registering the temperature. Then follows a chapter on local temperature in cerebral affections, and then one on lesions of the peripheral nervous system, in which is included the very important subject of lesions of the sympathetic nervous system. Amongst the other chapters, those on the local temperature in chest affections, and especially as a means of diagnosis in phthisis, and on the local temperature in lesions of the vascular system, will probably be found of most interest. The author shows himself to be well abreast of modern work, both in physiology and pathology, and the work will prove of great value to the teacher of medicine. In conclusion we may note that the author regards  $37.5^{\circ}$  ( $99.5^{\circ}$  F.) as the normal temperature of the human body in the axilla.

*Vorlesungen über Pharmakologie, für Aerzte und Studierende*; von D. C. BINZ (Bonu). Berlin: Hirschwald, 1885.—This is the second part of Professor Binz's Lectures on Pharmacology. In our notice of the first part, which appeared in 1884, we indicated the thoroughly readable character of the book—how it discusses in a light, conversational, demonstrative manner, the somewhat dry facts connected with the pharmacopœia. The present volume is as good as its predecessor. Many of our most important drugs are discussed here, such as digitalis, ergot, physostigma, jaborandi, strychnia, tobacco, and the æthereal oils; also iron, alkalies, bitters and tannin. We would particularly refer to Professor Binz's account of remedies, which he has himself especially investigated, including alcohol, and the phosphorus, arsenic, and antimony groups. We heartily recommend the volume to lecturers, and advanced students of therapeutics. Abundant references are given to the latest papers on pharmacology in all languages.

*Leçons Cliniques sur les Maladies des Voies Urinaires*, par le Professeur GUYON. Paris: J. B. Baillière et Fils, 1885, pp. 1,084. Deuxième Edition.—None but a French author, we opine, could have filled a thousand closely printed pages with what we English should call the surgical diseases of the urinary organs. The work is very thoroughly done, and written in that easy style which becomes habitual to French clinicians, who, as part of their routine duty, are expected to give set clinical lectures almost every day of the session. Regarded from this standpoint, it must be admitted that the work is a very excellent one indeed; the subject-matter of the different chapters appears to have been illustrated by the actual presence of cases in the lecture room. The author has divided his work into 31 "leçons," and each takes up and discusses some special point. The pathological changes which occur in urine, are carefully dealt with, the author showing himself to be a chemist as well as a surgeon. "Urinary poisoning" also comes in for very considerable attention. These lessons deserve very close study. The lectures on Litholapaxy, or, to speak more simply, the aspiration of calculous fragments, and the duration of operations are among those which have had to be entirely remodelled since the first edition was published. Those who desire to contrast French and English views will find in Dr. Guyon's work a very able summary of the subjects from the French standpoint, and to such we heartily commend the work.

## ABSTRACTS AND EXTRACTS.

### THE CORPUS CALLOSUM.

MOST, if not all of us, have hitherto been contented with the belief that the corpus callosum consisted of fibres passing across from one hemisphere to the other, and have never troubled ourselves as to where those fibres came from or went to, regarding the corpus callosum in fact as having little else to do than to prevent the two halves of the brain from falling apart. It is not our fault that we have such vague ideas on the subject, for our best text-books make no attempt to enlighten us. Professor Hamilton, of Aberdeen (*Journal of Anatomy and Physiology*, July), however, has come to our rescue, and in a paper which all must admit to be most instructive, whether they accept his results or not, has endeavoured to throw a little light on this hitherto neglected subject.

The objections to the view that the corpus callosum is a mere commissure he puts as follows:—1. A destructive lesion of the one hemisphere never spreads to the other as might be expected. 2. Destruction of one side of the brain does not interfere materially with the functions of the opposite side, unless, as in the case of the optic nerves, a partial decussation takes place in their peripheral fibres. 3. Animals which do not possess a corpus callosum, or in which it is rudimentary, are capable of combined action just as much as those which do possess it.

Willis, Foville, and Gratiolet did not regard the corpus callosum as a commissure, but held that it contained fibres passing from one corona radiata to the opposite hemisphere, and also of fibres passing between the two hemispheres.

One chief difficulty in determining anything about the corpus callosum has been the impossibility of tracing a fibre for a distance of more than a few lines in any one plane. This difficulty had to be circumvented by following up the course of a bundle of fibres, and this Professor Hamilton has succeeded in doing by what he calls his mezzoscopic method, viz.: the examination of thin sections of the brain with a lens after they have enlarged by means

of submersion in a mixture of potash and gelatine. Premising that that portion of the corpus callosum which lies over the lateral ventricles he calls the tectorial part, we may very briefly see what are the results derived from this method of examination. In the front part of a transverse section through the level of the corpus callosum, a broad band of fibres can be seen passing from this upwards, outwards, and downwards into the white substance, finally terminating in the internal and external capsules. As they enter the internal capsules, the fibres become closely aggregated and much curved. These fibres, he believes, spring from the opposite corpus callosum, and he proposes to call this the crossed callosal tract. The internal capsule also, however, receives another band of direct fibres from the cortex of the same side, chiefly from the region of the paracentral lobule, a few of which enter the corpus callosum, but the majority mingle with the fibres of the crossed callosal tract, and enter the internal capsule. The question at once arises, whence come these callosal fibres? They are supplied, according to Professor Hamilton, from an area extending mesially from the upper edge of the gyrus fornicatus round nearly to the free border of the operculum, and its continuation backwards in the upper lip of the Sylvian fissure. The fibres coming from above curve inwards, whilst those from the outer convex surface run in an almost straight line to their point of entrance into the tectorial part. As above mentioned, some fibres coming direct from the motor area of the cortex enter the corpus callosum, and opposite the central convolution other fibres, evidently motor, join it. It is from the extreme vertex that the greatest leash of callosal fibres is derived; they curve downwards and inwards intermingling with those fibres which have already crossed, and are then lost in the tectorial part. To their inner side is an immense mass of association fibres apparently uniting the margin of the longitudinal fissure with the gyrus fornicatus, the fibres of which by the way he regards as mainly association fibres. The bundles of callosal fibres on entering the tectorial part are at first parallel, and they then decussate, taking an oblique course towards the centre of the brain on the other side. Just over the lenticular nucleus they divide into two sets, the larger entering the internal capsule, the smaller the external capsule.

With regard to the fibres coming from the extreme frontal region, Professor Hamilton describes them as being concentrated into a somewhat oval-shaped area, which terminates in a tail-like leash of fibres, which he proposes to call the common frontal tract, and this tract he further subdivides into three, an internal, middle, and external tract. The internal tract, however, contains fibres coming from the opposite frontal region, as well as from the common frontal tract of the same side. The external tract, too, contains in addition to the fibres from its own common frontal tract, fibres from the opposite frontal region, and a third set from the gyrus rectus. This external tract, he notes, passes exactly beneath the centre for aphasia, and this leads to some interesting reflections as to the light thrown on some of the phenomena associated with aphasia by the fact that a lesion which extends at all deeply in this region is in reality affecting fibres which come from the opposite hemisphere. Ultimately this external tract splits into two, to form the internal and external capsules. The middle tract consists of fibres which pass outwards, backwards, and inwards to sweep round the anterior horn of the lateral ventricle, and terminate by joining the external tract.

Having thus traced the fibres of the crossed callosal tract

into the internal capsule, it remains to be seen what becomes of them after that. The whole of the anterior portion, as well as the fibres which go to make up the bend, terminate in the optic thalamus, very few of the fibres enter the caudate nucleus, and Professor Hamilton suggests that the striæ in the lenticular nucleus are derived from the fibres in the crossed callosal tracts; the posterior part of the internal capsule becomes the cerebral peduncle, and the data derived from pathology are thus confirmed in a most striking manner, for this portion of the internal capsule is formed by the direct fibres from the motor area, and not by the crossed callosal tract. Indeed, had he arrived at any other result, there would have been strong *primâ facie* evidence against him, as it would have been opposed to the almost universally accepted view that one side of the brain corresponds to the opposite side of the body. Thus the internal capsule is made up of fibres coming from both frontal regions and from the motor area of its own side. The centrum ovale consists, therefore, of direct fibres, of crossed callosal fibres and of association fibres passing from one convolution to another. In fine, Professor Hamilton is very doubtful if the corpus callosum contains any association fibres at all.

#### THE BASAL PATHOLOGY OF CHOREA.

PROF. HORATIO WOOD addressed a communication upon this subject to the Philadelphia College of Physicians, which has been since published in the *Boston Medical Journal*, for May 28th. "The first point which I wish to make," he says, "is that the term chorea is simply one which is analogous to the term paralysis, and that the choreic movement is no more the same thing, necessarily, in its basal pathology, than is palsy the same thing in its basal pathology. When we come to study the various forms of disease closely connected with choreic movements, we find in the first place the so-called cerebral or post-hemiplegic chorea, in which after cerebral palsy, there appear violent convulsions with choreic movements. The seat of this lesion has been assigned by Prof. Charcot to the corona radiata, near the lenticular nucleus, and there have been a number of *post-mortems* made which verify this view of its location. There can be no doubt that in many cases the lesion is situated in this position; but, on the other hand, it is equally certain that there have been cases of so-called hemiplegic chorea in which the lesion has been in the external capsule and in the cortex. We may, therefore, say that this form of chorea is associated with various lesions in the brain, as far as its seat is concerned. . . . . We are also forced to the conclusion that we may have post-hemiplegic chorea, which is without lesion, and hysterical in its nature. When we come to study the chorea of childhood, we find that the pathology is perfectly parallel to that of the other forms of chorea. We have a large number of reported cases in which the lesion evidently was capillary embolisms of various portions of the brain, especially of the corpora striata and optic thalami, but also in other portions. We have other cases in which no lesions are to be found. Then we have recent cases, especially reported by Dickinson and Ross, in which serious lesion was found in the spinal cord. The clinical history of chorea in childhood also shows conclusively, to my mind, that it may exist without any organic lesion which can be detected. We have it developing in a moment from emotion, passing off in a few weeks, and affected immensely by a few doses of arsenic, or other agencies which would be powerless to affect any severe organic lesion. So far as the study of the disease in the human subject is concerned, I think that these remarks sum up all that we can reach to, namely, that we may have chorea with various lesions and without lesions."

Dr. Wood has of late been much engaged in careful study of chorea in the dog. "It has been affirmed," he says, "that

chorea in the dog is different from chorea in the child. The great reason for believing the disease is distinct is that in the dog the movements are chiefly rhythmical, which they usually are not in the child; but I have seen dogs with absolutely arrhythmical chorea and with all the awkwardness of chorea in children, while occasionally we have more or less of the rhythmical type in children. When we come to look at the points of resemblance in the two diseases, we find first, in each case, it especially affects the young animal; second, in each the disease is associated with a constitutional disorder—distemper in the dog, rheumatism in the child; third, the symptoms are exactly analogous, except that there is more tendency to rhythm in the one than in the other; fourth, the clinical experience of veterinarians and of physicians has led to the same result, namely, that arsenic is the best remedy known in both cases. When I came to study chorea in the dog, the first point to settle was the seat of the lesion; I therefore cut the spinal cord so low as not to interfere with breathing. I found that, invariably, the choreic movement continued after section. Before the section the motions of the front and hind leg were synchronous—that is, a wave of motion starting in the front paw would pass down the hind foot. But after the section this synchronous movement was wanting. The hind legs were completely isolated from the upper portion of the nervous system, and yet continued to exhibit the choreic movements—a proof that the movements originated in the spinal cord. I therefore had my search for the seat of lesion narrowed down to a small fragment of nerve tissue. I found that not only did the movements originate in the spinal cord, but that they originated in all probability in the motor cells, because when I galvanized the bared sciatic nerve, although the animal exhibited no signs of pain, the movements in the hind leg were at once inhibited. The galvanism of the sciatic nerve could only affect the motor cells. Therefore, I came to the conclusion, physiologically, that we had to do here with movements which originated in the motor cells of the spinal cord. The next step was to examine the cord. Gowers and Sankey found in the cord a peculiar infiltration with leucocytes, and they came to the conclusion that leucocytal infiltration was the basal pathology of this disorder." Dr. Wood states that he has found the leucocytes in the cords of healthy dogs, and goes on to show, as the result of his numerous dissections of dogs suffering from the disease, that a change in the ganglionic cells is the basal lesion in chorea. "As I killed dog after dog, in different stages, I found the motor cells were to be noted in all stages of degeneration. First, the perfect cell, then the cell stained badly, then one with nuclei disappearing, the margin becoming obscured, the processes dropping off and opacity occurring; and finally the irregular protoplasmic balls. In a few cases I noticed a peculiar degeneration, the formation of vacuoles in these cells. Some years ago, Dr. Putnam, of Boston, studied chorea in the cat, and in one case found the lesion which I have described, the important point being that he found that the lesion not only pervaded the spinal cord but the whole nervous system. We all know that the choreic movement is only a part of the symptoms of the disease, and that the moral and intellectual part of the child also suffers. I believe that in children we have an altered condition of the ganglionic cells. The reason that no lesion is found early, is that the disease is at first functional. It is not necessary that I should call attention to the fact that there is no such thing as functional and organic disease. The line which we draw is a purely arbitrary one; for the moment there is altered function, there is altered protoplasmic change, and when there is altered protoplasmic change, there is altered nutrition, and then organic disease. Our microscopic eye is so blind and gross that it cannot see these fine changes until they become so distinct that we can detect them—and then we say that organic disease exists. The history of chorea I conceive to be this. Owing to emotional disturbance, some stopping up of various vessels of the brain, or sometimes owing to the presence of organic disease—now this cause and now that—there is an altered condition of the ganglionic cells throughout the nerve-centres. If the cause is removed, and the altered condition of the nerve-cells goes only so far, it remains what we call a functional disease. If it goes

so far that the cells show alterations, we have an organic disease of the nervous system. The capillary emboli, the clots, the tumours, and the various gross lesions which have been found in chorea, are not, in my opinion, the basal lesion; but the cause which produces these changes in the cells which are at the bottom of the choreic movements."

## REPORTS OF SOCIETIES.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JULY 1ST, 1885.

J. B. POTTER, M.D., F.R.C.P., President, in the Chair.

#### Specimens.

THE following specimens were shown:—

Dr. HARVEY (Calcutta)—Rupture of the Fundus Uteri during Pregnancy.

Mr. THORNTON—Malignant Dermoid Ovarian Cyst.

Dr. HERMANN—Atrophy of the Chorion.

*Notes of a Visit to some of the Lying-in Hospitals in the North of Europe, and particularly on the Advantages of the Antiseptic System in Obstetric Practice.*

Dr. PRIESTLEY read a paper with this title. The hospitals visited were those at Copenhagen, Helsingfors and St. Petersburg. At Copenhagen the new régime began in 1870. In the Maternity Hospital, in the 15 years from 1850 to 1864, the mortality was 1 in 24; between 1822 and 1843, it had been 1 in 19, *i.e.*, only slightly lower than the mortality in the Nightingale Charity of King's College Hospital, which compelled the author to close the ward. From 1865 to 1874, the mortality from puerperal fever was 1 in 51; from 1870 to 1874, it was 1 in 87, the improvement coinciding with increasing strictness in antiseptic precautions. The hospital is constructed in the most elaborate and expensive way, to secure hygienic perfection, including ventilation, isolation of each part of the building if desirable, and even a separate room for each patient. Moreover, the rooms are only used alternately, which is equivalent to halving the number of beds. The attendants are under strict rules of periodical purification, and are not allowed to pass directly from the convalescent to the lying-in wards. If a patient has been ill, the nurse is fumigated with sulphurous acid gas by an elaborate process. The same is used for disinfection of the rooms. The personal precautions include careful antiseptic hand-washing, soaking of catheters, &c., no sponges are used; the vagina is injected twice a day with carbolic acid lotion. The beds are of canvas, filled with chopped straw, which is destroyed after use. Each bed has its own basins, syringes, catheters, &c. The placenta and dressings are burnt. On suspicion of infection, the patient is isolated, and admissions suspended to that part of the hospital. The medical officers are not allowed to attend autopsies. The director lives in the hospital, of which he is absolute master. As in other hospitals there is an undue proportion of difficult cases in primiparæ, and the primiparæ have a large share in the mortality. The midwives of Denmark are compelled to use antiseptic precautions, and this has sensibly reduced the mortality. At Helsingfors the hospital is arranged on the pavilion system, one block being devoted to diseases of women, including wards for operations and rooms for out-patients. The wards for lying-in cases contained about 42 beds; the beds were in the middle of the rooms. The mattresses were sacks of fresh rye straw for the non-paying patients, and with horsehair or bark of the lime tree for paying patients, all being cleaned, baked, and remade for each new patient. Some patients lay on the bare boards of the bottom of the bed as is usual in Finland. Antiseptics were not as minutely carried out here. Midwives and nurses were made to wash their hands and arms with scap, and afterwards to rub them with dry hypochlorite of lime before

examinations. Abnormal cases were isolated. The medical officers were forbidden to attend autopsies or to touch infectious wounds without taking antiseptic precautions afterwards. Catheters were carbolised, and the wards periodically closed and cleaned. After labour, a single injection of carbolic acid was given, and often when specially indicated. The linen was simply washed, the blankets were fumigated by burning sulphur. Professor Pippinskold trusts largely to the excellent hygiene of the hospital (built on a rock high above the town), and to the clean habits of the people, but the external genitals are always washed before delivery; otherwise the object is to guard against external morbid influences, more minute care being thought unnecessary under the circumstances. Before the new maternity was opened in 1879, the total mortality averaged 1.83 per cent. From 1879 to 1884, the total mortality was 1 per cent. At St. Petersburg (the Grand Duchess Catharine Maternity Hospital), there were arrangements for isolating the various parts. Scrupulous cleanliness, the disinfection of rooms, concrete floors draining into a central gully, the careful use of antiseptics were included in the system. In the last three years there had only been one death from puerperal fever, though six from other causes.

Dr. MATTHEWS DUNCAN said that the subject of antiseptics in midwifery was the greatest subject in the whole obstetric department, but it got very little attention. The subject was greater than the prevention of epidemics which came occasionally, while puerperal deaths were constantly occurring in the most valuable members of the community. The value of antiseptics in midwifery had only lately been estimated, because it was only lately that the profession had agreed as to the mortality of childbed. Some men had their thousands of cases without a death, and while he did not doubt their veracity, he did not accept their statements. No man could claim immunity from deformed pelvis, placenta prævia, puerperal convulsion, phlegmasia dolens, puerperal inflammations, puerperal scarlatina, puerperal septicæmia, or puerperal insanity. Farre began by ridiculing the demonstrated puerperal mortality, but he eventually nearly accepted the received view—that about 1 in 120 die in childbed or within a few weeks after delivery. In the history of the subject all measures had failed to reduce mortality till antiseptics were introduced. Abroad, the great mass of women were attended by midwives who were compelled by law to use antiseptics; in Great Britain most were attended by doctors, very few of whom used antiseptics. He hoped they would be universally adopted.

Dr. JOHN WILLIAMS said that they should keep clearly in their minds that they could not abolish by antiseptics the effects of pregnancy and labour, but they might hope to abolish deaths from puerperal fever. The mortality of the St. Petersburg Hospital (1 death from puerperal fever in 3 years) was a near approach to this. The results at Copenhagen and Helsingfors were little better than those in the Rotunda of Dublin before antiseptics were used. In seven years of office Collins admitted about 16,000 women, had 2 epidemics of puerperal fever, in which about 80 died, and the total mortality was 1 per cent. Dr. Macan, the present master, admitted during his first year of office 1,090, and of these 6 died, 2 at least from other causes than septicæmia. This excellent result had been obtained by careful antiseptic precautions. Dr. McClintock calculated that one-fourth of the deaths in childbed were not due to childbed. Taking the deaths in childbed at 1 per cent., the lowest mortality in childbed after the destruction of puerperal fever would be a quarter per cent., or 2.2 per thousand, and their object should be to reduce our mortality to this level. This he believed might be attained by antiseptics. This was the object of Dr. Champneys and himself at the General Lying-in Hospital, but the object had not been attained. During the first four years there were 7 deaths in 1,174, or a little more than a half per cent. During the first 12 or 18 months carbolic acid was used; during a second similar period permanganate of potash, and since May, 1884, corrosive sublimate. During the first two periods there was a good deal of illness, though the mortality was low. Since the use of corrosive sublimate was begun there had been no deaths from puerperal fever, and almost an entire absence of morbidity. The mortality

mentioned was the *total* mortality, for all cases which were not well at the time of their discharge from the hospital were admitted into St. George's Hospital under Dr. Champneys or into University College Hospital under himself, and the result was incorporated with the statistics of the General Lying-in Hospital.

Dr. CHAMPNEYS said that the total mortality from all causes in the General Lying-in Hospital in the last four-and-a-half years, since Dr. Williams and he had had charge of it, was 9 in 1,360, equivalent to 1 in 151 or 0.66 per cent. The last two deaths were from phthisis, with which the patients were practically moribund on admission. These results were decidedly good at the present time, though it was hoped to improve them in the future. The greatest care was taken to follow up the cases; on discharge each patient was furnished with a postcard directed to the hospital, on which she was requested to write her state and that of the infant about a month after her discharge, or six weeks from her confinement. No statistics of lying-in hospitals were trustworthy which did not give the total mortality from all causes, and which did not state that no patient was transferred to another hospital, or that, if transferred, her progress was ascertained. The statement that no deaths occurred from puerperal fever was worthless in the absence of the whole mortality, and indeed all cases dying after child-birth were presumably, or in the absence of distinct proof to the contrary, cases of puerperal fever, and such cases often gave unmistakable though unexpected evidence of septic processes after death. Thus, the statement that in the St. Petersburg Hospital there had only been one death from puerperal fever in three years, while there had been six deaths from other causes, did not carry conviction. This was certainly a most unusual proportion. What were the causes of the other six deaths? The triumphs of antiseptics had been greatest in the most filthy localities; where cleanliness and general hygiene had been attended to, the benefit, though undoubted, was less striking. Antiseptic teaching should be as clear and as definite as possible; if details were unnecessarily multiplied, nurses, and even practitioners, were liable to confuse the essentials with non-essentials, and even to throw the whole thing overboard. He found no difficulty in carrying out the same details in private as in hospital. The all-important thing was scrupulous antiseptic cleanliness of the hands. On this he insisted on the part of nurses, as well as on his own, and inspection of the nails and skin of the hands of nurses was important on this account.

Dr. WEST thought that the teachers of midwifery, or, better still, the Obstetrical Society, should pronounce definitely as to what was essential in antiseptic treatment. In Vienna frequent vaginal washing and the introduction of iodoform into the uterine cavity formed part of the system. Women would, he thought, be apt to dislike this interference, and it would also suggest to them the great danger which there must be to necessitate it.

Dr. PLAYFAIR was sure that in private not one man in a hundred used antiseptics in any thorough way. There were not half the difficulties which Dr. West had imagined, and in his own practice antiseptics were as rigidly enforced as it was possible. Absolute surgical asepticism was, of course, impossible. He now supplied his nurses with antiseptic rules printed on a card, the chief rule being that the nurse should never touch the neighbourhood of the genitals without careful antiseptic washing of the hands. The same precaution was taken with regard to all sponges, catheters, &c.; corrosive sublimate was preferred to carbolic acid. These rules were even more important for nurses and midwives, who often touched the genitals, than for medical men, who, as a rule, only did so during labour. Nurses were apt to be careless of details and of cleanliness, and the result was visited on the medical man. He hoped that antiseptics would soon be the routine practice, and he was sure the result would be most satisfactory.

Dr. GIBBONS remarked on the common practice of pouring a few drops of antiseptic solution into an unmeasured quantity of water, which was useless. He asked Sir Joseph Lister what strength of carbolised vaseline should be used.

Dr. MURPHY (Sunderland) regretted that the discussion had not included the details of the antiseptic treatment

recommended. He asked the opinion of the Society as to the justifiability of attending a case of labour shortly after having examined a case of puerperal fever in consultation. The text-books said that practice must be given up for several months. Personally, he thought that a change of clothes and a warm carbolie bath 1 in 100 for half-an-hour gave sufficient security.

Dr. BRAXTON HICKS agreed with Dr. Matthews Duncan as to the value of antiseptics in midwifery, but not as to his estimate of puerperal mortality. He had in ten years of early practice some 800 to 1,000 cases, and only one death, which was from puerperal fever. Morbidity was as important as mortality. He referred to the injurious effects of human lochia inoculated into rabbits as showing their poisonous character. The antiseptic vaseline or oil was of little importance compared with antiseptic cleanliness of the hands.

Dr. HARVEY said that in Calcutta for many years carbolised oil had been used for vaginal examinations, and that vaginal injections of carbolic acid or corrosive sublimate were used if any fœtor was noticed in the discharges. When there was pyrexia besides, the uterus was washed out. Good had resulted; but the mortality in Calcutta would always be high, as patients were often admitted after many hours of labour, and after the establishment of septicæmia.

Dr. PRIESTLEY, in reply, congratulated Dr. Williams and Dr. Champneys on the results obtained by them, and said that he was informed by Dr. Grigg that of 1,100 deliveries in Queen Charlotte's Hospital between February 14th, 1884, and July 1st, 1885, there had only been one death, and that was from puerperal convulsions. He agreed with Dr. West as to the desirability of defining what amount of antiseptics were necessary, and he doubted if autogenetic infection existed. Antiseptic cleanliness in all things touching the genitals was all-important, but vaginal injection had better be retained meanwhile.

## SANITARY INSTITUTE OF GREAT BRITAIN.

ANNIVERSARY MEETING, JULY 9TH, 1885.

Sir JOHN LUBBOCK, Bart., M.P., in the Chair.

### *The Water Supply of Ancient Roman Cities.*

AFTER the medals and certificates had been presented to the successful competitors at the Exhibition held last year in Dublin, Professor W. H. CORFIELD read a paper on the above subject. He said that, as the supply of water to large populations was one of the most important subjects in connection with sanitary matters, and one upon which the health of the populations to a very large extent depended, he had thought that it would not be uninteresting to the members of this Institute were he to give them a short account of some of the more important works carried out for this purpose by the Ancient Romans—the great sanitary engineers of antiquity—more especially as he had had exceptional opportunities of examining many of those great works. Many of them were well known, but others, in many respects by far the most important, had not received the consideration that they deserved. Of the aqueducts constructed for the supply of Rome itself we had an excellent detailed account in the work of Frontinus, the controller of the aqueducts under the Emperor Nerva. He wrote his admirable work on them about A.D. 97, and not only described the aqueducts as they were in his time, but also gave a very interesting history of them. Before 312 B.C. there was no systematic supply of water to the city; the water was got direct from the Tiber, from shallow wells, and from natural springs; but these sources being found no longer sufficient, the construction of the first or Appian aqueduct was undertaken. It was not a very long one, being little more than 11 miles. It was carried underground throughout its whole length, winding round the heads of the valleys in its course, and was thus invisible until it got inside the city itself—a very important matter, con-

sidering how liable Rome was, in these early times, to hostile attacks. It was soon found that a larger supply was required, and it was determined to bring water from a greater height and from a greater distance; the River Anio, above the falls at Tivoli, was selected for this purpose, and the aqueduct, the Anio Vetus, was no less than 42 miles in length, and was also entirely underground, except at its entrance into Rome. Its exact course was not known, but during the lecturer's examination of the remains of the subsequent aqueducts at a place called the Porta Furba, near Rome, he had been fortunate enough to discover the exact position of the veritable Anio Vetus at that spot. These two aqueducts sufficed for the supply of Rome with water for 120 years; but in the 608th year A.U.C., the increase of the city necessitated a more ample supply, and it was determined to bring it from a still greater distance. Water was now brought from some pools in one of the valleys on the easterly side of the Anio, and the new aqueduct, called the Marcian, was 54 miles in length. Frontinus also gave the history of six other aqueducts in existence in his time, viz., the Tepulan, the Julian, the Virgo, the Alsietine or Augustan, the Claudian, and the Anio Novus; the last two being commenced by the Emperor Caligula, and finished by Claudius, because "seven aqueducts seemed scarcely sufficient for public purposes and private amusements." In order to allow of the deposit of suspended matters, piscinæ, or settling reservoirs, were constructed in a very ingenious manner. Each had four compartments, two upper and two lower; the water was conducted into one of the upper compartments, and from this passed probably by what we should call a standing waste or overflow pipe into the one below; from this it passed (probably through a grating) into the third compartment on the same level, and thence rose through a hole in the roof of this compartment into the fourth, which was above it, and in which the water of course attained the same level as in the first compartment, thence passing on along the aqueduct, having deposited a good deal of its suspended matter in the two lower compartments of the piscinæ. Arrangements were made by which these two lower compartments could be cleaned out from time to time. The specus or channel itself was of course constructed of masonry, generally of blocks of stone cemented together, and was frequently, though not always, lined with cement inside. It was roofed over, and ventilating shafts were constructed at intervals; in order to encourage the aëration of the water irregularities were occasionally introduced in the bed of the channel. The water supplied by the different aqueducts was of various qualities; that of the Marcian being very clear and good was used for domestic purposes. Frontinus gave the most accurate details as to the amount of water supplied by the various aqueducts, which it had been estimated was equivalent to about 332 million gallons a day, or 332 gallons per head per day, assuming the population of the city to be a million. When we considered that we in London had only 30 gallons a head daily, and that many other towns had less, we got some idea of the profusion with which water was supplied to ancient Rome. But the remains of Roman aqueducts were not only to be found near Rome. Almost every Roman city, whether in Italy or in the south of France, or along the north coast of Africa, could show the remains of its aqueduct. There was, however, one city which, from the fact that a great part of it was situated upon a hill, was more difficult to supply with water than any of the rest, viz., Lugdunum (now Lyons), the capital of Southern Gaul, built by Lucius Munatius Plaucus, by order of the Senate, A.U.C. 711. A somewhat prolonged residence in this city had given the lecturer the opportunity of examining on the spot the remains of the aqueducts constructed there by the ancient Romans, and as they were but little known, although by far the most remarkable of the Roman waterworks, he would give a somewhat detailed account of them. Water was at first brought from the hills of Mont d'Or, near Lyons, where a plentiful supply was found at a sufficient height, viz., nearly 2,000 feet above the sea, and it was necessary to cross the broad and deep valley now called La Grange Blanche, and the Roman engineers making the aqueduct end in a reservoir on one side of the valley, carried the water down into the valley, probably by

means of lead pipes, across the stream at the bottom of the valley by means of an aqueduct bridge 650 feet long, 75 feet high, and 28½ feet broad, and up the other side into another reservoir, from which the aqueduct was continued, along the top of a long series of arches to the reservoir in the city, after a course of about ten miles. In the time of Augustus it was found necessary to construct a second aqueduct, and the springs at the head of a small river, called now the Brevenne, were tapped, and conveyed by means of an underground aqueduct of about 30 miles in length. The lecturer exhibited a diagram showing a section of this aqueduct. The specus or channel was nearly 2 feet wide, and a little over 5 feet high, and was lined with a layer of 1¼ inches of cement. It was constructed of quadrangular blocks of stone cemented together, and had an arched stone roof. This aqueduct also crossed a small valley by means of inverted siphons. But neither of these aqueducts came from a source sufficiently high to supply the imperial palace on the top of Fourvières, and the Emperor Claudius determined to construct a third aqueduct. The sources of the stream now called the Gier, at the foot of Mont Pila, were chosen for this purpose, and from this point to the summit of Fourvières was constructed by far the most remarkable aqueduct of ancient times, an engineering work which reflected the greatest possible credit on the Roman engineers, and showed that they were not, as had been frequently supposed by those who had only examined aqueducts at Rome, by any means ignorant of the elementary principles of hydraulics. To tap the sources of a river 50 miles from the city, and to bring the water across ten or twelve valleys, one over 300 feet deep, and about two-thirds of a mile in width, was no easy task. At its source a dam appeared to have been constructed across the bed of the river, forming a lake from which the water entered the channel of the aqueduct, which passed along underground, except where it crossed certain small streams by means of bridges. In one or two places channels were cut for it through the solid rock, after which it reappeared on the surface at a point where now stood the village of Terre-Noire, and where it was necessary that it should cross a broad and deep valley. It ended in a stone reservoir, from which eight lead pipes descending into the valley were carried across the stream at the bottom on a bridge about 25 feet wide, and supported by twelve or thirteen arches, and then mounted the other side of the valley into another reservoir. Hence it again passed underground, except where it crossed valleys and streams, until it reached Soucieu, on the edge of the valley of the Garon, where there were still seen the remains of a splendid bridge, the thirteenth on its course, nearly 1,600 feet long, and attaining a height of 56 feet at its highest point above the ground. The object of this bridge was to convey the channel of the aqueduct at a sufficient height into a reservoir on the edge of the valley. Four holes were still to be seen in that part of the front of the reservoir which was left, being the holes from which the lead pipes descended into the valley. It would appear from the remains of the reservoir that there must have been nine of these pipes in all. These holes were elliptical in shape, being 12 inches high by 9½ inches wide, and the interior of the reservoir was still seen to be covered with cement. The walls of the reservoir were about 2 feet 7 inches thick, and were strengthened by ties of iron; it had an arched stone roof in which there was an opening for access. From this the nine lead pipes descended the side of the valley, supported on a construction of masonry, crossed the river by an aqueduct bridge and ascended into another reservoir on the other side, entering the reservoir at its upper part just below the spring of the arches of the roof. From this reservoir the aqueduct passed to the next on the edge of the large and deep valley of Bonnan, being underground twice and having three bridges on its course. The bridge across this valley had thirty arches, and was about 880 feet long by 24 feet wide. After crossing the bridge the pipes were carried up the other side of the valley into a reservoir, of which little remained, and then the aqueduct was continued to the next valley, passing over three bridges in its course. This valley, that of St. Irenée, was much smaller than either of the others, but nevertheless it was deep enough to necessi-

tate the construction of inverted siphons, of which there were eight. The aqueduct was then carried on a long bridge (the twentieth on its course), which crossed the plateau on the top of Fourvières and opened into a large reservoir, the remains of which were still to be seen. From this reservoir, 77 feet long and 51 feet wide, pipes of lead conveyed the water to the imperial palace and to the other buildings near the top of the hill. Some of these lead pipes were found in a vineyard near the top of Fourvières at the beginning of the eighteenth century. They were made of thick sheet lead, rolled round so as to form a tube, with the edges of the sheet turned upwards, and applied to one another in such a way as to leave a small space, which was probably filled with some kind of cement. These pipes, of which it is said that 20 or 30, each from 15 to 20 feet long, were found, were marked with the initial letters TI. CL. CAES. (Tiberus Claudius Cæsar), and afforded positive evidence that the work was carried out under the Emperor Claudius. It would be seen at once that the great difference between this aqueduct and those near Rome arose from the fact that instead of being carried across a nearly flat country, it was carried across one intersected with deep ravines, and that it was therefore necessary to have recourse to the system of inverted siphons. The Romans had been blamed for not using inverted siphons in the aqueducts at Rome, and it had been said that this was a sufficient proof that they did not understand the simplest principles of hydraulics, but the remains of the aqueducts at Lyons negated this assumption altogether. The Romans were not so foolish as to construct underground siphons many miles long for the supply of Rome, but where it was necessary to construct them for the purpose of crossing deep valleys they did so. It is thus seen that the ancient Romans spared no pains to obtain a supply of pure water for their cities, and Dr. Corfield thought it was high time that we followed their example, and went to the trouble and expense of obtaining drinking water from unimpeachable sources, instead of, as was too often the case, taking water which we knew perfectly well had been polluted, and then attempting to purify it for domestic purposes.

Among those present were Capt. Douglas Galton, R.E., C.B., F.R.S.; Prof. de Chaumont, F.R.S.; Mr. G. J. Symons, F.R.S.; Dr. Prosper de Pietra Santa, President of the Société Française d'Hygiène; Mr. Baldwin Latham, C.E.; Mrs. Priestley. A vote of thanks to Dr. Corfield for his address was proposed by Mr. Symons and seconded by Prof. de Chaumont.

### INDIA.

---

(From Our Bombay Correspondent.)

*The "Birthday Gazette" and Honours to Medical Men—  
An Inefficient Municipal Council—Cholera.*

June 20th.

ON the anniversary of the birthday of Her Most Gracious Majesty the Queen, it has been customary for the Government of India to issue what has been designated the *Birthday Gazette*, containing a list of names (by no means invariably well-chosen) of persons who are to be the recipients of honours. In this honours list I notice with regret the fact that, with the exception of one of two high officials, names of members of our cloth are conspicuous by their absence. At home, too, baronetries and knight-hoods are conferred on the profession of medicine with a grudging hand, and it is doubtless, as observed over and over again by your contemporary, the *Lancet*, a huge and ugly blot on the administration, whether Liberal or Conservative, that there should be no medical peer of the realm, though other professions, even those of the soldier and the sailor, are so honoured. My concern here is to note that there exists in India the same unwillingness, and at any rate neglect, to honour those of our profession,

who have laboured to advance the science of medicine. I hope that the next Parliament will contain a considerably increased proportion of medical men, who will be able to take up the matter, and urge on the Government, for instance, the claims of such men as Dr. Vandyke Carter, Mr. D. D. Cunningham and others, to a full measure of State recognition. I am glad, however, to observe that Mr. Cunningham has just been gazetted to be honorary surgeon to His Excellency the Viceroy.

Dr. Khory, a medical practitioner in Bombay, taking up a suggestion that a new medical school should be established there, offered in your contemporary, the *Lancet*, urges (*Bombay Gazette*, June 17th) under cover of this and financial grounds, the transfer of the management of the Goeldas Tejjpal Hospital from the Government to the Municipality, which would *de facto* mean that a body already ill-able to cope with what medical and sanitary matters it has in its hands, as exemplified by the very unsatisfactory sanitary condition of the city of Bombay, with its high death-rate and perennial existence of cholera, should be entrusted with an additional public duty. I have in these columns (May 23rd) urged on the Government to retain its hold on the hospital, and to continue to appoint to its staff gentlemen of the time-honoured Indian Medical Service about whose qualifications there would be less cavil than about those who, whilst aspiring to the higher walks of professional career, keep open surgeries, dispense medicine, and, in fact, keep drug-shops.

Judging by the latest reports in the newspapers, the cholera is extending its ravages not only along the Bolan route to Quetta, but also along the Hurnai route and in Quetta itself, and it is said to have been so bad that the works for the construction of the railway have had to be stopped and the labourers dispersed. As many as from 45 to 50 deaths are reported to have occurred in some of the places in those regions. I understand that typhoid fever is also bad at Quetta, which certainly cannot be ranked as a *Salutland*.

Dr. Beaumont, the residency-surgeon at Hyderabad in the Deccan, goes home on furlough, and Mr. Lawrie, M.B., Professor of Surgery at Lahore, is appointed to act for him. Mr. Keelan, civil surgeon of Hyderabad, in Sind, and superintendent of the medical school there, also goes home on furlough, and Dr. de Tatham acts for him.

## GENERAL CORRESPONDENCE.

### MALE NURSES FOR MEN.

[To the Editor of the Medical Times.]

SIR,—My attention has been called to a paragraph in your Journal of July 4th, stating that a plan has been set on foot by a Miss Hamilton for training men as nurses. The enclosed letter published in the *St. James's Gazette* of the 28th March last shows, I think, that this scheme was originated by and first brought under the notice of the public by

Your obedient Servant,  
JOHN H. LEWIS.

123, Edgware Road, 16th July.

To the EDITOR of the ST. JAMES'S GAZETTE.

SIR,—The Hospitals Association would, I think, do well to note that though every facility is afforded to women to acquire the knowledge requisite for a nurse, scarcely any opportunity is given to men to do so. I suggest that to men should be afforded at hospitals a systematic training in the art of nursing—for truly it is an art—such as now is only within the reach of women. For male doctors for women there is the forcible reason that the nerve of a man is often required in the performance of operations; nevertheless, female doctors for women is a very popular cry. For male nurses for men, I believe more cogent reasons can be produced than for female doctors for women. Female nurses are usually from 23 to 35 years of age. This is not an age at which a woman unrelated to a man by the closest ties of blood should be in constant attendance upon him, and have to perform duties scarcely within the province of either his mother or his wife. It is urged, I know, in defence of female nurses for men, that the nurse by her training becomes mentally as well as bodily qualified for her work. That some are so probably is the case; others, there can be no doubt, are

the reverse. I assert that female nurses for men are, both for patient and for nurse, morally unsuitable in many cases; in some, perhaps medically, their attendance is positively injurious. For obvious reasons I cannot enumerate these cases here; I may, however, remark that a man can with far greater ease than a woman carry a man, and a male nurse can endure more hours of consecutive labour than a woman. Though in hospitals relays of nurses are always procurable, in a private house a substitute can often not be found for the nurse when unusual illness of the patient necessitates extra care for some time. An efficient male attendant for an invalid is now difficult to obtain, not because many men capable of acquiring the knowledge requisite do not exist, but because few have any chance of learning the duties of a nurse, and they only in an imperfect manner. Moreover, these belong to classes of society not likely to supply good nurses. Many nurses usually have picked up their knowledge either in private lunatic asylums or military hospitals. Some few have been servants to medical men who had invalids resident in their houses, and thus have gained some knowledge of nursing. Under present circumstances it is strange rather that there should be any good male nurses than that there should be so few. In many cases a good male nurse would be a great comfort to an invalid gentleman. For steady, quiet, intelligent men, who do not mind work, who can find recreation in reading, and do not object to the solitude of an invalid's room, nursing appears to be suitable and remunerative occupation.

I am, Sir, your obedient Servant.

J. H. L.

March 25th.

## INVENTIONS AND IMPROVEMENTS.

### DR. WARD COUSIN'S NEW SOUND DEADENER.

THE accompanying illustration was by an accident omitted in our impression of last week. We must refer our

readers to that number for a description of it, but we may add that it is made in several sizes and of various degrees of softness. A prize was awarded to it last year in the Otological Section of the British Medical Association.

LIQ. EUONYMIN ET PEPSINE Co. — This preparation (introduced by Messrs. Oppenheimer Bros. & Co.) appears to contain both of its constituents in a thoroughly soluble and active form. There is no doubt that in order to get satisfactory results with euonymin, it is as a rule necessary to give it in repeated doses for a certain length of time, and not merely for two or three nights in succession, which, owing to a mistaken idea as to its resemblance to blue pill, was for long the favourite mode of administration. The present preparation, when taken after every meal, for a week, has been credited by us with good results in relieving the symptoms usually attributed to functional derangement of the liver.

VICTORIA NATURAL MINERAL WATER.—This excellent natural table water, which has achieved considerable popularity on the Continent, has recently been introduced to our notice by Messrs. Romenhüller (43, Finsbury Circus), and we do not hesitate to say that it deserves a fair trial at the hands of those who prefer a natural to an artificially aerated water. It is derived from a spring near Oberlahnstein at the entrance to the Rheingau, and contains about one part of sodium carbonate and two parts of sodium chloride in 1,000 of water, with three parts of carbonic acid. There is not a trace of iron, a characteristic which is

quite exceptional, and which renders it very appropriate for mixing with red wines with their varying amount of tannin. The water is very pleasant to taste, and is no doubt a valuable addition to those already in use.

**HAY'S AERATED DRINKS.**—We favourably noticed last summer some of the effervescent beverages introduced by Mr. Hay, of Hull (Agents: Ingram & Royle, 52, Farringdon Street, E.C.), which are as pure and palatable as any we have met with. The orange, lemon, and ginger champagnes have been improved in the last year, and the genuineness of the flavouring element is very obvious. The orange quinine tonic and the tonic ale are sweet effervescent drinks, containing bitter principles, the one quinine, the other quassia; they are likely to thoroughly commend themselves to jaded palates.

**COOK & TOWNSHEND'S "MODEL" BOOT.**—There are several bootmakers nowadays who understand how to make a rational boot, but the majority still keep in the old ruts, and it is almost useless to try to get them to cut the sole in any but the conventional method; and yet cases are constantly arising in practice in which a boot built on anatomical principles is an essential part of the cure. Messrs. Cook & Townshend's boots (Byrom Street, Liverpool) show that they have thoroughly mastered the science of making boots that will allow full and natural play to the foot. For old cases of ingrowing toe-nail they are especially adapted.

## LETTERS TO UNDISTINGUISHED PERSONS.

### V.—TO A YOUNG GENERAL PRACTITIONER.

MY DEAR R——.—I am glad you have reminded me of my undertaking to give you some advice as to your relations with consultants, not because I mean to make it good just now, but that, being desirous of delivering my soul of a matter of which it is over-full, I know of no such speedy and satisfactory means of relief as writing freely and unconstrainedly to a sympathetic reader like you. I have to-day been surprised, and I may even say shocked, to find a medical journal enunciating the strange doctrine that "absolutely none other than professional relations should subsist between those who attend the sick medically and the sick or their families;" "that medical practitioners should render only *medical services*," and again, "that the impulse to be kind to persons in difficulties is certainly not one which the practitioner of medicine ought to allow to get the better of his judgment." Now, the spirit of the man who believes that is the spirit of the tradesman, of one who is determined in any and every case to do no more than exactly what he is paid for doing. I can even imagine him giving discount for ready money to members of the "Stores." It is a pettifogging, pusillanimous spirit. Why, the reproach I have to make against myself at the end of a busy life is, that I have not been more of a friend to my patients, that I have too often forced back the impulse to be kind to persons in difficulty. If I had my years over again I would set myself to make more friends and less money. I would let slip no opportunity of helping my fellows, even at the risk of trouble and inconvenience and all the scandal that the writer of the article threatens one with. The man who weighs every service he renders, and balances every benevolent impulse against his personal comfort and safety, has not, in my opinion, mastered the prime elements of humanity. By one consent we call him

"hero" who thinks of himself as nothing beside the cause he champions, or the weal of those he loves, or even only pities. Well, we can few of us rise to the full stature of heroes, but we can all do something that way, and we all have impulses, however weak and occasional, to do that something. We have a piece of cake in hand, like Alice in Wonderland, which will help us to grow bigger, hero-wards, if we will only make the best of it, instead of shrinking into our shoes, like this poor leader writer, in mortal terror of being big enough to be found out. Reading one of Matthew Arnold's discourses the other day, I was reminded of what the Greek prophetess Diotima said to Socrates, how that love and impulse and bent of all kinds are but particular forms of the fundamental desire in men to have good for ever present with them. And yet our leader writer tells us we are weak if we yield to such desire! I should like to raise a statue to that sort of weakness.

I will relate, at the risk of wearying you, a slight episode in my life. Many years ago, when I was in practice in the west country, it happened that a young lady from my native town, whom I had known from childhood, married and settled down within a short distance of me. Some months later I was rung up early one morning by her maid, who, knowing of our intimacy, told me she feared her mistress was leaving her home, her husband being then away in London, and begged me to overtake her at the station and argue her back. I arrived in time to find her getting into the train. By an impulse which "got the better of my judgment," I hurriedly took a ticket and jumped into the same carriage with her. We had a long talk, and at last she promised me to return to her home by the next train. She was an innocent excitable creature, and had been thrown off her mental balance by certain discoveries she had made as to her husband's pre-nuptial relations. At the London station we were confronted by the husband, glowering at us. The maid, assuming my failure, had sent him a telegram. I had a difficult piece of diplomacy before me, but I got a quiet talk with him, and in the end we all journeyed back home together. They are now amongst my dearest and happiest friends. By our leader-writer's standard I fear I was abominably rash. Think what might have come of it: scandal, ruin to one's practice, dishonour to one's profession; but what would you or any true-hearted man have thought of me if I had turned back the weeping maid with a "No, no, I only render *medical services*;" like the village chemist who, when called upon to help in putting out a fire, is said to have replied, "What's the use of coming here? You know I only keep aerated waters."

The case I have related is no doubt an extreme one. Few of us have the good fortune to find two fellow-creatures' happiness thus put in the hollow of our hand. But many cases are likely to occur in a practice such as yours, wherein your own impulse rather than the patient's outspoken demand will prompt you to non-medical services, which if less sensational are also less hazardous. Why, our self-constituted adviser, if he carried his counsel to its logical conclusion, would forbid us to advise a parent to what schools or into what profession to send his sons, points on which a doctor's knowledge is often the best available; would frown at us for relieving some widowed mother of the sorry duty of lecturing a headstrong son; would censure our listening to secrets, the telling of which might give calm to a distracted mind. On such terms, I for one would never have practised medicine. Once I went out of my way to save a man from suicide. Was that a medical service? On another occasion a lady, not a

patient, told me casually that her husband was about to insure his life with a bogus company. I dissuaded him from it. Our vicar wanted to refuse to read the burial service over a dissenter, a good man to the core, who had been my patient. I took it on myself to confront the cloth, and a scandal was averted. You will think me a garrulous old man; our leader writer would probably call me something worse, a dangerous busy-body perhaps. But I know this, that looking back on my life I remember with greater thankfulness the few instances in which impulse has carried me beyond the strict limits of professional duty, than all the successes I have scored by attending conscientiously to my duty, and doing simply what I was paid to do. Enough! I apologise for having occupied so much of your time and spoilt so much good paper in combating a doctrine which I don't suppose is held by more than one member of the profession. Rate me as you please, but remember me to be,

Your sincere Friend,

SILAS PHANTOM.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed their primary examinations in Physiology at a meeting of the Board of Examiners, on the 9th instant, and when eligible will be admitted to the pass examination, viz. :—

J. H. Gordon and W. Rennie, Birmingham; A. M. Barford, T. H. Valintine, A. W. Hogg and H. Nichol, St. Bartholomew's Hospital; G. H. Trenfield and A. D. Owen, Bristol Medical School; G. W. Pettinger and H. Birkenhead, Manchester; H. L. Hudson, Sheffield School of Medicine; J. A. Eytton Jones, Liverpool; W. H. Hillyer and L. Franklin, St. George's Hospital; W. H. F. Goodwin, Westminster Hospital; W. Mortimer and F. J. Oxley, London Hospital; A. S. Taylor, Newcastle-on-Tyne.

Eleven candidates were referred for 3 months and six for 6 months.

Passed in Anatomy and Physiology on the 10th inst. :—  
E. Evans, St. Bartholomew's Hospital; W. Vost and D. T. MacLeod, Glasgow; E. A. Clarke, C. Pearce, and G. B. Howe, Manchester; G. I. Lough, E. S. Lewer, H. P. Sloggett, and J. Murray, Dublin; T. S. Dennison and C. W. Smeeton, Leeds; F. J. Fletcher, Birmingham; J. Mitchell, Liverpool; E. Ward, Bristol School of Medicine.

Passed in Anatomy only :—

A. E. Vaughan, Manchester; C. H. Stevens, University College; M. H. Hannigan, Dublin; R. S. M. Groves, Birmingham; G. B. Procter, Liverpool.

Passed in Physiology only :—

A. G. N. Goldney, Charing Cross Hospital; I. C. McLearn and H. Woods, Dublin.

Ten candidates were referred for 3 months and eight for 6 months.

Passed in Anatomy and Physiology on the 13th inst. :—

A. R. P. Sanderson, Newcastle-on-Tyne; T. Wilson-Smith, W. S. Cameron, and H. P. Ainsworth, Guy's Hospital; A. P. Lange, King's College; W. E. Stevens and H. J. Thomas, Bristol School of Medicine; E. P. Daniell, University College; R. S. Charsley, Westminster Hospital; T. G. Carr, Manchester; N. C. Selater, Liverpool; D. McD. L. Campbell and H. De Vere Stackpoole, St. Mary's Hospital; A. B. Blaikie, Cambridge; T. W. Bevan, St. Bartholomew's Hospital; W. B. Nelson, Middlesex Hospital; F. W. Style, London Hospital; G. B. French, Edinburgh.

Passed in Anatomy only :—

N. Nelson, Dublin; G. Alexandre, Basle; W. D. Wells, King's College; F. B. H. Caudwell, Charing Cross Hospital; A. C. A. Lovegrove, Westminster Hospital; C. R. Adams, St. Thomas's Hospital; W. G. Thorpe, Guy's Hospital; G. H. Thompson, St. Bartholomew's Hospital.

Passed in Physiology only :—

D. J. P. McNabb, Newcastle-on-Tyne; T. J. Bokenham, St. Bartholomew's Hospital; T. A. F. Quirk, Melbourne.

Eleven candidates were referred for 3 months, and ten for 6 months.

Passed in Anatomy and Physiology on the 14th inst. :—

R. F. Bate, Charing Cross Hospital; E. S. Robinson and H. H. A. Jones, London Hospital; H. B. Marriott and R. G. P. Lansdowne, Guy's Hospital; A. W. Boning, C. A. Locke, and P. R. Ponsford, University College; H. Layng, Westminster Hospital; J. Griffiths, King's College; S. B. C. De Butts, St. Mary's Hospital.

Passed in Anatomy only :—

G. E. Price and E. Carter, London Hospital; J. More, St. Bartholomew's Hospital; M. H. Vinrace, Birmingham; J. Harrison, St. Mary's Hospital.

Passed in Physiology only :—

H. B. Shillingford and A. R. Jessop, Guy's Hospital; Frank Brightman, University College; H. L. Ebdon and G. E. G. Metcalfe, St. Bartholomew's Hospital; R. Roberts, Middlesex Hospital; S. C. Skipton and R. W. Logan, St. Thomas's Hospital; F. A. Nicholas, Westminster Hospital; C. W. Hopwell, King's College.

Fourteen candidates were referred for 3 months, and ten for 6 months.

Passed in Anatomy and Physiology on the 15th instant :—

J. C. Gilmour, W. F. A. Clowes, and R. T. Temple, Guy's Hospital; E. W. Williams, London Hospital; G. D. Keer, St. Thomas's Hospital; H. W. Newton, St. Bartholomew's Hospital; John Rees and Robert Hill, Middlesex Hospital; H. W. G. Green, Westminster Hospital; H. W. Elphick, Charles Wade and S. S. Swift, University College; C. H. Duncan, Charing Cross Hospital.

Passed in Anatomy only :—

P. K. O'Brien, University College; R. F. Gordon, St. George's Hospital; G. Barton and J. Ash, Charing Cross Hospital; F. J. Troughton, Guy's Hospital; C. S. Fisher, St. Bartholomew's Hospital; O. W. Andrews, St. George's Hospital; W. J. Midelton and F. S. Jermaine-Lulham, St. Bartholomew's Hospital.

Passed in Physiology only :—

A. C. Elliman, Guy's Hospital; E. H. T. Harden, University College; E. J. Cross, St. Thomas's Hospital.

Examining Board in England by the Royal Colleges of Physicians and Surgeons. The following gentlemen passed the Second Examination in Anatomy and Physiology on the 15th instant :—

T. Nesbitt Wright, Guy's Hospital.

Passed in Physiology only :—

W. Pechey Smart, Guy's Hospital; W. Louis Abbott, Pennsylvania.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, July 9th, 1885 :—

Otto Jacobson Kauffman, M.R.C.S., Victoria Park, Manchester; Levi Stephenson Luckham, M.R.C.S., Studland, Dorset; William Algenon Winship, M.R.C.S., 10, Osborne Terrace, Newcastle-on-Tyne.

On the same day

Robert Hasby Barrett, Elms Road, Dulwich, passed his examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise.

The death is announced from Greifswald of Professor P. Vogt, the director of the surgical clinic in that University.

PROFESSOR MERKEL, of Königsberg, has been appointed to succeed the late Professor Henle in the University College of Göttingen.

THE Société d'Hygiène in Paris have elected the director of the Imperial Board of Health in Germany and Dr. Paul Börner as Foreign Members of the Society.

THE Good Service Pension of 100*l.* a year, vacant by the death of Sir W. Muir, has been bestowed upon Surgeon-General W. A. Mackinnon of the Army Medical Staff.

APPOINTMENTS TO THE VICE-REGAL HOUSEHOLD.—His Excellency the Earl of Carnarvon, Lord Lieutenant of Ireland, has made the following additional appointments to the Vice-Regal Household :—*Physicians-in-Ordinary*—Philip Crampton Smyly, M.D. Univ. Dubl. and George W. Hatchell, M.D. Glasg. *Surgeon-Dentist-in-Ordinary*—Robert Henry Moore, F.R.C.S.I.

ANOTHER MEDICAL CANDIDATE FOR PARLIAMENT.—Dr. Gordon Hogg of Gunnersbury, chairman of the Chiswick Local Board, has been finally selected as Liberal candidate

for the Ealing Division of Middlesex, in opposition to Lord George Hamilton. Dr. Hogg is an old Edinburgh student, he took his M.D. degree in 1873, having previously served as house surgeon to the Royal Infirmary.

**VICE IN LONDON.**—It is stated that the Government is likely to be urged to appoint a Royal Commission to enquire into the allegations with respect to vicious sexual practices in London. It is proposed that men of legal and medical eminence shall form part of the Commission, and that it shall have the power of compelling the attendance of witnesses and examining them upon oath.

**ST. BARTHOLOMEW'S HOSPITAL.**—On Monday last the Prince of Wales opened the new convalescent home at Swanley for the use of the patients at St. Bartholomew's Hospital. The building has been erected at the expense of Mr. C. T. Kettlewell in memory of his brother, and contains accommodation for 70 patients. It stands in about fifteen acres, which were purchased for the purpose by a governor of the hospital whose name did not transpire.

**EDINBURGH ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL.**—Dr. Keiller, who has been physician on duty since 1st May, will be succeeded on 1st August by Dr. Croom. Dr. Underhill, the assistant physician on duty, will be succeeded by Dr. Hart. The present house surgeons, Dr. William G. Anglin and Mr. Wm. Cotton, M.B., C.M., will be succeeded on 1st August by Mr. J. Haig Ferguson, M.B., C.M., and Mr. S. H. Puckle, B.A.

**PORTABLE HOSPITALS.**—A prize of 200*l.* has been offered by the Empress of Germany for the best portable hospital or sick-room tent for use in war and during epidemics, and will be awarded in connection with the Antwerp Exhibition, where the competing specimens are now being received, and will remain on show during the rest of the summer.

**POISONOUS PATENT MEDICINES.**—In the House of Commons on Monday, in reply to Mr. Warton, Sir H. Holland stated that the Government did not intend to proceed with the Bill introduced by their predecessors. The stamp would, however, in future contain the words "This stamp implies no Government guarantee." It is expected that the new plates for printing the stamps would be completed and the present stock of old stamps exhausted in two months.

**RIVER POLLUTION, SCOTLAND.**—As the result of the enquiry lately held at Dunfries, on the pollution of the river Nith, Dr. Littlejohn and Mr. M'Neil report to the Board of Supervision that the very large quantity of town sewage, and discharges from mills into the river, endanger the health of the town, and they suggest a large intercepting sewer as a remedy for the evil, the cost of which they estimate at about 3,000*l.*

**A FATAL BEE STING.**—While walking in his garden about a fortnight ago, a bee stung Mr. W. H. Blanchard ironmonger, of Poole, in the neck. Swelling shortly afterwards supervened, and notwithstanding medical treatment, and the calling in to the case several doctors, subsequently he grew worse, and died in great suffering, on the 9th instant, from the effects of the sting.

**ANCHYLOSTOMATA.**—Prof. Masins stated at a recent session of the Brussels Academy of Medicine, that since the end of January out of 37 miners attending the Clinic at Liège seven had voided Anchylostomata in their fæces. Five of the seven were distinctly anæmic. From this he concludes that this entozoon is not uncommon in the neighbourhood of Liège.

**A LARGE RHINOLITH.**—A large rhinolith has been extracted by Schmiegelow, of Copenhagen, from the left nostril of a man of 53; a powerful ecraseur was used, and two sittings were requisite. The stone was as large as a walnut, and somewhat forked as it embraced the inferior turbinated bone. The composition was chiefly phosphate of lime and magnesia, with some carbonate and traces of chlorides. There was very little organic matter, and no oxalate of lime.

**CHARITABLE BEQUESTS.**—Mr. Thomas Emsley, late of Burley, near Leeds, has bequeathed 1,000*l.* each to the

Leeds Infirmary, the Bradford Infirmary, the Ilkley Convalescent Home, and Harrogate Bath Hospital. Mrs. Elizabeth Douglas (formerly Wolterbeck), late of Elm Bankhouse, Castlenau, Barnes, leaves by her will 200*l.* each to the Central London Ophthalmic Hospital, the Royal Sea Bathing Infirmary, Margate; the West London Hospital, and the Consumption Hospital, Brompton; and 100*l.* to the Royal London Orthopædic Hospital. Mr. Mackie, the late member for the Borough, has left a legacy of 1,000*l.* to the Clayton Hospital, at Wakefield.

**PROVISION FOR FEVER AT GLASGOW.**—The Glasgow Town Council is considering the advisability of rebuilding a portion of the Fever Hospital at Belvidere at an expense of 2,600*l.* The existing building was formerly a mansion house, and it exhibits signs of advanced decay in certain places. When the matter was before the Council, Lord Dean of Guild MacEwen, lately Chairman of the Royal Infirmary, took occasion to declare that the hospitals connected with the city had been constructed at an extravagant expense. In the end, the question was remitted back to the committee.

**VITAL STATISTICS OF GLASGOW.**—Dr. Russell's report for the fortnight ending 4th July, shows 454 registered deaths, as compared with 467 in the preceding fortnight, representing a death-rate of 22.7 per 1,000 per annum, instead of 23.4. Diseases of the lungs were the cause of 142 deaths out of the 454. Two additional cases of small-pox were registered. One was the case of the wife of the undertaker who assisted at the interment of the body of the sailor who died in hospital on the 13th ult. The other case was that of a child, three years of age, one of a family of Poles, emigrating to America. They had reached Glasgow from Leith. The case was detected at the Tail of the Bank, and the child was promptly sent back to Glasgow, and conveyed to Belvidere Hospital. Dr. Russell also reported that the cases at present at Belvidere were, of scarlet fever 93, of enteric fever 40, of whooping-cough 25, of measles 22, of typhus 11, of small-pox 3. Last week, the death-rate was 21 per thousand, and for the three preceding weeks 24, 23, and 24 respectively. For the corresponding week last year, the rate was 21 per thousand, and for 1884, 1883, and 1882, 23, 24, and 22 per thousand respectively.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.**—A Quarterly Court of the directors was held on Wednesday, July 8th, at 8 p.m., the President, Sir James Paget, in the chair. A sum of 1,437*l.* was voted for distribution among 66 widows, 10 orphans and 3 orphans on the Copeland Fund. The expenses of the quarter were 39*l.* 4*s.* The treasurer informed the meeting that the grants already made this year exceeded by 308*l.* those for 1884. Fresh applications for relief were received from two widows, and grants were made to them. No new members were elected, the deaths of three were reported, the resignation of one was accepted, and four ceased to be members. The directors fear that owing to the increased demands on the funds it may not be possible this year to give the usual present at Christmas, unless by gifts or accession of new members the sum necessary, between 300*l.* and 400*l.*, be made up.

**THE SANITARY INSTITUTE OF GREAT BRITAIN.**—The anniversary dinner was held at the Holborn Restaurant on the 9th inst., Captain Douglas Galton occupying the chair, supported by a large and influential assembly. Among the toasts, "Success to the Société Française d'Hygiène," coupled with the name of the President, Dr. Prosper de Pietra Santa, was proposed, and responded to by that gentleman. The toast of the evening, "Success to the Sanitary Institute," was proposed by Mr. Selater-Booth, who referred to the influence for good which had resulted from the Public Health Act of 1875 (an Act he had helped to pass), and to the great advances which had been made in recent years in sanitary science, assisted as it had been by the action of the Legislature. The Chairman, in responding, expressed the hope that the Parkes' Museum of Hygiene would be united with the Sanitary Institute, as they were complements one of the other, and also that the work of sanitary education would be proceeded with by the latter.

DR. FERRÁN AND THE FRENCH COMMISSION.—An explanation is offered by a friend and admirer of Ferrán of the reason why the French Commission, who had been sent to enquire into his inoculation proceedings, left without making any observations. It seems that when they asked for information about how the "vaccine" was prepared from the microbe of cholera, Ferrán said to them, "Bring me a comma culture, and I will transform it into vaccine." They, however, thought he meant to keep the process a secret, and therefore left in "a huff," quite unaware that, so far from wishing to keep the process a secret, Ferrán had long ago written a full account of it to the French Academy, and they, as his name was at that time unknown, paid so little attention to it that it was put away to be relegated to their *comptes rendus*. All they had to do, therefore, was to go back and look for Ferrán's communication amongst their own archives.—*Independencia Médica*.

THE CHOLERA IN VALENCIA AND DR. FERRÁN.—Dr. Sereñana writes from Valencia that the epidemic is still increasing; no less than 200 deaths had occurred in the 24 hours preceding the date of his letter (July 3), and 139 bodies had been buried that day up to 3 o'clock. The panic was considerable, and the streets of the city deserted. Almost all the medical men had themselves been inoculated. One, however, a Dr. Peset, was not willing to try the remedy himself, though he was not opposed to it in general, and he died from cholera a few days ago. Dr. Ferrán has an inoculation-surgery in Valencia, where three medical men at a time are kept pretty hard at work from morning till night, scarcely laying down their syringes. The neighbouring towns are incessant in their clamour for inoculation. In one of these, where Dr. Sereñana himself and Dr. Garin were deputed by Ferrán to inoculate, the school was placed at their disposal by the authorities, and the scene was most extraordinary. Four hundred people inside and about the same number outside, the men with bare arms the women with holes cut in their jacket-sleeves, all clamouring to be inoculated. So great was the confusion that the aid of the police had to be called in. For nearly four hours the two doctors were incessantly occupied, and during that time inoculated 674 people.—*Independencia Médica*.

SANITATION IN CALCUTTA.—This subject, says the Calcutta correspondent of the *Times*, which last year gave rise to a somewhat acrimonious controversy, is likely to come to the front again. Two of the three commissioners deputed by the Government to hold an enquiry presented a most damning indictment against the Corporation for neglect of proper precautions. The Lieutenant-Governor has now suggested placing the city and suburbs under one municipal body as an important step towards reform, and a commission has been appointed to consider the proposal. The majority of the corporation is, however, likely to prove as intractable as last year, and equally unwilling to accept any reform which is not forced upon it.

LONDON UNIVERSITY MATRICULATION.—At the June examination, the results of which are just published, the lady students have achieved a signal success. More than 1,100 candidates, male and female, entered for the examination. Of these 615 have been successful, and for the first time a lady, Miss Wishart, heads the honours list, without being disqualified by age from receiving the exhibition of thirty pounds for two years. Two other ladies are among the prize-receivers, obtaining prizes of 10*l.*, and 5*l.* respectively. In all, thirty-five candidates have obtained either prizes or the number of marks qualifying for prizes, and eight of these are ladies. Of the 615 successful candidates, 100 are ladies out of about 150 who entered for the examination. Last year a total number of 972 candidates presented themselves for this examination, and 536 passed. But the great progress which the examination is making in popularity is seen by a comparison with the numbers recorded ten years ago. In 1875, at the June matriculation, there were but 499 candidates, of whom 290 passed.

INSANITY IN THE UNITED STATES.—Statistics recently issued show that in 1865 the number of insane persons in the United States was only 24,042. Five years later it had

reached 37,432, and by 1880 treatment was required for 91,959 lunatics. The increase in insanity during the ten years from 1870 to 1880 was nearly 150 per cent, while that of the total population was only about 26 per cent. But these figures do not represent the actual increase, as during the above period a large number of insane persons previously concealed were brought into public notice by more thorough investigation. Apart from several large county asylums in the United States, there are 80 State and 40 private institutions for the care of the insane, with a proper capacity for about 40,000, but containing 53,192, thus leaving some 45,000 lunatics to be cared for elsewhere. The proportion of insane is greatest in New England, but the increase has been most rapid in the Western States. In the State of New York there are 35 institutions for the care of these unfortunate people, accommodating 11,343 patients, while it is said that there are 4,000 provided for at home.

MR. ERICHSEN'S CANDIDATURE.—At an influential meeting of graduates, held in London on Saturday, to promote the candidature of Mr. Erichsen, it was moved by Dr. Robert Farquharson, M.P., and seconded by Dr. William S. Playfair, that "A London committee be formed, and that Sir James Risdon Bennett, M.D., be chairman thereof." It was moved by Dr. James G. Glover, and seconded by Dr. George Harley, "That the committee consist of those now present, with power to add to their number." It was moved by Dr. T. Lauder Brunton, "That the following gentlemen be a sub or acting committee, viz., Sir James Risdon Bennett, Dr. George Harley, Dr. Farquharson, M.P., Dr. T. Lauder Brunton, and Mr. Meredith, surgeon; that the honorary secretaries be Dr. George Ogilvie, B.Sc., 27, Welbeck Street, Cavendish Square, London, and Mr. Thomas Raleigh, barrister, 5, New Square, Lincoln's Inn, London." It was thereafter agreed to form committees in Manchester, Leeds, Liverpool, Newcastle, Bristol and Birmingham. Mr. Erichsen was to address the Members of Council of the Universities of Edinburgh and St. Andrew's yesterday (Thursday). In his written address, which has been published, he states that if elected, he would support all well-considered Liberal measures. "But I feel very strongly that the representative of a University seat has far higher duties to perform than those which attach to mere party politics. There would, indeed, be no justification for University representation, unless the Member devoted his chief attention to the interests of learning and of those professions which are based upon it. Edinburgh has always been distinguished for its great School of Medicine, whilst at St. Andrew's a very large proportion of the Members of Council are of the medical profession. . . . As more than one-half of your electoral body is composed of medical men, I cannot but hope that in the many subjects connected with medical science, education, and reform, they should like to be represented by a number of their own profession conversant with those subjects." After stating his views on University and School education Mr. Erichsen concludes: "All subjects depending upon the relations of science to social welfare, such as those relating to public health in its widest sense, to technical education, and to general culture, ought to receive the constant attention of the representative of a University. Your present member, Sir Lyon Playfair, has interpreted his duties to the Universities in this way, and my conviction is that such a course is the only justification for academic representation."

ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.—The following petition, representing the views of this body, is in course of signature:—"To the Queen's Most Excellent Majesty in Council. The humble petition of the members of the Royal College of Surgeons of England sheweth,—That whereas a petition has been prepared for presentation by the President and Council of the Royal College of Surgeons of England, praying for a supplemental charter, or alterations in the existing charters previously granted to the said Royal College, your humble petitioners approach your Most Gracious Majesty respectfully to point out that in the present charters the members of the said College (in proportion to the Fellows of 14 to 1) have no status of any kind in connection with the governing

body. Your petitioners most humbly submit that it would be both equitable and politic that the whole body of members should have a voice in the conduct of a corporation of which they are, and always have been, numerically and financially, the mainstay. At present the Council—elected by only 1,200 Fellows—deals absolutely with the interest, property, and moneys of the College, whilst 16,000 members are wholly unrepresented. The Fellows are of two classes, numerically nearly equal, viz.: (1) Members of the College before 1843, who have been elected on the nomination of 6 Fellows; and (2) Members who attain their Fellowship by examination—the fees payable and the advantages of each class being equal. The Council consists of 25, who are elected for eight years by the Fellows out of their own number, but of these none are eligible for election except the few who practise pure surgery. The Council accordingly monopolizes the power and privileges, and disposes of the funds, in entire independence of the remaining Fellows and Members, from whom the income is mainly derived. Your petitioners do therefore most earnestly pray that before granting any charter or supplemental charter to the said Royal College, their present position may receive Your Majesty's greatest consideration for measures of relief, which will create and secure for the Members (who so largely contribute to the prestige and welfare of the said College) the right of representation and other privileges of examiners, the conduct of examinations, and the expenditure of the College Funds, matters into which your petitioners believe thorough investigation is necessary, as well for the interests of the College as for its Members. Finally, your petitioners very humbly pray that in the event of no petition for a supplementary charter or otherwise being presented by the Council of your Royal College, your Majesty will be graciously pleased, in your wisdom, equity, and discretion, to sanction and provide for certain alterations being made in the present existing charter so that it may contain such provisions as are herein undermentioned:—1. That all Members having been registered may, conjointly with Fellows, exercise the privilege of electing the Council. 2. That a moiety of the Council may consist of Members of not less than ten years' standing. 3. That eight Censors may be appointed, half of whom shall be Members—two to be elected by the Crown, two by the Council, two by the Fellows, and two by the Members. 4. That Members of Council and Censors may be elected for three years, and may be re-elected for a similar period, but shall not be eligible for a third term until out of office for one year or more. 5. That Members and Fellows may be permitted to vote by voting papers. 6. That Members may be eligible for election as examiners. 7. That the Council formed as above shall elect the examiners annually, but that only one-third of the Council shall be permitted to act in that capacity. 8. That Members as well as Fellows may be present at *vidæ voce* examinations. 9. That no fees of any kind be paid to College Funds by Fellows or Members on election to office. 10. That the Council shall prepare a yearly report, together with an account of income and expenditure of the College Funds duly audited by the Censors and a Public Accountant, and after submission for approval to the Fellows and Members (annually summoned for this purpose by the President of the College) shall, on adoption, cause the same to be published in the medical journals. 11. That extra power may be given to the Council to suspend or revoke the license of any Fellow or Member on proof of infamous conduct, professional or otherwise."

**MEDICINE IN MADAGASCAR.**—A native of Madagascar who studied medicine in Edinburgh, has now a class of seventy young men studying under him, also another equally large class of young women whom he is training as nurses and midwives. He operates largely, having in a year performed 140 major operations, amputation, lithotomy, &c. Several prizes have been offered to the students by the Queen and others, and he says it is wonderful to see how well they answer the same questions as used to be given in America. He is apparently in favour at court, for he not only attends at the palace daily, but is about to marry the Prime Minister's daughter.

**SMALL POX AND VACCINATION IN LIMA.**—The good

people of Leicester and other centres of anti-vaccination might perhaps find a convenient resting place from the harshness of the British laws in Peru. The capital, Lima contains about 120,000 inhabitants, and vaccination is not only not compulsory, but its practice is legally limited to four official vaccinators. The result of this state of things is that notwithstanding a recent official assertion that most of the children were vaccinated, it has been found by inspecting the arms of all the patients admitted into the General Hospital of St. Anne that a considerable majority of both adults and children are unvaccinated. There has been a good deal of small-pox during the last few months, and the number of deaths from this cause has become so great as to cause serious alarm amongst the inhabitants. In the month of March statistics give the deaths from variola as 20.

**"GREEN CANCER."**—A case of "Green Cancer" or "Chloroma" has occurred at Christiana in a child of five. A tumour appeared on the cheek, followed by odontalgia and discharge from the ear, with deafness and exophthalmos. The green sarcomato-fibrous growth was found in nearly every part of the body, especially on the periosteum, but also in the viscera and the marrow of the long bones. Dr. Gade, who describes the case, agrees with Otto that the green colouring matter is not derived from bile or hæmatin, but from fat granules.—*Nordiskt Med. Arkiv.*

**THE LEAVESDEN ASYLUM FOR IMBECILES.**—The annual inspection by the managers of the Metropolitan Asylums Board took place on Saturday last. There are about 2,000 patients in the Asylum. The report presented showed that 38 acres of the 85 which the building and estate comprised were under cultivation. There were respectively 900 male and 1,100 female inmates, and for maintenance and clothing the cost per head per day was 1s. 8½d. It was stated that the managers had under their care nearly 6,000 patients in their various asylums.

**THE Library and Museum of the Royal College of Surgeons of England will be closed on Tuesday, the 21st July, for the purposes of the Final Examination for the Membership.**

## VACANCIES.

**BELGRAVE HOSPITAL FOR CHILDREN, 79, GLOUCESTER STREET, WARWICK SQUARE, S.W.**—House Surgeon. Board and lodging. Candidates must be qualified. Applications and testimonials to senior Physician at the Hospital, on or before July 20th.

**BRISTOL DISPENSARY.**—Two vacancies in the Medical Staff. Candidates must possess a diploma in Surgery from the Royal College of Surgeons of England, Scotland, or Ireland, or from the Faculty of Physicians and Surgeons of Glasgow, and must also possess a legal qualification to practice medicine in Great Britain and Ireland, and be duly registered. For salary and other particulars, apply to Mr. Stock, 57, Queen Square, Bristol, to whom testimonials must be sent on or before August 6th.

**COUNTY ASYLUM, WHITTINGHAM, PRESTON.**—Assistant Medical Officer. Applications and testimonials to be sent to the Medical Superintendent, on or before July 20th.

**EDMONTON UNION.**—Medical Officer for the Cheshunt District, in succession to Dr. E. W. B. Garlike, resigned. Area, 8,430 acres. Population, 7,736. Salary, £37 10s. per annum.

**MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.**—Medical Officer. Salary, £40 per annum, with board, apartments, and washing. Candidates must be qualified and registered. Applications, with copies of testimonials, to be sent on or before July 31st.

**ROYAL INFIRMARY, RYDE, ISLE OF WIGHT.**—House Surgeon and Secretary. Salary £50, with board, lodging and washing. Candidates must possess a surgical qualification, and be registered. Applications, stating age &c.; with testimonials to be sent to the Secretary, from whom further particulars may be obtained, not later than July 28th.

**WESTERN GENERAL DISPENSARY.**—Assistant House Surgeon. (*For particulars see Advertisement.*)

**YORK COUNTY HOSPITAL.**—Resident House Surgeon. Salary £100 with board and lodging. Candidates must be unmarried. Applications to the Secretary, 5, New Street, York, on or before July 25th.

## DEATHS.

**COOPER, R. G., M.R.C.S., Surgeon 2nd Regiment Scinde Horse, at Jacobabad, Scinde, India, on June 1st, aged 27.**

**SMYTH, J. E., M. D., F.R.C.S., at 7, Sugden Road, Lavender Hill, Clapham, S.W., on July 10th, aged 67.**

**WILKIN, T. H., late Surgeon-Major 4th Battalion Durham Light Infantry, at Leinster-road, county Dublin, on July 2nd, in his 81th year.**

## NOTES, QUERIES, AND REPLIES.

## "HOW IS IT WITH THE PROFESSION?"

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—You ask for the opinions of provincial men as to the professional welfare in your issue of July 4th, "How is it with the Profession?" Alas! I suppose the answer of most of them is, "It is not well." There seem to be so many different interests, and so few common ones, that we are unable to raise an effective voice in any matters political, using the word in its broadest sense. There is no *esprit de corps*, no union. How much better it would be if there were some body that we could all recognise as a professional head that would speak for us! Who, for instance, in Parliament has spoken up for the parish medical officers, who has considered their interests? They are passed over as so many dummies, who must quietly do any extra work that may be assigned them without a murmur. Why, even the medical papers have said nothing for them. You indeed, Sir, we see with regret, enter into party politics, and attribute falsely with Mr. Chamberlain the cause of the rejection of the Medical Relief clause to the supposed mistrust of the House of Lords for the new electorate, instead of to the late Government, who omitted to oppose it in their original Bill. We provincials, Sir, hold that as a body the Faculty should eschew politics, as the Church does. And we therefore regret to see that Mr. Erichsen in his candidature for Edinburgh University is fighting on party lines, whereas did he avoid them he might anticipate a triumphant return by the united body of medical graduates. But after all, it rests with us to decide most of our troubles. The Council and the heads of the profession in London can indeed do something by more stringently looking after men that are unqualified, and by endeavouring to remedy the abuse of medical charities. These same heads, however, do not directly represent us general practitioners, and being consultants, do not sympathise with our petty grievances. It is therefore the body of the profession that must find its own cure for most of its own ailments—such as under-selling, and the admission of people of all grades into so-called provident clubs. Sad misnomer! for neither party are they "provident." The medical man cannot afford to give their patients decent physic and fair time, and the doctor only benefits by, as he says, "keeping someone else out of it." The remedy lies in closer union; in brief, however odious the word, a trades-union is necessary. Where is the power and the courage to start it?

Yours very faithfully,

Birmingham, July 15th, 1885.

K.

## DR. JAEGER AND HIS PILL.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—With reference to the paragraph under this heading in your issue of 4th instant, we beg your permission to state that the remedy in question is of a homœopathic nature (although Dr. Jaeger has practised as an allopath), and its presence cannot be detected by analysis in the proportion of dilution, viz., a trillionth. Dr. Jaeger publishes that the body of the globule in question is formed of sugar of milk, and he supports his theory of the properties of the globule by arguments which at present meet, in some quarters, with as much derision and abuse, and with as little scientific reputation, as were at first bestowed on his Sanitary Woollen System.

We are, Sir, yours, &amp;c.,

DR. JAEGER'S SANITARY WOOLLEN  
SYSTEM CO., LD.

13th July, 1885.

A Surgeon.—The Secretary of the Society is Mr. C. J. Radley, 26, Wynne Road, Brixton, S.W.

## CLINICAL LECTURES

ON

### DISEASES OF THE URINARY TRACT IN THE YOUNG.

DELIVERED AT THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

By JOHN H. MORGAN, M.A. Oxon., F.R.C.S.,

Assistant Surgeon to the Hospital.

#### LECTURE II.

INCREASED functional activity of the bladder is more frequently due to an abnormal condition of the organ itself than to any departure from a healthy state of the urine. This latter cause, however, will often prove to be the exciting one for that frequent desire to pass water accompanied by pain, sometimes acute, in the neck of the bladder and in the urethra. It is, then, to be attributed to the irritating presence of crystals of uric acid or of oxalate of lime in minute quantities which have been discharged from the kidneys, and this may occur at a very early age. "In the pale urine of infants at the breast deposits of uric acid are common. These often appear as a yellow crystalline

sand, whilst the supernatant urine is frequently of low specific gravity, often 1,006, as pale as water and containing very little urea. This circumstance admits of explanation from the small proportion in which the alkaline phosphates, the presumed solvent for uric acid, exists in the urine of infants."—*Golding Bird*. "In children," says Sir B. Brodie, "the deposition of lithic acid sand by the urine will not infrequently produce not only pains in the glans, but bloody urine and all the other symptoms of stone in the bladder." Of this condition one meets with many instances in public and in private practice, and the symptoms will occasionally persist with great obstinacy, but when once the absence of calculus in any part of the tract has been established and this condition of the urine recognised, I have not seen a case which has not yielded to treatment by alteratives, &c., with specially careful attention to the nature and quantity of the food. The youngest child which has come under my care was brought to my house when less than eighteen months old. For two months he had been passing occasionally small quantities of blood with the urine; micturition was frequent and painful. On one occasion the testicles had become swollen, after which a great quantity of water was passed, but throughout, although every napkin was carefully examined, no formed calculus was seen, and nothing but the red sandy deposit with occasional blood. His diet had been far too liberal, and had consisted of a large proportion of nitrogenous food. He had been treated with bella-

donna, &c., in the country. By enforcing a strict and limited dietary he soon lost all symptoms. In the case of another and older boy, whose father had died of gout, and who had suffered from symptoms much the same, though more exaggerated than in the last case, I found the tendency to lithiasis so confirmed that, besides the usual regulations and treatment, he was obliged to pass a winter in a warm climate; but he is now a healthy well-grown lad, and has apparently shaken off for the present his hereditary tendency. We shall have occasion to speak of this tendency when dealing with the subject of stone, but I dwell on the fact that all the symptoms of calculus may be caused by this condition, because it is so little recognised, and also because it is so easily remedied. In Dr. Dickinson's recent edition of his work on Renal and Urinary Affections, several instances are given of this condition occurring at about the time of teething, and giving rise to hæmaturia, which he says cannot be described as otherwise than scorbutic, in all of which the diet had been conspicuously wanting in fresh milk. In one instance under Dr. Abercrombie hæmaturia together with spongy gums came on under a diet limited to Nestle's food, Robb's biscuits and water, and ceased under a regimen of milk and water. In this case blood-casts were found, showing that the blood was at least in part of renal origin. I have notes of many such cases, although the age has generally been past that of Dr. Dickinson's cases.

Passing, then, to the subject of calculus, the practice of this hospital affords much of interest. It is a notorious fact that in the better fed, or perhaps it should be said the better watched children of the well-to-do classes, calculus is rarely met with; indeed, I know of one case only in private practice where a stone was required to be removed by operation from a child. I have already alluded to the tendency to the lithic acid diathesis which is hereditary, and which is at least as prevalent among the rich as amongst the poor, and it cannot therefore be greatly due to their inheritance of this tendency that the prevalence of stone among hospital patients occurs, and we are left to conclude that it is to the errors of diet and to the neglect of early symptoms that the greater amount of deposit which is necessary for the formation of calculus must be ascribed. The prevalence of this want of care is amply seen by the vast proportion of rickety children which are brought to our hospitals, and since it is fully proved that this disease is mainly accentuated, if not developed by erroneous diet, we need hardly be surprised that in some children the vice shows not in the bones, but in the products of the excretory organs. It is stated by Dr. Ralfe that strumous and tubercular subjects are very liable, not only to deposit uric acid and urates from their urine, but also to excrete it in excess, and this is especially seen in young children, and is sometimes due to temporary disturbance of digestion, sometimes precedes some serious constitutional malady. Accordingly the greater majority of calculi in children are found to consist of uric acid and its compounds. That their origin is in the tubules of the kidney, where they have been observed as minute crystalline deposits, even in the kidney of the foetus, and have been found shed abundantly by the urine of some infants, there can be no doubt; whilst during their residence in the kidney or bladder they may accumulate additions of their original material, or may add to their bulk whilst in the bladder by the phosphatic deposits which their presence excites, by irritation of the mucous membrane. But notwithstanding the above observations, it is not in the tuberculous or in the very young that stone in the bladder is found to occur, but in stout children, between the ages of two and six years, according to the tables of Sir Henry Thompson, it is met with more frequently than at any period

before fifty. That is to say, that the deposits from the tubules are most excessive soon after the first dentition, when the organism is most in need of appropriate nourishment, and most liable to reject those constituents which it does not assimilate. Calculi of oxalate of lime are the next most frequently found, and the main sources of their formation are stated by Dr. Ralfe to be—

(1) Directly from the food by the ingestion of substances containing oxalate of lime.

(2) Indirectly from food, by incomplete oxidation of the saccharine amylaceous and oleaginous principles, a source probably the most fertile in the case of children.

(3) From increased tissue metabolism.

(4) From the mucus of the urinary passages.

The second and third of these are conditions which lead most readily to this result in the case of the young.

The stone here shown is of that very rare variety, the cystic oxide or cystine; its weight was 177 grains, and it was removed by lithotomy from a boy, aged 9.

As to the length of time which it may take for a calculus to form, the following history is of some interest. A boy, aged 8 years 9 months, was admitted under my care in May, 1884, with a calculus in the bladder; operation was delayed by reason of a slight attack of erysipelas which attacked the penis and scrotum, and soon after this subsided, an oval calculus was passed per urethrum. To make sure that there was not a second one present, I sounded the boy and found nothing in the bladder. This was at the end of May, 1884. In January 23rd, of the present year, the boy came back again with all the symptoms of stone, and this I removed by lateral lithotomy. The two stones I here show you, and you will see that the larger one, which was removed by operation, consists almost entirely of lithic acid, with a very thin coating of phosphates. As this was not in the bladder six months previous to its removal, we must suppose that it descended from the kidney soon after the passing of the first stone, and that as there was no evidence of its passage along the ureter, it was not of any size that would obstruct or give rise to pain. Its increase, therefore, must have been very rapid to attain even this size in so short a time. There was nothing in the state of the urine which showed an excessive tendency to the formation of acids, but the mother stated that the boy had a craving for sugar and sweet things, and would do anything to obtain them.

The calculus here exhibited, No. 51, is composed of carbonate of lime with phosphates, and some organic material, weighs 39 grains, and was removed by Mr. Smith from the bladder of a girl, aged 2 years 9 months, by an incision in the wall of the vagina, and through the vesico-vaginal septum. The aperture was closed with a cleft palate needle and sutures, which were removed at the end of three weeks. The child did not suffer from any incontinence, and the wound healed completely. Here is another larger calculus weighing 116 grains, No. 4, and consisting of uric acid with triple phosphates, which was also removed by a urethro-vaginal incision. Another very large stone which was removed in a similar way is here shown, No. 9. It weighs 215 grains, and consists of uric acid centre and a phosphatic covering. In this case, as might be anticipated from the size of the foreign body, the result was not so fortunate, and there was subsequent incontinence of urine. The other stones exhibited are peculiar either on account of their shape or of their size. These three (No. 30), of the same shape and size, were removed from a boy, aged 8, at the same time, and the symptoms had existed for a year. This one (19), weighing 243 grains,

and consisting of uric acid with a phosphate coating, is curious on account of its peculiar hour-glass shape.

Before passing to the question of operation, it is worth our while to consider the course of a stone which escapes from the kidney. I do not think it often happens that in children, calculi are long detained in the ureter, and still less that they become often impacted therein. If there is any delay in their passage to the bladder it occurs at the narrowed portion, where the ureter traverses the coats of that viscus. Neither in our own nor in any other London museum is there a specimen which illustrates any such impaction, although there are specimens of hydronephrosis in which contraction of the ureter is supposed to have resulted from the cicatrization which has followed the passage of a stone. In this specimen of hydronephrosis there were found after death four large phosphatic calculi in the bladder, one in the urethra, and others in the pelvis of the kidney. The following case is of unusual interest, and illustrates the symptoms which may be found when such impaction has in all probability taken place. A boy, aged 10, was sent to me by my colleague, Dr. Barlow, with the following history: Just a year previously, he had been struck in the lumbar region of the back with a pointer. That night, he suffered pain at the lower part of the abdomen accompanied with vomiting, and the urine was said to throw down deposit after standing. These symptoms recurred at different intervals. He was admitted into the hospital under Dr. Barlow, and was afterward sent to the Convalescent Hospital at Highgate, during which time no similar attacks were observed. In the following September, six months after the accident, he had a severe attack of pain in the right side of the abdomen, which lasted all one night, and was followed by passing of dark-coloured urine. When the urine was examined in October, it was found to contain one-sixth albumen, and blood corpuscles were detected. The attacks of pain occurred at intervals of a month or more, and were until March, 1884, followed by a dark appearance of the urine, when he was admitted under my care, after an attack of pain rather more severe than usual, the urine not becoming clear for two days. The boy was then pale, but not thin, though he was said to have lost flesh. Examination of the flanks, abdomen, and hypogastric region revealed neither tenderness nor abnormal fulness. A few days after admission, he had an attack of pain, which he described as slighter than usual, but during which he writhed and doubled himself up in the bed. The urine which followed was not smoky, and though still containing one-sixth albumen and deposits of triple phosphate, showed no pus or blood corpuscles. He was twice carefully examined, while, under an anæsthetic, and each time with negative result. After remaining under observation for some time, during which no further attacks took place, he was discharged and disappeared from observation; but a year after he sought admission at another hospital with the symptoms of stone in the bladder, and a small stone was found and crushed with a lithotrite. It is probable that an effusion of blood into the pelvis of the kidney followed the blow upon the back, and that some remaining portion of clot became the nucleus of a calculus which remained for some time in the ureter, but ultimately passed into the bladder.

The next place at which a stone is liable to be arrested in its passage outwards is the membranous portion of the urethra, and here, as you know, it is very frequently stopped in boys, and gives rise to retention and other symptoms. This may occur with a very small stone, as in the case from which I extracted this one from the bladder of a boy, aged 13, by the lateral operation. I was called to see him on

account of retention, which was relieved by the passage of a catheter, before which the stone was pushed back into the bladder. Had it not been for the irritation which had already been excited in the urethra, I might easily have got rid of so small a calculus by lithotrity, but thinking that the passage of any fragments would be sufficient to cause the symptoms of retention, I decided to open the bladder, and the stone was easily removed and the boy made a rapid recovery. On the other hand, this stone is much larger and of a similar shape which passed without pain from the urethra of the boy above mentioned who was only 8 years 9 months old.

These cases lead us to the subject of lithotrity as applied to children, and, notwithstanding the change which has of late years taken place in regard to this proceeding in the case of adults, the same objections continue to hold good with reference to its applicability in the young. The male urethra up to puberty is small and exceedingly tender, the mucous membrane delicate, and when not distended to allow the passage of urine is gathered into folds, as can be seen in sections under the microscope, in which any minute fragments are liable to be caught, and to excite considerable irritation. For the same reasons it is hardly possible to pass a tube by which fragments can be washed out and the bladder entirely emptied, which is so important an element in the successful lithotrity of adults. Thus it is only applicable to stones of the smallest size, and when performed these must be thoroughly reduced to very small fragments. Sir H. Thompson states that incontinence of urine after lithotrity in children is not a very uncommon result, although it generally disappears spontaneously in course of time. The instrument which he uses is one without a screw, the crushing power being obtained by simple pressure in the palm of the hand. The instrument must necessarily be small, and the blades, in consequence, short, and capable of grasping only very small stones.

In girls the conditions are different, the urethra is much shorter and is capable of considerable dilatation, so that not only can a larger lithotrite be used, but the fragments which it makes can be washed out and the whole of the calculus got rid of. This method, therefore, allows us to deal with larger stones in the case of girls than in boys, and in the child, aged 1 year 9 months, shown here at the last lecture, the stone, which was of a fair size, was crushed with an ordinary lithotrite, by Mr. Pitts, a considerable proportion being brought away between the blades. It was composed largely of phosphatic deposit, which rendered this mode of treatment all the more appropriate and facile.

But supposing that the stone is of such a size that it cannot be dealt with by this means, the choice lies between extracting through an incision in the vesico-vaginal septum or by the supra-pubic operation. You have seen the three large calculi which were removed by the former operation. An incision is first made from the posterior wall of the vagina backwards in the median line towards the anus, so as to give more room. The vesico-vaginal septum and the posterior wall of the urethra are then divided by a clean incision to the extent necessary, and the stone extracted with as little injury to the parts as can be managed. The latter incision is then closed with a cleft palate needle and silver sutures. In two of these cases the wounds healed firmly, and after extraction of the sutures no incontinence resulted, but in the third a fistulous communication remained, and was with difficulty closed. This is, of course, the great objection to such an operation, and I should therefore advocate recourse to it only in cases of moderate sized calculi of such shape or consistence as could not be easily crushed, and should prefer the high or supra-pubic operation in cases where the size of the stone is such as would

certainly cause laceration of the parts in the urethro-vesical opening. The operation is much easier of performance in children than in adults, as the bladder lies naturally much higher, and by pressure upwards of an assistant's finger in the rectum can be steadily maintained in apposition to the abdominal wall. The peritonæum, with proper care, should not run any risk of being wounded; but if this should happen, the use of antiseptics should greatly discount the danger. After removal of the stone, the bladder may or may not be sewn up. I should myself prefer to unite the edges of the wound, especially as the bladder can be so easily maintained in an empty and therefore a quiescent state by a catheter in the vagina; and in the case of a boy, where, however, the operation can hardly ever be necessary, the same result would be gained by means of a small median incision through the perinæum. I lately assisted in the extraction of a very large stone from the bladder of a little girl by this procedure. It was accomplished with very little difficulty and except for the first twenty-four hours, during which the urine did not pass freely through the catheter, the child made an excellent recovery.

The condition of incontinence of urine which goes by the name of Enuresis may sometimes depend upon an exceedingly acid state of the urine, but more usually it arises from an enfeebled state of system affecting the nervous centres. It is more frequent in boys than in girls, and is not often noticed at a very early age, occurring more commonly in children between 3 to 10 years. In boys the prepuce is generally found to be long and often adherent, and in either sex it may be aggravated by the presence of worms in the lower bowel. The incontinence may manifest itself during the day, but more often occurs at night or during the early hours of morning. The tendency of nurses to ascribe this habit as due to carelessness on the part of the child must be very carefully regarded, since the fear of punishment has not infrequently led the child to tie a string so tightly round the penis as to cut into the urethra. The treatment in the first place must be to remove all sources of irritation by the expulsion of ascarides or the circumcision of a long or adherent prepuce. Of medicines, belladonna in the form of extract is by far most efficacious, and it may be gradually increased to a large amount. Tr. Ferri Perchlor. Ergot, Strychnia, either alone or in combination, are often serviceable, but the cases are sometimes very obstinate, though they invariably get well sooner or later. More than once I have given permanent relief by the single passing of a sound or catheter, the child not being under any anæsthetic, but I should strongly advise against the application of any form of caustic to the urethra on account of the permanent damage which might ensue. A boy was exhibited at the last lecture who suffered from this condition in a very obstinate form, but it seems to be yielding at last to treatment by a combination of iron, belladonna, and strychnia. He is now aged 9, and seven years ago underwent lithotomy for the extraction of an oxalate of lime calculus, which had caused symptoms for five months before admission to St. Thomas's Hospital, where the operation was performed. He has since been circumcised, and has been sounded more than once with negative results. An interesting case of incontinence in a young lady is reported by Dr. More Madden in the *British Medical Journal*, which resulted from malformation and malposition of the right ureter.

Stammering of the Bladder, so ably described in Sir James Paget's lecture, is another affection due to nervous causes, and is greatly dependent upon the general condition of health. I have not met with a case in hospital practice, although in private practice the cases are not infrequent. The affection is, I believe,

never found to occur in girls, wherein is a greater analogy with the similar affection of speech, which is very unusual in females.

Beside these nervous affections, there are certain conditions of the mucous membrane of the bladder which may give rise to one or all the symptoms which have been mentioned. For example, there is that condition termed "rugous," from the rough and uneven surface that is felt by a sound, when passed into the bladder to ascertain the presence or otherwise of stone to which the symptoms may have pointed. No calculus is found, and if the opportunity occur of examining such a bladder *post-mortem*, nothing beyond, perhaps, a little hypervascularity of the mucous coat exists; and we are left to presume that the sensation arose from an irritability of the muscular coats which throws the mucous surface into folds.

Just as other mucous membranes are in some constitutional states very sensitive and irritable, so we find that, independent of any unhealthy state of the urine, the lining membrane of the bladder may be very intolerant in certain persons of delicate organisation. This is particularly the case in the scrofulous, and as an instance I may quote a family of four children who have all suffered from irritable bladder, as shown by frequent micturition, sometimes accompanied with pain, by incontinence at night, which in one of them has persisted from birth. The children's ages vary from 2½ to 9 years, and all have a markedly strumous type of countenance. One child of the same parents died in the hospital of tubercular meningitis when 7 years old. Their symptoms have improved under treatment with belladonna and cod-liver oil, but in all of them the condition varies with the state of the general health.

But over and above these symptoms, the bladder in children is sometimes the site of tuberculous deposits. This rarely occurs in very young children, although where tuberculosis is widely disseminated minute tubercles may sometimes be found in the mucous membrane of the bladder, and in the ureter, as has been shown by Mr. R. W. Parker, who has searched for this condition in children who have died of tuberculous disease of other organs. Primarily, I believe that the bladder is seldom the site of such deposit, but that it almost invariably follows similar disease occurring in the kidney. According to Dr. Wilks, tubercular disease of the bladder is secondary to more deep-seated disease in the abdomen, and the kidney has generally been long affected, the deposit in the course of years creeping down the ureter to the neck of the bladder, whilst later on it is exhibited in the prostate, the penis and the testis.

In a most instructive paper in the St. Bartholomew's Hospital Reports, Mr. T. Smith points out that the symptoms during life all tend to indicate such a progress of the disease, the earlier being always attributable to the kidney, and the later to disease of the bladder; and this is borne out by the pathological appearances shown in some of the specimens placed before you in which the kidneys are in a much more advanced state of disease than the ureters, and these than the bladder. The symptoms in the early stage resemble those oft caused by the presence of a calculus; the frequency of micturition is constant, and is more marked during the day than at night, and the pain may be such as to cause shrieking, and becomes more excessive as the disease progresses, which it does with only slight intermission of the symptoms. To relieve the pain the child will often pull the prepuce and pinch the glans until they become sore and œdematous. The urine is at first alkaline, and blood is seldom present, but later it becomes highly offensive, and is mixed with blood, pus and epithelium. There is often prolapsus ani. When examined *post-*

*mortem* the coats of the bladder are found to be thickened, and the mucous membrane is often extensively destroyed, but the ulceration, which is often extensive, undermines the mucous coat, and extends its thickened base for some distance beyond the destroyed surface of mucous membrane, which thus has a thin free edge overlapping. The ulceration is caused by the breaking down of minute tubercular deposits, which can be discerned in an early stage as small blue-grey elevations, raising the mucous surface, but which originate in the submucous tissue. These coalescing and breaking down cause destruction of the mucous membrane, and an ulcerated surface results which closely resembles that which forms in the intestine under similar circumstances. The diagnosis is not assured until the absence of calculus has been ascertained, and further information may sometimes be obtained by digital examination per rectum. In advanced cases the signs of tuberculosis in other organs, especially the lungs, are rarely absent. Little can be done to relieve these patients beyond palliating the symptoms by local and general remedies. Sometimes a median cystotomy may afford relief by draining, and thus giving rest to the bladder. A case in which this operation gave immediate relief was shown by Dr. Rawdon at the Liverpool Medical Institution; the boy was aged 7 years, but died some months subsequently from a lumbar abscess originating in the kidney. The boy whom you have seen me examine to-day seems to be suffering from the symptoms of this disease in an aggravated form. His desire to pass urine is sudden and constant, and the pain is excessive, the end of the penis being quite sore from the frequency with which it is pulled to afford some relief. The urine is alkaline, and contains thick masses of pus and epithelium. No stone can be detected, but the passing of a sound is followed by some discharge of pus and blood. In other respects the boy seems well.

NOTE.—The operation was subsequently performed, and a tube inserted into the bladder, giving some relief to the symptoms. The bladder was washed out daily with a solution of quinine, and subsequently also of cocaine.

---

## ON PICRIC ACID AS A TEST FOR MINUTE TRACES OF ALBUMEN IN THE URINE.

By GEORGE JOHNSON, M.D., F.R.S.,

Professor of Clinical Medicine, Senior Physician to King's College Hospital.

In a review of the fourth edition of Dr. Wm. Roberts' "Practical Treatise on Urinary and Renal Diseases" (*Medical Times*, July 4th, p. 23) there occurs the following statement:—"As regards the tests for albumen he, Dr. Roberts, declares for two only, viz., the old methods of boiling and nitric acid. All the new tests he had found untrustworthy, including his own brine test, and all for the same defect, viz., that they give a reaction with mucin and other substances which cannot be distinguished from that indicative of albumen."

As the subject is one of much practical importance, I beg permission to point out that this condemnation of "all the new tests" is not applicable to picric acid. A saturated solution of picric acid does *not* precipitate mucin, neither does it give any precipitate in normal urine except in the comparatively rare instances of a precipitate of urates, which the application of heat

completely removes, and so distinguishes from albumen. It is an indisputable fact that *albumen is the only material in urine which gives with picric acid a precipitate insoluble by heat.*

Dr. Wm. Roberts, in a paper published in the *Medical Chronicle*, No. 1, included picric acid with the other new tests for albumen in the list of those which are liable to the fallacy of giving a precipitate or an opalescence with mucin. When I read that paper, I wrote to Dr. Roberts and asked him whether he had not combined acetic or citric acid with picric acid in his method of testing, and he replied that in some instances he had done so. It is a well-known fact that acetic and citric acids precipitate mucin, as do also the mineral acids, including of course nitric acid, as Dr. Roberts himself admits in the paper referred to. On the other hand, picric acid alone, while it is a most delicate test for albumen, causes no precipitate or turbidity with urinary mucin.

The addition of a small quantity of acetic or citric acid to normal urine gradually renders it slightly but decidedly turbid by coagulating the mucin; and Dr. Roberts admits that when nitric acid is added to albuminous urine, "the albumen is thrown down just above the line of junction of the two liquids, while the mucin is brought into view toward the upper part of the column of urine, where it gradually forms a diffused haze, quite distinct from the opalescent haze at the line of junction."

To this it may be added that when nitric acid is placed at the bottom of a column of normal urine, a diffused haze of coagulated mucin gradually forms in the upper part of the column, so that even if it were the fact that picric acid as an albumen test is objectionable on account of a tendency to coagulate mucin, it would on this account be no more liable to fallacy than nitric acid; but the fact is, as I have stated and as I have abundantly proved, that picric acid, unmixed with any other acid, does *not* coagulate mucin, and therefore causes no precipitate in normal urine.

The merest tiro in urinary analysis can readily put this statement to the test. Let him add to about a drachm of normal urine in a test-tube an equal volume of a saturated solution of picric acid. The yellowish mixture will remain quite transparent, but the addition of a few drops of acetic or solution of citric acid will speedily render the mixture opalescent by coagulated mucin.

Picric acid being the only one of the comparatively new tests for albumen which does not require the addition of another acid, since a highly alkaline specimen of urine may be acidulated by an excess of picric acid, while no addition of citric or acetic acid is required to increase the delicacy of the test, is on that account the only one which is free from the fallacy which results from the precipitation of mucin. The potassium-mercuric iodide, for instance, which in the form of test paper has lately been much commended and used as an albumen precipitant, when uncombined with an acid, gives no precipitate in an albuminous urine, but with the addition of citric acid it renders every normal urine turbid from coagulated mucin, and is therefore entirely untrustworthy as a test for minute traces of albumen. After the abundant experience which I have had of picric acid I feel that I cannot too strongly recommend its use, alone, as a most delicate and trustworthy test for albumen, and combined with potash, as a most convenient and accurate qualitative and quantitative test for glucose.

Not the least amongst the advantages of this method is the fact that both the picric acid and the potash may be carried in a solid form in a pocket test case, the picric acid in the form of powder and the caustic potash in the form of grain lumps. The most convenient form of pocket test-case with which I am

acquainted is one made by Ernst Jahneke, Canonbury Works, Dorset Street, Essex Road, N.

Instead, however, of the small urinometer which the manufacturer supplies, I carry two test tubes, one within the other, a second test-tube being useful in case of the accidental breaking of one at the bedside, and in the inner tube is packed a small nipple pipette, which is very convenient for transferring some urine from the utensil to the test tube. The case contains besides three bottles and a spirit lamp. In one of the bottles I carry picric acid powder, in another grain lumps of caustic potash, and in the third a solution of homatropine for dilating the pupil preparatory to an ophthalmoscopic examination. The case with its contents is sold for the moderate price of 10s. 6d.

### PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEEVERS, C.I.E., M.D., F.R.C.S. Eng.,  
President of the Health Department, Social Science Association.

(Continued from page 849, Vol i. for 1885.)

In 1880, there was not any case of *Chorea* among the European soldiers' children in India. In the following year, there was only one; in 1882, there were three admissions. In the three years, I find the following: two European soldiers invalided for chorea; one European woman admitted; eight sepoys treated, with one death; one prisoner admitted.

A medical officer who was an eminent naturalist was the subject of moderate, but very marked persistent *Athetosis* (I then called it "*Chorea*"). He carried it off very lightly, and I never presumed to question him upon its history. Much of his time was spent in the field, and, otherwise, he appeared to be remarkably athletic and healthy, but he did not attain old age.

As I have mentioned, I never saw *chorea* in an English child in India. Acute rheumatism is rare in Lower Bengal. I had one choreal patient, a native girl. In the ward next to mine, Dr. Chuckerbutty had a native man of middle age, in whom universal choreal movements caused extraordinary rapid contortions of the features and limbs, giving him a most quaintly hideous appearance. He was suddenly attacked with spasm of the glottis. Tracheotomy was performed; he died from ichoræmia. As this was not my own case, I was unwilling to operate, but the tendency to death by laryngismus was so strong that the half hour during which I watched his sufferings, with the instruments at hand, was one of the unpleasantest in my life. The introduction of the tube at once relieved all distress in breathing.

*Hysteria* will be considered in the section on Diseases of Women. *Catalepsy* (hysterical) was markedly displayed in a case which I attended in England; I never saw or heard of the occurrence of this condition in India. For *Neuralgia*, vide the chapter on *Diseased Conditions consequent upon Malarial Cachexia*, vol. i, for 1884, p. 75.

I have seen *Spinal Apoplexy* twice—in a specimen brought by Dr. Clendinning to an early meeting of the Pathological Society, and in a native man who was picked up moribund on the road. In this case there were two large recent clots in the substance of the cord. A traumatic case which probably originated in this manner is represented by Prep. 801 in the Calcutta Medical College Museum. "Laceration and softening of the spinal cord near the corda equina, caused by a fall on the back from a height of ten or

twelve feet. The woman died paraplegic, with a fistulous opening leading from the bladder through the abdominal parietes, just below the navel, from a patient of Sir Joseph Fayrer."

*Spina Bifida* has been occasionally seen in natives. Recorded cases would probably be more numerous if these lives were not so extremely precarious.

Dr. C. Finch<sup>8</sup> treated the child of a Brahmin, aged three months, for lumbar spina bifida. The tumour was as large as an orange, the infant was emaciated and small. It was frequently noticed that, on the removal of fluid by puncture, the anterior fontanel became depressed. After an interval of two months, fluid began to exude through small ulcerations. There was increasing hydrocephalus. The removal of half an ounce of fluid by puncture, was followed by symptoms of fever under which the child sank. In a European child, attended by Dr. Finch, the covering of the protrusion, which was dorsal, sloughed and separated when the child was a month old. It became convulsed, and died almost immediately.

Preparation 1209 in the Medical Calcutta Museum Catalogue shows spina bifida, presumably from a native subject.

Assistant Apothecary G. W. Eate has reported the case of a native child, a month old, in whom he treated a lumbar spinal bifida by puncture and iodine injection with success. Assistant Apothecary Mitchell<sup>9</sup> has described the case of a man, aged 21,<sup>10</sup> caste Rajpoot, 5 feet 2 inches in height, pale and emaciated, who was born with a tumour as large as a pigeon's egg projecting from the upper part of the sacral region. He stated that it gradually increased from infancy, and that it suddenly broke, discharging an enormous quantity of pale fluid. When this occurred he was obliged to keep to his charpoy (bed), but subsequently he had walked well. In ten days, the tumour had resumed its original size; pain was not felt in two days during which the sac was discharging, but he used to be sick at stomach, and had giddiness while it was refilling. [How interesting it would have been to observe precisely the condition of an adult who had suddenly lost a large proportion of the cerebro-spinal fluid!] A tumour, of the size of two closed fists, was found depending from the lumbar and sacral regions. It was very tender and painful to touch, and its integument was "of dark hue." He had a strange feeling of cold running along the spine to the head, which he attributed to excessive weakness. He complained of giddiness, and answered at times incoherently. The pulse was soft and regular. He had walked from his village (22 miles) to seek aid. This had caused pain and exhaustion, and a feeling of great weight over the tumour. Mr. Mitchell immediately punctured the sac, drawing off some fluid to relieve tension. On the following day, another puncture was made and brought away twenty-seven ounces of fluid. A slight compress and bandage were applied. There were no bad symptoms with the exception of slight giddiness and a little heat of skin and excitement of pulse with excessive thirst. He did very well for two days, looked cheerful, and anticipated speedy recovery, but the sac filled again and became larger than it had ever been before, and the patient began suddenly to sink. [Here the account is not clear, but there appears to have been trismus.] "There was a difficulty in swallowing, and spasms of the face and throat, caused no doubt by the violent curvation backwards of the trachea and œsophagus." The tongue, lips, and teeth

<sup>8</sup> *Indian Journal of Medical and Physical Science*, N.S., Vol. v. p. 350.

<sup>9</sup> *Indian Medical Gazette*, Vol. ii., p. 122.

<sup>10</sup> Mr. Holmes says that, in a published case, the patient survived to the age of fifty, and he has heard of older cases in private. See Holmes's "*Surgical Diseases of Childhood*."

were covered with sordes, and an unhealthy redness (no doubt erysipelatous) was spread over the tumour. He expired six days after the first puncture. The friends would not allow an examination *post-mortem*.

I saw something of *General Paralysis* in India, both in natives and Europeans. One case, that of a member of the Civil Service, concerned me much, as I liked him, and saw and heard a good deal of him for seventeen years. When I knew him first, he was a very highly educated young man, and was regarded by the senior civilians as singularly well up in his work. His manners were those of a clever and very quiet person. Still, every one who knew him told stories of his eccentricity and oddity. He was absent-minded, and, on two occasions, when handling fire-arms in a slovenly manner, wounded servants. In about the sixth year of his residence in India, he was sent home insane. He recovered, and continued to serve, but was not entrusted with very important charges. In about the nineteenth year of his service, I found him still at work, but much altered in appearance and manner. His face bore very markedly the characteristic stolid flabbiness of commencing general paralysis, and his laugh, which had been pleasant, was abrupt and fatuous. Still, during an evening which I spent with him, I could discover no evidence of mental failure. Shortly after this, I received an official report from him to which he had affixed his signature upside down. I returned the document with an entreaty that he would be careful. For some years, he was prone to be cruel, as if in joke. Finding the children of the European residents standing at a fence listening to a military band, he burnt their noses with his cigar. His irrational persistence in torturing the pet dog of a high official led to enquiry and to his suspension. He became generally paralytic and imbecile. I am confident that he was not a drunkard when I first knew him, but I believe that he had recourse to alcohol when he felt depressed.

It has been remarked by Dr. Wise, Jun.,<sup>11</sup> that one of the most important points connected with insanity in India is the rarity of general paralysis. In the Patna Asylum Report for 1866, the deaths of two Patna women, aged respectively 26 and 35 years, are recorded. With this exception, no other cases are cited in the reports of the Dhullunda, Patna, and Moydapore Asylums between 1862 and 1867. In the Dacca Asylum, Dr. Wise was only able to discover three cases among 1,576 admissions and 925 deaths. This infrequency, he insisted, becomes more unaccountable when the records of European asylums are contrasted with those of Bengal. He cites the statement of Calmeil that there is one general paralytic in every 15 male (lunatic) patients, and 1 in 50 among women. Foville calculated 31 general paralytics to 334 insane, or 9.2 per cent. According to Bayle (1855), the proportion of paralytics in the asylums of Paris was 1 in 4; but Baillarger gave, for Bicêtre and Salpêtrière together, the proportion of 1 in 16. Dr. Wise thought that, if search were made in the case-books of the different asylums, cases would be found classed under the head of chronic meningitis which were really cases of general paralysis. He gives the histories of the only cases (natives), 4 in number, which had occurred in the large asylum at Dacca during the preceding 27 years.

In 1880, 1 European soldier died of general paralysis and 2 were invalided; 1 fatal case occurred in the native army, and 2 prisoners were under treatment.

In 1881, no case, in a European, was recorded; 2 sepoy were admitted, and 1 prisoner died.

In 1882, the disease does not appear in the European returns; a sepoy was treated, and 1 case (fatal) occurred among the jail population.

The ordinary diseases of the *Spinal Cord and its Membranes* are seen in natives and Europeans. Three interesting forms of *Spinal Paralysis*—Paraplegia, Locomotor Ataxy, and Lathyrism—occur.

*Paraplegia*.—At and near Chittagong, on the east sea-board of Bengal, a form of equine paraplegia, known as *Kumree*, is so prevalent that, as a general rule, horses are not kept there. Burmah ponies which, if let loose, might find their way home, do well in that climate. I saw the disease, at its very commencement, in a valuable horse, and, towards its close, in a favourite animal, which lived long and grazed comfortably in a field dragging the hinder half of its body after it with an appearance of extreme paralysis.

I believe that this disease does not originate in Calcutta or in the Upper Provinces, but it occurs in various Indian localities within the influence of the sea breeze. Thus, in the report on Travancore<sup>12</sup> we read: "Horses here, as well as all along the western coast, are very liable to become weak in the loins, particularly if exposed to the wind when much heated. Castration is often resorted to as a preventive, and it seems to be generally admitted that geldings suffer less frequently than entire horses; when attacked with this complaint, the animal is rendered completely useless."

In the report on Quilon, a marshy district,<sup>13</sup> we are told: "Horses in this climate are very liable to become weak in the loins; the nature of this disease is not correctly understood, but it appears to be an affection of the spinal marrow causing paralysis, or an approach to it, of the animal's hind quarters. A permanent cure has seldom if ever been effected. Castration, as mentioned in the report for Trevandrum, would appear to be the best preventive, mares and geldings being very rarely attacked by the disease. This disease is most frequent during the land winds in November, December, and January."

Those who may be desirous of going further into the literature of this disease will find many interesting particulars in papers by Messrs. Breton and Twining, at p. 337 of the first volume of the "Calcutta Medical and Physical Transactions," and in Dr. Shortt's remarks on the *kamree* of Orissa, No. ix., p. 187, of the "Indian Annals of Medical Science."

Bontius and his followers described *Barbiers*, from which that sage old Dutch physician himself suffered. He attributed it to "a thick, viscid, pituitous humour *seizing the nerves at night*." An article under this heading will be found in Copland's Dictionary of Medicine. All paralyzes of the lower extremities appear to have been thus designated. The word is no longer used, at least in India. A "*Stroke of the Wind*" is frequently spoken of. A well-known steamer captain, who had been in the habit of sleeping all night in the open air for years, was at length stricken in this manner on shore. I experienced the intense misery of a moderate attack. One of my windows having been blown open in the night, at a time when I was in low health, I found myself lying on my side in a chill damp breeze. Every voluntary muscle in my body seemed to be painfully cramped, and I was unable to move a single joint. After a minute or two of great suffering, I found that I had recovered the use of my right hand and forearm. By degrees, I chafed the other arm into action, and was then able to rub my body and lower limbs, and so regained command of their movements. In the morning, only some stiffness remained; but, from that time, I have been subject to muscular rheumatism. Had I been exposed during the whole night, the result would, I believe, have been *Barbiers* or paraplegia. Henry Marshall saw many cases of *Barbiers* among

<sup>12</sup> "The Medical Topography and Statistics of Madras," "Travancore," p. 89.

<sup>13</sup> *Ibid.*, p. 113.

<sup>11</sup> *Indian Medical Gazette*, Vol. iv., p. 75.

the Caffres of the 4th Ceylon Regiment, in 1812. He did not notice it among the Cingalese. We met with it in Europeans in Ceylon, and observed an analagous affection in horses and dogs; from which, however, they never knew them recover. The cause was evidently chill, especially in sleep. At the onset, there is generally partial paraplegia with pins and needles in the affected limbs. In the severest cases, the rest of the body becomes paralysed and deprived of both motion and sensation. The limbs become contracted, nutrition fails, and the patient sinks.<sup>14</sup>

I have noticed the loss of power in the lower limbs, which is a complication of Beriberi, at page 517, vol. i. of 1884. Much of the paraplegia seen in Bengal is attributed to chill; cases also result from meningeal apoplexy, morbid growths, sclerosis, syphilitic disease and other ordinary causes. In 1880, one European soldier was invalided for paraplegia, 26 sepoy were treated, with 6 deaths, and there were 18 admissions with 4 deaths amongst the prisoners. In the following year, 1 European soldier was invalided; 23 native soldiers were admitted, of whom 6 died; 10 prisoners were admitted, with 5 deaths.

In 1882, 2 Europeans were invalided. There were 18 admissions with 4 deaths among the sepoy; 7 prisoners were admitted, of whom 3 died.

I saw four cases of officers who recovered from paraplegia. Two of these gentlemen have been healthy for many years. The other two were free-livers. I met one of them, walking actively, at Charing Cross, but he did not live long. The other was fatally attacked with dysentery a few months after his return to Europe.

I had a very well-marked case of *Locomotor Ataxy* in a native man and saw a few others. In 1880 the number of European soldiers invalided for locomotor ataxy was 4. The admissions of sepoy were 10; of prisoners 8, one fatal. In the following year, 5 European soldiers were invalided for this cause. Sepoy, 3 admissions, 1 death; prisoners, 2 admissions. In 1882, 6 Europeans were invalided; 11 native soldiers were admitted; no prisoners.<sup>15</sup>

*Lathyrism*.—Palsy of the lower limbs, caused by eating the *dāl* of a lentil, *Lathyrus Sativus*, prevails extensively in Upper and Central India, especially near Allahabad and in Upper Scinde.<sup>16</sup>

Recently, M. Proust has observed this disease in the Jurjura Mountains of Algeria.<sup>17</sup>

I saw, but had nothing more to do with, two cases of *Pseudo-Hypertrophic Paralysis*, in a native male child in Calcutta and in a young native man in Bombay.

*Progressive Muscular Atrophy*.—A native lad was brought to me in whom this malady was advancing so very characteristically that I showed it to my class as a typical case. A well-marked case, occurring in a native surgeon, is given in the *Indian Medical Gazette* for June 1874, by Dr. K. M. Downie.

In his valuable commentary on *Functional Paralysis in Children*, already cited at p. 113, vol. i., for this year, Dr. A. Garden observes: "If this change [wasting] in the muscular structure is a diagnostic point of myogenic paralysis, but few of the cases" [of infants here] "commented on can be classed as such, nor can this form of paralysis be considered as one of childhood alone, for there is a class of cases by no means unfrequently met with in adults, in which all the diagnostic points, such as limited locality and wasting of the muscles without apparent change in the nervous

system, exist; for instance, the common paralysis of the deltoid and supra- and infra-spinatus following injury, excessive use or rheumatism, and leading rapidly to atrophy and wasting of these muscles, of which I have seen nine or ten cases amongst natives within the last few years."

*Neuroma*.—Under the head of malarious cachexia, I have spoken of certain forms of the disease. Knots on the nerves leading to the anæsthetic parts are almost invariably characteristic of leprosy.

Sir Joseph Fayrer has given<sup>18</sup> a description of the structure of a neuroma of the ulnar nerve, fusiform, and about as large as a pigeon's egg, which he removed from a middle-aged, healthy-looking Hindoo. It was firm and very painful to the touch, causing numbness and shock up the arm and in the hand on the least pressure. It had been of very slow growth. It appeared to consist of dense white fibrous tissue in which the nerve fibrils were distributed, not equally throughout, but so much so as to render separation of the nerve trunk from the tumour impossible.

*Facial Paralysis* is always likely to attack those Europeans who are so imprudent as to sleep in open verandahs during hot, damp, and changeable weather. I only recollect to have seen two cases in Bengal, probably because they sleep with their faces covered. In one of these, the poor fellow had been greatly exposed in a storm.

I am acquainted with one case of *Tic Convulsif* in a lady resident for many years in India. It was occasioned by mental shock, and has, I believe, been permanent.

I saw a well-marked case of *Scrivener's Palsy* in a surgeon, and another in an English portrait painter and drawing master, long resident in India, who was diabetic. The returns for 1882 give the case of a sepoy who was treated for this disease.

Cases of *Paralysis* from (1) *Lead* and (2) *Arsenical Poisoning* in India will be found at pages 293 and 126 of my *Medical Jurisprudence for India*.

*Sciatica*.—I do not find any allusion to this affection in the Sanitary Commissioner's returns for the three years ending 1882. In Lower Bengal, I saw a very few cases. In one or two, the attack was ascribed to sitting on a damp seat. I have alluded, in the chapter on Tetanus (p. 608), to the case of one of my patients, an East Indian woman, in whom an attack of tetanus was preceded and attended by idiopathic sciatica.

In a case of neuritis of the sciatic in a native gentleman setting in almost immediately after salivation for a venereal affection, Sir Joseph Fayrer, detecting deep-seated fulness and fluctuation at one point in the course of the sciatic, made a puncture with a long narrow knife down to the indurated part, and gave exit to more than half-an-ounce of clear serum. There was immediate and almost perfect relief; recovery was speedy.<sup>19</sup>

Dr. James Irving has recorded<sup>20</sup> the very obstinate case of a strong healthy gentleman in whom, after most other means had failed, cure was effected by applications of ice all over the affected hip and thigh.

Dr. Debove<sup>21</sup> has obtained a rapid cure in several cases of obstinate sciatica by applying chloride of methyl, in the form of pulverizations, along the course of the nerve. The chloride reduces the temperature to 23° below zero, Cent.

#### *Mania.*

I have so fully discussed the various forms of *Insanity* as it occurs in India, in my work on *Medical Jurispru-*

<sup>14</sup> Sir Dr. W. J. Moore's observations on "Maladies Attributed to Lunar Influence, Rheumatism, Paralysis, Ocular, &c." *Indian Medical Gazette*, Vol. iv., p. 180.

<sup>15</sup> See a case of *Locomotor Ataxy* in a sepoy, with valuable remarks, by Mr. B. Evans. *Indian Medical Gazette*, Vol. iv., p. 189.

<sup>16</sup> Buchanan Hamilton, Sleeman, Kinloch Kirk, and James Irving compiled in my "Medical Jurisprudence" for India. Dr. Irving's, leading papers will be found in the "Indian Annals," No. 12, p. 124, and 23, p. 89.

<sup>17</sup> *Lancet*, July 21st, 1883.

dence, (pp. 774—829), that I need only give a few additional notes in this place.

I have already mentioned that, in English regiments, when the men drink freely, there is a great deal of *Acute Mania*, which, like epilepsy, when it occurs under the same circumstances, is generally recovered from when the patients are sent to a cool climate and are kept sober.

Dangerous injuries to the skull and attacks of heat-stroke are frequent causes of mania in India. Important facts bearing upon this point will be found in the chapter on *Heat Stroke*.

I think that it must be added that drink-craving is not rare as a result of traumatic injury to the head and of heat-stroke.

A large proportion of the inmates of asylums for natives are found to be habitual gunjah-smokers and opium-eaters, and many of these are epileptic. Insanity from the use of intoxicating drugs is to be expected in a country where the Pindaree soldiers and their horses were drugged, whenever desperate attacks were to be made; where the women who underwent *sati* on their husbands' pyres were previously drugged, and where the assassin and he who resolves upon running amuck are always primed with *bhang* or opium. In his report on the Bengal Asylums for 1869, the Inspector-General of Hospitals observed that "among the recognised causes of insanity, the table shows that intoxicating drugs or liquors formed, as usual, the principal excitants of disease. In 1868, a percentage of 37.4 of the total treated was recorded under this head. During the present year, 35.2 is the proportion, gunjah and *bhang* alone forming 29.1 per cent. of the total in the preceding [year], 30.7 per cent. in 1869."

It appears<sup>22</sup> that, of 166 cases in which the predisposing cause of insanity was ascertained in patients admitted to the asylums of Bengal Proper, 107 were attributed to the excessive use of gunjah or *bhang*, 13 to undue indulgence in drink, and 2 to opium eating. Of 44 cases admitted or re-admitted to the Dullunda Asylum, 28 were attributed to the use of preparations of gunjah. In Patna, 41 out of 53; in Dacca, 16 out of 32; in Cuttack, 7 out of 8; in Berhampore, 7 out of 10; and in Hazareebaugh, 8 out of 9 belonged to this class. Of 410 lunatics from this cause treated in the asylums, 56 completely and 51 partially recovered. While it is most unsafe to venture to deprive the habitual opium eater suddenly of the whole of his noxious supply, my maximum daily allowance of the drug was never allowed to exceed nine grains of pure opium. I never observed any ill-consequence from my invariable practice of immediately withdrawing the supply of gunjah.

In his report for 1869 of the Dullunda European Asylum, Calcutta, Dr. Payne remarks: "It is observable that intemperance has been the imputed cause in an unusually small number of cases this year, in seven only of the total number (78). I have, in former years, recommended that statements with reference to this cause should be received with great caution, as intemperance, as an early manifestation of insanity, is so common that it is often mistaken for its precursor" [cause?], "and it will, I think, be generally found that the more carefully enquiry is made into the antecedents of insane persons, the less will be the proportion of cases whose origin is ascribed to intemperance."

There is another fact of which I have had ample experience, of which sufficient notice is not taken either in society or in military courts of enquiry. It

has been frequently observed, especially of artists and literary men who have lived by sustained mental toil, "Great as his talent was, he degenerated into a confirmed sot, and died mad or apoplectic." Here the true sequence and meaning of events is overlooked, sadly to the detriment of the unhappy man's moral reputation. The fact is that the unnaturally overworked brain having been found for a time capable of rallying under the influence of alcoholic stimulants, these were habitually resorted to until the worn-out nervous system failed under the double strain of labour and intoxication. It is clear that, in enquiring into a plea founded upon this law, sensible men will not allow that it can be taken as an excuse for the mere animal excess of the idle low-minded sot.

In my work on Medical Jurisprudence (p. 829) I alluded to the practice among Indian criminals of making cat's-paws or tools of "softies"—persons of decidedly and notoriously weak intellect, but gifted with a degree of unscrupulousness and cunning which, as qualifying for the commission of criminal acts, almost compensates for the higher faculties in which they are deficient. In this day of conspiracies, the following note, from Granger, may deserve a glance. Richard Langhorne, who was executed for treason in 1679, engaged, a little before the Restoration, a half-witted person to manage elections for him in Kent, and was asked by one who was privy to the secret why he employed so weak a man in that business. He very frankly replied that it was a maxim with him to employ men of this character, because, if such agents should take it into their heads to turn informers, it would be easy to invalidate their evidence by representing them as madmen.

Of late, there appears to be a disposition in the English mind, if not in our courts of justice, to demand that the homicidal maniac shall only be spared on proof that he "did not know what he was about" when he perpetrated the act. This might be, but is not received as a plea for the homicidal inebriate; but its application to the subjects of several kinds of madness betrays absolute ignorance of the first laws of insanity. The subject of acute mania may strike in unreasoning frenzy, as Elia's Mary Lamb d'd. Here there is no criminal responsibility, and restraint is the only just award. But crime is committed, under delusion, by undoubted maniacs just as calmly and thoughtfully, perhaps with a greater amount of steady deliberation, than murder for revenge or plunder is by the ordinary criminal. Thus, the first evidence of insanity in an accomplished and amiable medical officer in India, was that, at his usual morning visit, he prescribed for every one of his numerous sick a large dose of Glauber salts. When asked his reason for this novel practice, he calmly explained that he gave sulphate of soda as an antidote to carbonate of lead with which the Devil had poisoned his men. When this courteous, gentle-mannered officer requested me, as Secretary to the Medical Board, to inform him why he had been removed from his pleasant appointment to be sent to England when in perfect health, I found it difficult to answer him. I feel very little doubt that, had it appeared clear to him that it was to his child's good to remove it from the trials of life, he would, composedly and with equal deliberation and pain, have acted upon that conclusion. Here, again, had this unfortunate practitioner imagined that belladonna had been the poison employed and thus had killed the whole party with antidotal doses of opium, a sentence of restraint would have met all the exigencies of the case. There is, however, a class of homicidal maniacs who are, as I believe, so unquestionably subject to the fear of the law that, in the interests of humanity, they ought not to be exempted from its punishments.

<sup>22</sup> Government Resolution on the Report on the Lunatic Asylums in Bengal for the year 1877. Supplement to the *Calcutta Gazette* for August 14, 1878.

Not long before I left India, I had under observation a middle-aged European who was in custody for firing at a public character in a coffee-room. Although he was undoubtedly the subject of maniacal delusions, he was very soft-spoken, and reasoned upon certain false premises with the calmest deliberation. He told me that the act of violence was quite accidental; there was ample evidence that it was not an accident. I asked him why he carried a pistol—he replied that, lately, he had been in so much risk of being run over in Tank Square that he had determined to shoot the horse should the like occur again. I replied that, under these circumstances, the horse would not be to blame, and that he would, at least, have to pay for killing it. He then said that, being an usher in a school, he considered that the sight of a pistol on his desk would enhance his authority over the boys! While with me, he remained quite free from all appearance of excitement. He died of dysentery soon afterwards in the jail.

A man of education, one of a party of recruits of whom I had medical charge on board the transport in which I first went to India, then appeared to be a quiet and well-behaved person, generally regarded by his comrades as a "softy." Twenty years afterwards, he was sent to me for observation. He had been taken into custody for having endeavoured to break into a relative's house armed with a deadly weapon, and then having completely wrecked his own dining room. On being questioned, he said, with an air of the greatest mildness and good temper, "I am sure that you will not blame me when you hear the facts! Returning home from office tired and hungry, I found the table laid, but my wife was out. I certainly felt vexed, and, believing that she was at her sister's, I ran out. Recollecting that the door was generally padlocked, I caught up my gun barrels, with which I endeavoured to break the fastening. Failing, I went back and, feeling provoked, I drew the corner of my table-cloth off and broke the crockery. I then broke the furniture with the barrels. They say that I was mad; I deny it, I was only provoked, and, I think you will allow, with reason." The professional man, with whom he had worked for years, said that he had an excellent knowledge of his business and received a large salary. He remained for a considerable time under my observation, being always quiet in manner and civil-spoken; but he, at length, displayed such unmistakable and troublesome signs of mania (satyriasis) that we were compelled to remove him.

Wolves kill in obedience to the dictates of their instinct and appetite, but are powerfully deterred by a sense of personal danger. As long as the shooting of these animals is considered advisable, I would hold such madmen as the wielder of the pistol and of the gun-barrels subject to the terror and penalties of the laws—hanging them without remorse when they dare to commit murder.

In such homicidal maniacs, the sense of self-preservation is fully alive, and their consciousness of the peril of wrong-doing is as strong as that of the cat or the pickpocket.

*Osteo Malacia of the Insane.*—Cases of rib-breaking in lunatic asylums have been reported in all the three Presidencies of India. I have cited the case of a native at p. 442 of my Medical Jurisprudence.

(To be continued.)

HOSPITAL FOR WOMEN, SOHO SQUARE.—Dr. Protheroe Smith, the Founder of the Hospital for Women, Soho Square, has, after 45 years of active work thereat, resigned the post of Senior Physician, and has been appointed Consulting Physician to the Hospital.

REPORTS OF  
HOSPITAL PRACTICE IN MEDICINE  
AND SURGERY.

LONDON HOSPITAL.

HYPERTROPHY OF INFRA-VAGINAL CERVIX  
—PROLAPSE—ALEXANDER'S OPERATION  
—PERITONITIS—DEATH.

Under the care of DR. HERMAN.

(Reported by Mr. H. HOLYOAKE.)

E. B., aged 24, single, had been a general servant since the age of 14, but had never had to work very hard. Menstruated first at 16; since then regular, without pain, the flow scanty. No previous illness. In March, 1883, it was found that she suffered from tape-worm. Till then she had had no symptom of ill-health. She took some medicine for the tape-worm, and a day or two after a protrusion at the vulva was noticed. From this time "the womb" continued to come down every day, going back at night. In April, 1884, she began to have a yellow vaginal discharge, with irritability of the bladder and dragging pain in the back.

In October, 1884, she was admitted into the London Hospital. She was of short stature, slender build, and delicate appearance. There were no signs of disease elsewhere than in the pelvis, and no symptoms other than those mentioned. The cervix protruded from the vulva, and the upper part of the vagina was inverted. The hymen was entire. The vaginal portion of the cervix was about an inch and a half long. The body of the uterus was retroflexed. The sound entered three and a half inches. The elongated cervix was then amputated with the knife, the mucous membrane being brought together over the cut surface with sutures. After the cervix had healed, various pessaries were tried—a ring, and different varieties of the Hodge's pessary; but the lower part of the vagina was too large to retain any vaginal pessary. She was again admitted into the hospital, and on May 5th Alexander's operation was performed. As the prolapse was very great, the ligaments were pulled up as far as possible. On the left side, in freeing the ligament (which was found the more quickly of the two), a small opening in the process of peritonæum accompanying it was made. Listerian precautions were used, but with an omission which was not noticed in time to be prevented. The wounds were dressed antiseptically. The patient appeared to be doing well until May 9th, when in the evening she began to vomit. On May 10th she complained of abdominal pain, and the abdomen was slightly tender on pressure, but not swollen. May 11th the symptoms became those of collapse; faintness, cold extremities, feeble pulse, pinched features, constant retching. May 12th, she died. Throughout, from the time of the operation till the death, the temperature was taken twice daily, but it never exceeded 99. There was no carboloria.

On *post-mortem* there was found acute general peritonitis, with much lymph, but little fluid effusion. The parts involved in the operation were carefully dissected by Mr. Jonathan Hutchinson, Jun., who has supplied the following account of them: "The wound in the right groin was well healed, no pus beneath it. The canal of Nuck came close to it, and it was doubtful whether it opened just beneath or not. The wound in the left groin was inflamed at the outer part, and with it the

peritonæal cavity communicated by a channel containing pus. There was also a good deal of pus in the sub-peritonæal tissue adjacent, and in the left broad ligament. The uterus was normal and well drawn up. There was a very prominent transverse fold of peritonæum on its anterior surface between it and the bladder." The intestinal mucous membrane was normal. Liver, spleen, kidneys, supra-renal capsules, lungs and heart healthy.

*Remarks by Dr. HERMAN.*—This case is published because, when a new mode of treatment is under the judgment of the profession, it is most important that bad results as well as good ones should be fully made known. In this case the death appears to have been due to the entrance of septic germs at the time of the operation through the wound in the peritonæum made in freeing the ligament. The lesson of the case seems to be, that in separating the ligament from the process of peritonæum which often accompanies it, it is well to use the knife as little as possible: and that it is necessary to use the greatest care in the use of anti-septic precautions; or in what is equivalent, the attainment of perfect surgical cleanliness. The case is also interesting as an example of acute general peritonitis, without any rise of temperature, and with absence of any marked symptoms during the first four days. Dr. Herman's experience of other cases operated on by him, so far as he has yet been able to watch them, leads him to think that the operation is a valuable addition to our resources, but it does not appear to him profitable to publish cases, or to confidently draw conclusions from them, until they have been watched for a considerable time.

## APPOINTMENTS FOR THE WEEK.

### Tuesday, July 23.

UNIVERSITY OF LONDON, 5 p.m.—Extraordinary meeting of Convocation, to receive the report of the Committee on the reconstitution of the University.

BRITISH MEDICAL ASSOCIATION, Town Hall, Cardiff, 3 p.m. General Meeting 8 p.m.—President's Address, by Dr. W. T. Edwards.

### Wednesday, July 29.

BRITISH MEDICAL ASSOCIATION, Town Hall, Cardiff, 11 a.m.—Address in Therapeutics, by Dr. W. Roberts, F.R.S.; 2 p.m., Sectional Meetings.

### Thursday, July 30.

BRITISH MEDICAL ASSOCIATION, Town Hall, Cardiff, 11 a.m.—Address in Surgery by Mr. John Marshall, F.R.S.; 2 p.m., Sectional Meetings; 6.30 p.m., Public Dinner in Park Hall.

### Friday, July 31.

BRITISH MEDICAL ASSOCIATION, Town Hall, Cardiff, 10 a.m.—Address in Public Medicine, by Mr. T. Jones Dyke; 11 a.m., Sectional Meetings.

# Medical Times and Gazette.

SATURDAY, JULY 25, 1885.

ONE or two of our readers, under the impression that the *Medical Times* is a staunch conservative journal, are apparently somewhat aggrieved at the support we have given to Mr. Erichsen's candidature. Well, apart from the consideration that consistency in the expression of political opinions appears to be rather at a discount amongst professional politicians, and that a journal once conservative might find some difficulty in retaining at once its consistency and its political colour—apart from these exculpatory considerations, behind which we would not for a moment deign to shield ourselves, we would simply observe that we wish well to Mr. Erichsen's candidature, for the same reason that we should wish well to the candidature of any honest and honourable medical candidate to whatever party he might chance to belong. In short, we support and shall support medical candidates, on medical and not on political considerations. It is to our thinking far more important, not only to the profession, but also, as Mr. Erichsen has pointed out, to the public at large, that Parliament should contain a just proportion of men with a special knowledge of medical and sanitary matters, than that one or other of our heteromorphous political parties should gain a few odd votes. It is at present perhaps too much to hope that constituencies should be so wise as to elect medical men for their special aptitudes apart from their political partisanship: but Mr. Erichsen has done as much as could be expected of any candidate to minimise his party proclivities, and the fact that he reckons many strong Conservatives amongst his most enthusiastic supporters should be sufficient to reconcile the most conservative of our readers to the line we are taking. Moreover, Mr. Erichsen is fighting, not only for our profession and for scientific culture in general, but also for the continuance of University representation, for it does not take a prophet to foretell that, if University seats are to be contested with hot partisanship, it will not be long before they are swept utterly away, a result which no medical practitioner can desire.

THE extracts from the American medical journals which we print elsewhere, will be sufficient to show that the prevalent opinion in the States is that the Washington Congress is not only in danger, but absolutely doomed to failure. The leaders of the profession both in Boston and Baltimore have followed the lead of the Philadelphians, and withdrawn from the Congress, and it is not unlikely that their example may spread to other cities, though indeed enough has already been done to turn the meeting of 1887 into what an American contemporary, drawing its illustration from our common history, appositely terms a "rump" Congress. The only hope is that the American Medical Association will be startled back to its senses by the strong and decisive action of the

profession in Philadelphia, Boston and Baltimore, and will make haste to retrace its steps. It may be taken for granted that not even the leaders of the malcontents, and certainly not the members of the Association at large, realised that the result of their action would be destruction to the Congress of 1887 and danger to its successors. Such an event was probably far from their calculations. They simply reckoned without their host, *i.e.*, their leaders, and if they are wise they will cast another reckoning, this time with due regard to the said host. They have plenty of time to consider the matter, as they do not meet again until next May. An American journal humorously says that the question recently under discussion was whether Nation should be spelt with a big N, and it was decided in the negative. When it is seen that the medical representatives of other Nations who still use capital letters will visit the American Nation by thousands, but will not go to the trouble and distress of crossing the Atlantic merely to theorize and feed with a crowd of nobodies, we may surely expect some orthographical afterthoughts, though, by the way, in spelling difficulties, second thoughts are often not the best. We do not quite understand, by the way again, why neither of our English contemporaries has thought it worth while to inform their readers of this American dispute, a matter surely of some importance.

THE Government met with but little difficulty in carrying the second reading of the Medical Relief Disqualification Removal Bill on Thursday, last week. On the motion for the second reading, Mr. Pell moved an amendment to the effect that, in the relief of destitute paupers out of any poor rate, no distinction should be made in favour of enfranchising those who obtain it in the form of medical treatment, and those who are compelled to accept it in the form of bread; and he enforced his contention in an able and vigorous speech. He pointed out the disastrous effects the proposed measure must have in making the working classes still more disinclined to recognise the duty of endeavouring to provide medical aid for themselves and families in case of sickness, and he raised a question which later on became one of the principal subjects of contention, *viz.*, whether "medical relief" means medical attendance and medicines only, or whether it also includes "medical comforts," as food, nurses if necessary, surgical appliances, and so on. Mr. A. Balfour brought forward statistics to prove that the measure would affect but a very small number of people, for not more than 2.5 per thousand of those who apply for poor law relief apply for medical relief only. This has nothing to do with the rightness or wrongness of the principle of the Bill; and should it become law it is certain that applicants for medical relief will very largely increase in number. As for the rest of the debate, it consisted in exchanges of political amenities between the two sides of the house. Mr. Courtney proposed the adjournment of the debate, but gave way when the Government pleaded urgency, and Mr. Pell's amendment having been negatived by 279 votes to 22, the Committee on the Bill was fixed for Tuesday.

WHEN the motion to go into Committee on the Bill came on, on Tuesday, Mr. Courtney moved as an amendment that the House could not approve of a measure which would remove an incentive to independence, and fundamentally change the principle of the Poor Law, under which pauperism had steadily diminished; and the debate which followed occupied the principal part of the sitting of the House, which was a very prolonged one. Mr. Courtney supported his amendment by an able and statesmanlike speech, and was well seconded by Mr. C. S. Read, who characterised the Bill as a first step towards the extension of pauperism, and a fatal blow to benefit and sick clubs. Mr. Bryce also spoke well and strongly against the principle of the measure; but as to the rest of the speeches, and they were many, they were for the most part simply partisan, and those of the leading politicians on both sides of the House consisted largely of recriminations. Many hours were wasted in this way, but at last Mr. Courtney's amendment was negatived by 226 votes to 22; and then, in the small hours of Wednesday morning, the House went into Committee. But for some considerable time it seemed very doubtful whether any further progress would be permitted. An amendment to exempt Scotland from the Bill was withdrawn on the understanding that the question shall be considered before the report on the measure. A motion to report progress was, after some expostulation, rejected without a division. An amendment in favour of including medical comforts in the phrase "medical relief," was supported by Sir W. Harcourt, and by Mr. Chamberlain, who declared the Bill "would not be worth a rap without it;" but the Government refused to have anything to do with such an amendment, and after some brisk, and by no means dignified altercation, they defeated it by the narrow majority of 71 against 68, the Parnellites walking out of the House without voting. The Bill then passed through Committee after 3 o'clock in the morning. The next stage was to be taken on Thursday at about the hour that we went to press.

WHEN revised by the light of recent proceedings in Parliament, the following excerpt from a Transatlantic contemporary is not altogether pleasant reading:—"In spite of all that has been said of the abuse of medical charity, both here and in Great Britain, little if anything has heretofore been done to overcome it. We are glad to see, however, that the first effective blow seems likely to be struck by our English brethren in the form of a legislative measure disfranchising the recipients of medical services at the public expense. The project is not overstrained, since those who, for the sake of the public safety, are sent to hospitals for infectious diseases, are exempt from the operation of the Act."

ON Monday last Sir L. Playfair asked the Secretary to the Treasury whether any answer had yet been given to the request from the Marine Biological Association for aid in establishing a station on Plymouth Sound, with the purpose of investigating the fauna and flora, especially in their relation to the food fishes. Sir L. Playfair stated that 8,000*l.* had already been

subscribed from private sources towards the proposed work. In reply, Sir H. Holland was able to say that the application referred to had been carefully considered by both the present Government and their predecessors, and the Treasury had undertaken in general terms to ask Parliament for an annual grant for a term of years in aid of the association, on condition that they carry on their work in full concert with the Scotch Fishery Board. The Government hold that these two bodies are to be considered as working together towards the common benefit of the fishermen and the fish-consumers of the three Kingdoms. We believe that an annual grant of 1,000*l.* for five years is contemplated.

It will be recollected that the case of Dr. Bradley was strongly pressed upon the attention of the late Home Secretary as peremptorily calling for his examination and interference. Sir W. Harcourt could not, however, satisfy himself that he would be justified in questioning the verdict of the jury, or in interfering with the sentence of the judge. The case has since been brought specially to the notice of the present Home Secretary, and on Tuesday Sir R. Cross, in answer to a question by Mr. Macfarlane, stated to the House of Commons that with the assistance of both the Law Officers of the Crown and the Lord Chancellor, he had carefully enquired into the case, and had arrived at the conclusion that there was so much doubt about it that he did not think the prisoner ought to be further detained. He did not say that he was satisfied the man was innocent, but only that there was the greatest doubt in the case. Dr. Bradley was accordingly released on Wednesday. It is to be observed that Sir Richard Cross did not state whether or no he had the assistance of any medical adviser in forming his opinion of the value of the evidence given at Dr. Bradley's trial.

ON the same evening Mr. A. J. Balfour, the President of the Local Government Board, stated in reply to Lord A. Percy, that the Lunacy Act Amendment Bill which had been introduced in the House of Lords would not, he believed, be proceeded with in the present session; but that, as he strongly recognised the importance of express statutory authority for the temporary detention of lunatics in workhouses, he intended to ask for leave to bring in a Bill on the subject. The leave was granted and the Bill read a first time on Wednesday.

THERE was a fairly large attendance at the General Meeting of the Medical Officers of Schools' Association on Wednesday last, when the late President, Surgeon-Major Evatt, was present after his return from service in Egypt. After some routine business, including the election of new members, and a decision to increase the number of Vice-Presidents and to have two Honorary Secretaries instead of one, a paper on the influence of postures in schools upon the figure was read by Mr. Noble Smith. The paper was based upon enquiries undertaken on behalf of the London School Board. It may be admitted that such involuntary kakisthenics are

not peculiar to the Board Schools of London or of any other town; they may, indeed, be observed almost anywhere when children are made to read and write at ordinary desks and on ordinary seats for any time together. The effects are naturally most noticeable in the case of girls and young women. Boys have less compunction in assuming ungainly postures, which must often be regarded as natural attempts to antagonise the harmful results of school positions; while the rougher and more actively postural character of their play—which, again, is still far more largely a matter of the open air than is the case with girls—gives them a further advantage over the opposite sex. The school-girls of the present day are certainly more fortunate in these respects than were those of a previous generation. The tennis-lawn, which is now considered an adjunct to any good class boarding-school for girls almost as necessary as is that of a cricket ground for boys, is in itself an innovation of immense hygienic value. There can be no doubt, however, that girls suffer more, as they are more prone to suffer, from the causes which Mr. Smith has once more emphasized. On this ground it is a matter for some regret that ladies practically interested in the education of their sex were not present in greater numbers on the occasion.

THE following is the official tale of cases and deaths from cholera in Spain during the third week of the present month:—

	Cases.	Deaths.
July 15th .....	1,496	664
„ 16th .....	1,629	672
„ 17th .....	1,328	621
„ 18th .....	1,886	718
„ 19th .....	1,850	761
„ 20th .....	2,243	876
„ 21th .....	1,752	685
Totals ....	12,184	4,997

During the first two weeks of the month, the cases numbered 20,278, and the deaths 9,752, so that there has been a marked increase in the incidence of the disease, if not in its mortality. It is probable, however, that even these terrible figures do not represent the whole truth, as it is believed that many cases and deaths are concealed in country districts through fear of the severe sanitary precautions, by which it is attempted, at present with lamentably poor success, to keep the outbreak in check. During the week it has spread northward up the Ebro, in the province of Saragossa and westward down the Tagus in the province of Toledo, and has invaded low and marshy ground in the provinces of Jaen and Albacete. It is carried up to the hill-country by fugitives, but has not there assumed an epidemic form. The worst accounts now come from Saragossa, in which province, including the capital, people are dying at the rate of 200 a day. The accounts from both the city and province of Valencia are improving, though the mortality is still very great, over 200 a day, and the same is true in a less degree of Murcia, these being the provinces first attacked. The provinces of Alicante and Segovia, on the other hand, are suffer-

ing more severely. The cases, too, in the neighbourhood of Madrid have increased; while, on the other hand, at Aranjuez which was so severely visited in the first days of the month, the epidemic has practically ceased. The sufferings of the people must be fearful, and they are not mitigated by the well-meant but useless attempts of the local authorities to stamp out the disease. The new Minister of the Interior is, however, getting his subordinates in hand, and attempting to curb their arbitrary and panic-striven activity.

THE deaths recorded in London last week were 1,616, showing an increase of 200 over the previous week, and causing the death-rate to rise to 20.6, but they were nevertheless 60 below the corrected average for the week. The zymotic death-rate went up to 5.5 owing to the sudden increase in the number of fatal cases of diarrhoea, which experience teaches us to regard as normal at this time of year. There were 210 deaths from this cause, 173 being in infants under 12 months of age. Measles, whooping-cough and

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past thirteen weeks.

enteric fever all claimed more victims than in the previous week, 82, 77 and 17 deaths being respectively registered under these heads. There were only 15 deaths from small-pox, but the number of fresh cases showed a slight increase. Diphtheria numbered 16 and scarlet fever 13 victims. The death of a boy aged 11 years was referred to sunstroke. The diarrhoea season has set in at Leicester as well as in London, and the 25 deaths recorded caused the zymotic death-rate in that town to run up to 10.7. Measles still continues its fatal ravages at Liverpool,

where there were 17 deaths from it, and recrudescences of it took place in Sheffield and Newcastle, 10 deaths being attributed to it at each of these places.

THE long-expected report of the Special Committee appointed by the London School Board, to enquire into the existence of over-pressure in the schools of the Board, has at length been published, and a *résumé* of it will be found in another column. It is evident that the Committee have done their work conscientiously and thoroughly, according to their lights, and they find themselves obliged to imply that there was a considerable amount of truth in Dr. Crichton Browne's assertions, and abundant excuse for the agitation of which he was the main-spring. But as a scientific enquiry into the question of over-pressure, the report of the Special Committee is worthless. They had no medical help, being unable to obtain the co-operation of medical men of "sufficient authority," and in a delicate and difficult question like that which they had to deal with, it is quite possible for the evidences of over-pressure to have been crowded under their noses without their being at all aware of it. Thus in spite of all that the comfortable people who resent alarmism as a personal injury—there were, no doubt, some Romans in the Capitol who cursed the geese for disturbing their slumbers—may have pleased to say of Dr. Crichton Browne, there can hardly be a doubt that the substantial victory remains with him; or else why all this elaborate series of recommendations. We can bear personal testimony to the fact that the cases with symptoms plausibly attributable to over-pressure have markedly diminished in hospital out-patient practice since Dr. Crichton Browne raised his alarm, that much less is heard of "keeping-in" and home lessons, and that the parents generally are in much better temper with the School Board authorities. The main thing now is to keep an open eye, and to take care that matters are not allowed to slip back into the old groove. "Over-pressure" may be for the present scotched, though some even doubt that; but it is not killed, and for that matter never will be. For is it not one of those rough and cruel processes of natural selection—like famine in India—which are as tenacious of life as the human race itself, but which the evolution of a higher and humaner intelligence warns us must be kept in check, if the moral and intellectual progress of man is to continue?

OUR Edinburgh correspondent writes:—On Thursday last week Mr. Erichsen delivered an address to the electors of the Universities of Edinburgh and St. Andrew's, in the Freemasons' Hall, Edinburgh. The chair was occupied by Professor Maclagan, and the hall was filled in all parts. Mr. Erichsen on rising to speak was received with cordial applause, and it was evident from the first that he had secured the sympathies of the audience, and these he carried with him to the end of his address. On all hands it was admitted that both in manner and substance his address was just what such an address should be, and was in marked

contrast to any which have as yet come from his opponent. After referring in graceful terms to his having taken part in the rejoicings during the Tercentenary Festival, and his having been honoured with the degree of LL.D. on that occasion, he proceeded to announce his political creed in these terms:—"Let me say that in politics I am a Liberal, that I have ever been so, that I am so, and probably shall always continue to be so; that I am so to the fullest extent of the word, but not to its extremest extent; that I am so in all matters of politics, in all matters of social organisation, in all matters of religious toleration. But I am no party-man; I am no partisan in the ordinary acceptation of the term; I seek no office; I hold no place, I desire none. Were I a party-man, I should not be here, seeking to be the representative of an academic constituency. I look upon the representative of an academic constituency as having far higher, far nobler, and far wider duties than those which attach merely to party politics."

AFTER deprecating the violence and virulence of the language which has developed in the recent heat of party politics, Mr. Erichsen went on to explain his position as a medical man seeking the suffrages of the constituency. He pointed out how inadequately the profession was represented in Parliament at present, and how many and important were the matters of social interest which failed to meet with proper consideration by reason of the smallness of the medical voice in the House. He showed further how injurious their paucity of numbers in the House was to the well-being of the profession itself, in so far as it hindered the progress of medical legislation from the want of a sufficiently authoritative expression of the opinion of the profession as a whole on matters which come before the House. He called attention to some abuses which might readily have been rectified had some one with sufficient influence drawn the attention of the Legislature to them. Among others he instanced the Medical Council, whose constitution he showed was most unfairly arranged. He further pointed out how important a part a sufficiently numerous body of medical representatives would play in connection with hygienic measures, with questions relating to vaccination, vivisection, the stamping out of epidemics, the question of over-pressure in schools, &c. He concluded his address by defining his attitude to the question of Church disestablishment, at present the most burning question in Scottish politics. While not opposed to the existence of an establishment as matter of principle, he declared himself as willing to consider favourably any well-considered scheme of disestablishment, brought forward by a Liberal Government, and evidently in harmony with the views and wishes of the majority of the Scottish people. The speech as a whole was a masterly exposition of the functions of a University representative, and was received with expressions of lively satisfaction by the majority of the audience. It was felt, much as Sir Lyon Playfair's retirement from the representation is to be regretted, that one able to succeed him worthily had been found, and that

University interests would be in safe keeping in the hands of such a man.

ON Friday, July 17th, the Earl of Carnarvon received two deputations at Dublin Castle representing respectively the Colleges of Physicians and Surgeons in Ireland. Each deputation presented his Excellency with an address, congratulating him on his appointment as representative of the Queen in Ireland. The physicians in their address, which was read by the President, Dr. Cruise, claimed that their College had ever been mindful of the important trust committed to it, and had endeavoured to discharge its functions by furthering the advancement of medical science, and securing a succession of highly-educated physicians for the service of the State. It had at various times tendered its aid and professional advice to the Government in advancing and carrying into effect measures dealing with the public health; and now, as at all times, it would consider it to be its duty, as it was its most anxious desire, to afford every assistance to Her Majesty's Government in all matters relating to both Curative and Preventive Medicine. The address of the College of Surgeons, which was read by the President, Sir Charles A. Cameron, after the usual compliments, felicitations, and expressions of loyalty, ran thus: "We beg your Excellency to believe that our College is influenced by an earnest desire to fulfil, in the future as effectually as in the past, the important function of providing for the service of the army and navy, and of the public at large, highly educated and reliable surgeons, which her Majesty and her Royal predecessors have entrusted to it, and which, we trust, her Majesty has within the past year graciously renewed. We avail ourselves of this opportunity to express the hope that your Excellency will honour this College at the earliest convenient opportunity by visiting it, and satisfying yourself by enquiry and by inspection of our museums, libraries, and other departments of the College, that the institution which we represent is deserving of the confidence of your Excellency and of the public." Lord Carnarvon's replies to both addresses were in the best taste, and were delivered in a graceful fluent style, which was pleasant to hear.

THE name of Professor Herman von Fehling, whose death at the mature age of 72 has recently been recorded, is probably known with more than common familiarity to every practitioner of medicine throughout the world. The adoption of his method of ascertaining the presence of grape sugar in the urine was universal, and has never been altogether displaced by the more ready and portable means suggested by later physiologists and chemists. The fame of the late Professor, however, does not rest alone upon the world-wide recognition of the "Solution." A pupil of Liebig and of Dumas, he entered upon his duties as Professor of Chemistry at Stuttgart so long ago as 1839, and continued in the service of his University from that time forward. Many years ago he published a Dictionary of Chemistry, which received a full measure of public appreciation, and his contributions

to the advance of chemical knowledge have been both numerous and valuable.

THE City of Vienna has attractions of one kind or another for all classes of persons, and perhaps for the medically-minded more than all. Although too many of the bright particular stars have ceased to illuminate the medical school, the spirit of their teaching still inspires their followers, and for many years to come their methods will attract those of other nations whose native schools have not yet found out the way to supply their pupils' wants. Past, present and future residents in the "beautiful city" will be equally rejoiced to learn that serious attention has at last been aroused to the one plague-streak that disfigures the beauty of the town, and is a continual source of discomfort and disease to all who live in its neighbourhood. We allude to the reeking channel of festering filth which by some strange flight of fancy has been christened a "river"—the river Wien. A wide ditch, embanked with walls altogether out of proportion to the volume of water which they restrain, unevenly floored with banks, flats and hollows of the foulest black mud, exhaling the various vapours of animal and vegetable decomposition, the Wien is an unfailing source of wondering disgust to the foreign visitor, and an ever-present nuisance and danger to those who have the misfortune to live within range of its pestilential exhalations. It is probable that the excessive heat of the last few weeks has sufficed to rouse even official nostrils to rebellion. At last the idea appears to have dawned upon the sanitary authorities that the time has come when the fiction of a river must give place to the fact of a sewer, and a project is on foot to hide alike the Wien and its foul surroundings from the public gaze. No one is wise at all hours, says the proverb, and possibly no school of medicine can be wise in all subjects, but it is still remarkable that in a university which above all others has carried the system of special teaching to a point of practical perfection, the subject of practical hygiene should be so completely disregarded as it is in Vienna.

THE new number of Dr. B. W. Richardson's *Asclepiad* is notable for an excellent autotype of G. White's engraving of Boerhaave, and a pleasantly written account of the life and works of that great master in physic. The portrait shows Boerhaave at his prime, and is finely described by Dr. Richardson: "A broad Saxon face, with features large and fine, except the nose, which with Teutonic obstinacy will turn upwards, to the decided injury of the beauty of the profile, when another portrait showing that is looked at. The head is massive, the forehead broad and prominent, the eye full, the ear with a big lobe, the lips well developed and the cheek-bones rounded and expansive, but flattened. The expression is not commanding, but good-tempered, determined close up to obstinacy, and wanting altogether in Semitic subtlety and Keltic fire. In fine, the face of a pure Saxon, coming up as near to genius as any pure Saxon can

come by the forces of intense study, varied application and incessant indomitable industry." Dr. Richardson thus sums up Boerhaave's character and habits: "Born of a happy disposition, he was frugal and therefore wealthy, industrious and therefore learned, versatile and therefore happy, privately liberal and therefore careless about the false charges of parsimony raised against him. To him the outside world was of little moment; his garden, his study, his laboratory were the three worlds in which he lived, moved and had his being; nor is it possible to find any other worlds in this life more delightful." We cordially recommend Dr. Richardson's "Study of an Old Master" to all readers who are interested in the past history of medicine. The rest of the number is up to, but not above, *Asclepiad* average.

INSTIGATED perhaps by the analogy of events in the Soudan, where internecine war has for a time checked the progress of the religious epidemic of Mahdi-ism, Professor Arnaldo Cantani, of Naples, has lately hit upon a means whereby the progressive activity of the tubercle bacillus may be hindered in a somewhat similar manner. His views are founded upon the ascertained fact that the growth of other bacteria in the same soil is destructive to the power of Koch's bacillus. In the *Centralblatt für die Medicinischen Wissenschaften*, No. 29, 1885, he recounts some experiments by means of which he ascertained that bacterium termo, whether injected, inoculated or inhaled, exercised no sort of influence upon the tissues of living animals. He then caused a spray of fluid containing the bacteria to be inhaled by a patient suffering from tubercular disease of one lung, whose sputa contained the tubercle bacillus in large quantities, as proved by the microscope and by injection into small mammals. These inhalations, continued daily for a month, were followed by rapid improvement in the general condition of the patient. The sputa, examined at frequent intervals, were found less and less bacillary, but swarming with bacterium termo, and injections into lower animals no longer produced any signs of tubercular disease. A result such as this in a case of advanced disease of the lung, although at present standing alone, is worthy of all attention. It has yet to be conclusively proved, however, that the abundant inhalation of bacterium termo is in itself a harmless procedure in the case of the human lung, and it would be more in accordance with scientific practice that the process should first be tried upon factitious tuberculosis in lower animals. The idea, however, is a novel one. The use of septic material as a local antiseptic has not yet been tried.

It is well known that the rainfall during last spring and winter was, for many large districts, far short of all that was required to make up for the drought of the preceding months. The more preventable causes of our national water-waste, to which we directed attention less than a year ago, have continued in operation practically unaltered; and the weather of

this summer has not hitherto been such as would make good these defects. It is, therefore, not surprising that forebodings of another water famine should have ripened into actual experience in some districts even earlier than was the case in 1884. Two months ago the Thames at Richmond, after having been flooded for a few days with turbid storm-water, subsided so rapidly that, at low tide, the river might have been crossed on foot with little more than wetted ankles. Now we read of a Yorkshire village without a drop of water of its own, the farmers drawing their supplies from more than a mile away, and the cottagers "getting a little out of the farmers' carts as they pass their doors." But this supply is also becoming exhausted, and then the water for two villages will have to be procured from another source at least four or five miles distant. There is some reason to fear that another dry August and September might cause a repetition of the difficulties of last year, and this even in an aggravated form. A perusal of Dr. Corfield's paper on "The Water Supply of Ancient Roman Cities," and the idea of each of the million Roman citizens luxuriating in a daily water supply of some 330 gallons, with a literally constant service, suggests the question whether we are, after all, so very much wiser than our predecessors.

THE arrangements for the fifty-third annual meeting of the British Medical Association at Cardiff, on Tuesday, Wednesday, Thursday and Friday next week, are now nearly completed, and the meeting promises to be one of great success under the Presidency of Dr. W. T. Edwards, Senior Physician to the Glamorgan and Monmouthshire Infirmary, Cardiff. On Tuesday, the first day, the Council meet at 2.30, and at 3.30 the general meeting of members is held, at which the consideration of the report of the retiring council and other business will be transacted, the meeting adjourning till eight in the evening, when the President will give an address, and any adjourned business will be taken. On Wednesday there will be a meeting of the new Council at 9.30, and at 11 the second general meeting will be held, at which Dr. William Roberts, F.R.S., of Manchester, will give an address in Therapeutics. From 2 to 5 o'clock the sections will be held. Of these there are seven, viz. :—Medicine, Surgery, Obstetric Medicine, Public Medicine, Psychology, Ophthalmology and Otology, Pharmacology and Therapeutics; and a very goodly list of papers in each section are promised. On Thursday, the Council again meet at half-past 9 o'clock, and at 11 o'clock the third general meeting is held, at which an address in surgery will be given by Mr. John Marshall, F.R.S., of London; from 2 till 5 the sections will meet again. On the last day, Friday, an address on Public Medicine will be given by Mr. Thomas Jones Dyke, Medical Officer of Health, Merthyr Tydvil; at 11 o'clock the sections will meet, and at 2 o'clock the concluding general meeting will be held, at which the reports of various Committees will be considered. All the meetings will be held in the Town Hall, which has been most kindly lent for the week by the Corporation of Cardiff.

THE entertainments are to be numerous. On Wednesday from 5 to 7 a garden party will be given by the High Sheriff of Glamorgan and Mrs. Hill, and at 8 p.m. the same evening a *conversazione* by the President of the Association and the South Wales and Monmouthshire Branch, at the Park Hall, Park Place, which is one of the finest halls in the province. At the *conversazione* various entertainments will be provided, including an exhibition of scientific instruments and works of art; and the evening will terminate with a ball. The dinner of the Association will be held in the same hall on Thursday at 6.30 p.m. On Friday at 3.30 there will be a garden party with music and refreshments at the Windsor Gardens, Penarth, by invitation of Lord Windsor, and the whole meeting terminates with a reception at 8 o'clock on Friday by the Mayor of Cardiff, at the Park Hall. With such a programme and so generous a list of entertainments, a large and successful meeting is anticipated. The whole of the arrangements have been most ably carried out by Dr. Alfred Sheen, the Honorary Local Secretary, assisted by the local medical men, who act as Honorary Secretaries in the various departments, museums, excursions, and entertainments. On the Saturday excursions have been arranged to (1) Tintern Abbey and Raglan Castle, (2) to Glastonbury Abbey and Wells Cathedral, (3) to Caerphilly Castle, (4) to Symonds Yat and the Speech House and Forest of Dean.

---

#### THE HOUSING OF THE WORKING CLASSES BILL.

WHEN, not many weeks since, in discussing the Report of the Royal Commission on the Dwellings of the Poor, we expressed our conviction that though no new facts had been brought to light, the authoritative recognition of the existence of a state of things well known, but hitherto persistently ignored, must lead sooner or later to legislation on the subject, we little thought that our anticipations would be realised within the current session of Parliament. We have now before us the draft of a Bill in which are incorporated most of the points on which the Commissioners, however much their views might otherwise differ, were practically unanimous. There is nothing revolutionary about it, no creation of extraordinary powers or violation of the rights of property; it consists mainly of a series of amendments of existing Acts, of provisions for the extension of powers already enjoyed by sanitary authorities, and the removal of arbitrary restrictions and artificial obstacles to action on their part, of clauses for compelling neglectful Boards to do their duty, and of the application of recognised principles to other circumstances than at present. Only one or two provisions can be regarded by the most jealous as open to the suspicion of a tendency to socialism or confiscation, and they are, as we saw from the report of the Commissioners, those for which the Conservative Prime Minister is most directly responsible.

Fully half of the Bill is concerned with the Labouring Classes Lodging Houses Acts of 1851 and 1866. These Acts, which were intended to enable local authorities to provide suitable dwellings for the poor whether as a source of profit or not, have never, we believe, been put in operation, certainly not in the metropolis. The former of these is known, where known at all, as Lord Shaftesbury's Act, having had the singular fortune of being personally conducted in all its stages through both houses by that veteran peer, first as Lord Ashley, and then, owing to his father's death at the time, as Earl of Shaftesbury. The idea of sanitary legislation was then new, and the difficulties in the way of raising loans and otherwise carrying out the provisions of the Act would have been enough to deter bodies even more interested in such movements than local authorities usually are. It is the wish of the framers of the present Bill to facilitate in every way the adoption of the Acts in question, and with that view they have repeated no fewer than 45 sections wholly or in part.

Coming next to the better known Artizans' Dwellings Act, 1868 (Torrens), and the Artizans' and Labourers' Dwellings Improvement Act, 1875 (Sir R. Cross), and Acts amending the same, we find that the new Bill provides that when the sanitary authority, disregarding the report of their medical officer of health, as to the insanitary state of any street or premises, refuse to take steps to remedy it, any neighbouring authority or owner may complain to the Local Government Board, and the Board may, if after local enquiry they think it expedient, compel the local authority to put in force the provisions of the Artizans' Dwellings Act. In like manner, when a local authority has sent in to the Local Government Board its reasons for declining to condemn under Cross's Act any unhealthy area, the Local Government Board may compel them to make a scheme, subject to certain conditions and within a given time. Cross's Act is to extend to all urban sanitary districts in England instead of being, as hitherto, limited to those having over 2,500 inhabitants; and the owner of property condemned under Torrens' Act is no longer to have the power of forcing the sanitary authority to purchase, a premium on neglect for which it is but fair to say Mr. Torrens' Act itself was not answerable. Again, every sanitary authority is to be free to publish by-laws for the better conduct of lodging-houses (other than common lodging-houses), under Clause 90 of the Public Health Act, without previously obtaining the consent of the Local Government Board; and, on the other hand, when a local authority fails to make by-laws for securing decent lodging among hop or fruit-pickers, the Local Government Board may frame such by-laws, which it shall be the duty of the former to enforce.

A somewhat lengthy clause is introduced for the purpose of bringing the provisions of the Public Health Act to bear on vans, tents, &c., but the same end might have been as well attained by adopting the Canadian definition of a house as "including schools, factories and other buildings, huts and tents used for human habitation or work, whether such use is per-

manent or temporary, and whether the same are stationary or moveable." Lastly, the condition of fitness for human habitation implied in the letting of furnished apartments is to be extended to unfurnished houses in the sense that damages may be recovered for loss by injury to health or otherwise consequent on any breach of the implied condition. It may not in every case be possible to prove to the satisfaction of a jury that injury to health has been caused by defective sanitary arrangements; but when diphtheria or enteric fever occurs in a new house, the drains of which are found to be laid without cement, or with no connection with the sewer, it assuredly will not be judged "reasonably fit for habitation." Certainly this clause will enable the sanitary authority to make the thirty-fifth section of the Public Health Act retrospective, and it may be found an easier procedure than putting Torrens' Act into operation.

Thus far the Bill consists of mere amendments of existing Acts so simple and obvious that there can be no two opinions as to their propriety, but it must be admitted that the third and twelfth sections introduce a new principle into our legislation, and that there is some justification for the apprehensions expressed by Earl Wemyss and Lord Bramwell as to the possible remote results of such an innovation. The third section, embodying Lord Salisbury's own recommendation in the Report with regard to the sites of certain Metropolitan prisons now disused, or likely to be so, is, in fact, but a special case, the principle of which is enunciated in section twelve. This section, which constitutes an amendment of the Settled Lands' Act of 1882, besides including among the improvements on which capital money may, by the twenty-fifth section, be expended, any dwellings whatever available for the working classes, provided only that they shall not detract from the value of the estate, authorises trustees and bodies corporate to sell, exchange, or lease any land for the purpose of erecting thereon such dwellings, at a price or for a rent which shall be deemed reasonable by the Court, though less than what might have been obtained in the open market.

Lord Salisbury admits that the principle involved in this amendment is opposed to the doctrines of political economists, and the law of unfettered action of supply and demand, but he refuses to be frightened by the bugbear of socialism. It is purely permissive, and is actually based on a provision introduced ten years ago into the Duke of Westminster's re-settlement. In Lord Salisbury's words, "though the tenant for life may be perfectly willing to let the land for building workmen's dwellings upon it, and though it is for the public interest that he should do so, and every living man may desire that he should do so, yet he is forbidden by the Settled Lands Act to let the land for such purpose." Indeed, the section confers a power, it grants a greater liberty of contract, which cannot be said of recent land legislation in the sister island. Socialism as preached by certain political parties is antagonistic to property and destructive to Society; but socialism in another form underlies all co-operation, and is the principle on which some of the most successful commercial and manufacturing enterprises at home and abroad have been founded. Again, as Lord Salisbury

said in Committee on Monday night, "We only hear of *laissez faire* when it is a question of the State *giving* something, and very little when the State *takes* something." The State has given forcible possession to railway Companies, &c., of large areas on which a poor population formerly lived, compensating the owners of the houses, often little deserving of sympathy, but not the poor tenants driven by these improvements from house and home, and, what is still more important, driven to a distance from their work except on the condition of overcrowding neighbouring quarters. The State has done this, and it owes a debt of compensation to the poor; nay, more, the State, in one or other form, is a large, perhaps the largest, employer of labour in London; it has directly or indirectly drawn, or caused to be drawn thither, thousands of working men, and has thus, too, made itself responsible for much of the overcrowding. Why, then, as the Prime Minister asked, while landlords and large employers of labour regard it as a duty incumbent on them, not legally, indeed, but morally, to provide for the housing of their working people, is the State to be an exception to the rule?

---

#### THE REPORT OF THE ARMY MEDICAL DEPARTMENT FOR THE YEAR 1883.

---

##### [FIRST ARTICLE.]

WHEN noticing the Report for 1882, we commented on the special difficulties of Army Medical Officers, called upon to arrest preventable disease without being afforded due time for preparation, as must, indeed, always be the case to some extent when war suddenly breaks out in foreign countries. In that year the Egyptian Campaign upset all calculations and statistics, and Science was too late to prevent exceptional disease and mortality. In the Report for 1883, however, we find a record of the steady progress of sanitation in repairing damages, which is satisfactorily summed up as follows: "In Egypt the ratio per 1,000 of ordinary mortality is 14.93; this is considerably higher than the death-rate of the Mediterranean stations, and, compared with the three Presidencies of India, we find that the rate of mortality in Egypt is greater than that of Bengal by 4.76, than that of Madras by 5.70, and that of Bombay by 5.36 per 1,000. As, however, there has been continuous improvement in the health of the troops during the year, it may be confidently anticipated that the death-rate in succeeding years (apart from that due to epidemic influences) will be much lower than that registered for the year under report." We learn also that "the sanitary improvements in barracks and hospitals have been numerous and extensive, accommodation and ventilation have been improved, means for variety in cooking extended, facilities for ablution increased, and conservancy thoroughly supervised. These measures have undoubtedly conduced to the improved state of health which now exists among the troops."

But there are preventable diseases which cannot altogether be prevented by science for other reasons than want of time. We may take, for instance, some

cases of enteric fever, some of diphtheria, and some of malaria. Knowledge may do everything to make barracks healthy, but it cannot make some soldiers wise. We notice, for instance, in the report for 1883 "three cases of diphtheria and one death, and a case of diphtheritic paralysis are returned from Woolwich, where the disease also occurred to some extent among children; no insanitary condition in the vicinity of the barracks or quarters was discovered, but it is presumed the attacks may have originated by the men visiting dirty and insanitary parts of the town." At Limerick there were two cases, one being fatal. Here also "it is believed to have been contracted in a low street in the town, where it was known some cases existed." At the Mauritius we find that enteric fever broke out, and the medical officer says, "It is not thought that the disease originated within the barracks," but, "the men frequent low drinking shops, kept by Chinese, who probably often use very foul water in mixing their rum." Again, we find on looking over some reports from Nassau, that remittent and intermittent fever among the black troops, is due largely to the fact that the African soldier gets a night pass whenever he can, and passes his night in the unhealthy hovels of the dirty and immoral population of the island. There are also diseases where sanitation might do much good, but where it is warned off. Syphilis, for instance, seems to increase year by year, ever since tenderness for the liberty of the subject to be vicious prevented all restrictions upon indulgence, and overlooked all the dangers of a disease, which may become hereditary. In 1883 we learn, "The admission rate for all forms of venereal disease, including gonorrhœa and its sequelæ, amounts to 260.0 per 1,000, and the rate constantly sick from these affections to 18.54 per 1,000. Compared with the average rates of the four preceding years, the increase in the ratio of admission per 1,000 amounts to 30.1, and in the ratio of inefficiency through these diseases to 3.19 per 1,000." It is only wanting that mischievous legislation should make it optional with the soldier to be or not to be vaccinated, in order that small-pox might have as free play as syphilis. Among the recruits who presented themselves in 1883 it is curious to observe: "A decrease of 8.7 per 1,000 is observed among recruits bearing marks of vaccination, but an increase of 4.0 per 1,000 in those who had marks of small-pox, and one of 3.4 per 1,000 in those who had neither marks of small-pox or vaccination." We hope that vaccination may still be spared to the Army, for Science and Sanitation have already quite enough to do to keep the British soldier fit for his work. Service, we know, ages a man terribly, and the ratio of mortality per 1,000, which is so much in favour of the recruits when compared with civilians of their own age, fades rapidly away, and at 40 years of age the ratio of mortality among soldiers is double that of the civilian population. The rate of invaliding, too, tells its own story of the diseases that in the army have to be endured and combated. During 1883 1,857 men were so discharged, being in the annual ratio of 21.48 per 1,000. It is to be feared that a large proportion of these unfortunates will find it difficult to resume the battle of life in civilian employment.

The year 1883 was not unhealthy as regards the

troops serving in the United Kingdom. The ratio of admissions into hospital was 846.5 per 1,000, that of deaths 6.28, that of discharge by invaliding 21.48, and that of constant inefficiency through sickness 47.57 per 1,000. In comparison with similar rates for the average of the preceding ten years, a decrease is observed in the rates of prevalence, invaliding and mortality, but a slight increase in the rate of daily sickness. Enteric fever caused, in 1883, fewer admissions and deaths than in 1882; paroxysmal fevers were also less prevalent. Constitutional diseases were, in 1883, rather above the average of the preceding four years; and syphilis, as we have noticed, steadily increased. In the Sanitary Report for Home Stations we have to notice that, though defects are steadily brought before the authorities, the recommendations are not very promptly adopted. For instance, the Principal Medical Officer of the Chatham District remarks: "The Gravesend Hospital has been reported on unfavourably for several years, as being unsuitable both in construction and situation, but with the exception of small sanitary services and rectification of minor defects, nothing has been done. Plans for the erection of a new hospital are in course of preparation; a site has already been approved." Probably the delay has not been caused by indifference, but has been due to financial difficulties.

The total number of recruits inspected during the year was 59,436, of whom 35,841 were passed as fit, and 23,595 were rejected as unfit for the service. As compared with the previous year the total proportion passed was greater in 1883 by 27.78 per 1,000. As regards nationality, the proportion per 1,000 of recruits born in England and Wales was very high, they numbered 773 per 1,000; whilst Scotland gave but 91 and Ireland 125 per 1,000. The classes furnishing the recruits were much the same as in previous years. In every 1,000 inspected there were 605 labourers, 145 artisans, 158 mechanics, 54 shopmen and clerks, while professional men and students only numbered 11, and the balance were boys. The causes of rejection of 23,595 aspirants for glory were 42 in number. On looking them over it is impossible not to wonder why these men sought to serve in Her Majesty's Army, and still more how they hoped to do so? There were many under height, under weight, and under chest measurement; a large proportion had defective vision, and a goodly proportion had malformations of the spine. It is a strange satire on the boast that the British Army is a voluntary one, when so many who seek refuge in the ranks have apparently no choice between soldiering and starvation. We observe one cause for rejection that is unusual—three men were rejected as being over-height. When we remember that men of six feet and upwards were accepted, we are lost in wonder as to who these weak-kneed sons of Anak could have been? These unfortunate men must have envied the youths of short stature who were accepted as soldiers. The latter were rather too short perhaps, shorter than in previous years. We learn that out of 10,000 recruits there was an increase of 76 recruits *under* 5 feet 3 inches in height, one of 760 between 5 feet 3 inches and 5 feet 4 inches, and a decrease in all proportions among young men of more average stature. Taking the ages at which the greater

number of recruits are inspected, the highest proportion of recruits per 1,000 is between 18 and 19 years, and they boast of 33 and 34 inches chest measurement. Recruits have, we find, not been weighed by a large proportion of the medical men who enlisted them. We propose in another article to consider the effect of foreign service on our army in 1883.

---

#### SLIPS IN PRESCRIBING.

THE ordering of a tablespoonful in place of a teaspoonful, and, still more commonly, writing the symbol of an ounce for that of a drachm, has happened before now, and it will continue to be repeated from time to time so long as men continue to rely on the automatism of an oft-repeated action, and forget that the human automaton, although a very wonderful, is not an absolutely trustworthy machine. To prescribe the powerful extract of a drug notoriously uncertain in its strength in place of the same dose of the comparatively impotent "succus" is a more serious matter, since it indicates either ignorance of the physiological properties and doses of the medicine ordered, or such a degree of temporary mental abstraction as must necessarily be incompatible with the attention and exactitude which is properly looked for in a prescriber. Both of these mistakes were unfortunately illustrated in the course of an inquest lately held by Dr. Danford Thomas. A mixture, containing 5 grains bromide of potassium, 5 grains extr. conii, and 1 ounce of chloroform water, was ordered in tablespoonful doses for a child eight months old who was suffering from symptoms attributed to dentition. The chemist who dispensed the prescription told the parent not to give more than a teaspoonful, and that diluted. Six hours after the first and only dose the child died with convulsive movements of the arms and paralysis of the lower extremities. The *sectio* showed extensive cerebral effusion, and asphyxia as the immediate cause of death. The medical man who gave the prescription admitted the mistake in ordering doses of a tablespoonful instead of a teaspoonful, and also in writing extract for succus. The coroner's hope that such a mistake and its results would prove a lesson for life, will no doubt be realised by the person to whom it was immediately addressed. But the incident is also one which no member of the profession should feel too proud or self-confident to lay to heart; and it comprises warnings which others besides medical men will do well to ponder.

It is probable that prescribing suffers not a little from being spoken of and regarded more as an Art than as a Science. Art grows contemptible if she lags behind, and ugly and decrepit if she attempts to outstrip her sister Knowledge, with whom she should always march abreast. When one's chief attention is given to doing a thing nicely, there is always some risk lest it should not be done quite thoroughly. "Elegant pharmacy" is a catch-word of trade advertising. It is right to make our medicines as palatable and as sightly as possible, but to mere elegance we must never sacrifice either accuracy or efficiency. *Curare cito et jucunde* is right and proper enough, so long as we do not forget that *tuto* not only heads the triad of adverbs

which, theoretically at all events, governs our treatment of our patients, but that, rightly comprehended, it includes the meaning of them all. To prescribe no drug but with a definite and appropriate intention, and in the dose suitable to the occasion, is a broad foundation-stone of practical therapeutics. Adherence to such a rule would prevent the possibility of almost any serious mistake, even should a man feel urged to experiment with a preparation which he himself regards as "most unreliable in its action and as deserving to be expunged altogether from the pharmacopœia." It would not require more care to ensure that the medicine was ordered in appropriate doses. And to make assurance doubly sure, yet no more certain than is at all times desirable, it is an excellent rule *always* to read over the prescription once again after signing it. The value of this advice was frequently insisted upon by one of the most able and respected clinical teachers of a now rapidly passing generation, who once illustrated its importance by prescribing fifteen minims of hydrocyanic (instead of hydrochloric) acid in a single dose, being roused to a recognition of the mistake by his house-physician's suggestion that Scheele's preparation should not be dispensed.

The dispensing chemist is supposed to be, and should be, an additional safeguard to the patient against possible carelessness or mistake on the part of the doctor. But while it is intended that he shall be competent to detect errors in drugs and dosage, he was never intended to revise prescriptions, or thus invited to take upon himself the status and the onus of the prescriber. In the present instance it appears that the chemist not only suspected an error in the prescription which was brought to him, but was so impressed with its magnitude that he undertook the responsibility of correcting it, and accordingly directed that one teaspoonful only should be given to the patient in place of the tablespoonful ordered. Here he undoubtedly exceeded his province. Dr. Thomas did not put the matter too strongly when he said that it would "have been wiser," in such a case, to refuse to make up the prescription, at all events until after directing the prescriber's attention to the error which it was believed to contain. Had such a course been followed, disastrous results would have been avoided, and a lesson, less bitter but almost as emphatic, would still have been learned. A consideration of the whole subject supplies more than one argument on behalf of legitimate medicine, and, incidentally, against dispensing by medical men. The patient who consults a duly qualified practitioner, and who gets his prescription made up by a conscientious and reliable chemist, incurs the very minimum of risk from accident or error. Mortality is frail, and no medical man is more than mortal; but the typical dispensing chemist is a necessary complement, and may serve as a most efficient aid to the prescribing practitioner.

## CLINICAL PAPERS.

### XXIII.—THE CONSTRUCTION OF THE CEPHALOTRIBE.

THE qualities of a cephalotribe, and the skill of the operator who uses it, can only be tested by cases of the greater degrees of difficulty. In those in which the pelvis is but a little too small or the head but a little too large, cases, for instance, in which the conjugate diameter of the brim measures 3 or  $3\frac{1}{2}$  inches—a size of pelvis which will admit the passage of a small child, but not of a large one—delivery is quite easy when once the head has been perforated; and the use of any form of cephalotribe, craniotomy forceps, cranio-clast, basilyst, transforateur, forceps-saw, ecraseur, or any of the numerous instruments that have been devised for diminishing the size of head, will be followed by a successful result. Cases of this kind are no test either of instrument or operator. The advantage of any particular form of cephalotribe can only be estimated by trial in a difficult case; that is, a pelvis with a conjugate of  $2\frac{1}{4}$  inches or less. In such a case, success or failure may depend upon whether the instrument used is a good one or not. Judgment upon the merits of an instrument even after trial in a case or cases of real difficulty in delivery of the perforated head (and such cases are not common), is not a very simple matter; for the result effected by an instrument depends much upon the skill with which it is used. Skill comes by practice; and therefore any obstetrician will naturally be more skilful in the handling of an instrument he is accustomed to, than with one which is novel to him. The opinions of persons without much experience in difficult midwifery are on such a matter worth little; and the conclusions of those who have had such experience must be taken with due allowance for the natural bias in favour of the instrument, whichever it be, which practice has enabled them to use dexterously.

It is not creditable to obstetric science that cases should so often occur in which, after long but unsuccessful attempts to deliver with forceps, the use of the cephalotribe should be resorted to. If our knowledge of the factors of the mechanical problem in each case were complete, it ought to be possible to make an accurate estimate of what is practicable in each case; to say at once, "in this case delivery can be effected with forceps," or, "here the cephalotribe is necessary," without wasting time, causing suffering to the patient, exhausting her strength, and bruising and perhaps lacerating the parts, in vain attempts to accomplish that which is at length found impossible. But cases of this kind are no disgrace to individual practitioners, because we have no means at present of exactly estimating before delivery some of the most important elements in the problem, although they show how imperfect obstetric science is. The suitability of a case for forceps delivery depends upon the size of the pelvis, the size of the head, its degree of ossification and consequent hardness, its position, and the power of the expulsive forces. During labour, we can only approximately judge of these

---

MURCHISON MEMORIAL SCHOLARSHIP IN CLINICAL MEDICINE.—In the competition held at Edinburgh for the above scholarship, the first place has been gained by Joseph Griffiths, University of Edinburgh; *proxime accessit*, S. Plowman, St Thomas's Hospital, London.

points, with the exception of the position of the head ; and therefore there must be cases in which we cannot say that forceps delivery is impossible until an attempt has been made. But in all cases in which it is proper to make such an attempt, delivery by the cephalotribe is quite easy, even with a very imperfect instrument.

The modifications of the cephalotribe are very numerous ; and it is quite profitless to consider each in detail. For ordinary purposes we believe none is better than that of Dr. Braxton Hicks ; an instrument, which, like everything that this distinguished obstetrician has put before the profession, has been devised with knowledge derived from ample experience, and tested in practice. A good way of considering the construction of the cephalotribe will be to examine Hicks's instrument, and the modifications that others, mostly of less experience, knowledge and scientific acumen, have suggested.

The instrument is made in two parts, each consisting of one piece of steel ; and after the instrument has been applied, a screw is added. In each piece we have to examine handle, lock, and blade. The length of the instrument is  $15\frac{1}{4}$  inches. A shorter instrument is not long enough to reach the head when above the brim, and a longer one is unnecessarily cumbersome.

The first necessity of the instrument is that it should be strong, capable of *crushing* the head. Therefore, any yielding of the blades is an imperfection ; to crush the head they must be rigid. In some cephalotribes the blades have been fenestrated. This impairs the efficiency of the instrument by weakening it. A fenestrated blade is also generally made wider than a solid blade, and thus a larger piece of the skull is enclosed between the blades, and the resistance to crushing is increased. As weakening the instrument, and as widening the blades and therefore increasing the work thrown on the weakened blades, the fenestration is to be condemned. And it is absolutely useless, being introduced only for the purpose of lightening the instrument, which of course means weakening it. This cephalotribe, when closed, measures  $1\frac{1}{2}$  inches across the blades. It ought, when screwed home with the foetal head in its grip, to measure the same, and therefore will be able to draw the head through a pelvic brim measuring  $1\frac{3}{4}$  inches or even  $1\frac{5}{8}$  inches in the bony conjugate. A little margin must of course be allowed for the soft parts. If the instrument yield, it will not compress the head to this extent. A cephalotribe which yields is a useless instrument.

It is needful that the cephalotribe should grasp, as well as crush. Without some provision for this, it would be possible for the instrument to slip off when applied. This is secured in Hicks's, and in other good instruments, by curving in the upper ends of the blades, so that, when closed, these ends are in contact. Thus slipping, after the instrument is once screwed home, is impossible. Inventors have introduced various kinds of projections—studs, spikes, and the like—on the inner aspect of the blades, with a view of preventing slipping. They are quite unnecessary, and are objectionable because they make the introduction of the instrument difficult. The spikes or studs are apt to catch in the soft parts of the foetus, and prevent

the blade from slipping as easily into place as it should do. The way to prevent the cephalotribe from slipping during extraction is to screw it home ; and the way to prevent it from slipping during compression is to apply it to one of the greatest diameters of the head globe : to seize the head fairly in the middle. If it be not seized in its greatest diameter, it will slip from the instrument as soon as compression is begun.

The blades of Hicks's instrument measure about an inch across. This is quite wide enough. They are lightened by two longitudinal grooves on the inner surface, between which a median rib gives the necessary strength. The thickness of the blade at the situation of this central rib is about  $\frac{1}{4}$  of an inch. The rib is slightly serrated, but the serrations are not large or sharp enough to oppose its easy introduction. The blades have a slight pelvic curve, which enables them to be got into position on either side of the head with less backward pressure on the perineum than if they were straight. Any considerable pelvic curve is a disadvantage, because, when the head has been crushed, and the time for extraction has come, the first thing to be done is to turn the instrument round through a quarter of a circle, so as to get the crushed part opposite the narrow diameter of the brim. Remembering this necessary rotation, some obstetricians have made their cephalotribe straight. But a slight pelvic curve does not make extraction more difficult, and makes introduction more easy. As the head, when the time to extract comes, has been crushed quite out of its original shape, and the bones which kept it in that shape have been so broken up that they can be bent this way or that with ease, there is no longer any nice adaptation of the head to the pelvis in its passage through it. The normal mechanism no longer exists. Appliances for "axis-traction" are quite superfluous. The only rule is to pull in the direction in which traction seems to be accompanied by the greatest onward movement of the head. If pulling one way produces no advance, pull in the opposite ; remembering only to keep the diameter in which the crushing has been done in relation to the narrow part of the brim.

The lock employed is the English forceps lock ; one which is easier of adjustment than any other, and more easily cleaned. It will keep the blades opposite to one another, and that is all that is wanted. The French lock (button and slit) is more difficult to adjust, more difficult to clean, and has no counterbalancing advantage. To lock the blades with the French lock, the adjustment of the blades to one another must be very exact. Moreover, the French lock consists of a button-like pivot on the one blade which fits into a slit in the other blade. When the instrument is used to compress the head, it will be obvious that its blades act as a double lever, the weight being the head to be compressed, the power the compressing force in the handles, and the fulcrum this pivot. This fulcrum, therefore, must be strong enough to withstand the whole of the force used ; and in many instruments it is not strong enough. Dr. Matthews Duncan, in experimenting with the cephalotribe, found once that the pivot did break. Now, in the English lock, the levers have for their fulcrum the

whole thickness of the blades. Thus, in ease of application, and in strength, the English lock is better than the French; and in addition, it is more easily cleaned.

The remaining part to be considered is the compressing apparatus. The handles are roughened outside, grooved inside, to lighten them, and fitted at the end with a screw by which they can be approximated. In some instruments this screw is separate from the rest of the instrument, in others attached to it by a hinge. Each of these arrangements has its own advantages. If attached to the blade the screw cannot be mislaid, drop on the floor, or get hidden under bed-clothes. On the other hand, it makes the blade to which it is fastened more cumbersome to handle, and a little more awkward to pack in the obstetric bag; while the additional joint is a part difficult to keep clean. For the purpose of rotation the head of the screw is sometimes provided with three projecting spokes, like a capstan, sometimes with a simple bar, which only gives two limbs. The latter has the advantage that it packs more conveniently.

## REVIEWS AND NOTICES OF BOOKS.

*Abstracts of some of the Medical and Surgical Cases treated at the General Hospital for Sick Children, Pendlebury, Manchester, during 1884.* Edited by H. ASHBY, M.D., H. R. HUTTON, M.B., and G. A. WRIGHT. Manchester: J. E. Cornish, 1885.—Like its predecessors this volume is thoroughly practical, and as the authors plunge at once *in medias res* we shall do the same. The first report is by Dr. Ashby, on the cases of scarlet fever, for be it noted that, contrary to the usage of most children's hospitals if not indeed of all, at Pendlebury they admit cases of scarlet fever from without into a special ward; whereas some of our London hospitals do not even undertake the treatment of such cases as break out in their own wards, but transfer the children at once to the nearest fever hospital. The objection that is always raised to a special ward for the admission of these cases is the danger of the fever spreading to the general wards; it would be very interesting if we could compare the results in this connection between Manchester and one of our own hospitals, but unfortunately there are no reliable statistics. So far as we can judge, the experience of Manchester would seem to teach that the risk of introducing scarlet fever into the hospital can be reduced to a minimum, for only fifteen cases seem to have broken out in the general wards during the year, and we doubt whether any of our own hospitals could show a cleaner bill in proportion to the number of patients. The total number of scarlet fever cases was 225, of which 30 proved fatal; the number of cases of nephritis occurring in children who entered the hospital at the commencement of their illness is larger than we should have been prepared to expect, but doubtless in this, as in so many other cases, the particular character of the epidemic ought to be taken into consideration. Dr. Hutton analyses the 39 cases of typhoid fever that were treated during the year: there were three deaths, in two however not due directly to the disease. The most noteworthy point about them was that in only three cases was a relapse observed. Only thirteen cases of diphtheria were admitted, of which seven proved fatal and one was followed by facial paralysis; besides this we find no mention of diphtheritic paralysis, another point in which their experience differs very much from that of London. There is another table containing an analysis of 48 cases of croupous pneumonia, all terminating in recovery. We cannot but feel that, in the absence of *post-mortem* evidence, these statistics should be received with some caution; we have

been accustomed to consider croupous pneumonia as a very rare occurrence, especially in young children, and catarrhal pneumonia may, as is well known, give all the physical signs usually found in the other form; we therefore feel very doubtful whether all the cases in this table are rightly grouped. In the fatal cases of tuberculosis we find no mention of the condition of the choroid as regards tubercles, and we would venture to suggest a more systematic search for them in the future. Turning to the surgical portion of the report, we find that Mr. Wright has six times performed the operation for the radical cure of hernia, in one of which he took the opportunity to remove some caseous mesenteric glands; one case terminated fatally, in the others the result was satisfactory. There were twenty cases of excision of the hip and two of amputation at the hip joint; the knee joint was excised in eight cases. Five cases required tracheotomy. Altogether the report contains a large amount of most interesting matter, and if we have ventured to find fault at all, it must not be forgotten that we have a great deal more reason to find fault with the London institutions for not having followed the very excellent example which Dr. Ashby and his colleagues have been setting them for the last four years.

*The Medico-Legal Journal*, Vol. iii., No. 1; published by the Medico-Legal Journal Association, 128, Broadway, New York.—A rather rough portrait of the late Dr. Alfred Swaine Taylor accompanies this number, and a very brief sketch of his life is given signed with the well-known initials T. S. Mr. Clark Bell, the editor of the journal and Ex-President of the Medico-Legal Society of New York, contributes a paper, "Shall we hang the Insane who commit Homicide?" It is based on the case of Dr. L. U. Beach, who was lately executed for the murder of his wife under circumstances which could leave no doubt in the mind of an expert as to his insanity. The aim and object of the paper is to obtain some alteration of the law on the subject in Pennsylvania. Dr. Ira Russell has a paper on the causes of and remedy for the increase of insanity, which is followed by some communications relating to lunacy legislation in Illinois. In the next paper Dr. Savage discusses the question of insanity as a plea for divorce or nullity. As to the first part, the question of divorce from a partner who has become insane since the marriage, we shall probably all agree with him in thinking that this would be most undesirable, and especially so in respect of determining that in any given case the insanity is incurable. He believes that there will come a time when divorce will be possible in the case of a marriage during one of the lucid intervals of a person subject to recurring attacks of insanity, provided that the fact of the insanity was unknown to the other party at the time of the marriage, the reason being that he was not in possession of all the facts at the time of entering into the contract; just in the same way as any other contract would be void if vital facts affecting it were concealed by the one contracting party from the other. As regards the granting a decree of nullity on account of insanity, Dr. Savage cites three recent cases in which the husband applied for such a decree, one of them being the Durham trial. The same difficulty arose in each of them, and, indeed, in two proved too great to be overcome by the plaintiff, viz., the proving that at the time of the marriage the bride was insane and did not know the nature of the contract. Dr. Savage believes that it is quite possible that the insanity should pass unrecognised during courtship, to become more developed after marriage, but he admits that there are great difficulties in the way of proving the insanity medically, and is therefore content to leave the definition of incapacity to the lawyers. This number contains the report of the Committee on canned goods to the effect that it does not find that the present system of canning goods is either careless, incompetent, or dangerous to life; the Committee further expressed its approval of the statute recently passed ordering manufacturers of canned goods to put their names upon their products.

*Contributions to the Topographical and Sectional Anatomy of the Female Pelvis*; by D. BERRY HART, M.D., F.R.C.P.E. Edinburgh and London: W. & A. K.

Johnston, 1885.—Dr. Berry Hart and his publishers deserve the warm thanks of every anatomist, gynæcologist and surgeon for this new contribution to our knowledge of the pelvic anatomy of women. The present series of admirably executed plates may be regarded as supplementary to the magnificent Atlas of Female Pelvic Anatomy (same author and publishers) which we reviewed some months ago, and they will no doubt help to clear up many points which have hitherto remained somewhat obscure, in respect to the position and relation of the ovaries, the boundaries of the ischio-rectal fossa, the structural anatomy of the pelvic floor, and the relations of the ureters. The plates represent the appearances of frozen sections of the female pelvis taken in various new directions. Most of the plates are taken from what Dr. Hart terms axial coronal sections, *i.e.*, sections made through the pelvis parallel to the axis and transverse diameter of the brim, though the earlier and not the least important plates represent sagittal or vertical sections. In the letter-press which accompanies them, Dr. Hart not only describes the sections, but gives concisely the practical lessons to be derived from their study. The most important of these relate to the structure and functions of the pelvic floor, a subject in respect to which Dr. Hart was already recognised as an authority. The deductions which he draws from his anatomical studies have an important practical bearing, not only on the physiology of labour, but also on the pathology of uterine prolapse, in the production of which he shows that rupture of the perinæum is not such a predominant factor as is usually assumed. He further, by settling the relations of the ureters, makes a valuable contribution to the anatomical knowledge necessary for the safe removal of the entire uterus *per vaginam* for carcinoma of the cervix. As the ureters are situated an inch from the side of the vaginal portion of the cervix and the same distance from the side of the uterus, they could only be injured by a very free use of the knife. Altogether the present atlas will do much to enhance the reputation of Dr. Hart, and of the school in which he is one of the most original workers.

*Lectures on Diseases and Injuries of the Ear*; by W. B. DALBY, F.R.C.S., M.B. Cantab. Third Edition. London: J. & A. Churchill.—Mr. Dalby has greatly increased the value of this edition of his work by adding a chapter on *Adenoid Growths*. Considering the important relations these growths hold to catarrh of the middle ear, it has always surprised us that the author should have omitted some account of them in previous editions of his book. In discussing *purulent catarrh* of the middle ear, Mr. Dalby writes: "At one time I, in common with most other surgeons, was in the habit of ordering solutions containing some mineral astringent, such as sulphate of zinc. For many years past I have discontinued this practice, as experience has taught me that mineral astringents are not advisable, for although their employment will be found for a time to diminish the discharge, it will return in a short time after they are discontinued. Moreover, the hearing power does not receive permanent benefit from such treatment; indeed, the reverse of this is the case." Putting aside the fact that a discharge which is only diminished, but not stopped, can hardly be said to *return*, we question whether there are many, if there are any, aural surgeons who would endorse these opinions. However, putting aside a few dogmatic statements, like the above, scattered through its pages, the work is really a valuable one, and might be made more valuable still if Mr. Dalby would omit many of the cases described, which are of very little, if any, value to the reader, and devote the space thus obtained to a fuller account of treatment.

*The Essentials of Histology, Descriptive and Practical, for the Use of Students*; by E. A. SCHÄFER, F.R.S. London: Longmans, Green & Co., pp. 245.—This new text book of Histology, by Professor Schäfer, may perhaps be regarded as a condensation of the author's course of Practical Histology. Though it is chiefly intended for the use of medical students, it aims, without descending to details, at giving all the more important facts of Histology, so that it

will also be found extremely useful by those teachers who are proposing to give a course of histological demonstrations. The fact, too, that the book not only furnishes descriptions of the tissues and directions for their microscopical examination, but is divided into forty-two lessons, each of which is supposed to afford occupation for from one to three hours, is another merit from the teacher's point of view. We notice that the author does not make any new departures, but relies entirely on those methods which have been found in the past to give satisfactory results. With regard to the text itself, we may say that, coming as it does from a teacher of large experience, and only containing well-settled facts, it would be quite superfluous for us to point out the merits of this elementary Text-book of Histology. Indeed, it may be taken for granted that the textual portion is perfectly effective, while additional explanation is furnished through the eye by suitable and sufficient illustrations. At the end of the volume is an appendix which contains details as to hardening, preserving, staining solutions, etc. The table containing a list of the various tissues and organs with their appropriate hardening fluid will be found especially convenient. The book is extremely well got up. The plates, some specially designed for this work, most taken from the author's course of Practical Histology and Quain's Anatomy, are both numerous and excellent.

*Manual of the Antiseptic Treatment of Wounds for Students and Practitioners*; by W. WATSON CHEYNE, M.B., F.R.C.S. London. Smith, Elder & Co., 1885.—At last we have an authoritative manual of Lister's method of treating wounds from a distinguished pupil of the great antiseptic surgeon. We have often called attention to the want of such a work in this country. Germany and France have each long since had popular manuals for the use of students and practitioners, so that those whose hospital experience and training had been deficient in this respect, might have the means of remedying their shortcomings. We welcome the present volume therefore with a "better late than never," and recommend its careful study to every house surgeon and dresser. Whether he believe the germ theory of disease and putrefaction or not, the student will find a clear and brief statement of the methods of dressing wounds as practised by a distinguished surgeon of large and varied experience; and whether he decides to follow the rules given or not, the careful perusal of the little book before us can hardly fail to prove instructive. The chapters include—repair and dangers of wounds, the nature, life-history, and destruction of bacteria, aseptic surgery and antiseptic surgery. The book is well illustrated, special dressings, as applied to different regions of the body, coming in for a full share. Although there are points to which we cannot give unqualified adhesion, we refrain from criticism, for the book owes its chief value to the fact that it is the practice, and probably the teaching, of a single individual rather than a general text-book.

*On some Common Injuries to Limbs, their Treatment and after Treatment, including Bone-setting (so-called)*; by EDWARD COTTERELL, M.R.C.S. London: H. K. Lewis, 1885, pp. 108.—A neatly published little work, in which the author, a late house surgeon of University College Hospital, desires "to draw more attention than is generally given to the after treatment of injuries, and more especially to those injuries occurring in the extremities." In support of this view, Mr. Cotterell quotes the now hackneyed cases in which bone-setters have been successful, after the first surgical authorities have failed to give relief to an injured joint. Certain it is that the iteration of such sound doctrine can do no harm; whether, however, it is now necessary must of course be a matter of personal experience, and this will naturally vary with the opportunities and the methods of practice of the observer. We think that the profession are now about as alive to their former shortcomings as they are ever likely to be, and that surgical teachers, one and all, inculcate careful treatment in all these obscure cases. "Bone-setting" so

called is extensively advocated and practised now, since Wharton Hood's very instructive little book appeared, and there are few surgeons who, if called in to see a patient with a stiff or painful joint after an accident, would not try careful manipulation under an anæsthetic, and so accomplish all that which the old bone-setters used to accomplish. Mr. Cotterell's book is an interesting summary of curious old cases, and contains useful hints as to what should be done by the surgeon under similar circumstances.

*Endemic Goitre or Thyrocele, including its relations to Cretinism and Allied Disorders*; by Dr. WILLIAM ROBINSON. J. & A. Churchill: London, 1885.—This monograph is the thesis for the degree of Doctor of Medicine of the University of Durham for which the gold medal of the year was awarded. It is an admirable specimen of what such a thesis should be. Dealing, as it does, with a disease which is at present attracting a great deal of attention, it includes some personally observed cases, it gives a good summary of other recorded work on allied topics, while the subject matter itself is discussed from almost every possible standpoint—history, clinical characters, pathological characters, relation to cretinism and allied disorders, ætiology, distribution, diagnosis, and, finally, treatment. The English reader will here find, in his own language, a full account of the operative treatment extracted from many different sources; Koch's remarkable experience is carefully summarised, and the views of other German operators are also given. We confess to a little surprise, under the circumstances, that the author gives such full details concerning the removal of the gland; if cachexia strumapiva is possible as a sequela after removal of the gland, and of this there can now be no doubt, the operation for complete removal of the gland should be at once given up even in the case of very old people, the more so, as it is asserted on competent authority, that division or partial removal of the isthmus answers all the purposes of complete extirpation.

## ABSTRACTS AND EXTRACTS.

### THE AMERICAN MEDICAL PRESS ON THE PROSPECTS OF THE WASHINGTON CONGRESS.

The *New York Medical Journal*, in an article entitled "The Rump Congress of 1887," writes, "It looks very much as if the part of Hamlet would be left out at Washington in 1887, for our foreign colleagues will in all probability decide not to cross the Atlantic in any great numbers for the pleasure of meeting the rump of the American profession. And all this disgrace is the logical outcome of the false and artificial issues which for the past three years have enabled men in no way representative of the profession to masquerade as its leaders, through the medium of that degenerate and utterly ridiculous concern the American Medical Association. That organization long ago ceased to work for the benefit of the profession, and for a number of years past its annual meetings have been little more than scenes of the most shameless intrigue and demagogism. . . . That the wreck of the Congress of 1887 has not been irretrievably wrought we can now see no reason to hope. It is, of course, not to be supposed that the Congress will formally reconsider its acceptance of the invitation extended to it by the American profession, but the conclusion can scarcely be avoided, nevertheless, that the European members who would add lustre to the gathering will individually make up their minds not to attend the meeting, and it will simply go by default."

The *Philadelphia Medical News* says, "It seems clear that the meeting in 1887 is to be an International Congress in name only, and that it is really to be a very large meeting of the American Medical Association, and that the vastly larger body of the medical profession of the United States is to be excluded. What the result will be it is premature as yet to conjecture; but we fear that, under the circum-

stances, a number of distinguished men, both at home and abroad, whom it was hoped would be present and take part in the work, will not attend. The management of the matter has passed into the hands of a very different set of men from those who had charge of it at the outset, and the question whether any of the original Committee of eight, or of those who were added to them to form the enlarged Committee which did the work which the new Committee have just condemned and set aside, should consent to accept office under the new régime, demands serious consideration. From present appearances it looks as if there would be but little, if any, difference of opinion upon this point."

The *Medical Age* (Detroit) thinks that the American Medical Association has done a great injury to the profession in the United States, of which it only forms a fraction, by making it appear in the eyes of Europe as a quarrelling querulous agglomeration.

The *Kansas City Medical Record* says, "Judging the whole matter from an unprejudiced standpoint—although some features may savour of suspicion—we think the committee acted in the best interests of the medical profession, and we are pretty certain that the auxiliary committee of thirty-five will not undo any of the work of the original committee, but will lend their good counsel towards perfecting the work already begun, of making the Congress highly creditable to the medical profession of the United States. To this end we hope they will work in perfect peace and harmony."

The *Columbus Medical Journal* explains the origin of the rupture in the following characteristic manner: "The Committee had made no provision for the eloquent champion of the pap-chewing mothers of Texas; they had ignored the oleates; they had not tested all their appointees by the *shibboleth* of the Code; they had not given the 'rural destricts' their *numerical* ratio of the offices; whole States and Territories were entirely ignored; even Ohio had but fourteen, and of these her metropolis had all but one, while New York, Philadelphia, and Boston were liberally remembered. And so there was a kick. And so it was decided to increase the size of the Committee, and otherwise so arrange matters that the ranches of Texas, the prairies of Kansas, the mines of Colorado, and the forests and wheat fields of the great North-west should all be 'represented' among the officers of this Congress."

### THE LABORATORIES OF PROFESSORS MIGUEL AND PASTEUR.

DR. STERNBERG, of the American army, the well-known micropathologist, having been appointed a delegate of the American Government to the late International Sanitary Conference at Rome, took the opportunity of paying *en route* visits to the laboratories of MM. Miguel and Pasteur, of which he gives a pleasant account in the *Philadelphia Medical News* for June 6th and 13th. He visited Dr. Miguel at the Observatory at Montsouris, near Paris, and had full opportunity of learning the results of his elaborate researches on the minute organisms of the atmosphere. These Dr. Sternberg considers as highly interesting and of considerable scientific value; but patient and conscientious as they have been, he cannot regard either them, or those of other observers who have preceded him in such enquiries, as having been fruitful in practical results. *A priori* it would seem that the presence of disease germs should, by a carefully-made research, be demonstrable in an "infected atmosphere." But, as a matter of fact, no disease-germ has been discovered by this method, and all exact knowledge of pathogenic organisms which we now possess has been obtained by seeking them in the tissues, fluids, and excretions of infected individuals. At the commencement of his bacteriological studies in the Havana, in 1879, Dr. Sternberg had taken great pains in the attempt to discover the "germ" of yellow-fever, but without arriving at any satisfactory result; and in 1880 he examined the atmospheres of streets, hospitals, cemeteries, sewers, &c., of New Orleans, with no better effect. These examinations are, in fact, difficult from complications and possibility of errors, as the organisms are in a great

measure only accidentally present in the atmosphere, which is not their normal habitat, and their presence in which is much dependent on the amount and direction of the winds. "I would not have it understood that I under-estimate the value of such researches. This is comparable with that of carefully-made meteorological observations relating to temperature, pressure, direction of the wind, &c. But, in my opinion, altogether too much has been expected from studies of this kind by those who are especially interested in pathological and sanitary questions. Miguel admits that it is impossible by the microscope alone to distinguish with certainty the germs of bacteria present in the atmosphere, from certain non-living particles associated with them; and that it is only by culture-methods that they can be distinguished and enumerated with any degree of precision." In a well-equipped laboratory like M. Miguel's, and at the expenditure of an enormous amount of time and labour, one may make a complete biological analysis of the atmosphere of a given locality, together with the diurnal variations of the number of living bacterial germs, &c., present. M. Miguel's method consists in aspirating a given quantity of air through a tube provided with a filter of sterilized cotton, in washing the germs from this filter with distilled water, and in adding this to a sterilized culture-medium, which is distributed in a large number of germ-proof receptacles. The number of germs in the quantity of air passed through the filter is determined by the number of their cultures which are fertilized. When only two or three out of 20 tubes, for example, break down, it is assumed that these have each been fertilized by a single germ, and this is taken as a basis of a calculation of the number of germs per cubic metre of the air examined. If, however, a majority of the tubes break down, it may be that several germs have been introduced into each, and it will be necessary to repeat the experiment and to distribute the germs trapped by the cotton filter in a larger amount of fluid, distributed in a greater number of separate receptacles. The interesting and valuable series of experiments made by Miguel to determine the antiseptic value of various chemical agents, was terminated some time ago, and the results are published in the report of the Observatory for 1884." M. Miguel has recently found a highly-useful material culture in a jelly prepared from the *fucus crispus* digested in a bouillon, producing an excellent medium for bacteria of various kinds. Miguel is still a young man, about 35, and with his robust constitution, enthusiasm, mechanical skill, and indefatigable perseverance, he will, no doubt, do all that one man can do in a single locality for the advancement of that branch of science—Aëroscopy—which he has made his own specialty, and in which he is at present beyond question the highest authority." Dr. Sternberg, on his visit to Pasteur's extensive laboratory at Paris, endeavoured to ascertain whether the swine-plague, which Dr. Salmon some years ago found in the United States to be due to a micrococcus, is identical with the *rouget* or swine-disease attributed by Pasteur to an extremely minute bacillus, and he believes their identity to be real. "Pasteur," he says, "has not only demonstrated the ætiological relation of his microbe to the disease *rouget*, but has succeeded in producing an attenuated virus which is now offered for sale by an agent whose place of business is in the immediate vicinity, and who obtains his stock-in-trade from the laboratory of the famous chemist. The assortment of attenuated virus now offered for sale at his establishment is limited to three diseases, viz., anthrax, chicken-cholera, and *rouget*, or swine-plague. The price of the "anthrax vaccine," sent free in tubes, is a tube for 25 oxen or 50 sheep, first vaccine 2½ frs., second vaccine 2½ frs., total 5 frs. The demand for this is constantly increasing, and according to Pasteur, the mortality from anthrax in central sections has been reduced from 10 or 20 per cent. to less than one per 1,000. The number of sheep vaccinated during 1884 in France alone was 516,553, and of cattle 33,906 . . . . . Pasteur is still engaged in his studies on hydrophobia. His experimental inoculations are made on the extended scale so desirable in researches of this nature, and which the liberal policy of the French Government enables him to follow. His arrangements for keeping animals for experimental purposes are admirable, and he showed me with pride the well-made iron cases for dogs, the hutches for rabbits, and the yards

for fowls—all kept in perfect order and well-stocked with animals. Having succeeded in transmitting hydrophobia by inoculations upon the surface of the brain, by trephining with virus from the nervous centres of an animal recently dead of the disease, and in attaining an attenuated virus which produces a non-fatal form of the disease, by which the animal is protected from subsequent attacks, Pasteur's next object is to ascertain whether protective inoculation may be successfully practised after an animal has been bitten by a rabid dog. His experiments lead him to believe that this is practicable, and the test is being tried at the present time. The curious part about these experiments relating to hydrophobia is, that while the nervous tissue has been proved to contain the virus, which by inoculation gives rise to the disease, the exact nature of this virus has not been determined. No microbe has as yet been discovered, and all attempts to obtain culture of the germ, which Pasteur assumes must be present in this material, have thus far failed. In reply to a question, Pasteur informed me that he had not been able to recognize microscopically any difference between healthy brain-substance and that which, coming from an animal recently dead of hydrophobia, is capable of reproducing the disease. I enquired whether there was any truth in the report that Pasteur had been about to visit Brazil for the purpose of investigating yellow fever, and was informed by him that he had not entertained the idea of undertaking such an investigation, although invited by the Emperor of Brazil to do so. He has very little confidence in the alleged discoveries of Dr. Freire, and stated that the Emperor himself was very incredulous as to their scientific value. I may say that in a letter from Dr. Koch which I received, a similar want of confidence was expressed. My own views with reference to Dr. Freire's methods and reputed discoveries are in conformity with those of the high authorities above-named, and have been on record for more than a year. Pasteur is a vigorous and well-preserved man notwithstanding his 60 years and the attack of hemiplegia from which he suffered 18 months since. There is still some paralysis of the muscles of the left leg, and he is obliged to go up and down stairs with caution, but did not show any indications of fatigue from the extended trip which we made together through the laboratory and the yards in which his animals are kept, which are two or three squares distant from it."

---

A NEW THEORY OF PROTECTIVE IMMUNITY.—Dr. William Peuny contributes to the *New York Medical Journal*, June 20th, a theory in explanation of the limitation of certain febrile diseases to single attacks. He adduces the experience of Dr. Carmona y Valle, who is now engaged in inoculating for yellow fever at Vera Cruz. This gentleman having occasion to examine the urine of a number of persons who had suffered from yellow fever several years before, found the peculiar micro-organism which he had named *Peronospora lutea* in every instance; in one patient (then under treatment for some ocular trouble) ten years had elapsed since the attack of yellow fever. This is considered to prove that the specific microbia may exist in the body for an indefinite time after recovery from yellow fever, without producing morbid phenomena, and that immunity from subsequent attacks is due to their continued presence in the body. Dr. Peuny, therefore, supposes that the first introduced colony of pathogenic bacteria, finding a vast quantity of nutritive material, and under the stimulus of a regular temperature, reproduce themselves with exceeding rapidity, and after contaminating the fluids of the body with their secretions, perish. "The death of these countless myriads of bacteria is in all probability the cause of the febrile paroxysm." We may also infer that the febrile paroxysm destroys the power of sexual reproduction in those that survive. These survivors, while, therefore, not multiplying so rapidly as to produce subsequent attacks of the disease, "would by their presence so alter the chemical condition of the body as to prevent a new invasion from taking place;" and thus, sufficient numbers might still remain to protect the individual, "but not to make the individual a source of

infection to others." This theory is advanced only as a working hypothesis applicable to that class of diseases whose phenomena are usually constant, which have a definite stage of incubation, which culminate in a febrile paroxysm, and of which one attack is usually protective.

**INTRA-PULMONARY INJECTIONS.**—Dr. Wendell C. Phillips publishes two cases (*New York Medical Journal*, June 28th) in which this treatment was resorted to. In the first patient, who was in the third stage of consumption, a single injection of ten drops of dilute Lugol's (iodine) solution was made in the third intercostal space two days before his death. Although life was probably not prolonged, the dyspnoea and severe muscular pain were so much relieved that the patient was no longer compelled to sit up in bed, and his remaining hours were rendered much more endurable. The second patient, a widow, æt. 50, with phthisical symptoms of some six years' duration, was considerably benefited by five injections made at intervals of a few days; "her cough is now much less troublesome, and no longer causes vomiting; she is able to go upstairs more easily, and performs her work with less fatigue." Dr. Phillips uses an ordinary hypodermic syringe, thrusting his needle to its full depth of one-and-a-half inches in the nipple line, and usually in the third interspace. The injections can be safely made high up in the axillary region in the first, second or third interspace, the arm being held at right angles to the body. Pain is usually trifling; but occasionally a severe paroxysm of coughing supervenes, and iodine is at once tasted in the mouth (when the fluid has been thrown directly into a bronchus?). In the same journal Dr. A. H. Smith gives the case of a coloured patient who had been under observation for eight weeks. His weight had been taken every week, and the temperature, sputa, &c., had been noted for a considerable time previous to the commencement of the injections. Lugol's solution diluted with five times its bulk of water was used; and of this five minims, gradually increased to eight or nine, were injected every three hours. The patient tasted the iodine as soon as he coughed after the injection. The injections, which constituted the only change in the previous treatment, had been continued for two weeks, and his weight had increased three pounds and a quarter; the sputa had also become less purulent and tenacious, and were expectorated with greater ease.

**PROSTATIC MASSAGE IN RETENTION OF URINE.**—Dr. J. M. C. E. Le Rütte, of 's Gravenhage, writing in the *Weekblad*, recommends massage of the prostate in cases of retention of urine from its enlargement. The operation is performed by introducing the forefinger into the anus, and moving the prostate three times to the right, three times to the left, three times longitudinally, and then rubbing the surface. This proceeding causes some discomfort to the patient and cannot be long borne. A gentleman above 50 years of age, who for a year had found increasing difficulty in passing water, was seized with complete retention. Neither soft nor metallic catheters could be passed. Nelaton's bougie was, however, introduced, and a great quantity of urine drawn off. A large prostate was felt per anum. After twenty massages with warm bathing every evening, he regained the power of passing water normally, and he has now had no difficulty for two years. A gentleman aged 70 suffered in the same way. After fifteen massages a cure was effected, and the patient continues well. With both patients the massage caused some hæmorrhage from the prostate into the urethra which an iron mixture was found quite sufficient to stop.

**INTRA-UTERINE MEDICATION.**—In an article on this subject in the *Canada Lancet* for July, Dr. Algernon Temple says that nitric acid is the strongest of all the remedies, and should only be used for certain diseases; it is especially useful in the treatment of uterine fungosities, that sometimes obstinate disease to treat. The application of this remedy to the uterine cavity is not painful, nor has he seen any bad results ever follow its use. The patient should be kept quiet for two or three days in bed, and the remedy should not be applied again for ten or fourteen days. In the treatment of these growths he had seen the most excellent results follow; in fact, it was the

only condition calling for this strong caustic. Carbolic acid, he said, was a most useful remedy; he found it especially useful in cases of uterine catarrh, and also in cases of tenderness of the inside of the uterine cavity. Its action was slightly caustic and astringent and alterative. The preparation he used was Calvert's No. 5, simply because it was less caustic than the purer preparations. It caused very little pain, if any. Iodized Phenol.—Until he had learned the good effects of this preparation, he invariably used Churchill's tincture of iodine, but of late had quite abandoned it for this preparation. It was first introduced into practice by Dr. Battey of Georgia, and was made of one part of pure iodine to four parts of carbolic acid. This agent was particularly useful in cases of uterine hæmorrhage, profuse menstruation, the result of imperfect involution, accompanied by an unhealthy state of the lining membrane of the uterus, or in cases of menorrhagia, depending on the presence of vascular growths within the uterus. Dr. Battey likewise recommended it in malignant disease of the uterus, and Dr. Atthill spoke highly in its favour in malignant disease, for the purpose of both arresting the hæmorrhage and progress of the disease; he however used it by injecting  $\zeta i$  of the solution once a week within the uterine cavity, and adds, no unpleasant results were likely to follow it when thus used, providing the cervical canal was patulous enough to allow the surplus fluid to flow back, and that it was injected slowly and not more than one drachm at a time. He had no experience in the use of this remedy in this form. Iodoform he had used both in powder and crayons, but had not met with such good results from this remedy as to induce him to resort to it frequently. He had introduced from five to ten grains of powdered nitrate of silver in cases of dysmenorrhœa, especially the membranous form, but it was painful and sometimes produced unpleasant symptoms so he had abandoned it for safer and quite as good remedies.

## GENERAL CORRESPONDENCE.

### HOW IS IT WITH THE PROFESSION ?

[To the Editor of the Medical Times.]

SIR,—As you have, in your issue of July 4, asked for an opinion on the above question from hard-worked country doctors in remote districts, I venture to offer the following remarks to the notice of your readers, from having been associated for a great many years with what has been transpiring in the districts which you designate as the quiet back waters of the profession, "far from the madding crowd's ignoble strife." Let me first remark that in the country, and I suppose in thickly populated quarters also, the practice of the healing art is by no means confined to legally qualified practitioners. Irregular pretenders of all grades are as rampant as ever, taking advantage of the ignorance of the population in the weakened condition of disease. Of this sort are bone-setters, cow leeches, water doctors, and the like. Some are settled down, and remain at home to be sought for by the public in proportion to their fame, combining their medical practice with other avocations. Others are itinerant.

If you will kindly afford me a little space, I will illustrate this statement by two or three instances that have come under my own observation. A blacksmith, in a neighbouring village, whose stationary practice had been handed on from father to son, was famous for curing "takings," the vernacular name for all kinds of scrofulous tumours and abscesses; and numbers of country people were in the habit of going to him to be cured. A striking example of itinerant highway robbery I once witnessed in a poor old farm servant, who showed me a portion of medicine in a half-pint bottle (apparently a weak decoction of cinchona bark), for which two gentlemen in a gig, who went about the country professing to cure everything, made him pay *eleven shillings*, to heal an indolent ulcer in the leg; and

on another occasion, a cunning rascal, not without some display of humour, procured a large store of pill boxes, had them well labelled, and filled them with pills which he made himself of linseed meal and treacle, and then drove a roaring trade amongst some quarry-men and colliers a few miles off. Then, again, chemists and druggists (the numbers of whom in this town have increased since I have lived here, whilst the number of surgeons has diminished) do far larger general practices, and make more money by the healing art than some registered practitioners. The latter, indeed, however well qualified they may be for scientific investigations, are in many instances unable to compete with the former in gaining an honest livelihood. Your metropolitan bell-ringers afford them no protection.

I once made out, as I imagined, a case of violation of the law, with evidence that would have rejoiced the heart of a Q.C. seeking for a conviction whilst appealing to a jury, against a retail druggist, but was officially informed that, so long as a druggist refrained from visiting a patient at his own residence, the Apothecaries' Company could not interfere, so that through the loopholes of the Act of 1815, any druggist may creep into his little back parlour, make it a consulting-room, and there commit with impunity any amount of mischief. It should in all fairness be remarked, that many really good cures are effected by unqualified doctors which, by being well advertised, serve as a cloak for the still more numerous failures that are hidden from the public eye. It would be absurd to attempt to restrain the public from applying to whomsoever they choose for advice. Notwithstanding the contentions about titles, a doctor is a doctor to country folks, whatever his degree may be, and it is a fact that among the poorer classes, the title of Mr. is considered to be superior to that of Dr., and they will actually call a consulting physician of high degree "Mr.," whilst they call the general practitioner "Dr." Even at the old St. Thomas's Hospital I have known patients call Joseph Henry Green "Dr.," and Dr. Elliotson "Mr." Such indeed is the confusion in the public mind about nomenclature, that to save trouble any respectable practitioner is called Doctor So-and-so, and will even be addressed as such by judges on the bench. Veterinary surgeons are constantly addressed as "Dr." by their friends.

You speak of the indifference that exists in the country districts about medical politics; but what else can be expected when so little is done to ameliorate the condition of the less fortunate portion of the profession? Let any one interested in this matter run his eye down the list of candidates for public charity, doled out in such a showy and expensive fashion as that by the Royal Medical Benevolent College at Epsom, and the domestic information recorded in the expensive advertisements of their claims will be found very distressing. I don't see how it is to be remedied in the present shadowy and artificial state of society, but I would submit it as a fact that the fees paid to the higher grade of the profession are by far too high for anything like "value received," whilst what is so hardily earned by the lower grade is far too little. Take, for instance, the enormous fees paid to fashionable accoucheurs in natural cases of labour for doing what may be done by any respectable nurse. They are out of all proportion, and can only be rivalled by the ruinous fees exacted by successful barristers. Another standing grievance is the position of medical officers of unions. It is true that of late years some amelioration has taken place in some unions, but much requires yet to be done; but they wait and wait in vain, and the "hopes deferred make the heart sick." Cannot your bell-ringers do something here. Even in Ireland the union medical officers, as regards compulsory retiring pensions, are better off than in England.

A word about raising the standard of qualifications. The large proportion of rejections at examinations proves that it is injudicious. It may be well in the case of specialists and consultants, but not for the bulk of the profession. Real talent will always find its proper level, and the public in general are tolerably fair judges in this matter. It will be found, I think, in the long run, and in the treatment of ordinary cases of disease, that the

application of plain common sense to the "vis medicatrix nature" will be of more value than the servile imitation of the scientific application of untried theories, whether as regards remedies newly discovered or invented, or capricious rules of diet, or any other fanciful, fashionable or speculative systems of hygiene.

I am, Sir, yours, &c.,  
HENRY MEYMOTT.

Ludlow, 17th July, 1885.

---

## THE MISSION IN KURDISTAN.

[To the Editor of the Medical Times.]

SIR,—Will you allow me to ask in your columns if there is a young qualified man whose tastes would lead him to join a Mission to the Assyrian Christians in Kurdistan? The Mission was started by the two Archbishops in 1881, and its work has hitherto been confined to the Turkish side. It is now desired to extend it to the Persian side, and to send out two clergymen and a doctor. If anyone of your readers has a desire to take part in this interesting work, he may apply to me or directly to the Rev. R. Milburn Blakiston, No. 2, Dean's Yard, Westminster, S.W.

I am, Sir, yours, &c.  
GEORGE COWELL.

3, Cavendish Place, July 21st, 1885.

---

## MEDICAL NEWS.

### MR. ERICHSEN AT EDINBURGH.

MR. ERICHSEN addressed the electors of the Edinburgh and St. Andrew's Universities on Thursday, the 16th inst. The chair was taken at first by Professor MacLagan, and afterwards by Professor Crum Brown. The following are the portions of Mr. Erichsen's address which are of special medical interest:—

### THE BROTHERHOOD OF MEDICINE.

I should never feel myself a stranger in the University of Edinburgh, and for these reasons. In the first place, science is cosmopolitan, is world-wide, and of all the sciences those connected with medicine are the most so, and its Professors, wherever they find themselves, wherever there may be scientific institutions, or a large school of medicine, are immediately received into a brotherhood of professional friends, amongst whom they can never feel themselves as strangers. It is difficult for men in other professions than the medical to estimate the force of this professional brotherhood. I have travelled much in Europe and on the other side of the Atlantic; wherever I have gone, and wherever I have found a large medical school, I have invariably been received in the most cordial, the most hospitable, and sometimes in the most flattering manner by my fellow-brethren of that school. But I have also been much, although indirectly, connected through my profession with members of your great University. I have lived very much amongst those Scotsmen whom you have sent up to London. From my earliest days I have lived with Sir Robert Carswell; I have been the pupil and intimate friend of Robert Liston. I was associated with William Sharpey in my early scientific work. I have been on the closest terms of intimacy with William Fergusson; and there are few of the past generation of the medical professors of your great institution with whom I have not associated on terms of friendship and, indeed, of intimacy. I may say that from them and from those I have met in London I have learned to form a high appreciation of the Scottish character. I have learned from these men whose names I have mentioned the strength of the Scottish brain, the skill of the Scottish hand, and the

warmth of the Scottish heart—and from none more so than the last man I have mentioned.

#### ACADEMIC REPRESENTATION.

I look upon the representative of an academic constituency as having far higher, far nobler, and far wider duties than those which attach merely to party politics. The representative of an academic constituency has entrusted to his care the great academic interests of the institutions with which he is connected. He is the guardian of that learning and that science that are associated with those institutions, and above all, of those professions that are dependent upon that learning and upon that science. These are his duties, and if he fulfils them well and faithfully, he will find, I think, but little opportunity to enter into the general arena of party politics. Indeed, there could be no possible argument in favour of the representation of the Universities if it were otherwise. If a University contest were to be fought upon the ordinary lines that guide the contest for a Parliamentary borough, there would be no argument in favour of the continuance of that representation.

#### MEDICAL MEMBERS OF PARLIAMENT.

It has long been felt in the medical profession that it is inadequately represented in Parliament. That feeling has been a very strong and growing one amongst us. This inadequacy of representation of the medical profession in Parliament is undoubtedly injurious in two ways—it is injurious to the profession itself, and it is injurious to the public at large. To the profession itself it is injurious in this sense—that that legislation which is from time to time necessary in all professions, for their consolidation, for the reform of anomalies, for the improvement of the educational and scientific standard of their members, and for other causes and conditions of that kind, and, especially in the medical profession, for the protection of its members from unqualified and irregular practitioners—that kind of legislation is retarded or rendered abortive by the want of efficient advocacy and support in the House of Commons. But although I speak of this kind of legislation in the medical profession, do not think that I am one of those who desire too much legislation with regard to it. The medical profession is very much in the condition of the hare with many friends. The medical profession has suffered very much from a good deal of dilettante and amateur attempts at legislation which would be entirely stopped if there were an adequate number of medical men in the House of Commons to point out what is really desired by the various medical bodies, university or corporate, and how their requirements could best be carried into effect. There are many anomalies existing which might easily be removed, but there appears to be no one to move in the matter to get them set right. I would mention one as very striking. There is an institution, as most of you know—all medical men, at all events, know—called the Medical Council, which is a sort of Parliament, but it is a paid Parliament. It has its sittings in London, and very commonly sits a good deal during the season, and altogether we Londoners are glad when the gentlemen connected with it come, because there is a good deal of social amenity and festivity going on in connection with it. It is not altogether hard work. Well, that Medical Council represents, or is supposed to represent, the interests of the various bodies connected with the medical profession. If you look over the list of its members you will find that every corporation in the kingdom returns one member, however insignificant that corporation may be—the Society of Apothecaries of London, for instance, and somewhat similar societies in Ireland and elsewhere—small corporations of that kind—the smaller universities of England—return one member. The University of Durham, for instance, which has a very small medical school, and a most insignificant number of medical graduates, returns one member. But when you come to Scotland, what do you find? The curious anomaly that each University returns only half a member—that is to say, two Scottish Universities are linked together in order to return one member. Edinburgh

is linked with Aberdeen, and Glasgow with St. Andrew's, and in that way these four Universities only return two members. This upon the face of it is an anomaly that ought to be corrected. That the largest medical school in Great Britain—which undoubtedly the Medical School of Edinburgh at the present time is—that such a very important University as Edinburgh should only return half a member, while the University of Durham returns a whole one, and the Society of Apothecaries of London, which is gradually becoming extinct, returns one, is an anomaly that should not continue in connection with the representation of the profession, and which easily, one would imagine, might be corrected, provided there were anybody in the House to point it out, and to set the machinery in motion that is necessary to correct such an anomaly of representation as this. There are many other matters of that kind which I could point out, but it is not worth while to go into detail. I am only speaking on the general principle of the importance, of the necessity, of having more medical representation in the House, in order to correct these anomalies and abuses that still continue in the medical profession. The social status of medical men also suffers from inadequate representation. It suffers in this way, that the medical profession is not able to exercise a sufficiently direct action upon legislation in consequence of the paucity of its members in the House. There cannot be a doubt that a larger number of medical representatives would add greatly to the advantage of the medical profession in enabling the profession to represent what it considers its various grievances, so-called, to the Legislature, and to have them backed up by men who are competent to explain professional topics, through being connected with that profession itself. But to the public at large the inconvenience of the inadequate number of medical men in the House is still greater, I take it, than to the medical profession itself. One of the first and most important questions of modern legislation is undoubtedly how best to improve the sanitary state of the people at large. An improved hygienic legislation may be looked upon as of primary necessity. There can be no doubt of this, that the physical well-being of the community at large is the first step towards its moral advancement and intellectual improvement. It is as essential also to the activity of the people, and to the working power of the community at large, as it is to their moral or intellectual condition. This physical well-being of the people at large, dependent upon their sanitary and hygienic surroundings, is mainly in the keeping of the medical profession. With that well-being the Legislature largely, though still insufficiently, occupies itself, and it surely needs no formal argument to prove that the Legislature so occupied should be provided with adequate medical representatives to guide it in those medical questions that underlie most of the conditions connected with hygiene and with sanitary legislation. Besides these, there are a vast number of secondary or subsidiary questions which are constantly being brought under the notice of the House, and in the solution of which medical knowledge and medical experience as well as scientific knowledge are absolutely necessary. Such questions, for instance, as those connected with quarantine, with the prevention of the spread of infectious diseases, with the great question of compulsory vaccination, the amendment of the Lunacy Laws, the question of vivisection in all its bearings—the question—all those very knotty and difficult questions—connected with the Contagious Diseases Act, are questions involving medical considerations of the most important character, and for their guidance in which I believe many members of the House of Commons would be only too thankful if they were better provided with medical advice in the House.

#### EDUCATIONAL OVER-PRESSURE.

Dealing with Education by the State and the objections to it, Mr. Erichsen said:—There are other objections, undoubtedly, which have come under my cognisance as a medical man more than the question of expense, and those are objections with regard to over-pressure. That, as you are all aware, is a matter that has been discussed very largely of late, and discussed considerably in the medical

journals. So far as I can see, and so far as I am able to judge, over-pressure undoubtedly has existed, but not to a very great extent, and that over-pressure seems to arise rather from remediable than from irremediable causes. It seems in many cases to have been more the fault of the teacher than the pupil by a system of emulation being raised, in consequence of which children work at overtime, children strain themselves, take their books to bed, and so on, and work beyond their powers. Very little correction would enable this evil, I think, to be done away with. Then there is another point in connection with this subject which I think is a very important one. And it is, that the physical condition of the children should be attended to. It would be well if they were accustomed to physical exercise in some shape or way.

#### CONCLUSION.

In conclusion, Mr. Erichsen said: I come here as the representative of the medical profession, and of the science and of the learning connected with that profession. I have no object to serve that is personal to myself. I have devoted my whole life to my profession; I have devoted much time to the working of that profession in its public aspects, and I feel that the profession has still a claim upon me; and if it, and the members connected with it, think that I can serve it in Parliament, I am ready to do so. In doing this, as I have already said, I have no personal ambition to gratify. I have passed through everything that the profession can give to a surgeon in this country; I have served in every office I can hold in it; I have done every piece of public work I can ever hope to do in my own profession. If fortunate enough to be elected your representative in Parliament, all I can say is I will devote my time and attention to further the best interests of the Universities of Edinburgh and St. Andrew's. I should spare no time and no labour—and those who know me and what I have done in connection with my own profession know I am able to give both to any subject I take up—I should spare no time and no labour in trying to carry out to the very best of my ability all that is most conducive to the honour, and to the dignity, and to the welfare of those two great institutions.

A vote of thanks to Mr. Erichsen for his address was moved by Professor Laidlaw, of Edinburgh, and seconded by Professor Knight, of St. Andrew's, and unanimously adopted.

**UNIVERSITY OF EDINBURGH, MEDICAL DEGREES EXAMINATIONS.**—The following gentlemen have passed the final examination for Graduation in Medicine, those marked with an asterisk having passed with distinction:—

Robert Jackson, Hugh Jamieson, Hugh John, Thomas Johnstone, M.A.; Samuel Baker Jones, Robert Conway Joyce, David James Lawson, Charles Ashley Scott Leggatt, \*Robert Fraser Calder Leith, M.A., \*Charles James Lewis, \*Reginald Horace Lucy, James Smith M'Cracken, Duncan M'Diarmid, Henry Cox M'Ewen, B.Sc.; William Mackay, M.A.; Frank Wallace Mackenzie, Frederick Lumsden Mackenzie, Hector Rate Maclean, William Henry M'Lean, Robert Maclelland, John Macdonald MacLennan, M.A.; Alexander Ronald Macmillan, Robert Charles Maewatt, Daniel Grove Marshall, James Williamson Martin, David James Mason, Charles G. Matthew, Henry Bruce Melville, William Francis Menzies, William Cornfoot Miller, William Gordon Mitehell, M.A.; Robert Selkirk Morrison, William Murphy, William Ramsay Nasmyth, Frederick Augustus Neal, Johannes H. Neithling, Walter Blake Nisbet, Ernest Stanley Nutting, Glenmore Ozanne, John William Pare, Sydney Partridge, Ian Paterson, Maurice Paterson, Thomas Jackson Thyne, Matthew Bruce, William George M'Phee, Robert Sydney Marsden, D.Sc.; Hugh Hampden Priddle, Edward Thomas Pritchard, Alwyn Raimes, Francois Gideon Retief, John Theodore Richards, B.Sc.; John Brooke Ridley, George Matthew Robertson, Thomas Henry Robinson, \*Arthur MacLeod Ross, William Leighton Ross, Gerard Affleck Scott, William Edward Sowers Scott, Harold Scurfield, John Simpson, Ernest William Skinner, George Smith, Walter Charles Spiller, George Laird Somerville, M.A.; James Stewart, Robert Stewart, M.A.; \*Harold Jalland Stiles, Robert Stirling, M.A.; David Sturrock, John Frederick Sturrock, William Symington, William Evans Thomas, John Tatham Thompson, \*Joseph Charles S. Vaughan, Simon Thomson Vine, Sidney Taylor Williamson, George Edward Cartwright Wood; John W. Astles, Robert Newton Bell, Charles Norman Bensley, Charnchandra Bose, Alexander Brewster, Robert Napier Buist, Robert Francis Burt, Stephen Frazer Clark, Arthur James Cross, Dina Nath Prithu Datta, Alexander Davidson, Joseph Wm. Dawes, Robert Gordon, James Ashton Guthrie, Francis Kramer, M.A.; William Maxwell Little, Thos.

Arthur Leishman, Chas. Jas. Russell Maclean, Robt. Thornton Meadows, David Macbeth Moir, M.A.; John Kemp Murray, Alexander Paterson, James Hogarth Pringle, Selwyn Hall Puckle, M.A.; Charles Alan Renny, Charles F. D. Shaw, Alexander Henry Smith, John Sykes, Henry Thomas Tomlinson, Alfred Turner, James Roberston Wallace, George de Bourbonloun Watson, Alfred Bell Whitton.

**UNIVERSITY OF GLASGOW.**—*Final Examination for Degrees of M.B. and C.M.*—The following candidates have passed;—

Archibald S. Alexander, Samuel P. Alexander, John Allan, William Allan, W. Carrick Allan, Samuel J. Baird, Alexander M. Bankier, George G. Bannerman, Charles W. Bell, John Broom, H. Duncan Browne, H. Dryden Buchanan, John Buchanan, William Buchanan, William Butchart, M.A.; J. Wilson Cameron, William W. Campbell, Quintin Chalmers, William W. Christie, George M. Connor, Charles Court, B. S. Cowen, David K. Cross, Donald Currie, William Downie, M.A.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed their primary examinations in Anatomy only at a meeting of the Board of Examiners, on the 16th instant, and when eligible will be admitted to the pass examination, viz.:—

C. J. P. Hogarth, Student of Melbourne University; J. L. Johnstone and R. B. Smith, Manchester; W. M. Branson, Sheffield; F. A. Brooks and A. E. G. Roberts, St. Mary's Hospital; R. Thorpe and N. Robinson, St. George's Hospital; R. H. Brabant, Guy's Hospital; H. F. Whitechurch, H. H. Coates, and W. D. Gimson, St. Bartholomew's Hospital; A. Crook and C. L. S. James, London Hospital; A. Purvis, Charing Cross Hospital; C. E. Seal, University College; H. B. Seddon, St. Thomas's Hospital.

Twelve candidates were referred for 3 months, and seven for 6 months.

Passed in Physiology only:—

A. Pearce, A. Lucas, S. H. Hughes and C. R. B. Alexander, St. Bartholomew's Hospital; N. Tyacke, Middlesex Hospital; F. J. Lauder, A. L. Martyn and P. J. Spencer, London Hospital; G. C. Peachey, W. S. Holford, H. Cockerton, P. H. Menzies and F. J. Wadham, St. George's Hospital; G. Ley, University College; R. T. Wallace, T. O. Raw and W. E. Kelbe, Guy's Hospital; E. Dawson and G. I. Mac Munn, Westminster Hospital; G. R. Anderson and E. S. Bell, St. Thomas's Hospital.

Four candidates were referred for 3 months and two for 6 months.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, July 16th, 1885:—

Henry Percival George Elkington, M.R.C.S., 52, Gillingham Street, S.W.; Frank Wood, M.R.C.S., 1, Fennel Street, Warrington.

On the same day

Charles Jenner Parson, Godalming, Surrey, passed his examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise.

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—At the Quarterly Examination for the membership of the College, held on Tuesday and Friday, July 7 and 10, 1885, the undermentioned candidates were successful:—

Charles Edward Fitzgerald, M.D. Univ. Dub., Lic. Med., 1884; William Cox Neville, M.D. Univ. Dub., Lic. Med., 1884, Dublin.

At the Quarterly First Professional Examination held on Monday, July 6, and following days, the undermentioned candidates passed:—

Mary Crawley, Jessie Crosfield, Albert Edward Dyas, Lillias Emily Goodman, Alfred John Harwood, Jane Louisa Jarrett Haskew, Alexandrina Matilda MacPhial.

At a Special Examination for the License in Medicine held on Monday and Tuesday, June 22 and 23, the following candidate was successful:—

James Chambers, Dublin.

At the ordinary Monthly Examination for the Licences in Medicine and Midwifery, held on Monday, July 6, and following days, the undermentioned candidates were successful:—

*For the Licence to practise Medicine—*

Robert Hugh Arthur, M.D., McGill University, Montreal, Brighton, Ontario; Leonard Philip Banks, Risely, Bedfordshire; Louis Albert Frederick Bate, Dublin; Alfred George Beale, Dublin; Benjamin Blakemore, Manchester; Edward Carnall, Cornwall; William George Connor, Dublin; Francis Eldon Horsford Daunt, Dublin; Julius Barry Delany, Kilkenny; John Empson, Dublin; Henry James Flanagan, Dublin; James

Edward Roney Grant, London; Michael St. Lawrence Harford, Oldtown, Co. Dublin; Thomas Walmsley Heywood, Southport; David Humphreys, Murrall, Co. Limerick; Charles Granville Jackson, Thorparch; James Prytherde James, London; Charles Trickey Jones, Torrington, North Devon; James Gowans Laing, Southport; John Murray Maclean, M.D. Univ. New York, Londonderry, Nova Scotia; Timothy Aloysius Mulcahy, Limerick; William James Neale, Liverpool; Robert Carson Nicholls, Birmingham; Robert Richards, Wigan; William John Russell, Borrisokane; Francis Howard Sinclair, Belfast; Samuel Henry Steele, Halifax, Yorkshire; Alexander Stewart, Dublin; Davis Dederick Tate, Dublin; Richard Henry Vereker, Limerick; John Whyte, Westmeath; John Hall Woods, Coleraine.

*For the Licence to practise Midwifery—*

Robert Hugh Arthur, M.D., McGill Univ., Montreal; Alfred George Beale, Benjamin Blakemore, Edward Carnall, William George Connor; Joseph Thomas Daly, M.B., R.U.I.; Francis Eldon Horsford Daunt, Julius Barry Delany; Charles Cochran Dickson, Galashiels; Henry James Flanagan, Michael St. Lawrence Harford, Thomas Walmsley Heywood, David Humphreys, James Gowans Laing; John Murray Maclean, M.D. Univ. New York; Timothy Aloysius Mulcahy, William James Neale, William John Russell, Norman Smyth, M.D., R.U.I.; Alexander Stewart, John Whyte, John Hall Woods.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Court of Examiners, held on the 6th, 7th, 8th, 9th, 10th, 11th, and 12th instant, the undernamed gentlemen, having passed their final examination for the letters testimonial, and taken the declaration and signed the roll, were admitted Licentiates of the College, viz:—

Robert Abraham, George W. Armstrong, Thomas Browning, William G. Chute, Arthur R. T. Craig, Frederick A. G. Davis, George B. Elliott, Henry L. Finny, Henry C. Groves, Andrew Harris, Edward Heard, Gerard B. Irvine, John Keatly, Bernard B. Kennedy, Timothy Killeen, John B. M'Bride, Thomas D. Moore, Michael J. Moran, Samuel F. Murphy, William J. Peacock, William G. Rutherford, William Stritch, and John A. Whitty.

Forty-six candidates presented themselves, of whom twenty-four were stopped.

DR. A. JACOBY, the well-known Professor of Hygiene in Kharkov, has given up his post, and migrated to the University of Kasan.

DR. GUSTAV BUNGE, of the University of Dorpat, whose interesting *brochure* on vegetarianism we recently reviewed, has received and accepted a call to the Chair of Physiological Chemistry in Basle.

BRIGADE-SURGEON J. MACDOWELL, of the Indian Medical Department, has had conferred upon him an Indian good service pension.

SURGEON-GENERAL J. IRVINE, principal medical officer of the Madras Army, who lately resigned a similar position in the Staff of the Army of Occupation in Egypt, will succeed the late Sir W. Muir, as honorary physician to the Queen.

MEDICAL VOLUNTEER STAFF CORPS.—Surgeon-General Sir James Hanbury, the Principal Medical Officer of the Home District, made, on Saturday, at the Wellington Barracks, the first official inspection of the Volunteer Medical Staff Corps. The Corps paraded between two and three hundred strong, under the command of Surgeon-Commandant Cantlie, and divided into four bearer companies. A variety of ambulance work was performed, but chiefly it referred to the treatment of wounded men. Afterwards the Inspecting Officer addressed the Corps complimenting it on its high state of efficiency. On August 8th, 114 of the Corps will proceed to Aldershot for a week's drill in a military camp.

CHOLERA PRECAUTIONS, LONDON.—At the last meeting of the Court of Common Council, London, the Chairman of the Port of London Sanitary Committee gave an account of the steps which had been taken by the city authorities, as precautionary measures against a possible visitation of cholera in this country. The regulations issued in 1883-4 on the subject are again in force.

LEGION OF HONOUR.—The following promotions have recently been made in this Order:—Prof. Henri Roger, President of the French General Medical Association, as Commandeur; Dr. Galezowski, the well-known Parisian oculist, as Officier; Prof. Gavarret, General Inspector of Medical Instruction, as Commandeur; and M. Jannetaz, Assistant Naturalist at the Muséum d'Histoire Naturelle, as Chevalier.

THE HOSPITAL SATURDAY COLLECTIONS.—The total amount collected in boxes on Saturday has been found to be 2,365*l.* as against 1,890*l.* last year. By the Victoria Park Entertainment Committee 200*l.* has been realized, and the result of the cab trade and steamboat collection is estimated at 250*l.* and 50*l.* respectively. Various sums are yet to come in, and the grand total of the various collections is estimated at 4,326*l.* as against 2,907*l.* in 1884, leaving a balance in favour of last Saturday of 1,419*l.*

LARYNGEAL TUMOUR IN A VERY OLD MAN.—A Belgian medical paper states that Dr. Schiffers has communicated to the Liege Medical Society, a case of papilloma of the larynx in an old man over 80 years of age, which had lately been occasioning the patient considerable inconvenience. The author was able to remove it completely in one sitting by means of Maekenzie's forceps. The tumour was as large as a bean, and was situated on the right inferior vocal cord.

THE METROPOLITAN DRINKING FOUNTAIN AND CATTLE TROUGH ASSOCIATION.—The 26th annual report of this institution shows that 40 new troughs for animals, and 24 new fountains, have been provided during the past year, making a total for the metropolis and suburbs of 575 fountains and 597 troughs. The expenditure for the year have been 8,651*l.*, leaving a balance in hand of 123*l.* The increasing support the society is receiving is satisfactory, from its encouragement of temperance tendencies.

EXTRACTION OF LENS WITH CAPSULE.—Dr. R. Castorani, professor of ophthalmology in Naples, has published an account of his results in the operation he practises for cataract, which consists of three steps—incision at the sclero-corneal junction, iridectomy, and extraction of lens and capsule with a scoop. He has operated on 237 eyes, success resulting in 230, of which however 8 had to be operated on a second time. There was one death from cerebral apoplexy. Of the 165 persons operated on, acuteness of vision was  $\frac{2}{5}$  or more in 43 and  $\frac{9}{10}$  to  $\frac{1}{10}$  in 101.

UNIVERSITY SEATS.—The *Scotsman*, in an article supporting Mr. Erichsen's candidature for the Universities of Edinburgh and St. Andrew's, says: "The University constituencies need not fear destruction if they will elect representatives who hold the views of their duty expressed by Mr. Erichsen. As political constituencies in the ordinary sense, they are not needed; they are superfluous; they constitute an anomaly and an injustice. But they have an important part which they may play in public affairs, if they will recognise it and cleave to it. It is because they have not always done so that their right to exist is sometimes called in question. There is a wide range of public questions, of the greatest importance to society and the State, which their representatives ought to make their special study and care, and on which they should exercise a powerful influence in Parliament."

SMALL-POX AND FEVER IN THE METROPOLIS.—The comparative returns as to fever and small-pox in the metropolis laid before the Metropolitan Board of Works on Saturday showed a satisfactory decrease in the figures dealing with the last disease, while there was no change in the figures reported a fortnight ago of patients remaining under treatment for fever. There had been a total number of 221 patients admitted suffering from small-pox; 32 had died, 272 had been discharged recovered, and 769 patients remained under treatment. The totals for the previous fortnight showed that 232 were admitted; 52 died, 312 were discharged, and 852 remained under treatment. The fever returns showed that 77 patients had been admitted; 12 had died, 66 had been discharged, and 212 scarlet fever, 12 typhus fever, and 17 enteric fever patients remained under treatment.

THE METROPOLITAN CONVALESCENT INSTITUTION.—From the report just issued, it appears the Institution has now three homes, namely, one at Walton-on-Thames, containing 300 beds for adults; the children's branch at Kingston Hill for boys and girls, 200 beds; and the sea-side branch at Boxhill-on-Sea, 100 beds for adults. During the past six months 2,129 patients were admitted, of whom a large proportion were thoroughly restored to health after about three weeks' residence in the homes.

During the past half-year there has been a serious decrease in the donations, both to the general fund and sea-side branch. To provide for the poor convalescents, who are at no expense whilst in the Institution, necessarily involves a heavy outlay, and the Board looks for additional aid towards the expenses of maintaining the 600 beds of the combined homes.

**A NEW SANITARY EXHIBITION.**—The want of a central dépôt or registry, to which architects and builders could have recourse for acquiring information in regard to the best approved sanitary requirements, will, it is expected, be provided by what is purposed to be a permanent registry and agency of architectural appliances and inventions, opened a few days since at 10, Baker Street, Portman Square. Although great attention has been given, and a growing general interest felt of late years in domestic sanitation, much practical knowledge still remains to be acquired, before a complete and satisfactory system of house drainage, sanitary appliances, water supply and ventilation can be accomplished. This new exhibition opens under auspices which, it may be hoped, afford the expectation of future success, and will lead to important results. Exhibits and inventions have been sent by several prominent metropolitan firms of sanitary engineers.

**TYPHOID FEVER AT WIESBADEN.**—A correspondent of the *Daily News* gives some details of the outbreak of fever at Wiesbaden, which has suddenly converted that beautiful town, ordinarily so full of visitors in quest of health and recreation, into a solitude. The epidemic began to show itself in serious form about a month ago, since when nearly a thousand cases have been reported. Happily the percentage of deaths is much below the average in such attacks; but the fever has been pronounced to be decidedly of a typhoid kind. Wiesbaden is a well-governed town, and the authorities have gone vigorously to work to grapple with the evil both directly and by precautionary measures. Upon its first appearance a sort of panic set in, and the hotels in neighbouring towns were speedily crowded with fugitives. The boarding-schools were promptly closed by the authorities, and all children whose parents are not residents have been sent away. As to the causes of the outbreak, no satisfactory information is yet forthcoming. It is the more remarkable since Wiesbaden has long been famous for the healthiness of its climate and the excellence of its sanitary arrangements.

**BELGIAN PHARMACOPŒIA.**—The third edition of this pharmacopœia, whose recent appearance precedes our own by a few weeks only, has long been in preparation. Its predecessors appeared in 1823 and 1854, so that thirty years have elapsed since the publication of the second edition. The work is printed in Latin and French, and it forms therefore a decidedly bulky volume. A large number of medicaments given in the previous volume have disappeared, being no longer in use; but we suspect that under the head of simple medicaments our own pharmacopœia when it appears will be found to have far fewer items. For instance, there are thirty-five "folia," thirty-seven "herbæ," and fifteen "semina"; it is not likely that these numbers will be reached in our own volume. In the first portion of the work, the pharmacopœia proper, most of the recently introduced drugs have received official sanction, but cocaine does not find a place; we suppose that its sudden popularity occurred too late for the editors to be able to notice it. In the second section, tables of atomic weights, alcohol tables, re-agents for testing the purity of drugs, a list of articles which require to be kept from the light, a list of dangerous medicines, tables of maximum doses, and a list of antidotes are given. The new pharmacopœia will come into force on September 1st, and the price has been fixed at six francs.

**STREET VENDORS OF ICE CREAMS.**—It may be of some utility, in the present active demand for ice creams vended in the public streets, to notice Dr. Muter's report to the Lambeth Vestry, of an analysis of three samples of ice cream, purchased from a barrow in the Lambeth Walk. Dr. Muter, after a scrutinizing examination, thought that nobody could suffer any injury from this article through anything unusual in its composition. It contained no

poisonous matter, and the amounts of aniline colour and flavouring essence were so small as to be quite innocuous. Two of the samples actually contained fruit. "The matter," added Dr. Muter, "of the hasty consumption of ice upon a hot day, and an empty stomach, would in itself frequently cause unpleasant results, even if no poisonous article were present." The analytical examination of these samples was considered desirable, in consequence of the illness (resembling the effect of poison) of several persons after eating ices bought of a street vendor in the district. Analyses of this cheap ice cream should be still pursued. The probability is, that it too often contains deleterious ingredients in pernicious quantities.

**EXPERIMENTS ON DECAPITATED CRIMINALS.**—The following are further details of the experiments on the body of an executed criminal, recently conducted by MM. P. Regnard and P. Loye, and communicated to the *Société de Biologie*. The authors of the paper confined their attention and remarks to the trunk of the body; for three minutes after the execution there was a general contracture of the muscles of the whole body. After this rigidity had passed off, no reflexes could be obtained, except that the pupil, which was moderately dilated, responded to light. The authors directed their attention almost solely to the effects of experiments on the pneumogastric nerves; they found that excitation of the vagi induced pulmonary contractility, that it produced very obvious movements of the stomach and intestines extending as far as the transverse colon, and that during it the mucous membrane of the stomach was thrown into folds, and at the same time the secretion of gastric juice was encouraged. The last experiment was upon the palmar and dorsal interossei and lumbricales muscles, when the views of Duchenne regarding their action were entirely confirmed.

**THE RIO DE JANEIRO MEDICAL FACULTY.**—The professors of the Rio de Janeiro Medical School have published a review containing some of their observations during the year 1884, amongst which Prof. Lima gives an account of the failure of the hydrostatic test in the case of a fœtus, which, having presented by the breech, had to be perforated through the mouth before the head could be extracted, and whose lungs, nevertheless, floated freely in water even after all the usual tests had been applied. Prof. Gouvea discourses on various plastic operations about the eyelids, speaking highly of Lawson's and Wolfe's operations. Prof. Coelho contributes an interesting introductory lecture to the obstetric and gynecological course on the Limits of Experimentation in Practice. Prof. Lima e Castro describes a successful case of sub-periosteal resection of the femur, carried out with strict Listerian precautions; and Prof. Torres Homem a rare case of stenosis of the tricuspid without any other abnormality, a condition that was diagnosed during life, and exactly verified at the autopsy.

**OVER-PRESSURE IN LONDON BOARD-SCHOOLS.**—The report of the London School Board Special Committee on the question of "over-pressure" in schools, was laid before the Board on the 16th inst. The committee, who were appointed as long ago as November last, had examined witnesses who had special knowledge of the work in Board Schools, and had received information from 260 experienced head teachers in all parts of London. They had also endeavoured to obtain the assistance of eminent medical men in order to deal with the assertions of Dr. Crichton Browne; but they had been unable to obtain the co-operation of those who would have spoken with "sufficient authority." The committee then followed Dr. C. Browne's action, and all the teachers of the schools he visited were examined. The committee, in dealing with the class of children in the Board Schools, said that in many of the suburban and in some of the central regions the parents were in receipt of from 30s. to 60s. a week or upwards; their homes were comfortable and their children were well clothed and fed, and, as a rule, were healthy, physically and mentally. There were, however, very many children in Board Schools drawn from crowded, squalid, dirty, bare, and infectious homes, the mental and moral atmosphere of which exerted a constantly debasing influence upon the children, with

which the schools had to fight. There were many other poor homes, also, where lodging, food and clothing were only provided for the children on the most meagre scale, and, in both cases, the children were unhealthy. But the committee were convinced that whether the children came from comfortable or from squalid and filthy homes, they greatly gained physically, mentally, and morally by being able to attend comfortable schools. As to the principle of payment by results, attacked by Dr. Crichton Browne and by some of the teachers, it was a principle which the State was bound to secure, and the nature of the education given by the Board was that laid down by the authority of Parliament. The committee had found no ground for believing that the annual Government examination was awaited by the children with fear or unhealthy anxiety, as supposed by Dr. C. Browne. The committee believed that no better system for improving the health and intelligence of the infants could be adopted than that of the Kindergarten, and wished to see it adopted in spirit in every school. In conclusion, the special committee summarize their opinion thus:—(a) That the enquiry has not disclosed the systematic and universal over-pressure of large numbers of children in the Board Schools described in Dr. Crichton Browne's report, but, on the contrary, it was shown that, notwithstanding frequent ill-feeding and bad homes, they are gaining physical, moral, and intellectual benefit from attending school. (b) That the enquiry has disclosed over-pressure of some children, but that this over-pressure is confined to a comparatively small number. (c) That such over-pressure as exists is not a necessary consequence of the school system, but is due partly to the action of the parents who press their children with a view of getting them released from attendance as soon as possible; partly to the sickly and under-fed condition of some children; partly to the wretched state of some of their homes; partly to irregularity of attendance, and, in some instances, to unintelligent and unsympathetic methods of teaching. (d) That the School Board for London and the Education Department have already in various important ways modified their rules and practice so as to avoid any over-pressure, but that there are certain other modifications and alterations with regard to them which the committee consider would still tend in the same direction and to the benefit of the children attending the schools. With this view the committee recommend among other things:—That the Board grant facilities to local managers and to other responsible persons for the provision on the school premises of penny dinners on self-supporting principles for elementary school children. That a short statement of the admonitory symptoms of diseases likely to affect children, whether arising from over-work or otherwise, be drawn up by medical authority for the use of the teachers and local managers. That further encouragement be given to physical exercises and games, both in and out of school hours. That home lessons should not be given to children unless the circumstances of their homes are entirely favourable, and the parents give encouragement to them, and that they should never be set in infants' schools. There are further recommendations dealing with details of school management, and the assessment of results. The report was received, and will be discussed on an early occasion.

**DEATHS FROM WILD ANIMALS AND SNAKES IN BENGAL.**

—During the five years ending with 1883 the deaths were as follows:—

Year.	Killed by Wild Animals.	Killed by Snakes.	Total.
1879	1,264	9,515	10,779
1880	1,295	10,064	11,359
1881	1,367	9,268	10,635
1882	1,267	9,191	10,458
1883	1,302	9,153	10,455

In Calcutta there were only 9 deaths in 1883, all caused by snakes. The number of snakes destroyed in 1883 was 38,856. The total amount of money paid in 1883, as rewards for the destruction of snakes and wild animals, was Rs. 27,976/6/3.—*Indian Medical Gazette.*

**SOUTH LONDON SCHOOL OF PHARMACY, 325, KENNINGTON ROAD, S.E.**—The following prizes were awarded at the school examinations, held from the 1st to the 4th July, 1885:—Senior Chemistry: Medal, Francis W. Taylor; Certificate, John B. Nichols. Junior Chemistry: Medal, Andrew Craig; Certificate, Alfred L. Wood. Botany, Medal, John B. Nichols; Certificate, Ernest L. Ralling. Materia Medica: Medal, John Tirrell; Certificate, J. Burgess. Pharmacy and Practical Dispensing: Medal, Robert Pyle; Certificate, John W. Carr. Extra Certificates, of Merit to Messrs. Jackson, Lewis, Minter, Moore, and G. H. Taylor.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The Museum of the College will be closed on Tuesday and Wednesday, the 28th and 29th instant, for the purposes of the First Examination of the Examining Board in England.

**APPOINTMENTS.**

- BALL, JAMES B., M.D., M.R.C.P.—Assistant Physician to the West London Hospital, Hammersmith, *vice* F. G. D. Drewitt, promoted.
- BRISTOW, W. M., M.R.C.S., L.R.C.P.—House Surgeon to the Liverpool Royal Infirmary.
- CULLINGWORTH, C. J., M.D., M.R.C.P.—Professor of Obstetrics and the Diseases of Women at the Owens College, Manchester, *vice* John Thorburn, M.D., F.R.C.P., deceased.
- DAVIS, ARTHUR R., M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Sandgate District, Elham Union, *vice* Mr. J. W. Howard, deceased.
- DAWSON, A. W., M.B., etc.—House Physician to the Liverpool Royal Infirmary.
- DREWITT, F. G. D., M.D. Oxon., M.R.C.P.—Physician to the West London Hospital, Hammersmith, *vice* J. C. Thorowgood, M.D., F.R.C.P., resigned.
- GRAHAM, A., L.R.C.P., L.R.C.S., etc.—Honorary Medical Officer to St. Gabriel's Hospital for Infants, Grosvenor Road, S.W.
- HERBERT, C., Major, M.D., C.M. Ed.—Honorary Physician to the Bradford Infirmary.
- HUGHES, S., M.B., C.M. Ed., M.R.C.S., etc.—House Surgeon to the Liverpool Royal Infirmary.
- LIDDELL, HENRY J. S., M.R.C.S. Eng.—Medical Officer to the Buckland District, Tavistock Union, *vice* Mr. H. Copley, resigned.
- LITTLETON, PHILIP R., M.R.C.S. Eng.—Medical Officer to the Ashbourne District, Ashbourne Union, *vice* Mr. H. Greaves, deceased.
- LONGHEAD, WALTER HENRY, M.B., B.Ch., L.M., B.A. Dub.—Medical Officer to the North Somercotes District, Louth Union, *vice* Mr. C. J. Myers, resigned.
- MACLAREN, MURRAY, B.A., M.B., C.M. Edin., and M.R.C.S. Eng.—House Surgeon to the Bootle Borough Hospital, Liverpool.
- MYERS, CHARLES JOHN, M.R.C.S. Eng., L.S.A.—Medical Officer to the Workhouse and to the South District, Louth Union, *vice* Mr. W. E. Ditchett, deceased.
- NORBURY, THOMAS W., M.R.C.S. Eng., L.R.C.P. Edin., L.M.—Medical Officer to the Stratford-on-Avon District, Stratford-on-Avon Union, *vice* Mr. J. J. Nason, resigned.
- QUENNEL, R. W., M.R.C.S., L.R.C.P.—Junior Resident Officer to the Royal Free Hospital, *vice* M. N. Banergea, M.R.C.S., resigned.
- SMITH, PROTHEROE, M.D.—Consulting Physician to the Hospital for Women, Soho Square.
- WASSE, GEWAS MILES, M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Third District, Okehampton Union, *vice* Mr. J. A. Kempe, resigned.
- WATKINS, A. M., M.R.C.S., L.R.C.P.—Re-appointed House Surgeon to the Liverpool Royal Infirmary.
- WEIGHTMAN, A. E., L.R.C.P. and L.R.C.S. Ed.—House Physician to the Liverpool Royal Infirmary.
- WOODROFFE, AUGUSTUS W., M.B. Dub., L.R.C.S. Ire., L.M.—Medical Officer to the Second Western District, Billesdon Union, *vice* Dr. Hargitt.

**VACANCIES.**

- COSFORD UNION.—Medical Officer for the Lavenham District, in succession to Mr. F. T. Barkway, deceased. Area, 9,827 acres. Population, 3,298. Salary, £52 2s. per annum.
- COTON HILL LUNATIC HOSPITAL, STAFFORD.—Assistant Medical Officer. Must be duly qualified and registered. Salary £100 with board and furnished apartments in the Hospital. Applications with testimonials to the Medical Superintendent on or before August 8th.
- GREAT NORTHERN CENTRAL HOSPITAL.—Junior Resident Medical Officer. (*For particulars see Advertisement.*)
- ISLE OF MAN GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £100, with gas, coal, apartments, and attendance. At liberty to attend inmates of the House of Industry for which £10 is allowed. Applications with testimonials to F. Browne, Honorary Secretary, 46, Atholl Street, Douglas, not later than August 10th.
- MALTON UNION.—Medical Officer for the Rillington District, in succession to Dr. Adam C. Lyon, resigned. Area, 22,970 acres. Population, 2,577. Salary, £30 per annum.
- RAMSGATE AND ST. LAWRENCE ROYAL DISPENSARY AND SEAMAN'S INFIRMARY.—Resident Medical Officer. Salary £120 (£10 allowed for substitute during annual holiday) with furnished apartments, gas, firing, and attendance. Must not practice on own account. Applications with testimonials to S. G. Warman, Secretary, on or before August 1st.

SHIPSTON-ON-STOUR UNION.—Medical Officer for the Brailes District, in succession to Mr. Thomas H. Hitchins, resigned. Area, 17,233 acres. Population, 3,454. Salary, £58 per annum.

### DEATHS.

ALLEN, RICHARD, M.R.C.S., at Moorcot, Didsbury, near Manchester, on July 14, in his 76th year.  
BROWN, GEORGE DRANSFIELD, M.R.C.S., of Henley Villa, Ealing, in his 58th year.  
ENGLEHEART, STEPHEN PAUL, M.R.C.S.E. and M.D., drowned between New Calabar and Bonny, West Coast of Africa, on May 23, in his 55th year.

### COMMUNICATIONS RECEIVED—

Mr. JORDAN LLOYD, Birmingham; Dr. SIDNEY COUPLAND, London; Dr. E. C. MORGAN, Washington, U.S.A.; Mr. NELSON HARDY, Dulwich; Dr. BEDFORD FENWICK, London; Mr. WM. HAY, Hull; Mr. JAMES MARSHALL, Glasgow; Mr. J. E. STUART, Edinburgh; THE DEAN OF THE UNIVERSITY OF EDINBURGH; Mr. J. H. LEWIS, London; THE SECRETARY OF THE SOCIETY OF APOTHECARIES, London; Mr. HENRY MEYMOTT, Ludlow; Mr. PLOWRIGHT, King's Lynn; Dr. MAXWELL, Woolwich; Mr. NIELD COOK, London; Dr. HEBB, London; Dr. SHELLY, Hertford; Mr. COWELL, London; Mr. W. COLLIS, Faversham; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; THE REGISTRAR-GENERAL FOR ENGLAND, London; Dr. WILLOUGHBY, London; Mr. DONKIN, Faversham; OUR EDINBURGH CORRESPONDENT; OUR DUBLIN CORRESPONDENT; Dr. BENHAM, London; Mr. BAXTER, London; Mr. BACOT, London; Capt. A. DE RICHELIEU, Siam.

### BOOKS RECEIVED—

Army Medical Report for the year 1883—The Climate of Canada, etc., by W. H. Hingston, M.D., etc.—The Plan of the Central Nervous System, by Alex. Hill, M.A., M.B., etc.—Report of the Sanitary Condition of the Hackney District for the year 1884, by John W. Tripe, M.D.—Proceedings of the Royal Medical and Chirurgical Society of London, April-June, 1885—Annual Report on the Civil Hospitals and Dispensaries in the Madras Presidency for the year 1883—Inspector-General's Report on the Condition of Hospitals and other Institutions for the Insane in New South Wales for the year ending December 31st, 1884—Palliative Measures in Ruptured Extra-Uterine Pregnancy, by W. W. Jaggard, M.D.—Two Pamphlets, by A. E. Prince, M.D., Jacksonville, Illinois—Floating Minute Organic Matter, etc., by David Prince, M.D., Jacksonville, Illinois—Two Pamphlets, by L. Emmett Holt, A.M., M.D.—Our Dwellings, Healthy and Unhealthy, by Catherine M. Buckton—School Hygiene and Diseases Incidental to School Life, by Robert Farquharson, M.P., M.D. Edin., etc.—An Anomalous Human Lung, having Four Holes on the Right Side, by William A. Edwards, M.D.—Two Pamphlets, by G. Pecholier, Montpellier—Transactions of the South Indian Branch of the British Medical Association, April, 1885—Les Microbes Pathogènes, by Le Dr. C. Artigas—A Lecture on Fermentation, by Wm. Hibbert.

### PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Gazette Hebdomadaire—Nature—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medizin—Philadelphia Medical News—Weekblad—Le Progrès Médical—Berliner Klinische Wochenschrift—Centralblatt für die Medicinischen Wissenschaften—Deutsche Medicinische Wochenschrift—The Hospital Gazette—New York Medical Journal—The Canada Lancet—Scotsman, July 17—Journal of the British Dental Association, July—Rèvue de Médecine—Rèvue de Chirurgie—Giornale Internazionale delle Scienze Mediche—Westminster Review, July—Detroit Lancet, July—Asclepiad, July—Liverpool Medico-Chirurgical Journal, July—Archives of Neurology, July.

### HOSPITAL OPERATING DAYS.

Monday.—Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopaedic, 2 p.m.

Tuesday.—Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.

Wednesday.—Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopaedic, Great Portland Street, 10 a.m.

Thursday.—St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.; Chelsea Hospital for Women, 2 p.m.

Friday.—St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

THE MEDICAL TIMES is published on Friday morning. Advertisements must therefore reach the Publishing Office not later than Two o'clock on Thursday.

### SUMMARY OF CONTENTS, JULY 18.

#### LECTURES, &c.:

Dr. Octavius Sturges: Clinical Lectures on Disease in Early Life.  
Lecture IV. Tuberculosis.  
Messrs. W. Lang and J. W. Barrett: On Homatropine.  
Dr. J. A. Coult: On Arthropathies associated with Infantile Paralysis.  
Dr. James Oliver: On Perforating Ulcer of the Bladder.

#### HOSPITAL REPORTS:

King's College Hospital.

#### EDITORIAL NOTES.

#### LEADING ARTICLES:

The Washington Congress in Danger.  
The Lay Element in University Government.  
The Mysteries of Modern Babylon.

#### REVIEWS:

Minor Notices.

#### ABSTRACTS AND EXTRACTS:

The Corpus Callosum; The Basal Pathology of Chorea.

#### REPORTS OF SOCIETIES:

Obstetrical Society; Sanitary Institute of Great Britain.

#### CORRESPONDENCE.

#### INVENTIONS AND IMPROVEMENTS.

#### LETTERS TO UNDISTINGUISHED PERSONS.

No. 5. To a Young General Practitioner.

## ON SOME CAUSES OF DISEASE, AND ON REPARATIVE AND DESTRUCTIVE PROCESSES.<sup>1</sup>

By SAMUEL WILKS, M.D., LL.D., F.R.S.,

Senior Physician to Guy's Hospital.

At the annual meetings of our Association, it has been the custom to select one of its most distinguished members to deliver an address in Medicine, and afterwards proceed to the more practical business of the Section. On the present occasion, however, it has been determined to dispense with the usual address, an intention I had fondly interpreted into an eagerness to devote all our time to work. I was informed, however, a short time ago, that some kind of introduction was expected from this chair. This I heard with dismay, for I had no time to prepare a subject sufficiently elaborated to be worthy of this meeting. You will, therefore, pardon me for making a short address, and alluding to one or two subjects of interest to myself, and which, had time allowed, I should have felt justified in more fully unfolding.

There is a story told of Agassiz, that, at the commencement of his professorship, he prepared a lecture which, he believed, would occupy an hour in delivery, but at the expiration of half that time he found, to his dismay, that he had finished his discourse. He had, therefore, no other resource than to fill up the remaining half-hour by repeating in other words the same doctrines which he had already enunciated. In after years he used to say that the piece he had been enacting that half-hour, he had continued to do during the rest of his life; that is, he had been stating over and over again the same doctrines which had occupied the first eventful 30 minutes of his scientific career. I do not think that this is a solitary experience, for probably all of us are possessed of some leading thought which, in various forms, as occasion suggests, we are always endeavouring to impress upon our public. In our profession, certainly, we are witnesses of men above the middle age constantly repeating themselves; and I could turn to many instances in which some of the most respected seniors in medicine have made speeches, the exact counterpart of what they had delivered 30 or 40 years before. This is an attribute of human nature; and I only mention it to show how extremely difficult it is for anyone, who is getting on in years, to free himself from the trammels which age necessarily brings with it, and what a hard task you set an oldish man by expecting anything of him which can be called new. If science is advancing, we ought to grow with the times; but, unhappily,

<sup>1</sup> Presidential Address delivered at the opening of the Section of Medicine, at the Annual Meeting of the British Medical Association, held in Cardiff, July, 1885.

there is a period in everyone's life when his stature is reached, and he then stands still; fortunate is he if he can remain quiescent, and not fall back, reaching at last that stage of senility when he is only a "laudator temporis acti," and thinks that human nature, with its types of disease, has altered, and medical treatment retrograded, with his own decay.

For my own part, if special reasons had not stood in the way, I should probably have been repeating myself here, and setting free once more the long continued current of my thoughts. And what might these have been in connection with the science and art of medicine? The best method, I believe, to arrive at anyone's sentiments or opinions is to study his actions; and if I do this with myself, and look back to the addresses which I have given at this Association, at my hospital, or at the International Congress, I find the theme is the same. It is one which had its basis formed at a very early period of my career, and became more fixed as years and experience went on. It was this, that the peculiarity of different races of mankind must depend on climate, food, and other surroundings, and that these peculiarities are transmitted; that hereditary tendencies have, therefore, much to do with the physical and mental characters of individuals, and also that these temperaments and idiosyncrasies which are so evolved are most important in the production of our ailments; again, that these surroundings are, in themselves, sufficient to produce active disease—for example, a number of conditions tend to the prevalence of the gouty constitution in England, and this may be carried through several generations, but the same conditions, operating on an individual predisposed, may actually induce an attack in him: that the predisposing and exciting causes are the same. *Morbus Brightii*, and many other diseases, come about through the deleterious operation of our ordinary surroundings, both in the air we breathe and in the food we eat, and not from any well-defined specific cause. I have, therefore, considered that nearly all disease is slow in its origin and progress, and I have never been tired of quoting Hippocrates, the father of medicine, who said, "Diseases do not fall upon men instantaneously, but, being collected by slow degrees, they explode with accumulated force." I thought I saw, even in my student days, how erroneous the books and lectures were in giving descriptions of acute disease as occurring in healthy persons, and then how such affections became at last chronic. The truth, as I saw it, was very early forced upon me by making *post-mortem* examinations; when, for example, a person was brought to the hospital for obstruction of the bowels, attributed to an intussusception, or the lodgment of some indigestible food, and which proved nearly always to be due to a cause of very long standing, or even congenital; in the same way, acute peritonitis was but the termination of some old disease in the abdomen, and a meningitis the ending of a prior disease in the brain. I had thus come to look upon disease as essentially chronic in its nature, induced by the ordinary agents surrounding us, and to believe that the medical art should be mainly directed against the operation of these causes. I have no doubt, had I given an address, and shut my eyes to all the discoveries going on around me, I should have wandered back to the old theme, and found all my opinions confirmed by age. I cannot, however, be blind to what is now occupying the medical mind, and therefore with all sadness confess the truth, my occupation's gone. It is of no use talking any longer of the conditions of our climate predisposing to phthisis; of the hereditary tendency to this disease, much less of any peculiar conformation of chest and frame in those who fell a prey to it, for the disease is due to a bacillus, which may be taken by a husband from his wife, or *vice versa*,

or conveyed by a phthisical nurse to a number of children whom she suckles, or even, indeed, caught in the street; at least, this was suggested in the case of a lad who died of tubercular meningitis, having long had a sore tongue, which was called tubercular. It was surmised that it was primarily a simple ulcer, on which bacilli alighted as he walked through the streets. In order to mollify believers in predisposition, temperaments, and configuration, it is admitted that there must be appropriate soil for the cultivation of the germs, but, after the delivery of these platitudes, they are put on one side for the study of the one potent agent, the bacillus, and are no more considered than predispositions to small-pox, scarlatina, or cholera. I do not for a moment attempt to throw any discredit on modern research, for these bacilli undoubtedly exist, as anyone may prove for himself; but I am rather offering myself for pity, that, having preached on one long text, that it is the great aim of the physician to seek the causes of disease in our ordinary surroundings, and in the tendencies transmitted to us, and to try to remove them, I find my occupation gone; but perhaps I am only shunted for a time to let the express pass by.

It might be worthy of remark, in passing, how treatment accompanies and follows pathological discoveries, in opposition to the mistaken idea, which many seem to hold, that there is a science of therapeutics gained by a simple observation of the action of drugs on the body. It is sometimes said that therapeutics stands still or lags behind other departments of medicine. I think this is not true, and cannot be true; in fact, I am at a loss to know what pure therapeutics is apart from disease and pathological states. It seems to me it is the study of external agents on various diseased conditions; and it is not so much new remedies, but a better indication and knowledge of how and when to use them, which is required. For example, thousands of persons are now cured of nervous diseases, not by a new remedy, but by the old iodide of potassium, and this was done as soon as pathology had discovered the existence of visceral syphilis. So, in the same way, if the doctrine of bacillary phthisis is true, we have our antiseptics at hand, and we have not had to wait for iodoform, eucalyptus, and benzoic acid, and such-like remedies which are now in vogue. The improved treatment in the one case came from observations in the *post-mortem* room, and in the other from the pathological laboratory. If there be one-tenth of truth in the value of the remedies which we see weekly vaunted in the advertisement pages of the medical journals, therapeutics has shot far ahead of every other branch of medicine.

I might here allude to the fact that the discovery of germs in phthisis and some other complaints will probably oblige us to give up our old theoretical notions as regards the pathology of the exanthemata and other specific diseases. It is in these diseases, which are called zymotic, that no microbes have been found. It will be remembered how Liebig marked the resemblance of the course of a specific disease like small-pox to the process of vinous or acetous fermentation. When, for example, an organism is placed in a saccharine fluid, it begins to develop and grow until all the pabulum on which its multiplication depends has disappeared. The fermentative process, therefore, must cease, and cannot occur again in that fluid. In a similar way, a virus inoculated into the human body continues to develop during a certain term, called the period of incubation, and then rapidly multiplies a millionfold, accompanied by a great commotion in the whole system, when the process ceases, and is never capable of occurring again. The likeness to the fermentative process so struck Liebig, that he introduced

the term zymotic for this class of disease, and it has been made use of ever since. The theory may be rational, but it is very remarkable that it is in these very diseases, whose course would have suggested the growth of some organism like a ferment, that this has not been found—I allude to typhus fever, small-pox, scarlatina, &c. ; whilst, on the other hand, in diseases where no analogy can be traced between their symptoms and the fermentative process, microbes have been discovered, as in cholera. Here patients are sometimes suddenly stricken down, and die in a few hours, without any of those previous conditions which in any way resemble the stages of a fermentative process. In phthisis, again, there is no analogy between the symptoms and those of a specific disease where germs have been supposed to be present, since the disease may remain for a long time local, and the blood be unaffected. All modern discoveries regarding microscopic organisms do much to overthrow the zymotic theory of disease, were it not, indeed, under any circumstances, too extravagant a one to hold—a theory suggesting that there are several substances in the blood too subtle to be recognised by any known methods, but affording a pabulum for the growth of germs of small-pox, scarlatina, and such like diseases, when they fall upon us, and that this is the only use of those imaginary constituents of the system. It is a great pity that any word like zymotic, implying a theory of disease, should ever have been allowed to enter our nomenclature. Hitherto, no antiseptic or specific remedy has been found to prevail against the regular course of these diseases, and one reason may be that the enemy to be attacked was an imaginary one ; but from this it does not follow that antiseptics may not be of service in diseases where organisms have been found. I will not dilate more upon this subject, but felt it quite impossible for any one who was making medicine the subject of his discourse to overlook the fact, that all pathological enterprise is now engaged in the search for specific causes of diseases, and to found a treatment upon it. This has rendered the pathology of many diseases much more difficult to understand, since it is almost impossible to graft the new facts upon the old, or even reconcile them with those which are already established.

Amongst many other subjects in medicine of a general nature to which my thoughts have been directed, there is one with which I will occupy you during the remainder of the short time allotted to me. It is a subject which has two sides to it—a physiological and a pathological one—both highly important with reference to clinical medicine. The one aspect has reference to the mutual relation which exists between the different functions of the body, suggestive of the organs having varying activities and compensating actions ; the other aspect is the compensating or actual conservative process which we see going on during the progress of many diseases, a reparative as well as destructive action, and which can be recognised clinically during the life of the patient.

The readers of the lectures of Sir James Paget will remember how he dilates upon a law (which had already been formulated by the older masters in medicine), that the proper adjustment of the various functions of the body is necessary for its integrity ; and in this way every physiological process, however slight, may be looked upon in the light of a natural secretion. This seems like a truism, or mere platitude, and yet it is not seriously or practically considered. To preserve the integrity of the body of a given bulk, so much pure blood is required, and, therefore, suitable organs of a certain size for its production, also a definite amount of depurative organism for its purification. In this way life goes on.

It is so evident that the organs must be proportioned

to their use, that Aristotle maintained that Nature makes the organ for the function, and not the function for the organ. One of the most striking examples of this law is seen in the case of the kidneys. If one kidney be destroyed from any cause, the other will enlarge to compensate for the loss. It will grow until it has reached the point necessary for the discharge of its duties, and then cease to enlarge.

The same probably occurs in other organs ; where, for instance, a portion of the liver has been destroyed, the other lobe has proportionally enlarged ; and, in some chronic affections of one lung, the other one has evidently grown to maintain the balance. These processes are evidently conservative, and indicate a healthy organism. But it may be as well to ask, does a deviation from this line ever occur from some unknown cause, and in this way is an abnormal, or pathological, condition set up ? As regards the former, that is, an increased or diminished function, I do not know that this has ever been suggested in the more complex vital organs, and yet, of late years, a hypertrophy of the liver has been spoken of by pathologists. It is true that the term is given simply to express certain anatomical changes, and not necessarily implying that there has been an excess of the original secreting organ.

As regards less important viscera and structures, it would seem that this limitation to healthy size is not kept ; and, in the case of the spleen, the organ may grow to an immense bulk. Apparently the structure is healthy, and, putting together its supposed function and the state of the blood, it seems as if the balance was upset by the excessive development of one function, and the patient dies from having too much spleen. The same is thought to occur in the lymphatic glands, when they grow to an immense size by the addition of apparently healthy tissue.

Another structure, which sometimes will start into growth without any relation to the original framework, is the bony skeleton, the skull and all the long bones reaching an enormous size and weight ; so also the skin and fat develop until the person is of great bulk. Those are cases which, in a marked degree, show that there are causes in operation which sometimes upset the balance of growth, and the fair relation between all parts of the body.

Now it is worthy of consideration to inquire whether, when the balance is upset by the disease or destruction of organs, any other organs or tissue may take on their extra work. For example, we sometimes find the kidneys so exceedingly atrophied from disease, that we are at a loss to understand how life could have existed with so small a renal structure ; if in health, four or six times that amount is necessary. Must it not have happened that other organs have assisted in their work, notably the skin and intestinal canal ; and may not the record be true that, under these circumstances, urine has been excreted by the nipples, and other parts of the body ?

The liver, too, is sometimes found so small and hard, that it is not difficult to understand why its possessor is dead, but why he should have lived so long. In this case, the purpurine in the water would suggest that fresh chemical actions have been in operation. As regards organs which are not vital, peculiar effects may be observed in the system when they are destroyed, as in wasting of the thyroid body, of the testes, or of the suprarenal capsules. We ask ourselves in what way is compensation made when an organ is diseased, and an answer to this question is what the judicious physician should try to discover, so that, by following nature's laws, he may lengthen the days of his patient. I have observed that the most judicious medical men are those who will take the body as a whole, the good and bad, observe all the different functions, and so, by simple

methods, rule and guide the whole bodily organism, so as to bring it to a proper adjustment. I need not remind you that they could not have been specialists.

Now, when one organ is actually diseased, it is very clear that the balance is upset, but it is equally important to ascertain whether a temporary cessation of function may occur from the operation of any external agent, and so a like disturbance occur. The importance of this question will at once be made clear to you when I ask you to direct your memories to a paper read before one of the medical societies by Sir Andrew Clark, and entitled Renal Inadequacy. The author spoke of cases where the renal secretion had become in every way defective, with corresponding symptoms. The subject debated was whether such temporary abeyance of function could occur in a healthy organ, or whether it must not imply disease. The subject was so differently considered by various members of the society, as to show that this had never been thoroughly investigated. It is true there may be an excess of urine passed; but, if this hold the proportionate amount of solid matter, it shows only that more work is put upon the organ, and not that it in any undue way is depriving the system of more solid constituents than is required. If, however, there be a large excess of water alone, it does generally show a temporary excessive action of the kidneys, and this is usually due to a nerve cause.

It is curious that there is a widespread popular belief in the ever varying action of organs; as, for example, we daily hear of a liver being torpid, or secreting an excessive amount of bile. Bernard's theory of diabetes was that it was merely an excess of a normal function, that the liver was over-active in its glycogenic function. There is also a belief that the degrees of action of the liver are influenced by cold and heat.

In some organs, the action is clearly intermittent. In the case of the stomach, the organ when quiescent is small, containing little blood, and secreting no acid juice. As soon as it is stimulated by food, it enlarges, blood is poured into its walls, and an intensely acid juice is exuded from its mucous surface. The generative organs are more marked examples of the intermittent action, especially in women; but in man, everyone must know instances where a testis may be discharging its secretion every few days, and then be in abeyance for months or years. The lacrimal gland may, under emotion, pour out as much fluid in a week as at other times it would do in a year. The brain during sleeping and waking constitutes, of course, a well marked example of the intermittent action of organs. During violent exercise, it is evident that the organs are more fully at work; there is more tissue-change, and more heat is produced; the skin is acting profusely, and the lungs more vigorously. As regards the brain, we may go a step further; there is not only the general inactivity during sleep, but there probably is in all of us more or less inactivity during our waking hours. If a person be taken from a savage or uncivilized country, and his mental powers can be well defined, and he be placed in a school, and be educated, so that after a time he shows himself possessed of a considerable amount of intellect, we are bound to conclude that, if he had remained in his own country, he would have been in possession of an unused brain or a non-functioning organ. Must, then, the popular belief receive the sanction of the profession, that the liver may be torpid, the stomach inactive, the bowels sluggish, and the nerves unstrung?

Apart from the question of their own individual waking or sleeping, as they are in action or not, it might be interesting to know whether the function of organs is influenced during ordinary sleep, or the sleep of the brain. Seeing that they are under the influence of the nervous system, this might be supposed; but

since it is clear that the circulation is affected during sleep, it is almost certain that their action must be altered. Not only the brain sleeps, but other portions of the nervous system in part. It is said that the spinal system never sleeps, or the patient would die. Perhaps sometimes it does sleep, with the inevitable result. That it partially sleeps is seen in the paralysis of the whole muscular system when the head and limbs fall, and the mouth drops, counterfeiting death; snoring also being a counterpart of the apoplectic stertor. In heart-disease, the state of sleep evidently involves, to a certain extent, the spinal cord, for the interference with respiration and the gasping are among the most distressing symptoms of this complaint. But more observations are required to ascertain the state of the vascular system during sleep. At present, we must be content with the facts which are presented to us. These do not accord with our pre-conceived ideas, which are so strongly impressed upon us, that we act upon them rather than upon experience. The idea of sleep suggests quiet and repose, therefore the blood is circulating placidly through the body, and there would not be the same pressure on the vascular walls as during violent exercise. But is this warranted by facts? For example, are varicose veins found in those who are sedentary, or in those who take much exercise? A more important case is that of hæmoptysis in pulmonary disease, where hæmorrhage occurs much more frequently during the night, after several hours of rest, than during any exertion of the day. It is now many years ago I made this statement, which seemed to be absolutely true, when I was censured by a specialist for having maintained this before students, since it was obvious, he said, that there must be greater proneness to hæmorrhage during exertion. This opposition naturally made me observe still more narrowly, when I was more than confirmed in my original statement by discovering that it was the rule for hæmorrhage to occur in the night. I can only surmise that, during the quiet of sleep, the circulation is more impeded and the tension of the vessels greater, than when the lungs are expanding and the circulation free. If this be so, why should purely theoretic or imaginary reasons guide us in practice, and oblige us to frighten our patient suffering from hæmoptysis by telling him he must not make the slightest movements with his arms, must not move out of bed, or speak above a whisper? I have never yet met a medical man who has told me that he is acting on other than theoretic reasons by so doing, and he has no proof that this quieting and frightening method is the best.

Then, again, take the heart; is it not during sleep that the patient suffers most, and is it not during the night that a weak heart may rupture, or an aneurysm give way? I have known a patient with mitral disease and a quick acting irregular heart gain much by a little exercise: a few paces around the room have quieted and slowed the action of the organ. Many persons are kept in a state of perpetual terror, and become hypochondriacal, because the medical man has forbidden all movement, even in their house, and they have been carried up and downstairs in a chair.

If we look to sanguineous apoplexy, I cannot say what the proportion of attacks is during the quiet of night, and the active pursuits of the day. I myself am impressed with the great frequency of attacks during the night. Of course, many other causes may be in operation during the sleeping hours, as, for example, the cooling of the body towards the morning. It is then that the medical man is aroused by his night-bell during cholera epidemics, and it is then that other temporary troubles connected with the digestive organs occur. The altered circulation, no doubt, is the cause of epilepsy occurring in some persons during sleep, and the supine position may perhaps be the

cause of many backaches being worse at night, as well as increased irritability of the bladder, and other troubles.

There are many other interesting questions connected with the sleeping state, which might throw a light upon the cause of some maladies. For example, headache in many persons is intimately associated with sleep at night and somnolency generally. Now, if it be true, as appears from many considerations to be, that the brain is less vascular during sleep, it would show that headache depends upon the state of the circulation. It may be true that the quiet of sleep may remove many headaches, but it is also true that a heavy sleep is often followed by headache. I am aware of this personally, and can quite sympathise with a member of this Association who, in describing his own case a short time ago in the *Journal*, said that, after a hard day's work, when a feeling of sleepiness came over him, he hailed with delight the ring of the night-bell which was to keep him from his bed, and at the same time prevent the headache on the following morning. I know myself this evil side of sleep too well; and this, and others which I have depicted, are a few of the troubles which may arise during this time. It is true that sleep is "Nature's nurse," is "Nature's sweet restorer," and "the comforter when it visits sorrow," and is one of the best symptoms of the well-doing of the patient, so that, as perhaps you may observe in those obscure bulletins which issue from the fashionable medical men, the only information vouchsafed for the information of the public is that the patient has had a good night or a restless night; but a sound sleep is not always good, and there is many a patient who can exclaim with Coleridge—

"Sleep, the wide blessing, seemed to me  
Distemper's worst calamity."

The subject of which I am here speaking is somewhat vague, and I regret I had not an opportunity of bringing more substantial facts before you. I must be content, therefore, with saying that the varying activity of organs during the day and night, and under different conditions, is one which more thoroughly deserves our attention. The subject is, no doubt, physiological in the first instance, but is, nevertheless, highly important to us as practising medical men.

I will now briefly allude to the purely pathological part of the compensating function to which I have here alluded, that is, the conservative or reparative processes, which are seen going on hand in hand with the destructive ones. In examining a diseased organ, we do not sufficiently distinguish between the two processes; much less do we do so during the life of the patient. There is no doubt some general law in operation which provides for the two kinds of action, the formative and destructive; but the opportunity does not now serve to discuss the question of correlation of forces, and how far we may regard all processes going on in the body as of two kinds, vital and chemical, mutually opposed. In an ulcer, certainly, the two processes are very apparent; there are the disintegration going on, and also the formation seen in the cells and granulations. A very valuable and scientific paper on this subject is to be found in the "*Guy's Hospital Reports*" by Mr. Golding-Bird. It wants but a moment's consideration to see how all organic life on the globe is necessarily associated with death, and that the same law is in operation in pathological processes.

Let me for a moment suggest to you my meaning. Let there be a softening or destruction of the brain; we find it surrounded by a formative cyst or inflammatory products; and, in the syringo-myelus of the cord, the same thing is seen, large cavities associated with new products. It should be remarked, however, that, although reparation is going on, it is only by the

formation of the simplest material; the highly complex structures are never renewed (except, perhaps, in children under special conditions); no injury to any of the parenchymatous organs is replenished by the same material, the repair is made by simple fibre. Bone may be replaced, and skin in an imperfect manner. In the case of the lung, the two processes, destructive and reparative, are always seen together; indeed, an ordinary phthisical lung could never have been witnessed without the double process. The ulcerated tissue would have produced a fatal hæmorrhage or pneumo-thorax long before any extensive change could have occurred in the lung; but the vessel becomes closed, and the lung adherent. Now, the more chronic the case, the more are these reparative conditions marked, so that the pleura becomes greatly thickened, much of the pulmonary tissue cicatricial, and the cavity becomes lined with a firm membrane. Under these circumstances, we say that the signs of phthisis are well marked, the dullness on percussion is extreme, there is a falling in under the clavicle, and the pectoriloquy is pronounced. These are not so much signs of disease as of repair or cure. This is the reason why the young practitioner in such a case gives an unfavourable prognosis, forgetting the meaning of the signs, and, to his astonishment, may find his patient in much the same state a year afterwards. It is worthy of note that fatal hæmoptysis rarely occurs from the destructive process; it is due to the giving way of a dilated vessel in a localised and very chronically affected part of the lung. The same probably occurs oftener than is supposed in the stomach; the chronic ulcer is characterised not so much by the destruction of the tissue, as by the new growth around it; and it is in connection with this that the vessel becomes expanded and thinned, and subsequently ruptures. In cases of scirrhus pylorus, it is quite as much the hypertrophied natural tissue which constitutes the tumour as the adventitious substance.

In the case of the liver, it is often difficult to say what changes are reparative or constructive, and which destructive. As the liver wastes, we observe a large course of veins on the surface of the abdomen, and we regard these as one of the signs of cirrhosis; but it is rather to be regarded as a consequence of the disease than one of its constituent parts. For, while the liver is being compressed, new blood-vessels and new bile-ducts are being formed, and the blood from the portal vessels, which would otherwise be arrested, makes its way to the surface and systemic veins, through the opening out of the old umbilical vein. The case of cirrhosis is a marked example of what I have been saying of the ulcer, whose description would demand demonstration of both a destructive and a formative process; but, in the case of the liver, where the change is so complex, it would be difficult to draw the line; many of these changes, however, are clearly no part of the primary pathological process. I have seen it stated, but I do not know with what authority, that, if the pulmonary arteries be injected in phthisical lungs before removal from the body, the injection may extend into the chest walls through newly-formed vessels. I may take another example in the case of the pseudo-hypertrophic paralysis of children. Now, in all the cases which I have seen, there has been a marked atrophy of the muscles, so that parts are wasted whilst others are enlarged, giving a general deformity to the whole body. In those limbs, too, which are hypertrophied, there is often perfect helplessness, showing that the natural muscular tissue must have undergone a decay. In the case of a boy lately under my care in *Guy's Hospital*, the difference in the size of the legs was most remarkable, one being three or four times the size of the other, but they were

both equally helpless. The one showed merely wasted muscles, the other was firm from the production of new false tissue. The arms were wasted, and yet large masses of new tissue were felt in the deltoid and biceps. In these cases, there is atrophy of muscular tissue, but besides this, there is what is never observed in the adult, a productive process going on at the same time; the latter, however, has not the power to reach to the development of muscle, but remains in its lower state of fibre only. The example, however, is a striking one of the productive process going on with the atrophic one. In the case of the blood-vessels, degenerative and productive processes are constantly seen progressing together. In the cancers and other tumours of bones, we perceive a destruction of the original tissue, and yet new bone growing up in the tumour.

You must forgive me for these few desultory remarks. I should have liked, had time and opportunity served, to offer to your notice some well-developed theme; but I had on the present occasion, no other resource than to look around me, and see what subjects had occupied my thoughts; one or two of them, although crudely brought before you, are, I think, worthy of your consideration.

## ON THE DIAGNOSIS AND TREATMENT OF TUMOURS OF THE BLADDER.<sup>1</sup>

By REGINALD HARRISON, F.R.C.S.,

Surgeon to the Liverpool Royal Infirmary and Lecturer on Clinical Surgery in the Victoria University.

At the request of the secretaries of this section, I have undertaken the responsibility of opening a discussion on the diagnosis and treatment of tumours of the bladder. Only a few years ago, any one occupying this position would probably have felt bound to offer an apology to his audience for the scantiness of the material upon which he had to dilate; such, however, has been the progress of surgery within our recollection, that I feel myself differently circumstanced, and shall ask your indulgence in my attempt to compress the large amount of material which the experience of many has already supplied. Time is more than precious on occasions such as these, and I must, therefore, avoid all historical references, deeply interesting and instructive as they are, and deal with my subject from a purely clinical point, feeling assured that this is the direction which will best answer our purpose to-day.

Under the guidance of the distinguished surgeon who presides over our section, and in the presence of many who have made valuable contributions to this subject, I have the satisfaction of anticipating that the speakers who follow me will fill in the numerous gaps I must necessarily leave, and correct defects in my statement of which I am only too conscious.

I shall confine my remarks to tumours of the bladder proper, adopting where requisite the nomenclature set forth in the report of the Committee appointed by this Association, for the drawing up of which we are largely indebted to Mr. Paul.<sup>2</sup> It is hardly necessary that I should occupy time with any remarks on the diagnosis of these growths other than those which will incidentally occur. Chief reliance will be placed on the circumstances under which blood appears in the urine,

the manner in which the mechanism of micturition is interfered with, the presence or absence of evidences of new growth in the excretion, and the direct and indirect indications which may be afforded by the use of the sound or the catheter.

It will be convenient to arrange tumours of the bladders into two classes or stages: (1) those which, during their entire existence, or for a portion of it, occasion either slight or no distinct indications of their presence; and (2) those which declare themselves by symptoms either seriously disturbing the function of micturition, or which by their constancy or degree threaten the life of the patient.

From the manner in which I have thus attempted in general terms to make use of a classification, it will be at once understood that individually I should be guided as to treatment, not by the fact alone that a patient has a growth in his bladder, but by the symptoms it produces. The mere subjective evidence that a person has a tumour of this kind would not, I submit, warrant the adoption of any operative measures to effect its removal, even if in addition it were possible to demonstrate its existence by other means than digital exploration. Some tumours of the bladder which have been found in the *post-mortem* room appear to have had no history connected with them, and instances are known in patients of the total disappearance, after varying intervals, of symptoms which were unmistakably those of villous growth or papilloma. Of the latter I believe that I am acquainted with more than one case. These are important facts, as they seem to indicate that what nature can accomplish art may hope to imitate. How these growths thus disappear, whether it is by an accidental self-strangulation, or by an inflammatory act, it is impossible to say; but that they do so occasionally, without recurrence, I have not the least doubt. Unfortunately, however, by far the larger proportion of them sooner or later pass out of the condition where operative interference is not to be recommended, and enter upon what I have taken as the second stage of their existence. Whether the transition is slow or rapid, gradual or sudden, much depends on their kind; but whether innocent or malignant, primary or secondary, the great majority of them, sooner or later, make it apparent that life will eventually be destroyed, either by persistent hæmorrhage, or by the degree micturition is interfered with.

The question of operative interference will now be entertained, but before anything further can be said as to the hope of success which is likely to follow this, it is necessary that a more accurate knowledge of the connections of the growth should be obtained. This brings me to speak of digital exploration of the bladder. If you will look at the two drawings before you, you will see examples of two very opposite conditions: one where everything may be hoped for from operation, where complete recovery modern surgery has proved to be possible; and the other where nothing is to be expected except the relief of those symptoms of urgency which have rendered an opening into the bladder necessary. The first drawing represents a villous growth of three-and-a-half years' duration, with a narrow pedicle, and is taken from Quain's "Clinical Lectures" (Plate XXIV), which have recently been published; the second is an epithelioma extensively connected with the posterior wall of the bladder, from a specimen of my own in the Liverpool Museum. Illustrations like the latter tend to show that though the diagnosis may be correct, the prognosis, so far as operative treatment is concerned, may fall very short of our desire, as the propriety of attempting to remove such growths can never be foretold until the finger has been placed in contact with them.

Digital exploration of the bladder relative to the

<sup>1</sup> An introduction to a discussion on the subject at the meeting of the British Medical Association.

<sup>2</sup> *British Medical Journal*, January 12th, 1884.

treatment of tumours seems to me to be called for when it can fulfil at least three objects: (1) the relief of symptoms which are otherwise irremediable; (2) for verifying the diagnosis of tumour; (3) for determining whether the removal of the growth can be proceeded with. The circumstances which require a surgeon to open the bladder for the purpose of finding out what is inside it must be very exceptional, but when by this proceeding the three important objects I have mentioned are to be obtained with little risk, then its importance cannot well be over-rated. There are recorded cases which seem to suggest that if the exploratory examination had been limited to providing a means for draining the bladder, and for examining the growth, it would have been better. In the case of an epithelioma of the bladder, such as you see in the illustration, which I have also taken from Quain (Plate XXIX), to attempt its extirpation is obviously out of the question; to explore it with the finger, and to feel so far satisfied, and, at the same time, to give the patient an opportunity of emptying his bladder completely by means of a short and open road so long as he lives, is legitimate; nay, further, experience has already sufficiently shown that there is no better way of controlling the considerable bleeding which nearly always attends these cases than by providing the means of permanently maintaining the bladder in a condition of more or less contraction.

And now a few words in reference to the operation for exploring the bladder with the finger. If there are two ways to a place of about the same length, but with somewhat different surroundings, you may depend upon it you will have two sets of travellers, with the same aims, but with very opposite notions as to the respective merits of the two routes—so with the bladder: though we are agreed as to the necessity of exploring it, we are not so unanimous about the route. In this country, as well as in America, median perineal urethrotomy seems to be preferred; whilst in France, the claims of the supra-pubic operation have been forcibly urged by Professor Guyon, Pousson, and others. Sir Henry Thompson has advocated the former method, not only as being the safest and most convenient for exploration, but, as he has shown by examples, for extirpating these growths. It seems to me that this form of procedure is to be preferred on several grounds. In the first place, it provides a direct access to the more usual position of these growths; by a continuance of the incision forwards into the membranous urethra and backwards to the extreme limit of the prostate, it affords more room for manipulation than at first sight appears; but what is of more importance, it is, I believe, the best position for the drainage to follow, which is a most important item in the management of these cases. If a perineal exploration shows the position or character of the tumour to be such as would be benefited by an access from the front, should it be determined to remove it, there is nothing to prevent the addition of the supra-pubic incision, as Billroth demonstrated. A supra-pubic incision is none the worse for having a more dependent opening, as Frère Côme practised a hundred years ago in connection with his success as an operator for stone. But, as I have already intimated, the great importance of the after-treatment, in relation to thorough drainage, renders to my mind the perineal procedure almost a necessity. In connection with this point, it must not be forgotten what are the conditions under which these operations are often undertaken. In addition to the tumour which it is purposed to remove, there are usually present, either in the bladder itself, or in the organs associated with it, pathological changes which add considerably to the danger arising from the retention of anything which ought to escape. The viscus is occasionally sacculated,

the ureters are patent and frequently largely distended, whilst the kidneys are rarely sound where the obstruction caused by the growths has been of long continuance. Hence, we have much to fear from any extension of a suppurative process after the operation, as I have seen in two instances which have recently come under notice. One of the best safeguards against a contingency such as this is thorough drainage, and this I think can best be secured through an opening in the perineum.

The feasibility of attempting to remove the tumour having been determined by digital exploration, the precise means of doing so has now to be considered. It will not be necessary for me to describe at length how this has been effected after an opening has first been made into the bladder; in some instances the finger-nail has sufficed; in others, various kinds of forceps; quite recently, Mr. Pitts has recorded<sup>3</sup> a case where a growth was successfully removed by the *écraseur*. In examining two cases which terminated fatally, it appeared that if it had been possible to have applied a ligature round the pedicles, and then to have removed the growths cleanly, either with forceps or scissors, a different result might have followed. The nearest approach to such a proceeding seems to be one recorded by Mr. Henry Morris,<sup>4</sup> who, failing on the first attempt to remove a growth in consequence of the want of the most appropriate means for extraction, the patient was left for two days, when the tumour was found prolapsed into the wound. Having stretched the edges of the wound apart by retractors, he succeeded in placing a ligature of catgut over the base of the growth and removing it with scissors. The patient made a good recovery. When, after the bladder has been opened and explored, it seems practicable to remove the tumour, this should be effected as completely as possible; to take away a portion of it is to leave the remainder to inflame, suppurate, and possibly to become gangrenous, thus providing a fruitful cause for pyelitis, through the largely dilated ureters. Not being entirely satisfied with the forceps that hitherto have been used for the purpose of seizing and extracting these growths, I have had some others made for me by Messrs. Krohne and Sesemann, which, so far as I have been able to judge of them in practice, are well adapted for this object. They consist of an ordinary pair of bladder-forceps, with a free margin; by this contrivance it is almost impossible to do any damage to the wall of the bladder itself. The removal of the growth is effected partly by twisting slowly with the hand, and partly by the crushing action of the jaws of the instrument. In the exploration of the pedicle, both before and after removal of the growth, I have found one of Marion Sims' enucleator hooks exceedingly useful. If, however, the connections of the tumour are extensive, and there is a doubt as to whether all can be got away without doing serious damage to the bladder itself, I feel sure that we had better content ourselves with the opening, which may under all circumstances be safely made, and the drainage that this opening with a suitable apparatus will provide. The lesser proceeding has in many instances proved the means of arresting hæmorrhage, and of adding materially to the comfort, as well as to the life, of the patient, even where it has been found impossible either to remove the tumour or with safety to reduce its size.

Time will not permit me to illustrate these remarks with cases from my own practice, where I have operated in accordance with the views expressed in this paper; these have already been noticed in a previous communication.<sup>5</sup> I hope that Dr. Stein, of New York,

<sup>3</sup> Clinical Society, May, 1885.

<sup>4</sup> *The Lancet*, April 21, 1884.

<sup>5</sup> "On the Surgical Treatment of Hæmaturia," Liverpool, *Medico-Chirurgical Journal*, July, 1884.

who has contributed importantly to the literature of this subject,<sup>6</sup> can tell us something to-day as to the general results following operative treatment, drawn from his most recent investigations upon this point.<sup>7</sup> And what applies to the male is equally applicable to the female, though with the latter, by reason of the anatomical differences in the parts, both exploration and removal can be more readily effected. My friend, Dr. Alexander, of Liverpool, was, I believe, one of the first in this country to demonstrate the successful removal of growths from the bladder under these circumstances. Of excision of portions of the male bladder I have had no experience; so far as I am aware it has been limited to some experiments on the lower animals, in furtherance of the subject which we have now under discussion.

In conclusion, it cannot be denied that operative surgery has already proved itself to be of considerable service in the treatment of a very distressing class of disorders, and for which little is to be hoped for from medicinal agencies. If I may be thought to have been too general in some of my remarks, permit me to say that this has been my intention; my object has been to open a discussion, and not to narrow it unnecessarily. The time has not arrived when it would be possible to lay down hard and fast lines of demarcation; much must be left to individual judgment. Where therapeutics are to end and surgery is to commence, experience and the application of those principles which are of general utility, and are not the exclusive property of any one set of organs, will enable us to determine what is best for each case as it presents itself to our notice.

### ON THE INFLUENCE OF SEASON UPON CALCULOUS DISEASE IN NORFOLK.

By CHARLES B. PLOWRIGHT, M.R.C.S., F.L.S.,

Surgeon to the West Norfolk and Lynn Hospital.

THE prevalence of this disease in East Anglia has been so long remarked, not only by the profession, but also by the inhabitants themselves, that any observations upon its causation cannot fail to be of interest provided they be founded upon some accurate basis, and are not the mere outcome of a pet theory or haphazard guess. The most available data upon which to work consist not, as is the case with most diseases, in the deaths caused by the malady, because while the cases originate in various localities, the majority of the deaths occur in our hospitals. Fortunately, the statistics of the Norwich Hospital, extending over a period of more than a century, and embracing between 1,400 and 1,500 cases, have been kept in such a manner as to show the exact locality in which each case originated. Through the kindness of Mr. Cadge, I have been able to avail myself of them in working out the geographical distribution of the disease in this county. The results of this work must be left for a future communication, but I would remark that the general outcome of it is that calculus as it manifests itself in Norfolk is a water-spread disease, dependent in some way upon the quality of the water supply.

It would be, however, very unscientific to shut our eyes to the fact that other, even if they be subsidiary,

causes may come into operation, and if they do they are worthy of our attention.

It happens that at the extreme eastern and at the extreme western limits of the county are two hospitals, the Great Yarmouth and the West Norfolk and Lynn; one was founded in 1835, the other in 1838; the former contains 30 and the latter 48 beds. Both draw their cases in part from the respective towns in which they are situated, and in part from the surrounding country districts. From the time of their establishment to the present, one has admitted some 124 and the other some 107 cases. The Lynn Hospital, however, draws very nearly three cases from the agricultural district surrounding the town to every one from the last-named locality, whereas the case is just the reverse with the Yarmouth Hospital, which gets nearly three cases from the town to one from the surrounding district. I do not know of any published data from which the time during which calculi are forming can be estimated with accuracy; very probably such information does exist, but the general impression which existed in my mind, was that the process of formation was often a question of years, depending of course upon the nature of the calculus. Of course, it is with uric acid calculi that we have most to do in the present investigation. It usually happens that patients have suffered from symptoms of lithuria long before a stone is detected, but it does not follow that a calculus has actually existed all that time. The following case shows that in seven months a considerable uric acid calculus may become developed. A man was cut at the Lynn Hospital, on 5th October, 1870, and a uric acid calculus weighing 124 grains removed; he returned to his home—a highly calculiferous village—and was readmitted on the 29th May, of the following year, when a dense uric acid calculus was removed, weighing 279 grains, which is at the rate of 37 grains per month. It may be added that after the first operation the bladder was carefully examined for a second stone with the searcher, as is the routine practice at this hospital, but none was found.

Upon tabulating the stone cases of the Lynn Hospital for the past 50 years according to the months in which they were operated upon, we get an insight into the season of the year at which the disease is most frequently observed, for stone cases do not as a rule remain long in any hospital before operation, nor do surgeons usually give a patient much rest after they have once discovered he has a stone in his bladder. We notice at once that fewest cases occur during the cold winter months of November, December, and January, after which they gradually and continuously increase during February, March, and April, and attain their maximum in May. During June and July they decrease gradually, but take a sudden drop in August, rising again in September and October. The sudden fall in August shows very distinctly upon the chart, and is without doubt due to this being the month of the harvest, in which the whole agricultural population strain every effort, even at the expense of some personal discomfort to take part; the men because of the higher wages they obtain, the women in part to assist them, as well as with the children to participate in the benefits of the gleaning. The influence of harvest is observable with other diseases, inasmuch as the Lynn Hospital always contains fewest patients of all classes at this season. It is also shown by the less number of applicants for parochial relief at the agricultural unions, when old and young, ailing, and well, try if possible to keep out of these public institutions. Further, this August fall is not observable at Yarmouth, where the majority of the cases are derived from the town. The August fall is followed by a rise in September and October, which may be in

<sup>6</sup> "A Study of the Tumour of the Bladder." New York, 1881.

<sup>7</sup> "Results of Operations on Bladder Tumours," *New York Medical Record*, No. xxvii, 1885.

part compensatory, but which has doubtless another cause. In June, July, and August, the agricultural labourer has engaged in his most arduous duties, during the hottest season of the year, for the mowing and gathering of the hay has preceded the same operations in the corn field; he has necessarily lost a large amount of fluid from his body by cutaneous exhalation, resulting in a commensurate concentration in the urine. It is known that calculus is more common in tropical regions than in cool climates like Norway

out. On the other hand, all winds, especially easterly winds which, containing less moisture than any body with which they come in contact, must rob that body of more or less of its moisture as they pass over it. A more potent factor than the wind is to be found in the dryness of the atmosphere. The upper line upon the chart shows the average humidity of the air for a period of 15 years at Wisbech, 13 miles from Lynn, from the observation of Mr. S. H. Miller, F.R.M.S.<sup>4</sup> By this it appears that the rise in the

and Sweden.<sup>1</sup> Beale<sup>2</sup> has also shown that the concentration of the urine in cholera is associated with the formation of minute calculi in the kidney. The causation of calculi in this district, however, is not a simple question of heat and cold; if it were so, the disease would attain its maximum in July and August, whereas in point of fact it has done so two months earlier, namely in May. The theory has been advanced that the east winds are one of the main factors in causing stone in Norfolk, "by checking cutaneous secretion and deranging delicate digestion, they cast additional work on the kidneys and liver, and so derange their functions and lead to lithuria." In East Anglia we have on an average 42 days annually between 1st January and 21st June, in which the wind is north-east or east,<sup>3</sup> so there would appear to be some correspondence between the east wind and the vernal rise of our stone cases. It is not, however, the coldness of the wind which does the harm; the colder the surroundings, *ceteris paribus*, the more water passes through the kidneys, and the less consequently is the tendency of the solids, both crystalloids and colloids, held in solution in it to separate

number of cases accurately follows the rise in the dryness of the air, both attaining their maximum in May. I have only been able to obtain the particulars of the Yarmouth cases since 1863, and much reliance cannot be placed upon any deductions from them. It is worthy of remark that they do not show August or harvest fall so marked as in the Lynn cases. They do show a marked fall in June, corresponding to the increase in the humidity of the atmosphere. June is the commencement of the bloater season, but whether the herring harvest has anything to do with the fall I cannot say. The conclusions I would draw are:—

- (1) That most stone cases apply for treatment at the Lynn Hospital in May, which corresponds to the time of year in which the atmosphere contains the least amount of moisture.
- (2) That this may be in part due to the east and north-east winds of spring.
- (3) That the agricultural labourer either engenders or becomes cognisant of his disease after his exertions during the heat of summer.
- (4) That the disease is in abeyance in the winter months.

I must, however, remark that the above are only so to speak subsidiary causes; for the main cause of the

disease in Norfolk we must look further. Especially is this manifested by the fact that during the past 20 years, we have had 51 cases of stone in the Lynn Hospital, 50 of which came from the east side of the river Ouse and one only from the west. The east winds blow as much on one side of the river as the other, and the population live under similar conditions, they work equally hard, but they drink a totally different water.

IRREDUCIBLE FEMORAL HERNIA WITH  
OMENTAL SAC—OPERATION FOR RADICAL  
CURE.

(Under the care of Mr. R. CLEMENT LUCAS.)

(For the report of this case we are indebted to Mr. COOK  
and Mr. FISHER, the clinical clerks.)

This patient had been the subject of an irreducible femoral hernia on both sides, which not only caused her pain, but frequently gave rise to symptoms of strangulation, and no truss had proved efficient to keep them in place. The right hernia, which was of considerable size and believed to be the chief cause of her troubles, was operated upon by Mr. Lucas in July, 1884, and the report was published in the *Medical Times* for Dec. 13, 1884. There was found to be a large omental sac adherent to the peritonæal sac, and into the interior of this omental sac it was evident that the bowel was apt to descend. The sac and omentum were cut away, and the patient recovered without any abnormal rise of temperature, the wound healing by first intention. It was thought that a truss would prove sufficient to prevent any increase in size of the other tumour, and also to guard her from any risks of strangulation. She continued to wear a double truss until March, 1885, when, owing to pain in the left hernia, she gave up wearing an instrument. About the same time she had several attacks of sickness, but the side which had been operated upon gave her no inconvenience. The relief she had experienced from the operation on the right hernia induced her to seek operative relief for the left, and by the advice of her medical attendant, Mr. F. M. Corner, she again placed herself under Mr. Lucas's care.

S. A., æt. 28, was admitted into Guy's Hospital on May 5th, 1885. In the right groin was a faint vertical line about an inch and a quarter in length indicating the position of the operation last year. On the left side was a small tender hernial tumour lying just below Poupart's ligament. Mr. Lucas operated on the day of her admission. On examining the tumour before operating, it was found to contain bowel, which was reduced with a gurgle leaving something solid behind. Chloroform having been administered, Mr. Lucas made a vertical incision under spray about an inch and a half in length over the tumour. A small vessel was divided and secured in the cellular tissue. The sac was reached and opened. Within the sac was found a piece of omentum, almost spherical in shape, having a narrow neck, and hollowed out in its interior, which communicated directly with the abdomen. The omentum was tied in two portions at the neck and removed. The sac was then dissected up and cut

away, and the skin united by five wire sutures. An opium pill was ordered every six hours. Milk diet. Carbolic dressings were used.

May 6th.—The patient passed rather a bad night, but is otherwise doing well. Temperature, 99°.

May 7th.—Patient passed a good night. Has very little pain. Wound dressed and healing well. Temperature, 99·2°.

May 8th.—The wound is closing well. All the sutures were removed except one in the middle. Temperature 99·2°.

May 11th.—The remaining stitch removed. No sign of suppuration. Wound practically healed. Temperature, 99°.

May 14th.—Wound quite healed. Antiseptics left off. Temperature, 98·4°.

May 25th.—The patient went out wearing a truss, but the cicatrix is still tender and pains her a little in walking.

# Medical Times and Gazette.

SATURDAY, AUGUST 1, 1885.

THE fifty-third annual meeting of the British Medical Association opened on Tuesday afternoon at Cardiff. Every preparation had been made for the reception of the members, and there was evidently on every hand the most complete satisfaction at the arrangements. The Town Hall, with its various adjoining offices, which had been generously thrown open by the Mayor and Corporation, was admirably arranged for the carrying on of the work of the Association. At the first general meeting held in the Assembly Rooms, the retiring president, Dr. Cuming, of Belfast, delivered a short and graceful farewell address, in which he expressed his gratitude to the Association for the great honour which they had conferred upon him by electing him president. The position of the society was gratifying in the present and hopeful for the future. Its work was being carried on with increasing vigour and efficiency. The great organization should be conducted in a spirit akin to that by which the action of the individual professional man should be inspired—success should be sought not by striving after striking and general impressions, but in doing its proper work steadily, perseveringly and unostentatiously. Mr. Macnamara proposed, and Mr. Wheelhouse seconded a resolution that the cordial thanks of the Association should be given to Dr. Cuming. A high tribute was

paid to the retiring president for his firmness and geniality during his year of office, and for the very hearty reception which was accorded to the Members of the Association during the meeting held last year at Belfast.

THE motion for the adoption of the report of Council elicited a very interesting and animated discussion, especially that part relating to the printing of the *British Medical Journal*, and the provision of suitable premises for printing and for the prosecution of the editorial work. Dr. Balthazar Foster, President of the Council, proposed the adoption of the report. He stated that he had given considerable attention to the subject of the printing of the Journal, and that he was convinced that it should be carried on by the Association. He had made numerous enquiries of practical men of business who were of the same opinion. He then drew attention to the insufficiency of the present "shop" in the Strand. The printing of the Journal was carried on under conditions unworthy of the dignity and power of the Association. The editor had no suitable room for the proper performance of his work, and he was compelled to use his private residence for the work of the Association, while Council meetings were held in Exeter Hall. Mr. Henry Power, who seconded the adoption of the report fully agreed with Dr. Foster. Dr. Brown, in a very animated speech, maintained that the printing could be done more cheaply by an independent firm. The Association was not sufficiently strong to justify the expenditure on buildings of so large a sum of money as that proposed. Subsequent speakers spoke most strongly against the recommendation, which was not warranted by the requirements of the Journal or by the financial results likely to accrue in the sale of the paper or its advertising connection. Dr. Bampton suggested that the necessary premises might be found in the suburbs, where the cost would be nothing near the amount mentioned. The fact that a great deal of the prosperity of the Journal was due to the advertisements was no argument why, in these days of great advancement in telephonic and telegraphic communication, the premises should not be removed from London. Some speakers warmly advocated the establishment of central association rooms to form a club where members from provincial towns could meet. Dr. Foster, in his reply, pointed out that the Council had voted no sum of money—that no site had been decided upon. The Council desired nothing further than suitable room for carrying on the work of the Association. He referred to the great increase in the revenue of the Association since the printing of the Journal had been taken into the hands of the Association. The Association was not to be guided by those members who had been unfortunate in their speculations. A business house was absolutely necessary, and that business house must be central and within the reach of other business houses. It was pointed out that, notwithstanding the importance to which their Association had attained, it had no visible symbol of its existence in the metropolis as had other institutions of far inferior importance. The proposition for the adoption of the report was almost unanimously carried.

ON Tuesday evening the President, Dr. W. T. Edwards, delivered his address. Dealing chiefly with matters local, the early history and rapid strides of Cardiff, the public institutions, educational progress, sanitary arrangements of the town, and concluding with a short allusion to the great advance of science, &c., it was listened to with marked attention. Dr. Strange, of Worcester, proposed, and Dr. Wm. Roberts, of Manchester, seconded a vote of thanks to the President for his very interesting, able, and not too lengthy address. The discussion that followed, on the payment of the railway-fares of the representatives of the branches on the Council, was very lively and amusing. Dr. Dix proposed that the fares should be paid. Mr. Vincent Jackson seconded the proposition. It was pointed out by Dr. Ward Cousins that as arrangements were being made for the extension of this representation, the Association would, if the resolution were passed, be compelled to pay the expenses of representatives from Jamaica, India, &c., and this would involve a large expenditure. Dr. Phillippo, of Jamaica, who was received with great applause, stated that his branch did not wish that the expenses of its representatives should be paid. He felt only too happy and too honoured in being permitted to take part in the grand work of the Association. Mr. Dix, in reply, humorously stated that, according to his resolution, the representatives, even if they came from Jamaica, would only be paid their train fare. The resolution, on being put to the meeting, was negatived by a very large majority.

At the second general meeting held on Wednesday, Dr. Balthazar Foster proposed on behalf of the Council that the invitation to hold the annual meeting of 1886 at Brighton be accepted. The resolution was seconded by Mr. Macnamara and carried, and Dr. Withers Moore, of Brighton, was chosen President-elect. Dr. W. Roberts then delivered the Address in Therapeutics, which was on "Feeding the Sick." Dietetics, he said, covered more ground than any other branch of the healing art. But so far as he knew, there was no systematic teaching in the subject afforded to the student at any of our medical schools. He was left to pick up his knowledge of this subject as best he might, and during the earlier years of his life prescribed for his patient according to the likes or dislikes of his own stomach. After speaking of the use of alcohol, Dr. Roberts remarked that there was a clear difference to be discerned in the dietetic habits of the two sexes. Men consumed much more meat and alcohol than women. On the other hand, the consumption of tea and coffee, but especially of tea, was markedly more abundant among women than men. It might be regarded as certain—or as a very general rule, at least—that any food or food accessory, the use of which was not followed by a sense of discomfort, was beneficial to the individual. Dealing with the accessories used with our food, the lecturer said that distilled spirits, in the proportions in which they were commonly used dietetically had but a trifling retarding effect on the digestive processes, whether salivary or peptic. Taking this in conjunction with the stimulating action which they exercise on the glands which secrete the digestive

juices, and on the muscular activity of the stomach, their effect in moderate dietetic proportions must be regarded as distinctly promotive of digestion. Wines were found to be highly inimical to salivary digestion, but not when their acidity was neutralised by an alkali. The practice of mixing wines, especially sherry, claret and hock, with soda, seltzer, or some other effervescent table water was therefore highly commendable in the case of persons of weak digestion. Tea had an intense inhibitory effect on salivary digestion owing to its tannin, but the effect could be neutralised by the addition of 2 per cent. of carbonate of soda. Tea, coffee and cocoa all exercised a retarding effect on peptic digestion, and should therefore be taken very moderately by persons of weak digestion. On the subject of feeding the sick with liquid food, Dr. Roberts said widespread misapprehension existed among the public in regard to the nutritive value of beef-tea. The meat remnant should be beaten to a paste in a mortar and duly flavoured, when it constituted not only a highly nourishing, but exceedingly digestible food. The whole address constitutes a valuable addition to our very inadequate knowledge of a highly important branch of therapeutics.

At the third general meeting, on Thursday, Mr. John Marshall delivered his Address in Surgery, and the Sectional Meetings were continued in the afternoon. Some of the addresses by the Presidents of Sections are briefly abstracted in another column, and we have singled out that of Dr. Wilks for publication in full; but of the other Proceedings of Sections we have as yet received no report, with the exception of the Surgical Section. Here on Wednesday there was a short but interesting discussion on Mr. Harrison's paper on Bladder-Tumours, which we print in full in another column. Dr. Alex. W. Stein, of New York, remarked that in forming a judgment of the relative advantages and disadvantages of operations, we must not be guided simply by the percentage of deaths or recoveries in given cases, but must enquire into (1) the conditions which in each procedure favoured success; (2) the causes which determined fatal terminations; (3) the actual condition at the time reported as recovered; (4) the time that had elapsed since the operation. Success in removal of tumours depended entirely upon (1) early interference, and (2) complete removal of the growth. Dr. Stein advocated the supra-pubic removal of tumours. By the perinæal operation the bladder could not be properly manipulated—the work was all done in the dark. In the supra-pubic operation the parts were freely exposed to view and manipulated. There was no danger from the operation if due precautions were taken. For the proper exploration of the bladder he advocated bisection of the prostate. A very ingenious instrument was exhibited by Dr. Stein for the dilatation of the female urethra. Mr. Bennett urged the claims of the supra-pubic operation, which, when conducted with antiseptic precautions, prevented cystitis and pyelitis. He thought sufficient attention had not been paid to the proper suturing of the bladder after the operation. Where the tumour had a broad base, or where it was of a malignant character, it would be easy to remove a portion of

the wall of the bladder with the growth; this could be done in the supra-pubic operation, but not in the perinæal. Mr. Harrison, in reply, stated that one of his colleagues had, in a case of malignant growth of the bladder, opened the abdomen and removed the growth with that portion of the bladder to which it was attached.

THE Medical Relief Disqualification Removal Bill was read a third time in the House of Commons, on Friday last week, without discussion. The Government had not a word to say either for or against it, and her Majesty's faithful Opposition were conspicuous by their absence. On the Thursday evening the Bill had met with an altogether different reception, and had excited prolonged and angry debate. On the motion that the measure as amended be considered, Mr. Collings moved that the term "medical or surgical assistance" in the Bill shall include all medical and surgical attendance, and all matters and things supplied by, or on the recommendation of the medical officer having authority to give such attendance and recommendation at the expense of any poor-rate. This amendment was supported by Members on both sides of the House, but was determinedly and obstinately opposed by Mr. A. Balfour. That Minister proved very carefully, and much no doubt to his own satisfaction, that the Government never intended to give such a wide meaning to the term "medical relief"; but he failed entirely to recognise the temper of the House, and the consequence was that Government were beaten by 180 to 130 votes. The Chancellor of the Exchequer then declared that the Government would no longer assume any responsibility, for good or for bad, with regard to the measure; and it was taken in charge by the majority of the House. Mr. J. Collings moved and carried some amendments which had been placed on the business paper by Mr. A. Balfour. Mr. Orr Ewing made an attempt to get Scotland excluded from the Bill, but the Scotch Members themselves were far from being of one mind on the matter, and after considerable discussion Mr. Ewing's proposal was rejected by a large majority. Then followed what our contemporary the *Times* rightly calls "a heated and somewhat confused conversation," as to what should next be done with the Bill, and who should do it; but, after much waste of time and unseemly wrangling, the House in general decided, on the motion of Mr. Collings, that the third reading should be taken on the Friday.

HAVING thus passed through the House of Commons, the Bill appeared in the Upper House on Monday, and even in that usually calm and serene atmosphere its presence at once produced the same baneful effect that it had all along excited in the Lower House. Begot by Party Purpose out of Party Politics, and its bringing up and management having been as bad as its parentage, the unhappy measure is dogged by misfortune and evil. In the House of Commons it brought discredit upon nearly all who meddled with it; and in the House of Lords it at once produced discord and wrangling. It was read for the first time without any motion to that effect, but simply by the right of having come up from the

Lower House; and that done, Lord Milltown gave notice that he proposed to move that the Bill be read a second time on Thursday, July 30. This brought up Lord Granville, who complained of Lord Milltown's proceedings, and said that he himself intended to move the second reading on Tuesday, as it was a matter of great urgency; and he added that he did not see why the Earl of Milltown should have intervened. Lord Milltown replied that he had as much right to do so as any other peer, but that he should be most happy to meet the suggestion of Lord Granville and put down the Bill for the Tuesday. This did not at all satisfy Lord Granville, who said the measure had been abandoned by the Government, and therefore had naturally been cared for by the Opposition; and that he had been asked to take charge of it in the Upper House. On the other hand, Lord Milltown contended that the Bill was a derelict; that he had taken a great interest in it; had, as an independent member, taken charge of it; had been the first to give notice about it, and meant to keep that advantage. The wrangle over the question was renewed at length later in the afternoon; and the Clerk of Parliaments having been appealed to, stated that Lord Milltown had been the first to give notice of motion with respect to the Bill; but the dispute was not ended till the Earl of Limerick formally moved that Lord Milltown's motion be given precedence. Lord Granville then gave way, and the motion was agreed to without a division. It is difficult to understand why the two parties in the House should have thought the matter in question worth quarrelling about; and more difficult still to read the proceedings with any patience or sympathy. It is rather pitiful to find Lord Granville pleading that he could not on Monday walk quite so fast as he usually did, and therefore arrived at the House two or three minutes too late to be beforehand with Lord Milltown; and one cannot but regret that he thought it worthy of his dignity and position to continue the dispute with the latter nobleman for even ten minutes. And on the other hand, everyone will feel that Lord Milltown lamentably failed in courtesy to his much more illustrious opponent. The Bill was read a second time on Tuesday, without any division. Many speeches were delivered on the subject, and most of them were of an apologetic character. No one seemed to honestly like the measure, and some strong things were said against it; but no one cared enough about the matter to vote against it. The next stage was to be taken on Thursday.

THE Secretary of State for War, Mr. W. H. Smith, in replying to questions put by Mr. Beresford, informed the House that service in Egypt and the Soudan does not count as a tour of foreign service unless it extends to twelve months; and that, therefore, medical officers who have returned home after less than that service there will have to complete their periods of foreign service, and will probably be sent abroad during the autumn for that purpose. The tour of home service during peace ranges from two and a half to three years; but campaigns abroad reduce this average in proportion to the medical officers

required. As a rule these officers have 61 days' leave yearly, during which time they can of course adopt any means they may think desirable to enlarge their professional knowledge, and to fit them for examination for promotion. Special leave was sometimes granted for the purpose of attending civil hospitals, but the demand for medical officers was so great that such special leave could rarely be given. Every endeavour was made to keep officers at the same station during a tour of home service; and they were at liberty to attend civil hospitals or schools so long as such attendance did not interfere with their military duties.

NEVER surely was the truth of the vulgar saying that "a fasting stomach has no conscience" better exemplified than at the London University on Tuesday. Convocation met on that day for the long-anticipated discussion on the proposed reconstitution of the University. Distinguished graduates were present in large numbers, and members had come from far distant cities to give their opinions and their votes. For more than two hours the discussion was carried on with increasing vigour. As each speaker in succession sat down, members sprang up by the dozen in hopes of catching the chairman's eye, and it was clear that the discussion could have been carried on with activity for another two hours. And yet, when the clock pointed to the dinner hour, the proposal of a member to adjourn the discussion until November was received with suppressed delight, and in spite of the protests of the gentlemen from the provinces, was carried by a large majority. In the interests of the University the decision was a wise one, for there could be no doubt that the majority of those present were hostile to the adoption of the proposed scheme of reform. But their eagerness to dispose of their dinner was more pressing than their desire to dispose of the scheme, and its promoters, doubtful of securing a majority in their favour, wisely contented themselves with a majority in favour of dinner.

THE discussion mainly turned, as we predicted that it would, on the effect which the scheme would have on the influence of Convocation in the affairs of the University. The supporters of the scheme did their best to show that the powers of Convocation would remain unchanged, but even Lord Justice Fry admitted that the centre of gravity in the administration of the University would be changed, and that not to the advantage of Convocation. There can be doubt that this difference in the views of the opposite sides is a vital and irreconcilable one. Men who hold with Dr. Silvanus Thompson, that Convocation is the University, and men who hold, with some of the supporters of the scheme, that the powers of Convocation always have been, and always ought to be extremely limited, cannot expect to find a common standing-ground, however much the latter may gild their opinions by conciliatory speech. The question then really is, whether Convocation will consent to surrender a certain visionary influence in a mere examining body, threatened with serious rivalry, for a more limited and perhaps more visionary influence in a real Univer-

sity, standing without a rival at the head of the educational activity of the largest city in the world. A compromise will of course be offered in the direction of increasing the representation of Convocation in the Senate. But the vital point in the scheme is to give the teachers a substantial voice in the government of the University, and that cannot be secured without demanding some sacrifice from Convocation.

WE think that the action of members of the Senate, in coming down to Convocation to oppose the scheme, was not conceived in the best taste, and yet we must admit that their arguments against it were more worthy of consideration than those of the less distinguished graduates, who chiefly directed themselves to playing on the *amour propre* of Convocation. Mr. Hutton's contention that the proposed Boards of Studies, each representing a different faculty, would be likely to pull different ways, and so nullify the effect of their respective recommendations to the Senate, was the most business-like objection in what Mr. Anstie justly stigmatised as a very unbusiness-like debate, so far as the opponents of the scheme were concerned. On the whole, it must be admitted that, conceding certain valid objections to the scheme, its supporters undoubtedly had the best of the argument, and all reasonable members would have felt, if Convocation had persisted in rejecting the scheme, that it had been guided by its tail, and not by its head. The assertion of Mr. Savory, who seconded the proposal for the adoption of the scheme, that it was not intended to lower the standard of the degrees of the University, was received with such general applause, that it may be definitely concluded that the London University can never be looked upon as likely to provide the average medical student with an accessible degree, and hence can never come into serious rivalry with the Colleges, one of which Mr. Savory so ably represents. It may also be concluded that, being thus minded, Convocation will not oppose the Colleges in their attempt to satisfy the hankering of the aforesaid student after the style and title of "Doctor."

THE news from Spain grows worse every day, and the misery throughout the fifteen or more provinces now invaded must be terrible. But it does not seem as yet to have touched the English heart, or if so, it has also touched it with a sense of the hopelessness of any efforts on our part to relieve it. So far our compassion has not got beyond the preaching stage. The daily official records of cases and deaths from cholera are admittedly so incomplete that they are not worth publishing, but we shall not be overstating the case in saying that there are some 2,500 fresh cases, and over 1,000 deaths every day. The province of Saragossa is still suffering severely; it witnessed 3,526 cases and 1,349 deaths in the first three weeks in July. At Madrid the mortality is slowly but surely increasing. The accounts from all the places attacked concur in describing their sanitary condition as something inconceivable. Aranjuez is depicted by a correspondent of the *Scotsman* as an oasis of almost perfect beauty soaked in universal filth, its streets and houses devoid

of drains, and its water-supply derived from surface wells. No means were taken to avoid the terrible pestilence which has destroyed one-fifth of its population. The people might easily have been transferred to tents on the surrounding heights, but there was no one to suggest it. Even the soiled linen of cholera patients was thrown on the grass and allowed to swelter in the sun. One-tenth of Dr. Ferrán's energy would have probably saved thousands of lives, if it had been directed to carrying out the teaching of well-proved principles, instead of being wasted in a wild-goose chase in the track of a hypothetical bacillus.

LAST week the deaths from diarrhoea in London numbered 284 as against 110 and 210 in the two previous weeks, and owing to this rise the zymotic death rate reached 5.7. None of the other diseases under this head call for any special remark; there was a slight decrease in the number of deaths from measles and whooping-cough. The total number of small-pox patients under treatment at the end of the week was 648, so that the steady decline of the last few weeks continues. The general death-rate was 20.9, the total number of deaths having been 1,636, of which number 627 were of children under the age of one year. The

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past seven weeks.

death of an adult male was registered as due to glanders. Leicester is as usual remarkable for its diarrhoea mortality, the 35 deaths recorded being in excess of the record of any two of the chief provincial towns, Leeds and Birmingham coming next with 11 and 10 deaths respectively. Measles has not entirely spent itself in the provinces yet, as testified by the fact of 15 deaths in Manchester, 12 in Liverpool, and 11 in Newcastle.

OUR Edinburgh correspondent writes:—A deputation representing the majority of the lecturers in the Extra-Academical School, waited on the Lord Advocate on Thursday week for the purpose of bringing the subject of the incorporation of this school under his notice. It may be remembered that a Charter of Incorporation was applied for last year, and the application is at present before the Privy Council. I need not discuss the arguments advanced by the deputation or his Lordship's answer, as neither seem the least likely to affect the matter at issue. Mr. Macdonald's reply was characteristically irrelevant, and as was to be expected from his present somewhat invertebrate condition, committed his Government to nothing. It might, however, be worth while to consider how far such an incorporation as the majority of the lecturers desire is fitted to promote the efficiency of the Extra-Academical School of Medicine.

SUPPOSE the scheme, as at present before the Privy Council, should receive the sanction of that body, and a Charter of Incorporation be issued, we should then have in our midst an institution of such a nature and composition as never before entered into the heart of man to conceive. Presuming that all the teachers at present lecturing in Edinburgh outside the University became members of the teaching body of the new college, we should have to start with the following somewhat plethoric staff:—

2	Professors of	Anatomy.
5	„	Chemistry.
3	„	Materia Medica.
2	„	Physiology.
5	„	Midwifery.
4	„	Surgery.
3	„	Practice of Physic.
2	„	Pathology.
1	„	Jurisprudence.

Besides a considerable number of professors of special subjects, such as diseases of the eye, ear, skin, &c. No charge of deficient teaching power could be laid at the door of such an institution! But further, we must recollect that this institution springs into existence destitute of a farthing of endowment, and consequently each of those professors will depend entirely on his students' fees for remuneration. Thus we shall have the interesting spectacle of a college having five professors of midwifery, four of surgery, and so on, engaged in active competition with each other, with the result that each man's success means the comparative failure of some one else—an arrangement eminently fitted to ensure harmonious co-operation for common ends! Yet this is the great argument in favour of incorporation. Truly the President of such a *Senatus Academicus* would have a pleasant time!

BUT this is not all. At present any competent person may have recognition as a teacher in the school, and may have his lectures accepted as qualifying, provided he passes a certain examination before one or other of the colleges, and shows that he is possessed of suitable teaching appliances. It is to be supposed that compliance with similar conditions would secure admission

to the Professoriate of the proposed "Queen's College." Any one then who desires what dignity the title of professor might bring him could obtain it by a simple process. It would not be necessary for him to have an overflowing class-room—one or two students gathered from the hedges and the by-ways would serve his turn. No doubt, then, we should have by this means a large accession to the teaching staff in the shape of youthful aspirants who might justifiably think that they could begin life at the top of the ladder as "Professors" instead of at the bottom, when the process was so beautifully simple and easy. It would then be impossible to define the limit to the teaching staff of this unique institution. It is much to be feared that its professors would shortly out-number its students—a state of matters which, however well-calculated to insure sound discipline, could scarcely be considered a financial success.

THE fact is, that to anyone outside the school the scheme is obviously an outrageous absurdity. It is an attempt to bring into close administrative relation a number of men whose individual interests are in every way opposed. The merest glance will show to anyone not led away by the superficial arguments advanced by the promoters of the scheme, that the first attempt at working such a complex system of heterogeneous elements would lead to confusion and disintegration. And what are the arguments advanced in support of it? First, that money would be left to the school, when incorporated, for endowments and bursaries; and, secondly, that in its corporate capacity the school would have a voice in questions of medical legislation, &c.; as if any sane man would think of leaving money to such an outrageous association of diverse interests; and as if a body composed of such antagonistic and incoherent elements could present a united front on any question of importance. The whole scheme as it stands seems like a chimera which has sprung from the disordered imaginations of a few unsuccessful teachers and disappointed candidates for university chairs.

THE classes at Edinburgh closed for the summer session on Friday, the 24th ult., on which day the last of the candidates for the second professional examination appeared for their orals. The recognition by the College of Surgeons of England of the second professional examination of the University of Edinburgh, as exempting from the Primary College examination, has been much appreciated by students here, to whom it comes as a great boon, saving trouble, anxiety, and expense. And so long as the standard of this examination is maintained at the same level as it is at present, the authorities of the College need have no fear that they are lowering their standard by the concession. As I surmised last week, most of the "remits" from the final examination passed the examination for which they had the opportunity of presenting themselves, and are to be cut away from *alma mater* on the 1st August, along with the other hardier annuals who were found to bloom without artificial forcing. Is it cruel to hope that they will

have as much difficulty in obtaining an entry into responsible work as they had in "getting through"? It will certainly be all the better for their prospective patients if they have to "wait a wee."

BRIGADE-SURGEON CAMERON J. F. MACDOWALL, F.R.C.S., of the Indian Medical Service, Bombay Establishment, to whom, as we stated last week, the Government have awarded a good service pension on the recommendation of the Indian authorities, has been in the service for nearly twenty-nine years, his first commission bearing date August 4th, 1856. He has seen a good deal of active service in the field, having served in the Crimean Campaign, and with the Turkish Contingent. Shortly after he served with the Persian Expedition, and was present at the capture of Mohumra. A few months later his services were called into requisition during the Indian Mutiny. He also served in the Abyssinian Campaign of 1867-8, and was present at the storming of Magdala. He has just returned to India after serving in the Soudan Campaign. We believe he has served twenty years as Medical Officer of the 3rd Bombay Light Cavalry. Mr. MacDowall is well-informed as a medical practitioner, and is at the same time thoroughly *au courant* with the literature of his profession. After being present on the French side during the Franco-German war, he published an interesting pamphlet on the surgical aspects of it. He is also author of a little pamphlet entitled "What to Wear in India." Some ten years since, conjointly with Dr. John Lucas, he published a paper on the Pathology of Hepatic Abscess and its Causation, in the columns of the *Indian Medical Gazette*. He has also contributed some interesting letters to the *Lancet*. During the late cholera epidemic in France, he visited the infected places to observe and learn the course of action and views adopted by our Continental neighbours.

THE report of Dr. Manning, the Inspector-General of the Insane in New South Wales, for the year 1884, has lately been placed in our hands. It appears that during the year there were 121 more persons registered as insane in the colony than in the previous year, the average annual increase being 93. The excess was due mainly to the larger number of admissions, of which an unusually large proportion were idiot and imbecile children, and aged, weak-minded or demented persons. The prevailing commercial depression is accounted a sufficient explanation of these admissions; in prosperous times people keep their demented and imbecile relatives at home. Dr. Manning is perfectly satisfied with the way in which the present regulations as to the admission of the insane into asylums works, and considers the safeguards at present in force against improper admission or detention sufficient; he deprecates any addition to the present formalities as likely to have the effect of postponing early treatment, and to result in an increase of suicides and offences against the law. Dr. Manning does not think that the system of "boarding out" pauper lunatics can be tried in the colony on any large scale with any prospect of success, at any rate for some years to come. Intem-

perance in drink is put down as the first cause of insanity, and heredity next, though the exact part played by this is very difficult to determine, owing to so little being known of the previous history of many who go out to the colonies. A large number of the patients belong to no definite class; they have started as bushmen or miners, and after vicissitudes of fortune in a pecuniary sense, have become incurable vagrants, and ultimately incurably insane.

No one who has had experience of epilepsy amongst the poor can fail to sympathise with the object of a recent article in a contemporary, which suggests the establishment of hospital workshops for the epileptic. Of all the ills to which mankind is liable there is probably none which so completely debars a man from following any ordinary avocation as that protean malady the falling sickness, nor can we blame an employer for refusing to retain in his service one in whom undoubted manifestations of the disease have shown themselves. But the subject of the disease is not by any means unfitted for work, though no one cares to employ him, and instances of men who have attained the most eminent positions in spite of it are not wanting in history. As regards a poor man, however, the fact remains that epilepsy constitutes an almost insuperable barrier to his earning a livelihood for himself in any honest manner. The suggestion, therefore, to found a sort of combined hospital and workshop where the victims of this disease could be more or less constantly under medical supervision and treatment, whilst at the same time they were enabled to follow an occupation with such regularity as their malady permitted, is one that should strongly commend itself to the philanthropically disposed. The writer of the article in question proposes to place all the inmates under the care of a properly qualified nurse, who would see that the treatment was duly carried out, and report to the visiting physician any change in reference to any of the patients. In this way the writer is hopeful that a large amount of valuable information, at present almost always inaccessible, would accrue, but inasmuch as the information would have to be largely derived from the patients' own statements, we are unable to share the writer's optimistic views as to the scientific value of statistics so collected. The one objection to the scheme, as it appears to us, and it has not been mentioned in the paper, is that an outburst of epileptic mania, which is one of the results of the disease, and the most dangerous one both on account of the violence and suddenness of its paroxysms, would be rendered additionally serious by the fact of its occurring in a work-shop well stocked with implements which might so easily be employed with disastrous effects.

A DEEP sorrow will be felt by all who had the good fortune to know him, at the news of Dr. A. B. Shepherd's death, which took place, we hear, somewhat suddenly from apoplexy, on Sunday last, at his new residence in the Lake District. It is but quite lately that Dr. Shepherd retired from his hospital appointments, with the view of spending more of his time in the country, and he will be very fresh in the now

saddened memory of his many friends in London. Although in quite recent years he was not much heard of in the profession, outside his hospitals and the College of Physicians, he had previously done much and valuable work, and was an admirable teacher of any subject he took in hand. His Gulstonian lectures in 1877 on the Natural History of Pulmonary Consumption, were a model of sound and scientific criticism, and his various "Reports on Medicine" for the Sydenham Society's publications were of the highest order, being marked, like all his work, with a thoroughness and conscientiousness that is rare in compilations of this kind. Alike in his work among his hospital patients and his teaching of students, the same earnestness and thoroughness were apparent. His most striking characteristics, besides those of a most courteous gentleman and an able physician, were indeed, strict conscientiousness and high-minded honour. There are many now in London and elsewhere who owe not a little to his friendship and influence, and will deeply mourn an irreparable loss.

At an ordinary meeting of the Royal College of Physicians held on Thursday, the 30th ult., after the minutes of the last previous meeting had been read and confirmed, six gentlemen who had satisfied the requirements of the Censors' Board were admitted members of the College; and the Licence of the College was granted to 51 candidates who had been approved by the examiners; nineteen other gentlemen also, who have passed in Medicine and Midwifery, will receive the Licence on obtaining a Qualification in Surgery recognised by the College. On the nomination of the Council, Mr. W. Kitchen Parker was appointed Baly Medallist. The Annual Reports of the Library Committee and of the Curators of the Museum were received and adopted. The Quarterly Report of the Finance Committee, which showed that the income of the College is steadily and largely increasing, was also adopted. The Building Committee appointed by the two Colleges of Physicians and of Surgeons, presented a Report, in which they stated that they considered that accommodation for examination purposes should be provided in the new Examination Hall for at least 600 candidates at one time, the experience of the past year having proved that less than that accommodation would not meet the requirements of the two Colleges. The Committee therefore recommended the Colleges to adopt the plans which they submitted to them, and which had been approved by the Duchy of Lancaster. These plans will provide a building with the necessary accommodation, occupying a little more than half the ground taken on lease by the two Colleges. The estimated cost of the proposed building is approximately stated to be 30,000*l*. The report was adopted, and the College passed a resolution authorising the Building Committee to carry out the proposed plans; but these plans and all the architect's drawings are to be in the library of the College until the end of next week, in order that the Fellows may examine them and offer any criticisms or suggestions with respect to them which they may think fit; such criticisms or suggestions to be sent to the

Building Committee on or before the 8th of August. A somewhat lengthy opinion on the way in which the Croonian Trust and its increased income can be dealt with by the College, was received from the Counsel to the College, and was referred to the Committee on the Trust. A very important report was received: the Committee of Delegates appointed by the Royal College of Physicians and the Royal College of Surgeons to consider the advisability of granting the title of "Doctor" to those who received the diplomas of the two Colleges. The report was only received; and is to be considered by the College later in the year. But it is pretty well known, we believe, that the Committee consider that it is desirable that the Colleges shall in some way have the power of conferring a Degree in Medicine and Surgery on persons who satisfactorily pass their conjoint examinations. And with reference to this we may observe that the Executive Committee of the Association for Promoting a Teaching University for London say, among other things, in their first report that they would regret any severance of the machinery for granting degrees in London from academic influences; which must mean, we suppose, that degrees should only be conferred by Universities. The Censors and College officers for the ensuing year were elected, and a list of them will be found elsewhere in our pages.

#### THE BRITISH MEDICAL ASSOCIATION.

THE large class of practitioners who are in the British Medical Association, but not of it, must regard that body with somewhat mixed feelings. As in the case of a colossal building, its very bulk reconciles one to details the good taste of which in a smaller affair would be open to doubt. Its financial success is another element in its favour, for nothing turns the sharp point of criticism like a big balance at the bank. Again, it must be admitted that, except for occasional lapses, both the Association and the Journal which forms its chief *raison d'être* have been conducted with a discretion amounting almost to genius. The lamentable muddle into which the sister Association in the United States has thrown the medical profession in that country, has come upon us as a revelation, to make us grateful for the policy which has kept our own Association free, on the whole, from the machinations of self-seeking wire-pullers, and has kept a sufficient place of honour for the scientific leaders of the profession. Reading of what has recently happened across the Atlantic, we ought to be thankful that the powers of our own Association have not been abused, as they might have been, to the forcing upon us of leaders whose only claim to leadership is skill in the lobby. An Association, again, which can tolerate homœopaths upon its roll, contrasts very favourably, in respect of discretion and liberal feeling, with one which like the American Association ostracises regular practitioners, simply for claiming the individual liberty of holding consultation with whom they please. And yet, after all, we cannot help feeling that the success of our Association is a little hollow. Resting as it does for its prosperity on the degree in which its Journal favourably commends

itself to the reader and the advertiser—that is to say, on the pre-eminent ability of one of its *employés*—rather than on the *esprit de corps* and affectionate brotherhood of the profession at large, it gives one the impression of a pyramid standing on its apex; and there is always the fear that the larger it grows the less stable will be its equilibrium, however carefully it be propped up by scientific grants, Parliamentary services, and festive congresses. The Association, in short, cannot be declared to be an assured success until it has weathered, once or oftener, a change in the editorship of its Journal.

That it should be an assured success—that is, that it should be able to show itself independent of individual ability—must be amongst the wishes of every member of the profession. For such a success would probably silence all criticism. We are glad, therefore, to observe that, at the meeting at Cardiff this week, the Association decided, on the recommendation of the Council, to adopt the one policy which of all others seems to give greatest promise of securing the desired stability. The Council proposed to secure the freehold or the lease of a site in London for the erection of Association Buildings—buildings intended mainly for the purposes of the Journal, and for providing rooms for the various Committees to meet in. The scheme, it is objected, will swallow up more than the entire savings of the Association, *i.e.*, over 20,000*l.*, and it met on Tuesday with considerable opposition. But to us it seems to constitute the beginnings of a policy of the highest wisdom. To build publishing offices for the Journal, however, and to stop there, would be to justify the taunt that the Association ought to be called the British Medical Journal Association. If the Council are wise, with that boldness which is often the truest wisdom, they will regard their scheme as only the first step in a large policy, which shall in the end raise a home for the Association in every large city in the kingdom—one, say, for every Branch which shall number 400 members. If the Association provided house-room, the Branch might be safely counted upon to provide the cost of maintenance. At any rate, whether this large scheme be ever adopted or not, there cannot be two opinions as to the wisdom of providing a central home for the Metropolitan Counties' Branch, and for the use of such country members as may from time to time visit the metropolis. That seems to us to be the only plan for seating the Association as firmly in London as it is seated in many of the counties. The scientific and social requirements to the meeting of which the Branches owe their main success are not felt in London; and another sort of attraction must be devised for metropolitan members, if the Association is to be in any degree independent of the changes and chances which may happen to its Journal. Bricks and mortar, whoever may scoff at them, have been recognised from time immemorial as the surest means of binding man to man, and we are sure that an Association which could offer house-room to its members, and in some degree the conveniences of a club, would be in a much better position for appealing to their loyalty than one which only attempted to attract and retain them by the frail bond of print and paper.

#### DR. WILKS' CARDIFF ADDRESS.

ALL thoughtful readers of this, the most suggestive and noteworthy by far of the Cardiff addresses, will readily accord to the author the grace he asked for the somewhat sketchy nature of its contents, when they realise, as they cannot fail to do, the depth of reflection and richness of knowledge which make it by no means the least weighty utterance of perhaps our most philosophical physician. It is the man with at once a comprehensive power of grasp and an accurate knowledge of detail who alone is qualified to speak profitably to his fellows from time to time on the actual state or the possible progress of medicine. For the rest, we generally have to be satisfied with a reiteration of common-place, or with something that although original is brought unduly into relief, and viewed quite out of proportion to its intrinsic value and true relations. The profession should be sincerely thankful to have the opportunity of occasionally hearing the result of the experience and thought of such men as Dr. Wilks on some of the most important medical subjects, and especially on what may from time to time be called the topics of the day. Nor should we be disappointed if we find a recurrence in their later work of some leading ideas which have marked their earlier writings. The best thoughts of the best men are ever fresh and stimulant.

Dr. Wilks does not tell us in vain of the importance of remembering the chronicity of disease, a subject which he has especially made his own, and the dictum of such an experienced pathologist that the "acute" results of chronic disease are, contrary to the superficial teaching of the text-books, of far greater moment than what have been called the chronic results of acute disease, will be laid to heart, perhaps for the first time by many. The truth of it is known to observant workers in the *post-mortem* room, and too often forgotten even by them. By most it is altogether ignored. The passing remark again, that, in spite of the modern outcry about the backwardness of therapeutics, this branch is certainly not behind the rest of medicine, is of great value, because it is freshly put. Most will at once endorse it who from want of reflection would have enunciated the opposite view. "If there be one tenth of truth," says Dr. Wilks, after giving some excellent illustrations of his dictum, "in the value of the remedies which we see weekly vaunted in the journals, therapeutics has shot far ahead of every other branch of medicine." And when he says again, "The idea is mistaken that there is a science of therapeutics gained by a simple observation of the action of drugs on the body, and I am at a loss to know what pure therapeutics is apart from disease and pathological states," he suggests a line of thought most valuable to many of our modern "authorities" in medical education, and not altogether unprofitable to some who recently endeavoured to make a most astonishing change in the subjects for the Oxford medical degree. We must pass by without remark, the suggestive criticisms of Dr. Wilks on the bacillary aspects of phthisis, and the subject of zymotic disease in general, merely saying that the lesson we learn from him here, as elsewhere, seems to be "stop and

think, now, more than ever, in these days of push and progress." And is it not necessary to stop and think on this matter at least, when we reflect that in the very diseases whose nature suggested to us a specific germ as a cause, and set us searching for it, no such germ has been discovered, while specificity of origin has been now asserted of diseases whose clinical course in no way suggests it? Thus we have the bacillus of phthisis all too early recognised by the medical mind as causal, while small-pox, in spite of all our striving on its behalf, still goes a-begging for a germ.

The latter part of Dr. Wilks' address is occupied by no less suggestive and interesting remarks on the mutual relation which exists between the different functions of the body (the organs having probably varying activities and compensating actions); and on the compensative or conservative processes going on during many diseases, a reparative as well as a destructive action. On the former of these points, the author remarks that "the judicious physician takes the body as a whole—the good and the bad—observes the different functions, and so by simple methods rules or guides the whole bodily organism so as to bring it to a proper adjustment." Such physician, he adds, cannot be a specialist. In conclusion, we would especially direct the reader's attention to the remarks made on the influence of sleep over certain organs and functions. This part of the address alone might well be developed into several lectures. One point only shall be emphasized here, viz., the teaching of Dr. Wilks, supported by a long experience, that pulmonary hæmorrhage occurs most frequently at night, when the circulation is less free than when the lungs are more fully expanding; and his consequent disagreement with the common theoretical treatment of moveless rest in hæmoptysis. Those who have been interested in this point through Dr. Wilks' earlier teaching or their own observation, and have paid particular attention to it, will in our belief be entirely in accord with these remarks. Such a reflection as this last, coupled with the pathological reminder that what are often called the "well-marked signs of phthisis," such as extreme dulness, falling in of the chest walls, and pectoriloquy, are often signs of repair or cure, may well set many thinking, and, therefore, acting better; and will emphasise the truth that Dr. Wilks has illustrated by his life-long teaching and example, that the soundest pathology leads to the best prognosis and treatment, however specialised the disease may appear to be.

---

#### THE HOMERTON HOSPITAL ENQUIRY.

THE Eastern Fever and Small-pox Asylum Enquiry which has just been brought to a close, after some forty sittings spread over the last three months, has long ceased to present any special interest for medical men, though at the outset it appeared that the alleged shortcomings of Dr. Collie were to form the chief subject of investigation. It will be remembered that this enquiry, which has been conducted at the instance of the Local Government Board, was demanded by the

Managers of the Metropolitan Asylums District after a preliminary investigation on their own account into the extraordinary expenditure at the hospital in question, at the close of which the Chairman of the Committee, the Steward of the Asylums and the Clerk of the Committee sent in their resignations, and Dr. Collie, the Medical Superintendent, was suspended. The result of the official enquiry will not be divulged until after the Commissioners have made their report to the Local Government Board, and it is not for us to speculate as to what that result will be, but there can be little doubt that Dr. Collie, even if he does not come out of it exonerated from all blame, will not figure as the only or chief scapegoat.

The expenditure under the head of wines and spirits formed practically the only topic on which Dr. Collie could be found fault with, and the figures under this head are, it cannot be denied, somewhat startling. In one quarter, for instance, the average number of patients being 239, there were consumed 1,455 bottles of champagne, 970 bottles of beaune, and 2,447 bottles of port, representing an aggregate cost of 570*l.* But, on the other hand, it should be noted that the bill for other wines and spirits only amounted to 21*l.* This large expenditure in wines, such as champagne and burgundy, only given in ordinary hospital practice under special circumstances, Dr. Collie stoutly defended when under examination as necessitated by the circumstances of the case, and he was able to point to the fact, a very strong one in his favour, that his statistics were more favourable than those of similar institutions, and this, too, though the patients as a rule belonged to a more destitute class, and the cases were generally more severe than those met with in other districts. It appears to us indeed that Dr. Collie successfully met the charges raised against him on this score, for there was some doubt as to whether the very large quantities that sometimes appeared on the diet sheet had really been ordered by him, and the evidence of one of the witnesses pointed to the possibility that the figures had been tampered with. The other matters brought up against Dr. Collie related to his having neglected certain routine duties attached to his position as Medical Superintendent, viz., "to sign and furnish to the steward daily a written statement of the diet and extras required to be supplied for the inmates of each ward." He frankly admitted that he had not complied with this regulation owing to the great pressure of work which the recent severe epidemic had thrown upon him.

So long as Managers of Hospitals and Committees impose upon medical men in addition to their own work, duties not strictly medical, which would more properly be allotted to the matron or some functionary in a similar capacity, so long must they be prepared to find those duties neglected when they clash with the interests of the patients. No medical man would be worth his salt as a medical superintendent who devoted his energies to mere clerical routine when his time could be better spent in the treatment of the sick. It is notorious that in many, if not most, asylums for the insane the senior medical officer is often so much occupied with routine duties which ought to fall altogether outside his province that he is

*medical* superintendent merely in name; and it is only within the last few years that the house-surgeon in country general hospitals has ceased to hold a similar altogether anomalous position. Now that the attention of the public in general and of the Local Government Board in particular has been forcibly drawn by this long drawn-out enquiry to the absurdity of requiring medical men to play a part in the management of such institutions as those involved in the present enquiry, which is quite out of their own sphere, we hope that we are not too sanguine in believing that this much at any rate will be the outcome, that in future a medical man when he accepts office will have the satisfaction of knowing that he is to be the *medical* superintendent and nothing else.

---

## ESSAYS ON MEDICAL CLASSICS

---

### IX.—MARSHALL HALL.

MARSHALL HALL, the son of a cotton-manufacturer who had distinguished himself by introducing improvements in the process of bleaching, was born in 1790 at Basford, near Nottingham. At the outset of active life, he worked for some time with a chemist, but yielding to a natural bent towards the study of medicine, he went to Edinburgh University in 1809. His career as a student was highly successful, and his stay at Edinburgh, including two years' residence in the Royal Infirmary, lasted until 1814. Soon after leaving the University he availed himself of an opportunity of paying a visit to Paris, and extended his travels to Berlin and Göttingen, with the aim of seeing the chief foreign hospitals. Returning to England in the following year, he commenced practice at Bridgwater, but after a six-months' trial of rural work, he decided that it offered him no sufficient opportunities of distinction or usefulness, and accordingly he transferred himself to Nottingham, where he remained for ten years, achieving a large practice and considerable reputation. In 1818 he had been elected F.R.S. Ed., and in 1825 he was appointed physician to the Nottingham Infirmary. It was during this period that he published his earliest works. The first, on "Diagnosis," appeared in 1817, having been written by him four years previously by the bedside in Edinburgh Infirmary. It is a treatise on symptomatology of great practical value and showing much close observation of disease. A second work, on the "Mimoses," 1818, and another on the right treatment of certain complications of the puerperal state, were based on his experience of practice at Nottingham. These and other writings had the effect of making his name well known, and he was led to expect a favourable reception and a sufficient share of success in London; so with a longing to satisfy his love of science and his desire for wider recognition, he gave up his practice and hospital work at Nottingham and came to live in London in 1826. He soon published other books, "On the Constitutional Diseases of Females," "Observations on the Use of Blood-letting," &c. In 1832, while engaged in making experiments on the circula-

tion, he observed the occurrence of reflex movements in the separated tail of a triton, and starting from this discovery as a first step, he was led to make a special study of the functions and diseases of the nervous system, and finally to arrive at, and enunciate his doctrine of the excito-motor functions of the spinal cord. These early observations with many others on physiological subjects were published in the "Philosophical Transactions," and he was elected a Fellow of the Royal Society in 1832. His later investigations on the same subject, however, were refused a similar honour, and for a long time his views encountered much opposition from his colleagues in the Royal Society, and from the medical press. Fully conscious of the value of his work, he defended himself with vigour, but without much bitterness or personal controversy, and in the end he thoroughly vindicated himself, and won from the leading physiologists at home, as well as from the profession in general, the full appreciation which almost from the first he had obtained on the Continent. In his travels in Europe and America in later years, he found that his fame had preceded him to the remotest parts, and he was everywhere received with expressions of esteem.

In spite of the work in which the duties of a large and growing practice involved him, Marshall Hall continued to devote himself with enthusiasm to scientific research. In 1834 he began to deliver a course of lectures at the Aldersgate School of Medicine, then at the Webb Street School, and also at the Sydenham College, often lecturing twice daily. He was never, however, physician to a London hospital, nor did he ever hold office as clinical teacher, though in 1842 he was appointed lecturer on Medicine at St. Thomas's Hospital. In that year he gave the Gulstonian, and in 1850-2 the Croonian lectures at the Royal College of Physicians. In 1836 he was one of the first to promote the formation of the British Medical Association; and his interest in public affairs is shown by his issuing in 1850 a pamphlet containing a scheme for improving the sewerage and means of communication in London; and in later years, whilst in America, he wrote much in opposition to slavery. In 1839 he began to suffer from an affection of the throat, marked by pain and dysphagia, and apparently brought on by over-exertion in public speaking; in a few years it became serious, and his health showed signs of breaking down. He accordingly retired from practice in 1853, travelling much in America, and living quietly in England after his return until his death in 1857. All details of his private life may be gathered from an interesting biography by his widow, which bears ample testimony to his benevolence of disposition and simplicity of character.

Marshall Hall was a copious writer. Besides those mentioned above, his chief works are "The Principles of the Theory and Practice of Medicine" (1837); "Diseases and Derangements of the Nervous System" (1841); "Practical Observations and Suggestions in Medicine" (two series, 1845-6); "Theory of Convulsive Diseases" (1848); "Theory of Paroxysmal Diseases" (1849); "Synopsis of the Diastaltic Nervous System" (1850); "Prone and Postural Respiration" (1857); besides many papers in the *Edinburgh Medical and Surgical*

*Journal, Medico-Chirurgical Transactions, Philosophical Transactions, Lancet,* and foreign periodicals.

He is an excellent example of the philosophical physician. He had an eminently scientific mind, an intellect acute rather than massive, active rather than profound. He was always engaged upon some special object of enquiry. His prime characteristic was simplicity; he had an equal horror of blind empiricism and of baseless unpractical speculation. His thoughts were exquisitely simple and clear, and his language was a copy of his thoughts. His style is lucid, terse, and impressive; though in all his essays he endeavours to write suggestively, so as to excite others to labour on in the same direction. His chief fame rests undoubtedly on his knowledge and discoveries as a physiologist. Among many other researches he investigated more thoroughly and carefully than had hitherto been done the phenomena of hibernation, the conditions of the circulation and respiration, and other familiar problems of interest and importance. His greatest achievement, however, as we all know, was his discovery of the functions of the spinal cord. Here he carried to a much further point the anatomical indications of Sir Charles Bell; he showed that the spinal cord may be regarded as a central nervous organ, which, subordinate to, but in a manner distinct from the cerebrum, governs directly all the muscles of the body, with especial control over the orifices, and ordinarily performs its functions by reflex or excito-motor action—the incident and motor nerves, composed as they are of distinct elements, being brought into communication and co-ordination in the cord and medulla oblongata. But of these discoveries, amongst the most important of the century, we will say little here, partly because they may be found fully set forth with their later developments in all works on physiology, and partly because we do not wish them to overshadow the benefits he wrought and the advancement he effected in the field of general and practical medicine. Even, however, when we encounter him as physician and pathologist, he still remains *par excellence* a physiologist; repeating often in phrases as enthusiastic as any he ever employed the objects he strove after and the method he loved, *e.g.*: “Chiefly he would see *physiology applied to clinical medicine*”; “Hunter introduced physiology into surgery . . . and we still want the physiological spirit of a Hunter in our medical clinical wards”; “He would deserve a civic crown who should accomplish the same great good for the physician’s department of our profession.” Accordingly the key to his excellence as a scientific and practical physician lies in the fact that he devoted himself most attentively to symptoms, and most of all to the commonest symptoms of the commonest diseases. His object in writing his work on “Diagnosis” was to show the importance of appreciating symptoms, and thereby obtaining an adequate notion of a malady before attempting to treat it; and by means of the thorough knowledge he had of the fundamental principles of physiology, he was enabled to distinguish and analyse the manifestations of disease, and to attach to them their due significance with remarkable accuracy. He says, “I am persuaded that physiology, or a knowledge of the healthy actions, is

the only foundation for practical medicine. This physiology should be at once experimental and clinical. The biblio-physiology of the day can issue in no good whatever.” “It is not crude and *post-mortem* ‘morbid anatomy,’ but a knowledge of the state of the living morbid actions which must guide us in practice. . . . There is a *living pathology*, certainly not less important than *pathological anatomy*, but hitherto little known in medical enquiry. An important department of this living pathology is that of diseases consisting of primitive symptoms, yet leaving no trace of pathological anatomy behind them.” It is astonishing how many difficulties and obscurities in the troublesome ordinary diseases may be made to disappear by the very simplest explanations; in this way Marshall Hall has rendered great and lasting service to the cause of healing. From his active and penetrating mind, always seeking vent in some direction of practical enquiry, and from his industry as a writer, he has left much behind him to illustrate and remind us of his labours.

His most valuable works are, in our opinion, the “Principles of the Theory and Practice of Medicine,” “Practical Observations and Suggestions in Medicine” (1st and 2nd series), and “Commentaries on the Constitutional Diseases of Females.” One of his most important bequests to us is the distinction of “irritation” from “inflammation.” Previously, it had been usual to regard most conditions seriously marked by pain or excitement as due to inflammation, for which active depletory measures were prescribed—very frequently with dangerous consequences. Thus, blood-letting, &c., was practised not only at the commencement of fevers and inflammatory diseases, but also indiscriminately for relapses and for various complications in the later stages which we now know to be essentially due to debility. In this way bleeding was enormously abused, an abuse which Hall’s influence helped more than anything to check, though it must be remembered that he himself continued to employ it freely in appropriate cases. His attention was first called to the subject by observing how much injury was inflicted, and how many lives were lost by bleeding in some puerperal affections which were really due to irritation, and recovered under aperients. From this he extended the application of his ideas, and determined when and how far bleeding was indicated, by employing as a test observation of the quantity of blood necessary to be withdrawn to induce incipient syncope, in various diseases and states of the constitution: the rule hence obtained being that, “if there is tolerance of blood-letting, it is remedial and safe; if intolerance, it is replete with danger.” In inflammation, much blood has to flow, in irritation very little. “There is, in my opinion, no single fact in physic of equal importance and value in the diagnosis of acute diseases, and in the use of a powerful remedy.” It decides also the violence of the disease, the powers of the system, and the degree to which to push the remedy. On these lines he drew up a table of diseases, benefited and aggravated respectively by blood-letting, which still remains one of our best guides on the subject.

From the great attention he had paid to the spinal system and the knowledge he had acquired of its

actions, he was enabled to make material contributions to the elucidation of many nervous diseases. Thus, he was the first to suggest a reasonable hypothesis with regard to the pathology of stridulous convulsion, eccentric epilepsy, the paroxysms of hydrophobia, &c., viz., that they were due to peripheral sources of irritation acting on a morbidly sensitive spinal marrow, and that they could be mitigated or cured by carefully ascertaining and removing the cause. He thought, too, that the seat of all spasmodic diseases is the spinal cord, and that according to the part attacked, various complications are liable to occur. For instance, closure of the glottis takes place in epilepsy, and is the chief factor in producing the violent expiratory efforts and convulsions; in a certain class of cases of this disease, there is protracted closure of the glottis, which endangers life from asphyxia, or imperils the mental condition by the great venous congestion of the head it produces; in these cases Hall recommended tracheotomy. The conditions of the muscles in various kinds of paralysis also attracted his attention.

His work on the "Mimosos," deals with states of debility due to digestive derangements, and their numerous manifestations and results; the title was given on account of the way in which these complaints simulate organic disease, but it was afterwards changed for a simpler one. The descriptions are good, and the treatment recommended is by aperients on the plan of Abernethy and Hamilton. The "Diseases of Females" is a work in the same style, but more elaborate; it shows much nice and careful observation, and the method of treatment he recommends is sound. It is a book well worth reading. It would be impossible without abundant space to comment upon all the subjects discussed in these volumes; they abound in striking remarks on physiology, medicine and hygiene, and contain many practical hints for which we must refer the reader to the books themselves. We cannot conclude, however, without recalling the fact that Marshall Hall was the first to devise a method of artificial respiration in cases of asphyxia, and to bring it into actual use. It was with great delight that he read of case after case of drowning being saved by its instrumentality. The method is still known by his name, and is sometimes resorted to, though mostly superseded by that of Sylvester. But to have been the originator of a scheme of such immense value was by no means the least of his achievements, and would in itself constitute sufficient claim to our lasting regard.

N. H.

**PARALDEHYDE IN ASYLUM PRACTICE.**—Dr. Harris, in a paper in the *Philadelphia Medical News*, May 16th, states that an experience of the employment of paraldehyde in 152 cases has convinced him that it is a very valuable agent for procuring sleep in the insane. Given in moderate doses (50 minims) it induces in from 10 to 45 minutes a quiet sleep which lasts from 2 to 7 hours. Its advantage over chloral is that, even when given in large doses, it produces no ill-effect upon the heart or respiration. "When a sleep-producer must be given for a length of time we consider it is a most efficacious, safe, and reliable remedy, the sleep produced being in proportion to the dose administered."

## REVIEWS AND NOTICES OF BOOKS.

*An Introduction to Practical Organic Analysis*; by G. E. R. ELLIS. London: Longmans, 1885, pp. 72.—This is a small cram book, intended to aid the student in identifying the solutions given at the intermediate examination in medicine at the London University, but it is unsatisfactory alike in method and detail. Mr. Ellis expresses his indebtedness to Prof. A. W. Williamson, of University College, but we cannot think that that eminently scientific teacher would approve the peculiar use or abuse of symbols as "Cold  $H_2O$ , hot  $C_2H_6O$ , add  $(KCl + H\bar{A})$  and even  $F_2Cl_6$  is an acid liquid [*sic*]." In our student days the Professor used to insist on the fact that  $H_2O$  was not an abbreviation for the word water, but represented a *molecule* of 2 grams of hydrogen with 16 of oxygen and in this as in other respects Barff's little work truly reflects the teaching of the great master. The style of Mr. Ellis's book is slipshod, and some of the expressions are remarkable, as " $F_2Cl_6$  gives a colouration which is precipitated on adding  $H\bar{A}$ " and " $SO_2$  is evolved, as also an irritative cough-causing vapour." The statement that *oxalates* are not decomposed by dilute sulphuric acid is certainly open to exception, and the description of the behaviour of tartrates with silver salts is scarcely intelligible. We are unable to see the point of the formula for nitrate of urea,  $\left. \begin{array}{l} CONH \\ NH_3 \end{array} \right\} HNO_3$ , as if urea were a mere compound of hydric cyanate and ammonia. The author represents aniline as phenyl-mine  $C_6H_5(NH_2)$ , why not urea as carbamide  $CO(N_2H_2)$ ? And we notice that he does not follow Dr. Williamson's rule of distinguishing a molecule from a number of atoms by the position of the small figure above or below the line as in  $Fe^2Cl_6$ . If the author would thoroughly revise and rearrange his book with the assistance of some one more practically familiar with work in the laboratory, it might be made really useful, at any rate for the purposes of candidates for examination, and he might at the same time make good the omission of several bodies which, from their technical importance, are not unlikely to be given, such, for example, as picric acid and the salicylates.

*A Manual of Health Science*; by ANDREW WILSON, F.R.S.E., F.L.S. London: Longmans, 1885; with 74 illustrations.—Another manual of hygiene called into existence by the action of the Department of Science and Art, far less thorough and scientific than those of Dr. Newsholme and Dr. Willoughby, but incomparably more accurate and trustworthy than that of Mr. Pilley. Since candidates in hygiene are required to have gained certificates in physiology, the chapter of the general functions of the body might have been spared and room gained for matter of more immediate interest. The treatment of food and digestion is fairly satisfactory, but not quite up to the latest researches of the Munich School; and the difference between nutritive value and utilisation is not insisted upon as it should be especially in a comparison, between the animal and vegetable albumins. The nature and indications of the several impurities in water are scarcely touched on, no reason is given why chlorides are to be regarded with suspicion, nitrates and nitrites are not hinted at, and Clark's process for softening chalk waters is ignored. We miss any consideration of ground air and ground water, and the movements of the latter, as well as of "nitrication," notwithstanding the importance of these phenomena in relation to rites, water-supply and sewage disposal. There is no attempt at the mathematical treatment of the *principles* of ventilation, warming or sewerage, and the description of house drainage, traps, &c., is very meagre, while recipes for hair-washes seem to us rather *de trop*, and we cannot conceive why one should be warned against wetting the head at the morning bath. Mr. Carr's "Domestic Poisons" has been

largely drawn on, ambulance work and "First aid" are well handled, though, by the way, chloral surely deserves mention in strychnine poisoning, but though there is little to find fault with in the information given, we fear that any one trusting to this manual as a text book for any examination would find it a broken reed.

*Hygiene: its principles as applied to Public Health;* by EDWARD F. WILLOUGHBY, M.B. Lond. London and Glasgow: W. Collins, Sons & Co.—This complete but concise summary of the principles of hygiene is primarily intended for the use of candidates for the examinations of the Science and Art Department, but it may be safely recommended as a text-book for the university examinations in sanitary science, and indeed as a book of reference to the large class of persons who now take an interest in sanitary matters. It is written on a thoroughly scientific method, the principles on which the practice of hygiene depends being clearly and fully enunciated. Few writers on hygiene have so complete a knowledge of the literature of the subject as Dr. Willoughby, and there are frequent evidences throughout the book that this knowledge has been fully utilized in its preparation, the results of the latest researches finding a place in it. The chapters on ventilation and heating, and on sewage disposal and drainage are especially good, numerous illustrations contributing to render clear these somewhat difficult subjects. The chapter on personal hygiene is also a most useful one. It is not too much to say that a comprehensive and conscientiously written work on hygiene like this of Dr. Willoughby's deserves to be read and mastered by every person who has a care for his own health and for the health of those for whom he is responsible.

*Lumley's Public Health;* Second edition; by W. PATCHETT, Q.C., and ALEXANDER MACMORRAN, pp. 1,135. London: Shaw & Sons, 1884. This bulky volume is intended as a book of reference for the use of members and officers of local authorities. When the various statutes relating to Public Health and Local Government were consolidated into the Public Health Act of 1875, Mr. Lumley, who was counsel to the Local Government Board, published the text of the Act with practical explanatory notes. The work before us is a new edition of the work so published; and in the ten years that have elapsed since the publication of the first edition, so many legal decisions have been given on points relating to Public Health, and so many fresh Acts have been passed, that very considerable additions were necessary. The editors appear to have brought great industry and sound judgment to their work. Mr. Lumley's valuable practical notes are retained, while the notes relating to the construction of the Public Health Act have been greatly enlarged. Considerable pains have been taken to bring the work up to date, and it is stated that every decision of importance up to the time of publication is duly recorded. It is a book which should be on the shelf of every Medical Officer of Health.

*Health Lectures for the People;* Manchester: John Heywood, 1885.—This volume comprises the lectures delivered in the years 1882-4 under the auspices of the Manchester and Salford Sanitary Association. The standard of the five preceding series is well kept up—is, indeed, even improved upon—in the present sixth and seventh series. The idea of the lectures now before us is to treat especially of the science of healthy life, or as Dr. Ransome terms it in his preface, "Sanitary Biology." The lectures are not popular in the ordinary sense of the term, but they are quite within the comprehension of intelligent people, whatever their previous training, while some of them are full of suggestion even to an expert. The volume deserves a very wide circulation.

## ABSTRACTS AND EXTRACTS.

### THE BRITISH MEDICAL ASSOCIATION AT CARDIFF.

#### INJURIES OF THE SKELETON: VALUE OF ACCUMULATION OF SPECIMENS.

UNDER this heading, Prof. E. H. Bennett, of Dublin, in his opening address to the Section of Surgery, attempted to show that, in the pathological and clinical study of injuries of the skeleton, real progress was to be made, not by the study of rare and attractive specimens and cases, but by the accumulation of large numbers of examples of ordinary injuries, for only by the examination of a large number of individual specimens could the details of any typical injury be worked out. Thus of Colles's fracture of the radius, the Dublin University Museum contained 100 specimens, and among these 48 gave proof of having been impacted fractures, while 52 were injuries in which positive evidences of impaction were absent. They therefore had ample evidence in these facts, to put aside alike the opinions of Voillemier and of Smith. In another group of injuries—fractures of the ribs—his investigation of a great series of specimens had led him to endorse the opinion of Malgaigne, in opposition to the commonly accepted theory of Petit that when the ribs broke as the result of compression of the chest, as a whole their fragments were thrust outwards. Speaking of fracture of the fibula, Prof. Bennett said that every one knew the great importance that attached to fractures of the lower end of the fibula, their great surgical interest, and the writings of Pott and of Dupuytren. In all these and elsewhere no mention was made of fracture of the upper third of the bone, except as it occurred as an element of fracture of both bones of the leg, or with a complete diastasis of the bones at the ankle. In looking over his specimens, he was struck with the fact that one feature was constant in them all, a fracture of great obliquity, but without material displacement. What was the cause? Certainly not casual direct injury. Going on with the study, he was not long in finding evidences that the injury was in some associated with lesion of the ankle-joint; in some, a very special fracture of the tibia existed, which, when present, was alike in all. In others, evidence of past traumatic inflammation of the bones at the ankle bore testimony to the origin of the force from the ankle. In one, the fracture was associated with fracture at the usual site of Pott's fracture in the lower third. He could produce several fractures of the fibula in its upper third similar to these, where, unfortunately, the tibia had not been preserved, which were no doubt of the same type, for the extreme obliquity without displacement was quite distinct from the form of lesion which went with fracture of both bones. Any way the number was remarkable, ten in all, where both bones were preserved. Seeing these facts, he could not doubt that the injury, although unfamiliar as a clinical observation, must be sufficiently common. The following case observed by his colleagues in Sir P. Dun's Hospital was a case in point. "A man slipped in carrying a sack of grain down a sloping plank in unloading a vessel. His foot was suddenly checked in its slide by some irregularity of the plank, and he fell, conscious that something had given way in his leg. He did not strike or hurt his leg otherwise in the fall. Admitted to hospital, as he was unable to bear weight on the limb, he presented the ordinary features of a sprained ankle, without the ordinary signs of fracture of the ankle-bones. Treated for sprain, the case attracted but little attention for several days, when the circumstance of ecchymosis, high up in the limb, attracted notice. On this part being examined, the localised pain and crepitus peculiar to fracture left no room for doubt as to the diagnosis." In conclusion, the speaker dealt with united fractures of the metacarpal bones, the closer study of his specimens of which showed that one particular fracture outnumbered all others. There were, in fact, six examples of fracture of the base of the metacarpal of the right thumb, and no others of this

bone. In each of these, the injury was the same—an oblique fracture, detaching the palmar half or more of the articular surface which faced the trapezium, with that projection of the base of the bone into the palm which supported the surface. The entire bone, except the little piece so separated, slipped backwards, simulating in the living a subluxation of the bone in this direction. The appearance in the living of a subluxation was confirmed by measurement; for, as the fracture did not implicate the dorsal surface of the bone, the length on this aspect was unaltered. "When I published my first note on this injury in 1879," continued Prof. Bennett, "I had but the experience of a single clinical observation, and so I spoke with but little confidence about it. Since then, and as the immediate result of my publication, I have seen a great number of examples both of the recent injury and of the united fracture. Most remarkable is the fact that in every case the accident has been on the right side of the body. Certainly this injury, once we know of its existence, becomes vastly more common than any other of the metacarpus. If left to itself, it unites with such deformity as this case shows—a trivial deformity, after all. Why, then, deem the matter worthy of the notice of this Surgical Section of the British Medical Association? Simply for this reason, that I have ample proof that a hand so injured remains, under the best of treatment, long disabled, and, without treatment, for a greatly longer time. When we consider the value of the right thumb to anyone who lives by handicraft, or indeed to any, rich or poor, we should not let pass unnoticed and undiagnosed this common injury. One point I have omitted to mention—the cause. In every case but one which I have seen, the cause has been a fall which might well have broken the radius, but some slight deviation has directed its force against the thumb. Once I have seen it as the result of a blow of the fist against the jaw of an adversary in a fight. I have already mentioned the essential features of the injury. One word as to the reason why probably it has long escaped notice. The pain and swelling of a sprained thumb are familiar to all, and prevent the ready appreciation of crepitus in the recent injury; but this may be found readily if pressure be made on the base of the bone from palm to dorsum, while a slight traction is made, sufficient to reduce the large fragment into place. I am confident that, before long, many of my hearers will test this matter for themselves, and perhaps then excuse my weary discourse to-day. I have said enough to establish the merit of patient and diligent pathological study, combined with clinical observation."—*British Medical Journal*.

#### THE DEATH-RATES FROM CHILDBIRTH AND CANCER: VALUE OF ANTISEPSIS IN MIDWIFERY.

DR. GERVIS, the President of the Section of Obstetric Medicine, chose this as the subject of his opening address. Commenting on the deaths in this country from childbirth and childbed-fever, which, in the ten years from 1861 to 1870, averaged 60 in every 100,000 women living between the ages of 20 and 55, while in the five years, 1876 to 1880, they fell to 53, he said that there were, doubtless, more factors than one in the production of these favourable results—such as the more early use of the forceps in lingering labour; the more frequent induction of premature labour in cases of contracted pelvis; the better treatment of eclampsia; and the better treatment, prophylactic and actual, of *post partum* hæmorrhage. But the greatest gain had, without question, been in the practical development of the principles of antiseptics. Too little notice, however, had been taken by most writers of antiseptics before and during labour. The consideration of antiseptics before labour had to do with questions of drainage, ventilation, and general health; in a word, with the hygiene of the house and of the individual. The better the patient's surroundings, and the better her health, the fewer would be the sources from which germs might spring, the better able would she be to resist their entrance, and the less likelihood would there be of their development from within. Antiseptics during labour had been sought in Germany by the conduct of labour under the spray. This, even if

practicable, was not absolutely satisfactory as a safeguard; but, during the course of labour, although not in this way, the principle of antiseptics should never be lost sight of. "In every case," continued Dr. Gervis, "the hands of the attendant should be washed in carbolic water before he proceeds to examination, and both before and after the labour the vulva should be sponged with warm antiseptic solution; and if the case tend to be tedious, though not sufficiently so to necessitate forceps, it is advantageous to sponge out the genital canal from time to time with a similar solution. In all operative cases, I need hardly say it is now customary to dip the instruments in hot carbolic water; but I am satisfied it is also most useful to sponge out with the same solution the genital canal prior to their application. In a labour in which the forceps, and *à fortiori* where craniotomy is demanded, there has, at least very often, been sufficient delay to lead to a septic condition of the discharges; and the removal of these by sponging much diminishes the chance of subsequent infection, should any breach of mucous surface occur as a result of the delivery. So also, in the induction of premature labour, the vagina should be antiseptically cleansed before the use of the bags; and between the removal of one and the introduction of the next, the same precaution should again be taken. In all cases of version, I need hardly say that, where the hand is to be introduced into the uterus, not merely the hand, but the arm also, should be sponged with carbolic water before its introduction; and, lastly, in cases of miscarriage, where it may be necessary to resort to manipulative proceedings, whether for the removal of the entire ovum, or of a fragment merely of retained placenta, careful attention to antiseptic details immensely lessens the subsequent risk of pelvic inflammation and systematic infection." Of antiseptic solutions for irrigation purposes after labour, Dr. Gervis said that the mercuric chloride solution, in a strength of one in 2,000 for injection, and one in 1,000 for washing purposes, was certainly of the highest value. That it must be used with caution was doubtless true; but this was also true of carbolic acid. The solution of boracic acid, in a strength of 10 grains to the ounce, was also of much value.

Dealing with the alleged increase in the mortality from cancer, Dr. Gervis said that his own experience, nevertheless made him hopeful that we should yet be able to diminish this increasing mortality, and probably by earlier diagnosis and earlier treatment. In cases where the local disease could be effectually extirpated, he believed that there was good ground for hope that it might not re-appear. The diagnosis of early cancer was undoubtedly, in many cases, attended with difficulty; but he would venture to press the more general adoption of microscopic observation as an aid of the first importance. Not very unfrequently, also, early treatment was hindered by the fact that early symptoms were so slight, that the disease might have seriously advanced before even the patient's attention had been attracted to it as a matter of any importance. Dr. Gervis concluded his address with a plea for the study of Pathology in relation to Obstetric Medicine. "A close study of pathological changes, at all events in gynecology, is one of our most pressing needs. So many of the maladies for which our advice is sought are not fatal in their character, often little more indeed than sources of local discomfort and general ill-health, that our views are too apt to be based on clinical observation merely, not rectified by *post-mortem* research. If, for example, the precise morbid anatomy of flexions had been worked out, would it be possible for one set of writers to think the condition of flexion the foundation of nearly every other ill to which women are subject, and another that a flexion is scarcely abnormal at all? And as a quite recent illustration of the same need, I may refer to the discussion at the June meeting of the Obstetrical Society on serous perimetritis, a malady of much graver importance than flexion, in which it was evident that even on the primary question of diagnosis there was much to learn that could only be learned by careful necroscopic research. In the puerperal diseases, on the other hand, very much has been done by way of attention to morbid anatomy; and it is to this, I think, that we are chiefly indebted for the great stride made in our scientific knowledge

of their course and results. In discussing puerperal fever, we feel, thanks largely to the researches of morbid anatomy that we are now treading on far surer ground than was possible but a few years ago, although still, as to the nature of the poison whose pathways we can track, we have much to learn. And we may fairly hope that, with the aid of the many scientific observers now at work in our department of medicine, before long similar and equally appreciable progress may be made in the morbid anatomy of the uterus and its appendages."—*British Medical Journal*.

#### ON PROGRESS IN OPHTHALMOLOGY.

MR. HENRY POWER, the President of the Section of Ophthalmology and Otology, devoted his opening address to the above subject. Besides giving a concise summary of recent discoveries, he offered some remarks on the influence which this progress may be expected to have both on the specialist and the general practitioner. "If the ophthalmic surgeon of the future," he said, "is to maintain the reputation and position of his predecessors in this branch of the profession, it appears to me that two things will be necessary: first, that he should possess a sound general knowledge of medicine and surgery; and, secondly, that he should have a good preliminary training in physics and mathematics. And if an adequate knowledge of the principles of physics, and especially of optics, be constantly required in ophthalmic practice, how much more important is it that this branch of the profession should not be pursued as a specialty, without the possession of a broad sound knowledge of medicine and surgery. Whilst the eye has afforded to pathologists some of the most reliable facts with which we are acquainted in regard to the causes, phenomena, and events of disease, it would be absurd to deny that our treatment of any case must be founded on a correct appreciation, not of the local changes only, but of constitutional states which engender and modify local disease. Many of the best essays that have appeared of late years have been directed to show the immediate relation that exists between local and constitutional disease, and a knowledge of both is essential to successful results in practice. It is for this reason I hold that no man should commence ophthalmic practice without long preliminary work in general or dispensary practice, or in the wards of a hospital; and I venture to dwell strongly upon it, because I think there is a tendency amongst the younger members of the profession to regard ophthalmic practice as an easy means of obtaining a livelihood, which is at once less troublesome, clean, and more satisfactory than any other branch of surgery." In a later portion of his address Mr. Power observed, "It has now become trite to say that the general practitioner might often obtain useful hints in regard to the nature and treatment of disease from a careful inspection of the fundus of the eye, even were he unable to recognise the finer gradations of colour, or the more delicate lesions which are discernible by the practised eye. Optic neuritis and hæmorrhages are sometimes amongst the earliest symptoms of Bright's disease; similar appearances recognised in the later months of pregnancy might open the question whether it were expedient or not to induce premature delivery, and thus save lives that would otherwise be lost by the supervision of puerperal convulsions. Finally, a study of the fundus of the eye in such affections as whooping-cough, in measles, and in scarlatina, in diabetes, in cases of disordered catamenia, and in locomotor ataxy, would be replete with interest, and supply information much needed in regard to the failure of vision to the later stages of, or after recovery from, these diseases in elucidation of them and many others."—*British Medical Journal*.

#### THE TREATMENT OF CEPHALOCELE AND SPINA BIFIDA.

A PAPER by Professor Schatz, of Rostock (*Berliner Klinische Wochenschrift*, No. 28, 1885), on the respective advantages of expectant and operative treatment of cephalocele and spina bifida, is of some interest when considered in

relation with the report lately presented to the Clinical Society by its Spina Bifida Committee. Taking as his text the expressed opinions of Heinecke and Steffen, both of whom speak in gloomy terms of the prospects of success after any radical operation, he presents a list of cases of encephalocele to illustrate the relative prognosis with and without operative interference. Of 105 cases, 59 were occipital and 46 frontal in position. Of the former, 24 were left untreated, and only three recovered, 35 were operated upon by incision, injection of iodine or ligature, with 6 recoveries. Of the frontal encephaloceles, 6 out of 32 survived without treatment and only 3 out of 14 cases after operation. A few cases of spina bifida, quoted from Lorinser, show much the same proportion of success, and, in the opinion of that author, justify the view that no operative interference should be attempted when it can be clearly shown that a communication exists between the sac and the vertebral canal. Professor Schatz himself considers that operation is only justified when there is no such communication, and when the tumour is covered with healthy skin, is fully translucent and not painful. In other cases, however, he would endeavour to secure the isolation of the tumour from the arachnoid cavity by means of graduated constriction or pressure calculated to set up a process of plastic adhesion, when applied to the base or pedicle, if there be one, of the tumour. He relates the particulars of three cases in which he operated by emptying and removing the sac, the base or pedicle of which was firmly secured by means of a long clamp, such as is at times used to secure the stump of an ovarian tumour. His first case was one of spina bifida, and was not successful in saving the life of the child. In the second a large encephalocele was successfully emptied and removed with but little disturbance of the child's health, life being prolonged to the eleventh year. The symptoms and physical signs of internal hydrocephalus were, however, always present, and gradually increased, the child remaining paralysed in the lower limbs and of very feeble intelligence. In the third case, a series of cephalic protrusions were in like manner clamped and removed, and notwithstanding the great extent of the hernia, the case, after some suppuration and many fluctuations of temperature, ultimately recovered and is still living, although with a steadily increasing hydrocephalus. All these cases were in themselves severe, and hence the merits of the operation must be considered apart from them; it is possible, however, that the method of compression by clamps, when applied to the more simple cases of the kind, may be found to enhance the chances of success to a very considerable degree.

#### THE CONFERENCES AT THE MORGUE.

In the *Boston Medical Journal* for June 11th, a correspondent furnishes an account of the "Conférences de Médecine Légale" of Professor Brouardel, which, unique as they are of their kind, are regarded by students as of great value. They are held three times a week in a small amphitheatre attached to the morgue, capable of holding about 50 persons. One of these is conducted by Professor Brouardel himself, his two assistants conducting the other two. "There is, of course, always a body to be examined, death having occurred by violence, drowning or poison, or there has been a false diagnosis at the hospital where the death occurred. At all events, the purpose of the autopsy is to discover the cause of death. In the case of a body drawn from the Seine, for example, the question to be decided is whether death occurred from drowning or from violence before immersion, or whether the drowning was probably a suicide, &c. Every step has a medico-legal bearing. The most minute external and internal examination is made, and a careful record is kept. At the beginning of the autopsy, and as it advances, the student who holds the knife is questioned as to his opinion concerning the meaning of every abnormal sign, and if he fail to give a correct reply, or has no opinion to give, the audience is called upon for judgment. This creates the 'conference' and the professor and his assistants being very able, the course is made unique in its great value to the students. Occasion-

ally, Brouardel does the entire work himself, thus converting the conference into a demonstration. The conference lasts one hour, and I have seen Brouardel examine and pronounce upon three bodies within that period. The manner of the necropsy is peculiar. The eyes are first incised, and the lenses removed for examination. The body is next opened by a cut, beginning at the bifurcation of the trachea, descending over the left costal cartilage, and sweeping in a curve just inside of the crest of the ilium, across above the pubes, back to the bifurcation by a similar path on the right side—an oval incision, which lays open abdominal and thoracic cavities at once. The tissues are dissected away from below upwards (the costal cartilages having been first cut through), and the sternum and tissues come away together. The organs are removed in the usual order, but a very much longer time is occupied in opening the intestines by the French than by the German method. For purposes of examination, longitudinal incisions are made two inches apart, up each leg from ankle to hip, up each arm from wrist to shoulder (including the entire circumference of each limb), and also up the whole back from rump to shoulder and neck. This leaves the cadaver in a state of mutilation which probably would not be permitted at home. Indeed, even the Paris lay journals are complaining of what they consider unnecessary injury of bodies of people of the better classes, who have met with violent death, and whose remains are subjected to legal *post-mortem* examination. The cranium is opened by two methods. By one the skull is quickly broken through in the usual circle, with the sharp edge of a heavy steel hammer (shaped like that of a mason), and the brain is removed entire. The other method is to cut straight through the centre of the skull and brain longitudinally, with a thin saw, from the middle of the os frontis, to the occipital protuberance. Half the brain comes away with the top of the cranium. It seemed a very convenient cut. What was done with the remains of the bodies I did not learn. The organs, after examination, are thrown into a bucket and carried away. A convenient use of water is managed by having the water pipe come down from above, along the pipe of the gas-burners. The dependent hose is not in the way, cannot fall on the floor, and is always at hand. It is easy to imagine the great usefulness of this course to students who attend the three weekly conferences (the tickets are good for a month). Every variety of medico-legal question in connection with autopsies is carefully discussed, and nothing is left undone to make each case clear in all its bearings. At one of the conferences, during which two stalwart male bodies were examined, there was present a young female student, quite near the table, and who talked and laughed with the men. It was not at all charming, but she did not appear in any way disturbed by her extraordinary surroundings."

## REPORTS OF SOCIETIES.

### ACADEMY OF MEDICINE IN IRELAND.

#### SUB-SECTION OF STATE MEDICINE.

Dr. J. W. MOORE in the Chair.

THURSDAY, MAY 14TH, 1885.

#### *Relative Disease and Death-Rate in Town and Country.*

THE REGISTRAR-GENERAL (Dr. GRIMSHAW) gave a *résumé* of his paper on the relative prevalence of disease, and on the relative death-rate in town and country districts in Ireland.

The CHAIRMAN regarded the remarkable coincidence between the average disease and death-rate as one of the strongest arguments that could be adduced in favour of the registration of disease. Some of the epidemic diseases seem to fall more heavily upon Dublin South than upon Dublin North, but measles and scarlet fever the reverse.

Dr. JACOB asked how far these interesting and important facts ought to be discounted by the deficiencies of registration; because the curves on the charts, even on a cursory view, revealed certain points which he should not have expected.

Dr. HENRY KENNEDY emphasised the extreme value of the Registrar-General's information and remarks. The fact had been long established that the towns were less healthy than the country, and there was a perceptible difference too in favour of the healthy appearance of the country population, townspeople being more or less pallid. He had no doubt that a dry climate had an important bearing on health; for instance, people who went to reside in England, at once lost rheumatism with which they were afflicted here. The registration of the causes of death depended on the professional knowledge of the medical men in each locality, and he had no reason to believe that facilities of knowledge differed in one place more than another.

The REGISTRAR-GENERAL replied.

#### *Compulsory Notification of Infectious Disease.*

Dr. JACOB read a paper on the compulsory notification of infectious disease.

Dr. FITZPATRICK concurred in Dr. Jacob's observations that the medical profession would be placed in a most invidious position, without any possible good arising to the public.

The REGISTRAR-GENERAL (Dr. GRIMSHAW) differed from Dr. Jacob in everything he said, being strongly in favour of compulsory notification. Two questions were mixed up which should be separated—one, whether there should be compulsory notification of disease; and the other, whether the medical man should have any responsibility in directly notifying to the sanitary authorities. That notification would tend to prevent and diminish disease he was certain. People complained individually of the losses inflicted on them by it, but the losses inflicted on others who caught the disease were just as great or greater, and on moral grounds, independent of anything else, nobody had a right to inflict the misery. With regard to the figures brought forward, having read all that had been quoted in some shape or other before, he was bound to say he never could discover anything to show that injury had been produced by the notification of infectious disease. On the other hand, the sanitary authorities, knowing that a particular disease existed in a particular place, could take precautions to prevent its spread, and thereby benefit the community. But where the sanitary authorities were unable to interfere, the disease had spread, destroying numbers of lives, and creating misery among the working classes, who were deprived of every penny they had.

Dr. COSGRAVE, having had practical experience of the working of the Act for two years in Huddersfield, pointed out that at least two of the objections urged against it did not amount to anything. One was that the voice of the profession was not heard against the Act. Now, although the severity of the Act had been increased in Huddersfield, he did not find his brethren there complain of having to carry out its provisions. But it was quite right that certain cases need not be notified; for instance, where a case can be isolated and treated in the house. With regard to the loss of money, in the majority of cases where the people were able to pay medical men the patients could be treated in their own houses. But it was different with the people who lived in tenement dwellings, and if those cases were moved into hospital, as they should be, the dispensary medical officers would have a much easier time of it. As to imposing a penalty, he did not see how the principle differed from that of imposing it for not certifying the disease of which a patient died. The best mode of notification was to hand the form filled up to the person in charge of the case, whose duty it was to transmit it. He thought that preferable to the present mode of direct notification. At the same time he concurred in Dr. Jacob's appeal for an investigation into the working of the Acts, the question involved being one affecting the health and life of the population. He believed that notification struck at the root of infectious disease.

Dr. HENRY KENNEDY inclined largely to Dr. Jacob's

views, and regarded the evidence which he adduced as conclusive.

Mr. EDGAR FLINN, speaking from experience of the working of the Act in Leicester and Nottingham, believed that a measure for notification of disease would be of no great harm. He admitted, however, the great hardship of asking medical men to become detectives, and therefore thought that the measure should not be compulsory.

The CHAIRMAN avowed himself to be strongly in favour of the compulsory notification of infectious disease. The relation which the profession held to the State, or rather to the people of the country, should be remembered. The licensing bodies were acting under charter, and likewise the universities existed by the favour of the State, and, therefore, anything ordered to be done by the profession must be done, protest as they may. Dr. Jacob had drawn purely fancy pictures of the existing state of affairs. He had mentioned that the Act had led to concealment of disease, forgetting that, in towns where it was not in force, greater concealment prevailed. This was notoriously the case in Dublin. What they wanted was a code making infectious notification applicable to the whole country, rich and poor, but with modifications. A difference would be made in the treatment of rich and poor patients to the end of time. He approved of an enquiry into the subject such as had been held in reference to the Public Health Act.

Dr. JACOB said, in reply, that it was not the notification of the existence of disease to a sanitary authority that he deprecated, but the proposition that such notification should be effected through the agency of the medical profession; because he held that that would result in the exclusion of the medical man once he was forced to act as a detective. The whole pivot on which this argument turned was the concealment of disease from the sanitary authority. Where there was a medical man to the fore to give good advice and see it carried into effect, the concealment of disease was of comparatively little importance; but the concealment of disease where there was no medical man in the case was fraught with every element of destruction to the community. He affirmed that the Acts which had been working for seven, eight, or nine years in twenty-two towns had utterly failed to produce any amendment of the public health, and, therefore, he asked the Academy to take a prominent position to prevent the further extension of the system.

The sub-section then adjourned.

## SPECIAL CORRESPONDENCE.

### INDIA.

(From Our Bombay Correspondent.)

*The Proposed New Medical School at Bombay—The Goculdas Tejpal Hospital—Increase of Cholera—Pay of Veterinary Surgeons—The Grievances of the Junior Officers of the Indian Medical Department.*

July 6.

AN agitation has lately been set on foot in Bombay by local medical licentiates, having for its object the establishment of a new medical school, in connection with the Goculdas Tejpal Hospital there. The agitators further desire that the staff of this new school should be selected, albeit by a municipality which has but little spare time or funds at its disposal, from among the agitators aforesaid, to the exclusion of members of the time-honoured Indian Medical Service. They also desire to have minor chairs and appointments created for the benefit of local practitioners who may fancy the taking-up of special subjects, also to the exclusion of members of the covenanted Indian Medical Service. The *Indian Medical Gazette* did good service the other day by printing a schedule showing the professional hospital, jail, and other appointments reserved as a special right for the Covenanted Medical Service. The agitation now being raised in Bombay by the promoters of such schemes is fraught with evil, and tends, doubtless, to beget an ill-feeling between the two classes of medical men.

I see no reason why the existing Grant Medical College and its staff cannot be augmented, of course from among legitimate candidates belonging to the Covenanted Service, which, I should think, would be quite able meet all wants. It is to be hoped that better counsels will soon prevail in the city of Bombay, and that its municipality will be induced to direct its attention to the many sanitary shortcomings which stare them in the face.

I have before me a copy of the last annual report on the working of the Goculdas Tejpal Hospital of Bombay, by Dr. Vandyke Carter, of the Indian Medical Service, the medical officer in charge of the institution. He writes first on the "Conservancy and Water Supply," and on this he has nothing to say of very great importance, except to point out the interruption of the water-supply through non-filling of the tanks. Concerning the hospital buildings, he makes certain remarks which are not of sufficient importance for me to note here. Under "Attendance of Patients," he states that the total number of indoor cases treated was 2,374 as compared with 2,709 of last year; and the total admissions were 2,268 or 333 less than in 1883. There were no admissions from cholera or small-pox during the year, while in 1883 there were 116. The out-door cases treated numbered 17,858, or 1,108 more than in the preceding year. The average daily attendance was 153.3 as contrasted with 122.9 in 1883. The most common diseases among the in-patients were malarial fevers and syphilis; next in order of frequency came affections of the respiratory system, including phthisis, dysentery, diarrhoea, rheumatic, hepatic, splenic, and cardiac affections, gonorrhoea, abscess, ulcers, &c., and there were a large number of cases of poisoning, poisoned wounds, and injuries. There were 104 major operations performed, including 1 case of nephrotomy, 2 of herniotomy, 17 aspirations for hepatic abscess. Under the head "Mortality and its Causes," Dr. Carter reports 262 deaths amongst 2,374 in-patients treated during the year, which is equal to 11 per cent., as contrasted with 11.8 per cent. during the previous year. A considerable number of cases were admitted in an almost moribund condition, dying within four-and-twenty hours. Several of the cases, I learn, were "discussed before the Medical and Physical Society in anticipation of the surgeon-general's approval, there being necessarily a large amount of valuable professional knowledge rendered available in hospitals like the Goculdas." As regards the "Conduct of the Establishment," Dr. Carter writes that he resumed charge from Mr. Hizel on 7th May. On the 22nd July, the two honorary assistant-surgeons tendered their resignation, and two assistant-surgeons in the service were appointed in their places. Dr. Carter writes that, as regards the conduct of the honorary assistants, report had already been made, and he does not say anything more on the subject. He speaks in terms of eulogy about his subordinate staff; and lastly, under the head of "General Observations," he writes that the hospital is working to his satisfaction. He urges the building of two isolation and emergency wards. He recommends the appointment of a second (junior) surgeon on the permanent staff, a recommendation which I have every reason to endorse, having myself urged it before this.

I have again to notice a considerable increase of cholera in Quettah, and the adjoining districts. The cantonments have had to be evacuated, and the troops placed in tents at a distance from the place. The works on the railway under construction have had to be suspended until the abatement of the disease. The cholera is now raging virulently at Kurrachi. It is all very well for the promulgators of the non-contagion theory to stick blindly to a view which can never hold for a moment where both sides of the question are duly represented. In the case of the Quettah epidemic, there is little room for doubt that the cholera was carried by human intercourse from Bombay, which now may take rank as an "endemic area."

The Government of India have, I observe, issued an order whereby the pay of veterinary surgeons of the army in this country is considerably improved. This has caused a somewhat acrimonious correspondence between the Army Medical Staff and the Veterinary Department in the columns of the *Pioneer*, the former naturally feeling indignant that the Government should hold the services of

their horse medical attendants at a higher estimation and pecuniary value than those of their soldier medical attendants.

Owing to a new order, of employing junior surgeons of the Indian Medical Service, not provided with appointments, or in other words on "general duty," in what are out here called "station hospitals," *i.e.*, hospitals for British troops, of which there is one at each military station, a great deal of dissatisfaction has been produced among them. The reasons alleged for this I understand to be—firstly, that they do not like the idea of being placed under the orders of what they deem to be an "alien department"; secondly, because the Army Medical Staff leave all the heavy duties, together with the dirty and unpleasant ones, to the junior Indian medical officer while so placed temporarily to do duty under them. The latter very rightly complain that if some unpleasant duty, such, for instance, as going out into cholera camp with troops, requires a medical officer to be deputed, it is almost invariably the junior Indian medical officer, though there may be at the time in the station juniors of the Army Medical Staff, and this they maintain when the troops are those for whom they are brought out to India, and paid for—*i.e.*, British troops. The Indian Medical Service has another grievance of which complaints are made, and this is that such appointments as staff surgeoncies, which used formerly to belong to them, are now being bestowed on the sister service. It is to be hoped that these points will receive the attention they merit, so as to remove any heart-burning that there may exist in the service, and so prevent the best candidates from being deterred from competing for admission thereto.

The Simla Correspondent of the *Bombay Gazette* telegraphs, under date June 27, that "a virulent form of fever has proved very fatal among the Jamshedees. Dr. Owen will take an early opportunity of diagnosing it." This refers to Sir Peter Lumsden's Boundary Commission.

## GENERAL CORRESPONDENCE.

### MEDICAL EDUCATION.

[To the Editor of the Medical Times.]

SIR,—Much has recently been said at various meetings of British Medical Branches, and in letters to you as well as in papers to contemporaries, on this subject of medical education. It appears to me that the *useful* end in view in the present age of "cramming" and examining is quite overlooked. We want in our midst medical men when we are ill, who can recognise practically the nature of our ailments, who know what is going on in structures out of sight, and also know how to *interpret* symptoms which, as matters of fact, are on the surface and capable of being so far recognised by laymen, though the latter may not and generally do not understand their deeper value; in addition to knowing these points we want them to go a practical step further, and be able to do something to *relieve* our agony while intelligently (not *curing* like a quack, we have no *cures* for the majority of ailments) conducting our *treatment* in successive stages to restoration to health. Now are these the points *prominently* kept in view in the school and examination schemes in the present age in the so-called education of the future medical man? The fact is there is a tremendous standard set up in respect of preliminary non-essentials, and what Dr. Latham said in his day speaking of the same subject is true now, "I am persuaded that there does not exist at this day in the profession an individual who comes up to the standard which (it is implied) all ought to reach. If all medical students had fifteen or twenty years at their command, and could dedicate them all to professional education, we might pardon a little innocent declamation in displaying the rich and varied field of knowledge about to be disclosed to them, but even then, sober truth would compel us to confess that the field so

pompously displayed far exceeded in extent what the best minds could hope to compass, even in fifteen or twenty years. When, however, we recollect what space of time the majority of men so addressed really can give to their education, the whole affair becomes inexpressibly ludicrous." "Turn away then," says Dr. Latham, "a little further on from the contemplation of this ideal perfection which can only make you despair and look to some real examples for your encouragement. But take care that they be *high* examples, and such as no small or ignoble efforts can imitate." He then points to Dr. Baillie and Dr. Babington as great exemplars of what a physician ought to be, and he remarks, "Now the reputation of Dr. Baillie and Dr. Babington would not be exalted by any lavish praise of them for qualities which they did not possess. They do not need our commendation for what they were not. Enough will still remain to make us content to be what they were, although it should be denied that either of them was remarkable for the extent or variety of his acquirements. We may still take them as our examples, although neither of them did, or ever pretended to possess a knowledge of one half the things now recommended to the medical student as indispensable. . . . I will venture to affirm that had Dr. Baillie and Dr. Babington been constrained to accomplish half the course of literature and science now recommended for common professional education, they would from the very texture of their minds have been utterly spoiled as physicians." How true is the following observation: "Knowledge may be an incumbrance as well as a help; many men know more than they are able to wield. There is a point in the acquisition of knowledge beyond which if more be acquired the whole mass becomes useless to its possessor. I am acquainted with men who never have *done* and never can *do* anything because they know too much. . . . In laying down any scheme of education you must take care to make it suitable to the majority of those who are to be educated. . . . Their knowledge should be of things obviously and confessedly necessary, and this knowledge ought to be rigidly exacted and nothing more. . . . There are doubtless many things *out of* the profession by the previous knowledge of which the things within the profession are better understood. Such previous knowledge you may *recommend*, but you must not demand it. You may *recommend* that every man before he enters upon the study of physic should obtain the best general education within his reach, but you must specify nothing as absolutely necessary but what bears immediately upon professional use." A quiet mind is the inceptive mind, knowledge of a practical and applicable kind is what the student needs to have put within his reach. Where can be the harm in the professor being also the qualifying examiner? He can *explain* the scientific points in the case for instance, and properly and for purposes of after practice *associate* the ideas which crop up while analysing a case, he can point out possible fallacies, he can show how the proper investigation of the case is to be conducted by judicious questioning, he can fix attention and also give the information required, of which the students may have proper time to make a note from his dictation, or refer to portions of authors to be read; thus the trumpet would give no uncertain sound, a great deal of *useful* science would be taught pleasantly, almost insensibly and by constant reviewing and repetition, the information being of *standard* value would become a part of the student's mental self. Then *knowing* his subjects thus thoroughly, at the examination time let Professor A. examine him as to his knowledge and power of using A.'s information of standard value previously given to him—not as now, let B. and C., who may differ from A. in many points, examine him in something or other, A. not being present, which he has not had brought under his notice—but B. and C. might be at the examination conducted by A., and see that the ground was well covered and the answers given satisfactorily. Thus with a *quiet* in class the student would feel conscious of treasuring up *useful* information for after years in practice, while the *detailed, daily, practical* bed-side work and *post-mortem* work, anatomy, &c., in class would be *telling* for his degree examination. Mere straight lecturing is of very little use, but I should advocate that there be class

tutoring, with demonstrations, questions and careful and full note-taking from tutor's dictation—much more like the University and College class-room work for Latin, Greek, &c., with at suitable intervals trials in written, practical, and *vis-à-voce* examinations. One other point might be worth the attention and consideration of some students, that is, three months or so to be spent with a tutor *before* entering on the regular course, so as to lose no time in getting into the mode of working. At present the medical student has anything but a quiet mind. There is a tendency in the present day to over-examine, preceded by a "cram-class" preparation, and to over-lecture the student and to keep the examiner always in view. Instead of this, the prominent idea in the student's mind should be to learn his subjects in a lasting manner, with such associated ideas that whatever he learns may be remembered at the right moment in after-practice. In the medical student's education there should be a concentrativeness aimed at constantly, *i.e.*, the *habit* of regarding each accession to the stock of knowledge in all its probable uses and bearings, how the dead anatomy might be vivified by associating practical points with the mere dissection, *e.g.*, fascia in certain parts in association with waiting or not for "pointing" of an abscess, &c., *ad infinitum*, little points *dropped* in, but of immense value to remember at the right moment in practice. There is a great loss in having a *mere* anatomist to teach anatomy. In the present system the examiner's notions and the examination room with its appliances are kept too prominently before the student; and his profession for which he is preparing, might be more aptly described as that of *Examinee* than that of a sound practitioner of medicine. The student should be relieved from his present injuriously fevered condition of apprehension of the *Examiner*, and should be able with a calm brain to bestow his attention upon, and with the kindly assistance of *experienced* and naturally gifted tutors—not lecturers—to put by practical knowledge for use in future time, for the *legitimate* purposes of his profession—to relieve from suffering and prolong life.

I am, Sir, yours, &c.,  
E. P., M.D., M.R.C.P. LOND.

London.

## A NEW PHASE OF LISTERISM.

[To the Editor of the Medical Times.]

SIR,—Though I have long ceased to practice Listerism in any of its details, or to be in the least degree fascinated by the wondrous charms put forward in its name, it still remains to me a most interesting study, chiefly by reason of the ever-varying aspects which it is made to present. Dr. Herman has added another to these, perhaps the most curious of all, and concerning it I certainly should like a little more information. In the case which is reported in your paper of to-day of a death from peritonitis after the performance of Alexander's operation, Dr. Herman says "that the death appears to have been due to the entrance of septic germs at the time of the operation through the wound of the peritonæum made in freeing the ligament." This sentence, with other minor points in the narrative of the case by Mr. Holyoake, makes it quite clear to me that the new view concerning these germs is that, it is their entrance into the cavity of the peritonæum alone which is held to be responsible for their ill-results, and that the operator would be perfectly satisfied that his proceeding would be safe from danger if he had the said germs completely secured outside the peritonæum. In fact, in other words, this view means that on the one side of the peritonæum the germs are harmless, whilst on the other they are full of mischief, and that a membrane which is certainly not more than the one-hundredth part of an inch thick has therefore a perfectly preservative influence against the evil machinations of these germs. That, in fact, you may do what you like so long as you keep on the right side of this sacred boundary, but that once inside it a germ obtains the mastery. This is certainly

a most staggering doctrine to one who is in the habit of opening the peritonæum ten, twelve, fifteen times a week without the slightest regard to the presence or absence of germs, and without the slightest precaution for their destruction. The reason of my writing this letter is to ask Dr. Herman, in the first place, if he really seriously means to advance the conclusion which his words indicate; and again, if he does so, to indicate something like evidence in favour of a view which seems to be a sort of resuscitation of the old and now long-since dead dread of opening the peritonæum. If it is no more than this, the sooner it is discontinued the better; if it is, perhaps Dr. Herman will inform us.

I am, Sir, yours, &c.,  
LAWSON TAIT.

Birmingham, July 25th, 1885.

## MEDICAL CONSULTATIONS.

NO. XVI.—MEDICAL M.P.'s.

SCENE.—A room in TURBITT'S house.

DRAMATIS PERSONÆ.

TURBITT.—A distinguished provincial physician.  
MALLOW, } In practice in the same city.  
RUE,

TURBITT. Very glad to see you, gentlemen, I'm sure, but—

MALLOW. Sir, we have the honour of calling upon you as the representatives—indeed I may say the delegates—of the medical profession in this growing centre of intelligence and commerce. It may perhaps have come to your knowledge, Dr. Turbitt, that an invitation—a numerously signed invitation—is about to be presented to you, begging you to allow yourself to be put into nomination for the representation of this city in the new Parliament.

TURBITT. Upon my word, gentlemen, you take my breath away. An honour I had not dreamt of. Pray be seated.

MALLOW. No dream, Sir, I am glad to say, but an actuality.

RUE. Upon ten sheets of foolscap.

MALLOW. With power, and I may say with full certainty of adding to their number.

TURBITT. Dear me! I had no notion of such popularity.

MALLOW. Sir, we are fortunate in being the first to advertise you of it. To proceed: at a meeting of the whole medical profession in this city, without respect of party—a meeting over which I had the honour of being called upon to preside—it was decided without a dissentient voice, to beg you to take the petition of your fellow citizens into your most favourable consideration, and we have all pledged ourselves, again without respect of party, to do our utmost, individually and collectively, to secure your return.

TURBITT. Very obliging of you, I'm sure.

RUE. The plain fact is, we want to send a doctor to St. Stephen's.

MALLOW. Excuse me, Rue; we are anxious to be represented by the most distinguished of our brother practitioners.

TURBITT. You honour me too much. But, gentlemen, your reasons?

RUE. They are as plentiful as blackberries, with a little more variety.

MALLOW. I will expound them *seriatim*. In the first place, we are desirous of reinforcing the phalanx of medical talent in the Lower House of the Legislature.

RUE. Not much of a phalanx at present; a four-wheel cab would carry them, while as for the lawyers, they would crowd a penny steamboat.

TURBITT. Fit emblems of the two professions.

RUE. True, Sir, we are too jog-trot.

MALLOW. You interrupt me, Rue. It must have occurred to you, Dr. Turbitt, that there are many questions of medical import—and I include therein the whole range of sanitary and prophylactic science—in respect to which ninety-nine hundredths of our representatives are entirely unenlightened. The experts are lost amongst them—*rari nantes in gurgite vasto*.

TURBITT. Excellent! And you wish me to make one in the Maelstrom?

MALLOW. Sir, we wish you to be our representative. Look at medical legislation. Do you opine that the brewers, or the lawyers, or the ship-builders, or any other class representatives who sit in the House would have allowed Bill after Bill dealing with the loud abuses of their business to be talked out?

RUE. Tossed from one party to another like a shuttlecock, thrown to the Medical Council for repairs, and then pigeon-holed as past praying for.

MALLOW. Do you think that if we had a score of our members in the Commons, they would sit down in peace, while chemists and herbalists, and the growing tribe of unauthorised quacks, are stealing work and wage from educated practitioners?

TURBITT. Really, gentlemen, I hardly think that I could consent to go before a large constituency like this, pledged to restrict their liberty to get drugged where they pleased.

MALLOW. We do not put it so crudely as that, quite. We merely ask for legislation, for and by the advice of the profession, to the end that the medical needs of the poor shall be supplied by regular and competent practitioners. If the standard of the authorised practitioner is too high, let it be lowered. But that is a matter to be considered by Parliament, under the competent advice of a fair number of medical representatives.

TURBITT. That is a very different case.

MALLOW. We think, even, that a Select Committee should be asked for to consider the present medical provision for the working classes.

TURBITT. A reasonable demand, though I fear the Select Committee is often but a prelude to the pigeon-hole. But my impression is that if I stand—and as yet the idea has come upon me so suddenly that I can decide neither one way nor the other—but if I stand I should be inclined between ourselves to say as little as possible about medical matters, and to rest my claim on my anxious desire for the physical well-being of the masses, and on the knowledge and experience which I can bring to that object—a knowledge indeed which, small as it is, is yet greater, as you say, than that of the vast majority of our present representatives.

MALLOW. I am sure, Sir, I need not reiterate the many directions in which such a knowledge as yours would facilitate the passing of wise and beneficent measures of sanitary reform. I may predict that the most important duty of Parliament for the next generation will consist, not so much in consolidating our empire beyond the seas, and taking measures for the protection and extension of our commerce, as in stemming that rapid degeneration and decay

of our crowded home population, which all men of extended medical experience must admit to be the most pressing problem of the day.

TURBITT. There is not a doubt of it.

MALLOW. Then, Sir, may I have the pleasure of informing your brother practitioners that you will gratify them by accepting?

TURBITT. Stay a moment. I fully endorse all you have so eloquently said. It cannot be denied that medical knowledge and experience ought to and must have a predominant voice in the legislation of the future. But it does not seem to me to follow that this can be best secured by placing medical men in Parliament; and still less that it can be best secured by placing me there.

RUE. Pray do not disappoint us.

TURBITT. Certainly not, if I can help it. But the thing wants arguing. Grant that the medical voice must be heard, we have to ask how will it best be heard? By sending into Parliament a score of medical men, perhaps like myself of no proved aptitude for it, perhaps like others who may be returned elected for considerations entirely apart from their authority in matters of medicine? Or, again, will the medical voice best make itself felt, as at present, informally; by ministers and members of Parliament seeking advice from the highest available authorities, from distinguished fellows of the College of Physicians or the College of Surgeons, from the medical adviser to the Privy Council, and so on? It seems to me that if you have an increased number of medical representatives in the Commons, they must, however chosen, *ex officio* take the place of the present informal advisers, and so you may substitute inferior advice for the best that is to be had.

MALLOW. I follow your point, but I don't see that the one expression of the medical voice need drown the others. Government would still seek advice from its chosen experts. But remember, the experts only speak when asked, that is infrequently, and perhaps only when it is known that their advice will be agreeable; whereas you and your medical colleagues would have a right and a duty to speak whether asked or not, to give advice whether welcome or otherwise.

RUE. Besides, could not you consult the experts as well as Government, and convey their views to Parliament with a great deal more weight than some bungling under-secretary?

TURBITT. I concede these points. But there is another reason for my hesitancy. Is it not probable that the next Parliament will be a stop-gap Parliament?

RUE. What? Stop-gap, after our leap in the dark?

TURBITT. I mean, is it not likely that the first act of the new House of Commons will be to pass a large measure of local government, and to throw all those matters on which medical advice is needed into the hands of the new county-boards? Where would be the function of doctors in a central Parliament, dealing mainly, as I suppose it would, with imperial finances and defence. I speak with diffidence on the subject, but would it not be well for medical candidates to reserve themselves for the important duties which will fall to the Local Parliaments?

MALLOW. I would not attach too much importance, Sir, to that objection. In the first place, it is founded on a forecast which is very uncertain of fulfilment. And secondly, assuming that local parliaments are to be created, it is highly important that medical authorities should have some voice in defining the duties to be allotted to them and their mode of election. Your idea that medical men will play an important part upon them—which I admit to be

a desirable, if not a probable issue—renders it all the more important that medical men should be seated in the new Parliament, in order that they may provide that the system of election to the local Councils shall not be such as to exclude members of their profession. Thirdly, there will be still many duties left to the central Parliament—provision, for instance, against the importation of disease, the health of the army and navy, &c., in which the medical voice ought to be heard.

TURBITT. There is much in what you say. Well, I will consider the matter, and you shall be the first to hear my decision. I must consult Mrs. Turbitt, for one thing.

RUE (*aside to MALLOW*). Ah, Mallow! you should have kept your eloquence for the lady.

## MEDICAL NEWS.

### CONFERENCE OF HEALTH OFFICERS ON CHOLERA PREVENTION.

ON July 16th, a Conference was held between Dr. Buchanan, Medical Officer of the Local Government Board, and the Metropolitan Medical Officers of Health, as to the preparation of London against cholera. Dr. T. Orme Dudfield, President of the Society of Medical Officers of Health, presided, and introduced the subject by an account of the steps that had been taken since the summer of 1883, with a view to preparation against cholera.

Dr. DUDFIELD said that in 1884, when cholera made its appearance in France, a Conference to concert measures of defence for London was held by the Medical Officers of Health, with the General Purposes Committee of the Metropolitan Asylums Board, that Board having been constituted a "Local Authority" under the Diseases Prevention Act, 1855, by the Diseases Prevention (Metropolis) Act, 1883. One of the objects of the latter Act was to make better provision, as regards the metropolis, for the isolation and treatment of persons suffering from cholera, and by it the Board was enabled to utilise its buildings, ambulances, and staff, for the execution of the powers and duties imposed on it under both of the Acts. Immediately after the passing of the Act, the Board resolved to provide accommodation for cholera patients in the metropolis, as a whole, without respect to parochial boundaries, partly by the use of its own hospitals, partly by the acquisition of sites for huts, and partly by arrangements for the use of beds at general hospitals, at infirmaries, and at workhouses. The beds placed at the disposal of the Managers were about 1,700, irrespective of 250 available at their own hospitals. The design in the proposed arrangements was to constitute the Managers a first line of defence for immediate action on the appearance of cholera.

Had cholera come, the other local authorities (the vestries, &c.) would have been liable to provide additional accommodation for the sick, if necessary, as well as refuges for the other inhabitants of houses where there were cholera patients too ill to be removed to a hospital.

The questions considered by the Conference were mainly how an epidemic of cholera could best be met, and what convenient buildings or sites for hospitals could be made available in the several districts.

The Committee had previously addressed a communication to the Medical Officers of Health in which questions connected with provision of hospitals, disinfection of excreta, hand-ambulances, notification of cholera cases, &c., were dealt with, and to that communication a collective reply was sent, in September last, through the secretaries of the Society of Medical Officers of Health.

In 1883, and again in 1884, the Local Government Board addressed communications to the several "Local Authorities" with reference to cholera. The Board also issued two orders, with a covering explanatory letter: one

addressed to the Port of London Sanitary Authority, who of necessity would constitute the outer line of defence; and the second addressed to all the other Port Sanitary Authorities, &c. The Board also forwarded, for the information of all Sanitary Authorities, a "Memorandum," prepared by their medical officer, on "Precautions against the Infection of Cholera."

The regulations issued by the Board in 1866, imposed on the vestries, &c., as "Local Authorities" the duty of making arrangements for the prevention and treatment of cholera, including the medical visitation of the houses of the poorer classes, for the purpose of detecting cholera and diarrhoea, and the supply of medical attendance and nursing, and of medicine and disinfectants. What the Board had done in the past might be taken as an indication of what the Board would be likely to do in the future, should occasion arise. It was to be supposed, also, that the arrangements of the Asylums Board, made in 1883 and 1884, would hold good at the present time.

Dr. GEO. BUCHANAN then made some observations, in the course of which he said that the threat of cholera in 1883 was more serious than that which was now exciting attention, it being a peculiarity of cholera in Europe that it usually made a threatening appearance for about three years in succession, and then was heard of no more for a time. His object in desiring to take counsel with the Medical Officers of Health was to avoid fuss and panic. In this country no confidence was reposed in quarantine, but much in the practice of medical inspection through the officers of the several Port Sanitary Authorities. The duties of those authorities were defined by the Board's Order of 1883. A vessel coming from an infected country was required to anchor where ordered until inspected. If found healthy, all passengers were allowed to go free. If there were any sick on board they were detained, the healthy being allowed to depart, their several destinations being recorded, and the vessel was disinfected. The Board had been looking to the defences of the principal ports, by inspections made in 1884. During the present year the survey had been extended, and the various arrangements had been investigated, including the provision of hospital accommodation. The Board's inspectors had looked closely to the condition of the several towns, and to see how the local authorities were doing their work. At some of the ports the arrangements were very satisfactory, the authorities being careful and thoughtful in their preparations. At others there were shortcomings. The inspectors had striven to rouse less careful Authorities. A principal danger to be guarded against was the importation of cholera in rags, and so it had been arranged that rags should not be imported without proper precautions against possible mischief. With reference to the Society's views on the supervision of the water supply, from its sources to the consumers' cisterns, expressed at the Conference in 1883, he had conveyed them to the Board. In Colonel Sir Francis Bolton, the water examiner, the Board had an officer who devoted much thought and attention to this important subject. His reports showed the work done by the companies to safeguard the supply. In 1883 the Sanitary Authorities took steps for securing the purity of the water in the cisterns, and this combination of local vigilance with central vigilance should be continuous. With respect to hospital provision it should be remembered, as had been stated, that the Asylums Board would only profess to provide a first line of defence. The 2,000 beds they were said to be able to provide would be very useful, but it was important to enquire as to the convenience of the proposed hospitals in point of nearness to those of the sick who would be likely to require hospital treatment. The Vestries and District Boards would form the second line of defence, and this would be the more important should cholera come. The Vestries would have to provide places of refuge for the healthy when the sick were too ill to be moved. With this branch of work, probably the most important, as being the best way of dealing with cholera, the Asylums Board would have nothing to do, nor with the provision of disinfectants, medicines, &c. He concluded by inviting suggestions from Officers of Health.

A discussion followed, in which the Medical Officers for Poplar, Bermondsey, Marylebone, Newington, the Strand,

Chelsea, Battersea, and others took part, the general feeling being—and with this the Medical Officer to the Board agreed—that in the event of cholera making its appearance the local Sanitary Authorities should be prepared to do their own duty, not resting too much on what the Asylums Board might be able to do, but depending primarily on their own efforts, alike for removing those conditions which allowed the spread of cholera, and for dealing with the disease if it became epidemic.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen having undergone the necessary examinations for the diploma were admitted Members of the College, at a meeting of the Court of Examiners, on the 23rd ult., viz. :—

John Michell Clarke, M.B. Cantab, Bristol; Henry Alexis Thomson, M.B. Edin., Edinburgh; Reginald Bowman, M.B. Edin., Edinburgh; Charles Louis Lightfoot, M.B. Edin., Newcastle-on-Tyne; Frederick Brentnall, L.K.Q.C.P.I., Manchester; John Woodward Crowther, L.S.A., West Bromwich; Ernest Robertson, M.B. Edin., Auckland, New Zealand; Harry Adcock, L.K.Q.C.P.I., Liverpool; William Ernest Porter, M.B. Edin., Goole, Yorks; Frederick Proud, M.B. Durham, Bishop Auckland; Frederick William Collinson, M.B. Edin., Edinburgh; Thomas Matthews Angion, L.S.A., Bootle; Edwin Leonard Lees, M.B. Edin., Bristol; George Parker, M.D. Cantab., Cambridge; Herbert Shackleton, L.K.Q.C.P.I., Bradford; John Lockhart Gibson, M.B., Brisbane, Queensland; Henry Claxton Bowman, L.S.A., Woodley, near Stockport; John Charles Lamont, M.B. Edin., Edinburgh; Alfred William Hughes, M.B. Edin., Corris, North Wales; John Warnock, M.B. Edin., Melbourne, Victoria; Richard James Reece, L.S.A., Edwards Place, W.

One gentleman was approved in Surgery, and when qualified in Medicine and Midwifery, will be admitted a Member of the College; 1 candidate was referred for 3 months, 5 candidates for 6 months, and 1 candidate for 9 months.

Admitted Members on the 24th ult., viz. :—

John Archibald Cones, L.S.A., Powys Square; Alexander Louis Achard, L.S.A., Brixton Rise; William Henry George Stephen, M.B. Edin., Edinburgh; Thomas Hindle Sykes, L.R.C.P. Lond., Southport; Stephen Robert Thompson, Dulwich; John St. Leger Clarke, L.K.Q.C.P.I., Dublin; John McLachlan, M.B. Edin., Edinburgh; Adolf Bronner, M.D., Heidelberg, Gower Street, W.C.; Charles Dennis Fitch, L.S.A., Kidderminster; Howard Decimus Buss, L.S.A., Southall Park, N.W.

Six gentlemen were approved in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College; 1 candidate was referred for 3 months and 9 for 6 months.

Admitted Members on the 27th ult. :—

Samuel Gordon Smith, L.S.A., Richmond Road, N.; Gerald Schofield, L.R.C.P. Lond., Beckenham; William Grimshaw Bigger, L.S.A., Londonderry; Otto Jackson Kauffmann, L.S.A., Manchester; Thomas Rushbrooke, L.S.A., Amptill; Andrew Alexander Brockatt, L.R.C.P. Lond., Denmark Hill; John Jarvis, L.R.C.P. Lond., Bury St. Edmunds; Daniel Flockton Whiteley, L.R.C.P. Lond., Wakefield; John Oliver, L.R.C.P. Lond., East Dulwich; Edward Buxton, L.R.C.P. Edin., Liverpool; John Hall White, L.R.C.P. Edin., Stratford, Manchester.

Nine gentlemen were approved in Surgery, and when qualified in Medicine and Midwifery, will be admitted Members of the College, and 9 gentlemen were referred for 6 months.

Admitted Members on the 28th ult. :—

William Algernon Winship, L.S.A., Newcastle-on-Tyne; James Edward Roney-Grant, L.K.Q.C.P.I., Harrow Road; Benjamin Blakemore, L.K.Q.C.P.I., Tyldesby, near Manchester; Levi Stephenson Luckham, L.S.A., Studland, Dorset; William Lees, L.S.A., Ealing, W.; Thomas Wingrave, L.S.A., Hemel Hempstead; William Glover Moore, L.R.C.P. Edin., Liverpool; Leonard Charles Talbot Dobson, L.S.A., Ealing, W.; Lewis Brown, L.S.A., Bolton; Henry William Brooks Saville, Radcliffe.

Nine gentlemen were approved in Surgery, and when qualified in Medicine and Midwifery, will be admitted Members of the College, and 9 gentlemen were referred for 6 months.

Admitted Members on the 29th ult. :—

Frank Cecil Clarkson, L.R.C.P. Lond., Surbiton; Harry St. George Standish Hore, L.R.C.P. Lond., Dulwich Common; Francis Albert Saw, M.B. Durham, Maze Hill, S.E.; Walter Henry Bernard Moore, L.R.C.P. Lond., Straits Settlements; Edward William Du Buisson, L.R.C.P. Lond., Newstead, Hereford; John Smith, M.B. Edin., Hackney; Evan Lewis Hickey, L.S.A., King's Road, Chelsea; Henry Willingham Gell, Buxted, Sussex; Thomas Slater Jones, Bangor; Frederick William Burton, L.R.C.P. Lond., Weybridge; Charles Henry Taylor, L.S.A., Newport Pagnell.

Eight gentlemen were approved in Surgery, and when

qualified in Medicine and Midwifery will be admitted Members of the College.

Four gentlemen were referred for 3 months and 8 for 6 months.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, July 23rd, 1885 :—

Alexander Louis Achard, M.R.C.S., 33, Bonham Road, Brixton Rise; Hugh Exton, Bloemfontein, South Africa.

On the same day the following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise :—

Herbert Bertram Cavell, 21, Brook Street, Grosvenor Square, W.; Arthur Deaker Owen, Dart View, Totnes; Frederick Stoman, Farnham; George Richard Radmore, 47, Tonsley Hill, Wandsworth.

**UNIVERSITY OF GLASGOW.**—The following candidates have passed the Final Examinations for M.B. and C.M., viz. :—

A. S. Alexander, S. P. Alexander, John Allan, William Allan, W. Carrick Allan, S. J. Baird, Alexander M. Bankier, George G. Bannerman, Charles W. Bell, John Brown, H. D. Browne, H. Dryden Buchanan, John Buchanan, William Buchanan, William Butchart, M.A.; J. Wilson Cameron, William D. Campbell, Quintin Chalmers, William W. Christie, George M. Connor, Charles Court, B. S. Cowen, David K. Cross, Donald Currie, James K. Duff, M.A.; James Dunlop, M.A.; Henry S. H. Foster, John R. Gibson, Robert C. Gilroy, John Graham, Adam Hamilton, Herbert Hickin, John Hogg, William J. Holme, Joseph Horne, John Hughes, William Huntly, M.A.; David G. Johnstone, William Kirkland, J. Bertie Laing, George Marshall, John Marshall, Joseph G. Marshall, John Martin, Alfred E. Miller, Robert A. Miller, Trafford Mitchell, David C. Muir, William C. E. Muir, Alexander Munro, James J. McArthur, James R. R. McCrindle, John A. MacDonald, Alex. McKean, C. A. Mackeuhnie, John MacKeith, John Mackie, James J. Maclean, John A. Macquarie, Charles Mactaggart, Henry T. Neilson, John F. Orr, James Parker, W. W. Paterson, Andrew Richmond, John Ritchie, J. A. Robertson, M.A.; James A. Robertson, David Roxburgh, Pramath N. Roy, Thomas Rutherford, B.A.; Walter Sandeman, Joseph Scanlan, William W. Semple, William Seright, J. C. A. Smith, Gregory Sprott, David Stiell, David H. Storer, Charles D. Temple, William Wallace (Glasgow), James Wands, James Watson, Charles Whish, Andrew Wilson, John C. Wright, John S. Wright, Robert R. Young, Robert Wallace, William Watson.

\* Out of 115 candidates 25 failed to pass.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH—Double Qualification.**—During the recent sittings of the Examiners the following gentlemen passed their Final Examination and were admitted L.R.C.P. Edinburgh, and L.R.C.S. Edinburgh, viz. :—

Charles Dudant Grant, Edinburgh; Vernon Edmund Russel Ardagh, East Indies; Benjamin Sidney Browne, West Bromwich; John Robert Henry Dubourg, Elgin; Michael English, Adamstown; James William Fox, Edinburgh; Charles O'Farrell, Dublin; Harry Gordon Leigh-Gilchrist, Manchester; Charles Louis Gabriel, Sydney; Godfrey Ernest Garde, Cork; Henry Edward George Johnson, Liverpool; William Owen Magoris, West Hartlepool; George Thomas Hartley, Castleford; Robert Morrison, Toberdoney; James Joseph Moran, Ireland; Patrick Hickson Moriarty, Ireland; Robert Thomson Paton, Edinburgh; John Godfrey Nixon, Tralee; William Henry Roberts, Dublin; George William Robinson, Huddersfield; Herbert Toft Phillips Sinclair, Belgium, India; William James Shiell, Dublin; Charles Augustus Thorne, Cork; William Overton, York; Robert Francis Martin Quin, Ireland; and John Thomas, Gisborne, Australia.

**ROYAL COLLEGE OF SURGEONS OF EDINBURGH.**—During the recent sittings of the Examiners, the following gentlemen passed the Final Examination, and were admitted Licentiates of the College, viz. :—

Luther Laurence Hooper, Canada; Neil Charles McKinnon, Canada; Joshua Jackson, Canada; James Lindsay, Canada; and William Jaques, Canada.

The following gentlemen passed the First Professional Examination for the Licence in Dental Surgery :—

Gordon Reid Shiach, Elgin; Arthur Cocker, Halifax; and Frank Gordon Allen, Ripley, Derbyshire.

The following gentlemen passed the Final Examination, and were admitted L.D.S. Edinburgh :—

Thomas Prettie Ritchie, Edinburgh; David Browne, Montrose; and Andrew Burns, London.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH, AND FACULTY OF PHYSICIANS AND SUR-**

GEONS, GLASGOW.—The Examinations for the Triple Qualification of these Bodies in Edinburgh were held in July, with the following results:—Passed Third Examination, and admitted L.R.C.P. Edinburgh, L.R.C.S. Edinburgh, and L.F.P. and S. Glasgow, viz.:—

James Anderson, Chelmsford; John Donaldson, County Cork; John Horatio Drake, Bucks; James Doyle, Manchester; Joseph Septimus Fallon, London; Octavius Stevens Fisher, Stroud; Arthur Broadfield Frost, Wolverhampton; Franzoni Antonino Faria, India; Arthur Morley, Leeds; Murdoch Mackenzie, Kilmore; James Nesbitt, Belfast; Canice Joseph McGrath, Cork; James McKenzie, Canada; Viriato John Pinto, India; Herbert de Curle Woodcock, Sheffield; and Robert Stevenson Wadsworth, County Fermanagh.

THE Library of the Royal Medical and Chirurgical Society will be closed on Monday, August 10th, and reopened on Thursday, September 10th.

DR. VAN ERMENGEM, of Brussels, has gone to Berlin to study the new method of investigating the cholera bacillus discovered by Dr. Koch.

DR. TITF has been elected a Corresponding Member of the Gynæological Society of Boston.

DR. MILNE EDWARDS, the celebrated naturalist, died on Wednesday, at the age of 85. He succeeded Cuvier in 1833 as Professor of Natural History at the Paris Academy of Sciences, and in 1862 he succeeded Geoffroy St. Hilaire in the corresponding post at the Museum of Natural History.

EDINBURGH UNIVERSITY.—Last week Professor Cossar Ewart was presented by the students of his class with a pair of handsome lamps, as a mark of esteem, on the occasion of his marriage. The proceedings were marked by great enthusiasm on the part of the students, and the Professor made an appropriate acknowledgment.

THE Secretary of the Doncaster Infirmary has received, from an anonymous donor, a bank-note for 1,000*l.*, and the Secretary of the Yorkshire Institution of the Deaf and Dumb, at Doncaster, 500*l.*, not to pay for deficiencies, but to be invested with the view to increase the annual income.

THE CONVALESCENT HOME FOR SCARLET FEVER.—In consideration of the first anniversary, on the 14th ultimo, of the opening of the Mary Wardell Convalescent Home for Scarlet Fever, Stanmore, the Princess of Wales has sent portraits of herself and the Prince of Wales for the "Alexandra" day room, and the Duchess of Albany has given her portrait for the "Helen" room. Other presents were received on the anniversary, amongst them an offer of an annual subscription of 10*l.* for four years, if nineteen others would do likewise.

CENSUS (ITALY).—According to an official statement, the total population of the kingdom at the close of the year 1884 was 29,361,032 souls, exhibiting an increase of 1.21 per cent. upon the previous year, which then amounted to 29,000,652. The births (exclusive of still-born) is given as 1,130,741, namely, 581,413 males, and 549,328 females. The mortality showed a total of 790,361.

PORT OF LONDON.—On Saturday afternoon a new iron screw steam vessel built for the Port Sanitary Committee by Messrs. Edwards & Symes was successfully launched at their works, North Greenwich. The boat, which is 59 feet long and 11 feet beam, is arranged to accommodate the medical officer and inspectors forward, and has a large cabin aft for the conveyance of sick persons to hospital. She was built from the designs of Dr. Cellingridge, the Medical Officer of the Port, and Mr. A. D. Lewis, Naval Architect.

TWO CENTURIES OF SMALL-POX.—The statistics of the hospital belonging to the Brothers of Charity, in Prague, shew that the mortality from small-pox from 1670 to 1815 was 27 per cent.; while, after vaccination had been introduced, the mortality as shown by their registers from 1815 to the present time is about 4.5 per cent. Dr. Haas, who has published tables containing the elaborate statistics of the diseases treated during the last 200 years in the hospital, is very strongly of opinion that re-vaccination should be made compulsory.

MEDICAL MISSIONARY APPOINTMENTS.—Several old

Edinburgh students have recently received appointments, and have left or will soon leave for their distant spheres of labour. Mr. Churcher, M.B. and C.M., will be leaving in the autumn for Algeria, as the agent of the Mission to the Kabyles; Mr. James Wilson, L.R.C.P. and S., sailed early in June for Johore; Mr. Scholes, L.R.C.P. and S., has left for the Congo, in connection with the American Baptist Union; Mr. Fry, M.B. and C.M., has been appointed by the London Missionary Society to Neyoor, S. Travancore; and Mr. Pritchard, M.B. and C.M., will go to China in connection with the same society.

OFFICIAL REPORT ON PUBLIC WORKS (IRELAND).—The 53rd annual report of the Commissioners, on the loans voted, and the various services entrusted to their management, for the year 1884-5, shows a comparatively satisfactory progress in public sanitary improvements. Of the loans, *inter alia*, sixteen, amounting to 38,072*l.*, were for labourers' dwellings in towns, and 167, involving a sum of 84,738*l.*, were advanced under the Labourers' (Ireland) Act, 1883. In respect to this Act, it seems that 68 poor-law unions have obtained or are attempting to procure the necessary provisional orders to put the Act in force, in 685 electoral divisions, to provide, at a total cost of 418,600*l.*, or at an average of 100*l.* for each, 4,186 dwellings.

CHARITABLE BEQUESTS.—Mr. James Vaughan, formerly Surgeon-Major, Honorable East India Company's Service, late of Bui th, Breconshire, has bequeathed 100*l.* to the Brecon Infirmary. The late Mr. Thomas, of Maxwellton, near Perth, has by his will left 100*l.* to Perth Infirmary, and 200*l.* for distribution amongst the public charities of Perth.

PRESENTATION TO DR. MACCABE.—A testimonial, consisting of an illuminated address, a silver salver, and a clock, has been presented to Dr. MacCabe in recognition of his services while inspector to the Local Government Board in Ireland. The presentation was made by Sir Charles Cameron, the chairman of the testimonial committee.

THE LATE DEPUTY SURGEON-GENERAL BARNETT.—On Monday, a military funeral took place at Woolwich, on the burial of Dr. Barnett, principal medical officer. The deceased had recently returned from Egypt, where he superintended the medical arrangements, and he died on Friday, the 24th ultimo, at Eastbourne. Detachments from all the corps in garrison attended the funeral, as also many officers, including Director-General Crawford. The interment took place at the Charlton Cemetery.

DR. FERRÁN'S INOCULATIONS.—The Royal College of Surgeons, in Madrid, has declared by a large majority that it can neither recommend nor condemn inoculation as a preventive for cholera, without further data or information, nor as long as Dr. Ferrán keeps secret the scientific method of his culture of the bacillus comma. The College, however, adds that it sees no grounds for prohibiting Dr. Ferrán's proceedings, because he has produced some strong statistics in favour of his system. Doctor Brunetti, a distinguished Professor of the University of Padua, has been sent to Spain by the Italian Government, in order to study on the spot Dr. Ferrán's system.

HEALTH OF GLASGOW.—During the fortnight ending 18th July, 1885, there 427 deaths registered, as compared with 454 in the fortnight preceding—a decrease of 27, representing a death-rate of 21 in place of 23 per 1,000 living. The number of deaths from diseases of the lungs was 128 in place of 142; from diarrhoeal diseases 18 in place of 6, and of these, 14 were of children below 5 years of age. This was the first indication of the usual summer increase in diarrhoea. The number of deaths from fever was 4 in place of 1—viz., 3 from enteric fever and 1 from typhus; from infectious diseases of children, 33 in place of 51—viz., 24 from whooping-cough, 6 from scarlet fever, and 3 from measles. No cases of small-pox were registered for the week ending the 25th ult.; the death-rate was 24.1 per 1,000 per annum.

THE ASYLUM FOR IMBECILES, CATERHAM.—The annual inspection by the Committee of the Metropolitan Asylums Board, accompanied by gentlemen interested in medical

poor law administration, was made on Saturday last. At present the Asylum contains 1,107 female and 945 male patients. A very slight fluctuation in these numbers, it appears, occurs in the institution, and it can, therefore, be worked on a fixed scale, and at as low a cost as 6½d. per head for maintenance and clothing. A noteworthy feature is the well-managed home farm on the estate, on which those of the inmates who are able work upon. The visitors approved, and were well pleased with the regulations and management of the institution.

**POOR LAW MEDICAL OFFICERS ASSOCIATION.**—At the annual meeting of this Association, which was held at Cardiff on Wednesday, the chairman, Dr. Joseph Rogers, referred to the Lunacy Act Amendment Bill, and denounced Section 5, which provides that an order for the admission of a lunatic into a workhouse should be made on the application of the relieving officers, supported by a medical certificate from the hands of a duly qualified medical officer, not being an officer of the workhouse. This provision should be resisted on the ground that it was a gratuitous affront to and reflection on the medical officer who was to have the care and custody of the lunatic for 14 days or more, that some medical man from outside was to step in and fill up the certificate and pocket the fee. The Bill for the Disqualification of Medical Relief was denounced as retrograde.

**THE WASHINGTON MEDICAL CONGRESS.**—In a leading article on the prospects of the International Medical Congress, the *New York Medical Journal* says, "If the American Medical Association can be made to feel that its action in this matter meets with very general condemnation, there is some hope of its being rekindled in St. Louis next year. If the *status quo* should then be restored, there would still be more than a year in which to prepare for the Congress, and the gentlemen whose further services in its organization have been lost for the time being, in consequence of their having resigned from the committee in disgust, might perhaps be induced to reconsider their determination. It seems now, therefore, that a break may be made in the impenetrable hopelessness of a week ago. But the only way to bring the American Medical Association to its senses is for those of the committee's nominees who have the success of the Congress more at heart than their own tenure of office, to continue the good work which has been begun in Philadelphia, Boston, Baltimore, and Washington. These cities happen to be situated in the east, but it is assuredly by no sectional feeling that they have been led, and we think our friends in other quarters of the country make a great mistake if they so interpret the action taken. It has unquestionably become the duty of every well-wisher of the Congress, no matter where he may live, to decline any participation in the emasculated affair which its present organization must necessarily lead to. The impression thus made upon the American Medical Association, together with the unusual care which we hope to see taken in the choice of delegates to its next meeting, may result in the regeneration of that body. This is matter of even greater importance than the success of the International Medical Congress."

**CALCUTTA AND THE CHOLERA.**—The Calcutta correspondent of the *Times*, on the 26th ult., writes: "The question of the sanitation of Calcutta continues to attract much attention. The lieutenant-governor, commenting on the report of the Commission appointed last year to make a searching enquiry into the subject, recently expressed an opinion that the Corporation had power to do more than it was doing in the way of sanitary reform, that its action in adhering to an inadequate standard of taxation, in face of a most pressing sanitary emergency, was indefensible, and that it should spare neither trouble nor expense in completing the required reforms. He suggested, among other measures, that the city and its suburbs, which now form distinct municipalities, should be united under one corporation. Unfortunately, the large majority of the Municipal Commissioners, carried away by the idea of their own importance, and supported by nearly the whole of the native press, choose to regard Sir Rivers Thompson's action as infringing what they call 'the sacred principle of local self-government,' and they seem bent on opposing it to the

bitter end. I have on former occasions pointed out the more than local importance of this matter. The recent Sanitary Conference at Rome gives it even greater importance than it previously had. Cholera is always present in Calcutta, although its extent and severity vary in different years and seasons. It is absolutely certain that the disease can be stamped out. It is equally certain that only the most searching and vigorous sanitary measures will succeed in stamping it out. English and Indian physicians generally agree that quarantine is useless as a defence; but it is evident that Continental nations are not disposed to accept that belief. If therefore, the Calcutta Corporation refuses to exert itself to the utmost in getting rid of the sources of pestilence which exist on all sides, it is by no means unlikely that the city may some day find the Suez Canal and all Continental ports closed to it by a perpetual quarantine—a step which would not only ruin the trade of Calcutta, but also inflict a most serious blow on the interests of the British Empire."

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—At the ordinary meeting of Fellows, on Thursday, the following office-bearers and examiners, nominated by the President and Fellows, were elected:—Censors, Samuel Osborne Habershon, M.D., William Henry Stone, M.B., James Edward Pollock, M.D., William Howship Dickinson, M.D.; Treasurer, Dyce Duckworth, M.D.; Registrar, Sir Henry Pitman, M.D.; Harveian Librarian, William Munk, M.D.; Assistant Registrar, William Henry Allchin, M.B.; Curators of the Museum, William Wegg, M.D., Lionel Smith Beale, M.B., Henry Charlton Bastian, M.D., John Curnow, M.D.; Finance Committee, Charles John Hare, M.D., William Wood, M.D., Edward Liveing, M.D.; Examiners (Chemistry and Chemical Physics), Charles William Heaton, F.I.C., Thomas Stevenson, M.D., Albert James Bernays, Ph.D., William J. Russell, Ph.D., William Foster, F.C.S.; *Materia Medica*, Medical Botany, and Pharmacy, Thomas Lauder Brunton, M.D., John Mitchell Bruce, M.D., Frederick Taylor, M.D., William Murrell, M.D., David Bridge Lees, M.D.; Elementary Physiology, William Ewart, M.D., Vincent Dormer Harris, M.D.; Physiology, John Harley, M.D., Leonard Wooldridge, M.D., Professor Schäfer; Osteology and Anatomy, Robert Edward Carrington, M.D., James Anderson, M.D., Henry Morris, F.R.C.S., L.R.C.P.; Medical Anatomy and Principles and Practice of Medicine, Lionel Smith Beale, M.B., Octavius Sturges, M.D., Henry Gawen Sutton, M.B., William Selby Church, M.D., Walter Butler Cheadle, M.D., Philip Henry Pye-Smith, M.D., Thomas Henry Green, M.D., Henry Charlton Bastian, M.D., William Cayley, M.D., Thomas Tillyer Whiplam, M.B.; Midwifery and Diseases peculiar to Women, Henry Gervis, M.D., John Williams, M.D., James Watt Black, M.D., Clement Godson, M.D.; Surgical Anatomy and Principles and Practice of Surgery, George Pollock, F.R.C.S., John Couper, F.R.C.S., Marcus Beck, F.R.C.S.

**SOCIAL SCIENCE ASSOCIATION.**—At the annual business meeting of members, held on Wednesday, the 22nd July, a report from the Council, detailing the action taken by the Association during the past year, was presented and ordered to be circulated. The Council reported that they had had under their consideration a proposal to add a further department for the discussion of temperance subjects, and had decided that it was one which they could not support, in the interests either of the Association or of the cause of temperance. Recommendations or resolutions passed in such a special department would, it was felt, lose much of the weight they would otherwise possess if arrived at in a general Section or Department. The Council expressed their regret that, for the first time in the history of the Association, they had considered it prudent this year to forego the preparations for a provincial meeting. Owing to the general election it was proposed, however, that in lieu of a Congress a two-days' Conference on "Temperance Legislation" should be held in London in the month of January, all the expenses in connection therewith being raised by a special fund. This was a subject which, at the opening of a new Parliament, would receive wide-spread attention; and in its legislative aspects it was

one in the solution of which the Association might usefully be able to take a part. The holding of such a conference would afford an opportunity for the official expression of opinions as held by the leading societies interested in this subject. It would not, and under the constitution of the Association it could not well, be organised for the purpose of carrying out any distinctive policy. The outlines of such a policy would, it is hoped, be arrived at by the votes of those present, and the Council confidently trusted that they might afterwards be found of some use in the proceedings of the Legislature. The appointments for the ensuing year, 1885-6, were then made, the Presidents of Departments for the past year continuing in their respective offices for a second year. Dr. Cheevers thus remains President of the Health Department, the Secretaries of which are Mr. H. H. Collins and Dr. Edward Seaton.

**THE LONDON SCHOOL BOARD AND OVER-PRESSURE.**—The over-pressure report on which we commented last week, came up for discussion on the motion by Mr. Bousfield, that the references of the Board on the 20th and 27th of November last, appointing the committee, should be discharged. Mrs. Westlake took an initial objection to the report that the committee had done that which they were not empowered to do, and had not done that which they were instructed to carry out. They had not investigated the specific charges of Dr. Crichton-Browne, set forth in letters to *The Times*, and she held that the committee should have come to the Board for fresh instructions when the Presidents of the Royal Colleges of Physicians and Surgeons refused to afford the assistance of physicians and surgeons in the manner sought by the committee. Miss Taylor moved as an amendment that the report should be referred back, in order that the committee should take the evidence of women teachers. This was seconded by Miss Hastings. The amendment was rejected by 25 to 8, and the reference was accordingly discharged. The consideration of the recommendations was adjourned.

**PRODUCTION OF WINE IN FRANCE.**—The *Revue Scientifique* (July 4) extracts from a recent report of the Minister of Agriculture some interesting figures relating to this subject. According to this, 53 departments are still "phyloxerated," and of 2,185,713 hectares in these departments, which were planted with vines before the invasion of the phylloxera, 429,116 hectares have been totally lost for this purpose. But the deficiency of 420,000 hectares does not give the exact loss that has been incurred, for 600,000 hectares have been planted since the invasion of the phylloxera, so that but for the ravages of this scourge the vine-culture should be above 3,000,000 hectares, while in fact it is reduced to 2,000,000. This loss of 1,000,000 consists of 903,000 hectares destroyed in the 23 departments originally invaded, and which have been authorised to cultivate American vines, and 7,500 hectares in 25 departments more recently invaded. While in 1883, 28,000 hectares were replanted with exotic vines, in 1884 the replantation occupies 52,777 hectares in 33 departments, or an increase of 70 per cent. At the present time, the departments authorised to cultivate exotic vines have 1,313,000 hectares, of which 680,000 are healthy, and 633,000 more or less diseased. Proportionally to the number of hectares invaded, the superficies of protected or reconstituted vines, which was only 11.33 per cent. in 1883, was raised to more than 17 per cent. in 1884. Of the 115,812 hectares protected or reconstituted, 23,308 have been treated by submersion, 33,416 by the sulphuret of carbon, 6,286 by the sulpho-carbonates, and 52,777 by replantation with American slips. Still, in spite of the hard trials of France for so many years, she still remains the country which produces more wine than any other; for, of the 113,000,000 hectolitres which is made on the entire globe, France produces 35,000,000, or nearly a third. Next comes Italy with 23,500,000, or nearly a fourth; Spain following with 22,000,000; Austria-Hungary with 8,500,000; Portugal with 4,000,000; Germany with 370,000; Russia with 350,000; Cyprus with 1,600,000; Switzerland with

1,300,000; Greece with 1,300,000; the United States with 1,000,000; Turkey with 1,000,000; and all other States 2,000,000.

### APPOINTMENTS.

FIRMAN, CHARLES G., L.F.P. and S. Glasg., M.R.C.S. Eng., L.S.A. Lond., L.M. Glasg.—Medical Officer to the Wansford District, Stamford Union, *vice* Mr. F. M. Brown, resigned.  
 FITZGERALD, WILLIAM EDWARD, L.R.C.S. Ire., L.K. and Q.C.P. Ire.—Medical Officer to the Hogsthorpe District, Spilsby Union, *vice* Dr. Rainey, deceased.  
 GILBERTSON, JAMES H., L.R.C.P. Lond., M.R.C.S. Eng.—Medical Officer to the Second District, Hitchin Union, *vice* Mr. R. R. Shillitoe, deceased.  
 HAWKINS, CÆSAR FREDERICK, M.R.C.S., L.S.A.—Medical Officer to the First District, Barton Regis Union, *vice* Mr. L. M. Griffiths, resigned.  
 JAMES, PHILLIP, M.R.C.S. Eng., L.R.C.P. and L.M. Edin.—Medical Officer to Western District, Bridgend and Cowbridge Union.  
 LANGDON, HENRY WILLIAM, M.R.C.S. Eng., L.S.A.—Medical Officer to the Seventh District, Bath Union, *vice* Mr. Barrett.  
 LLOYD-WILLIAMS, H., L.D.S. Eng.—Assistant House Surgeon to the Dental Hospital of London.  
 OWEN, ROWLAND, L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the South Sefton District, Derby Union.  
 PEVICE, FRANCIS, M.D., F.R.C.S.I.—Medical Officer to the Upton District, Wirral Union, *vice* Dr. Warren, resigned.  
 RANDALL, WYNDHAM, M.R.C.S. Eng., L.R.C.P. Edin.—Medical Officer to the Bridgend District, and to the Workhouse, Bridgend and Cowbridge Union.  
 RIBOT, CHARLES F.—Deputy Assistant House Surgeon to the Dental Hospital of London.  
 THOMAS, DAVID JOHN, M.R.C.S. Eng., L.R.C.P. Edin.—Medical Officer to the Ogmores District, Bridgend and Cowbridge Union.  
 VIPOND-CROCKER, J. C., L.D.S. Eng.—House Surgeon to the Dental Hospital of London.

### VACANCIES.

CUMBERLAND INFIRMARY, CARLISLE.—House Surgeon. Salary, £70, with board and lodging on the premises. Applications, with testimonials, to Joseph Lowthian, Secretary, on or before Aug. 5.  
 CROYDON GENERAL HOSPITAL.—House Surgeon. Candidate must be unmarried, doubly qualified, and registered. Salary, £100 (progressive), with board and residence in the Hospital. Applications, with testimonials, to Alfred G. Roper, Hon. Secretary, not later than the morning of Friday, August 7th.  
 EPSOM UNION.—Medical Officer for the Leatherhead and Fetcham District, in succession to Mr. Allan McLean, resigned. Area, 5,230 acres. Population, 4,003. Salary, £65 per annum.  
 LINCOLN COUNTY HOSPITAL.—House Surgeon. Candidates must be unmarried, doubly qualified, registered, and under 40 years of age. Salary, £100, with board, lodging, and washing. Copies of testimonials to W. B. Danby, Secretary, on or before Aug. 15th.

### DEATHS.

BARNETT, OLIVER, C.I.E., Deputy Surgeon-General, Army Medical Department, at Eastbourne, on July 24th.  
 CROZIER, GEORGE, M.R.C.S., at Twickenham, on July 26th.  
 ELLIS, ROBT., M.R.C.S., at Sunset, Westward Ho! on July 22nd, aged 62.  
 SHEPHERD, AUGUSTUS BURKE, M.D. Oxon, at Brunt How, Amble-side, on July 26th, aged 46.

### NOTES, QUERIES, AND REPLIES.

*Medical Congresses—A Parody.*—Those who have a relish for humorous and good-humoured chaff should read a skit on Medical Congresses published some little time back in the *New York Medical Record*, under the title of "A Full Report of the Great National Congress of Scientific Animals." There we learn that in the Section on Neurology, the Rabbit related the outcome of his special studies on the "Tendon Reflex in the Hind Extremities of Irritable Mules," and showed several flattened skulls to illustrate the effects and beauty of this phenomenon. In the Section on Orthopædic Surgery, the Lamb read a paper upon the "Development of the Hump on the Camel," and showed an apparatus which, if worn constantly for seventeen years, relieved the deformity in a large number of cases. In the Section on "Diseases of Women and Obstetrics," the Goat opened the debate upon the question, "Whether the Physician should Support the Perinæum, or the Perinæum should Support the Physician?" which was well maintained. Professor Gulielmus Capricornus read a paper contending that pessaries were a great national blessing and that all animals should wear them. Professor Suis Ferus reported two thousand operations for sewing up the cervix uteri, with fifteen successful results, upon which he was warmly

congratulated. In the Section on Surgery, the Ring-tailed Ape described his new operation for the treatment of intestinal wounds. This consisted in opening the abdomen, removing the whole abdominal contents, and substituting carbolized cotton, thus making the individual thoroughly aseptic. The Sacred Ox of Burmah made a report upon plastic surgery. He described a case in which he had successfully attached the hide of a rhinoceros to the back of a horse, thus rendering a saddle unnecessary. He had also transplanted the skin of a hen to the head of the Bald-headed Eagle, which had much relieved that animal from the effects of extreme heat and cold, and put a new face on the whole matter. In the Section on Skin Diseases, the Rhinoceros reported the results of an analysis of one hundred and ninety-seven thousand cases of eczema treated by excision, each one having been treated in a different manner. The Congress then adjourned to a Grand Banquet, and having visited the insane asylum, two shoe factories, and an orphan home, broke up to meet at the same place next year.

## ADDRESS IN SURGERY,

DELIVERED BEFORE THE BRITISH MEDICAL ASSOCIATION AT CARDIFF.

By J. MARSHALL, F.R.S., F.R.C.S.,

Late Professor of Surgery, University College, London; Consulting Surgeon to University College Hospital.

MR. PRESIDENT AND GENTLEMEN,—Assuming that on such an occasion as the present my discretion is entirely unfettered, and feeling anxious to avoid wearying my audience with a formal essay, I have chosen for the subject of the Address in Surgery, which I have the honour of delivering here to-day, a comparative view of surgical practice, as I myself observed it, when acting as dresser under Robert Liston in the wards of University College Hospital, and such as now prevails amongst us, particularly as exemplified in my own wards in that institution.

I at first contemplated, for the purpose of this comparison, the selection of the years 1843 and 1883, moving backwards from the last named date, because it coincides with that of the latest of our surgical registrar's reports, compiled by my former house-surgeon, Mr. Victor Horsley. But, on searching the old case-books, I found that, in the medical year

1844-5, I was myself one of Liston's dressers, and accordingly I resolved to compare that year with 1883, which two years, in fact, constitute the first and last of a series of 40. I soon found, also, this advantage, that the perusal of my own descriptive notes, and those of my contemporaries, brought back vivid remembrances of the many more important cases then under treatment.

It gave me great pleasure to discover that two of my old and yet surviving friends, James Hakes, of Liverpool, and George Yeoman Heath, of Newcastle, were acting as Liston's house-surgeons in the year selected; and that amongst my fellow-dressers were Henry Wigglesworth, of Ashford; John Newton, of Liverpool; the late Thomas Atchison, of the Indian Medical Service; T. W. Marshall, of Brundall, near Norwich; and William Cadge, of that city. It is with equal pleasure that I mention here the excellence and value of their reports.

Whilst thus limiting my comparison as to period and locality, and to events more or less within my own cognisance, I hope to be able to direct your attention to numerous points of practical interest, whilst occasional generalisations need not be excluded.

I propose to take up, in order, the following subjects:—(1) The numbers of the cases, and the character of the diseases and injuries treated in the two selected periods; (2) the methods and means of investigation employed, whether clinical or pathological, for the purposes of diagnosis; (3) the treatment of the cases,

understood in its widest sense, hygienic, dietetic, and curative; (4) the results obtained, as indicated by such factors as the duration of the treatment in the wards, the progress of the cases, and the relative mortality.

In dealing with these questions, either exact figures are given, or, when general statements are introduced, they are founded on the best attainable data.

(1) The numbers of cases, and the character of the diseases and injuries to be compared.—In the year 1844-5, 284 patients were admitted into Liston's wards (excluding eye-cases); of these, 196 were males, and 88 females. In 1883, there entered my wards 396 patients, of whom 223 were males, and 171 females. Liston's cases constituted about one-half, whilst my own formed only about one-third of the total number of patients received into the surgical wards.

In both sets of cases, fractures of various kinds, chiefly of the lower limbs, reached a very high number; next to these, especially in the earlier series, were wounds of the soft parts, chiefly affecting the head, neck, and upper limb. Burns and scalds were few in each period. Malformations of the lips, palate, fingers, and foot were more numerous at the earlier date, but, as might be expected, genu valgum is not mentioned. New growths, though actually more numerous, were not relatively so in the later period, the proportions of these to the total number of cases being about  $7\frac{1}{2}$  per cent. in 1844-5, and only 7 per cent. in 1883. There is, however, a marked increase in the epitheliomata, though scirrhus and sarcoma remain the same; whilst fatty tumours are more numerous in the earlier period. Of course, the numbers contrasted, 21 and 26, are too small to furnish evidence either way as to the commonly supposed increased prevalence of cancer amongst our existing population. The widespread and well grounded belief in the value of the early removal of all new growths, and the more ready submission of patients to operations, now rendered painless by anaesthetics, must here be taken into account, as tending to swell the later numbers. Cases of venereal disease were formerly much more freely admitted into the wards of a general hospital than now, and accordingly are more numerous at the earlier date. Ordinary abscesses and ulcers are equally represented at the two periods. Gangrene was, and is, rare. Diseases of the joints, and also diseases of bone, are abundantly represented in each set of records; but in the later period, cases of caries particularly abound, probably owing to the greater success of modern operative interference. *Fistula in ano*, and stricture of the rectum are mentioned in both the early and the later list; but it is remarkable that not a single instance of operation for hæmorrhoids occurred in Liston's wards in the year in question. Diseases of the rectum, however, were at that time marked subjects of the specialism founded by Von Butchell. Strangulated hernia, calculus, stricture of the urethra, and affections of the testicle, are met with, though in varying proportions in both lists; but cases of stricture especially are now more frequently admitted as in-patients for the purposes of the so-called radical cure. A single case of ovarian tumour, one of vesico-vaginal fistula, and one of aneurysm, occur in Liston's set of cases; but the last-named disease is now comparatively rare, and the two former evils are usually relegated to special hospitals.

As to the various forms of specific inflammations, and their consequences, which are now classed together as septic diseases, and which have long been the bane of surgical, and especially of hospital surgical practice, it is well known that they were not so clearly differentiated in 1844-5 as they were at the present time; but it is evident, from a study of the hospital records of the older date, that they were then extremely prevalent. Indeed, the chief lessons to be

drawn from the facts I have undertaken to review relate to this class of diseases.

(2) Comparison of the methods and means of investigating surgical disease forty years since and at the present date.—In 1884-5, the finger, the educated finger, passed down the throat, or up behind the soft palate, was used to explore parts now examined by the laryngoscope or pharyngoscope. The convenient specula, which we now possess for various internal examinations, were then but rarely represented. There was no endoscope, and, above all, no ophthalmoscope. The place of the modern aspirating syringe was but imperfectly supplied by the exploring needle or trocar. Means were not then devised for measuring variations in the corpuscular and chemical elements of the blood in disease and convalescent states. The presence of albumen and sugar in urine was, no doubt, easily and commonly detected; but quantitative determinations of those substances were troublesome and difficult to make, or were left unattempted; and the same is true in regard to such normal urinary constituents as urea and the chlorides, sulphates, and phosphates.

The clinical thermometer was not in use; yet, truth to say, it had been suggested as far back as the 17th century by Senebier, and was actually employed as a measurer of the strength of fever, by De Haen and Dr. James Currie, at the end of the last century. But, though the thermometers were not employed in Liston's time for ascertaining the temperature of the body generally, it is interesting to note that, in a case in which he tied the external iliac artery for aneurysm, exact observations on the temperature of the two lower limbs were made by aid of that instrument.

In the absence of this now ubiquitous clinical registrar, on the indications of which we now justly set so high an estimate, great care was then taken to note other signs of the febrile condition. Hence, in Liston's case-books, are to be found constant and minute records of the state of the skin and tongue; of that of the pulse and breathing; of the occurrence of rigors and sweatings; of the supervention of delirium; of the quantity, character, and specific gravity of the urine; and of the occurrence of albumen in that fluid. In these respects, the notes upon the cases are for the most part perfect. There are also occasional stethoscopic observations; but there are no sphygmographic pulse-tracings. The elaborate temperature-charts and diagrams of the present case-books are necessarily absent; so, likewise, the electric and other tests, applicable to the detection of diseased conditions of the muscular and nervous systems, are entirely omitted.

Forty years ago the microscope had just come into use for pathological, and therefore for clinical, observation. Liston's intimacy with Dalrymple, Gulliver, and Kiernan had its scientific as well as its social side, and served to stimulate his interest in microscopic investigations. He possessed one of the best and most powerful instruments of that day; and, as I know from having had the privilege of assisting him, he was particularly interested in the character and mode of growth of new vessels in granulations and elsewhere, in the structure of tumours, the constituents of cancer juice, the seat of the pigment-granules in melanotic tumours, the presence of spermatozoa in the fluid of certain hydroceles, and in many other facts of micro-pathology. The researches of Müller were then becoming familiar; but the further labours of Schwann and Schleiden, of Addison, of Virchow and Cohnheim, and of many others, had to be made generally known before the grand microscopes of the few were supplemented by the clinical microscopes of the many, which now, indeed, are in daily use in every hospital ward. Liston's "Elements of Surgery" (last edition, 1840), though beautifully illustrated by Wm.

Bagge, contains only one solitary woodcut devoted to a microscopic object—namely, a cluster of red blood-corpuscles, represented upon a scale of squares, without a single white blood-corpuscle amongst them. What a contrast to the countless illustrations of minute structures, organisms, and crystals, scattered through the pages of the modern text-book!

It is not surprising that the older case-books contain no account of the microscopic structure of morbid growths, or of the minute constituents and deposits of diseased fluids—much less any illustrative sketches of either; whereas, in the modern case records of 1883, pen-and-ink drawings constantly occur, more especially it must be admitted, representative of the larger facts of size, shape, and other obvious characters. Formerly, we find, in the notes, a mere statement that such and such a growth “exhibited the usual characters” of a fatty, sarcomatous, or scirrhus tumour; now, those characters, when necessary, are fully described, or, it may be, actually figured. Permit me here to emphasise the importance to the medical student of the art of drawing accurately, and to express my gratification at the contrast between the useful sketches which serve here and there to illustrate the pages of my own case-books, and the funny caricatures of the features of my old surgical master which decorate the covers of his.

As a natural consequence of the improved methods and means of pathological and clinical observation which we now possess, the notes by the clinical clerks have become more ample. Indeed, I find that the average space now allotted to each patient's history and record is twice what it formerly was; and this is independent of the temperature chart or charts now affixed to every case, of occasional diagrammatic curves, and of certain hygienic tables, in which are recorded the septic or aseptic condition of every wound in a ward, and the concurrence or absence of serious infective disease. Nevertheless, as I have already hinted at, the older notes are usually full and intelligent in all particulars to which they relate; and, as the duties of dresser and clerk, now assigned to different students, were, forty years since, performed by the same person, the observation and the description of characters and symptoms were the work of the same mind, and thus they probably gained in exactitude and completeness.

At the same time, the effects of the non-use of the microscope for purposes of diagnosis may perhaps be recognised in the application of the terms “ichthyosis” and “wart growth” to what would seem to have been the one a dry epithelioma of the lower lip and the other a papillary epithelioma on the margin of the tongue, both of which, however, were successfully excised. Of six cases of “lupus,” so-called, it is almost certain that two at least were carcinomatous. Again, the obvious appearances of a growth named “medullary sarcoma” of the tibia, and those of a “fungus hæmatodes” springing from the skin of the forearm, are admirably depicted in words; but there is, of course, no recognition of the modern nice discriminations between the different forms of sarcoma, or between a soft sarcoma and an encephaloid cancer. Different morbid conditions of the kidney could not then be indicated by the various kinds of casts or other deposits in the urine; nor, lastly, were the numerous phenomena of disturbed sensation and motion, which enable us to determine the nature, and even the locality of certain lesions of the brain and spinal cord, capable of being recorded. It would indeed become tedious, were I to recount all the references in the case-books of 1883, which serve to show the great advance which has been made in the methods and accuracy of surgical diagnosis since 1844–5. But it is in regard to the questions which next arise,

namely, those which relate to the treatment followed in the two periods, that the contrast I have attempted to institute deepens in interest and force.

(3) Comparison of the treatment adopted in University College Hospital, at the two selected periods, considered in reference to hygienic conditions, general comforts, diet, medicines, and surgical appliances.—(a)—Hygienic conditions.—In 1844–5, the north wing of the Hospital not having been built, the surgical wards were much crowded; whilst, in 1883, in spite of an increase in the total aggregate of patients, the numbers in each ward were diminished, and the cubical space per bed proportionately increased. In the pre-sanitary period of forty years since, sculleries and waterclosets were but imperfectly separated from the wards; whereas now their separation is complete. Formerly the doors, windows, and chimney-flues furnished but intermittent means of ventilation; now suitable channels, both inlets and outlets, are provided for the constant renewal of the air in the wards. Besides this, a laundry has been expelled from the basement, whilst that and all the corridors are now efficiently ventilated. The traps and drains are also maintained in good order. It is true that, in 1844–5, the Hospital had been built only ten years, and so far was relatively freer from the dangers of so-called hospitalism than now; but, to meet such contingencies, the walls of the wards have been recently lined with an impervious cement, which is regularly painted; whilst the floors are kept carefully purified. Lastly in the good old times, there were no special isolation-wards for infectious diseases; whilst now there are special erysipelas-wards for both sexes.

(b) Diet and general comforts.—It cannot be doubted that quite as great attention is now paid to the question of diet as was formerly the practice; and, as all hospital committees well know, the expenses of general maintenance have increased. In the year 1844, for example, with a total of 1,410 medical and surgical in-patients, the total general expenditure of the University College Hospital was 4,976*l.*, whereas in 1883, with 2,849 in-patients, it was 19,822*l.*, so that whilst the number of patients was doubled, the total expenses of the establishment were multiplied fourfold. We may safely conclude that a certain share of this large increased expenditure arises from a bountiful attention to the dietary of the in-patients. As regards the personal care and comforts bestowed upon these patients, it may be pointed out that the salaries of nurses and domestics, which were somewhat more than 1,600*l.* in 1844, amounted to 2,300*l.* in 1883; finally, it is with sincere expressions of gratitude to the sisterhood who now so solicitously watch over the nursing and general economy of the wards, that one alludes to those numerous manifest improvements, which conduce not only to the comfort and cheerfulness, but to the well-doing and speedier convalescence of the inmates.

(c) Medical and surgical appliances.—In 1884, the total expenditure on medical and surgical stores for the hospital was 643*l.*, but in 1883 it amounted to 3,239*l.*, that is, the number of in-patients having become double the cost of their medical and surgical treatment had multiplied five times. The payments for medical stores only amounted, in the two periods, to 437*l.* and 1,474*l.*, showing an increase in the ratio of 3·3 to 1; but those for the surgical stores (exclusive of instruments) were, at the two periods in question, 206*l.* and 1,765*l.*, making an increase of eight to one. Of this last named large sum, no less than 1,273*l.* are specially set down to payments for “antiseptic dressings,” of which, of necessity, by far the larger proportion was employed on in-patients. This great cost of the antiseptic system, as it is carried out at the University College Hospital, in a startling financial fact; but, if the results can be shown to justify the outlay, such expenditure is is

itself more highly to be approved. It is obvious, moreover, that the public which provides the needful funds ultimately reaps the benefit of this, as of all other improvements. Wealthy donors should remember this, in meting out their contributions to hospital resources.

The constant use of anæsthetics, not merely in operations, but for the purpose of more thorough and otherwise painful examinations in cases of injury and disease, greatly increases the relative cost of hospital maintenance at the present day. In 1844-5, these were yet unemployed; although it was Liston himself who, two years later, was the first in this country to perform an important operation under their influence. For it was in 1846 that he amputated through the thigh, the lower limb of a man, put into a condition of insensibility by the vapour of ether, administered by the late Mr. Peter Squire, in the presence also of the late Sir John Forbes, the then editor of the *British and Foreign Medical Review*. Liston's surprise and gratification when the patient, having recovered consciousness, refused to believe that his limb was off until it was shown to him, is still well-remembered by spectators of the scene.

Besides antiseptics and anæsthetics, to which we may add hypodermic injections, many new and expensive medicinal preparations are now ungrudgingly used in every hospital. Improved instruments for the performance of long-established operations, and innumerable and ingenious clamps, cauteries, and other novelties for the accomplishment of new and difficult surgical proceedings, are also freely provided for the modern hospital-surgeon and his patients. The cost of these at University College Hospital has doubled since 1844. In a word, it may be unhesitatingly affirmed, that the means, as well as the methods of surgical treatments, whether hygienic or curative, were, in 1883, far in advance of those which were available 40 years before that date.

Let us next proceed to consider the ultimate and practical question of results.

(4) Comparative view of the results of treatment at the two selected periods.—Under imperfect sanitary conditions, without special isolation wards, with less attention to the details of ward-management and to their cheering influences, with fewer scientific means of diagnosis, with no chloroform or ether, and no hypodermic method of quelling pain or other nervous disturbance, with simpler instruments, and less recondite dressings and appliances, were the results obtained in 1844-5, inferior to those realised in the same hospital, under other conditions, in 1883. The reply is "yes," in certain particulars, but not in all.

In the first place, I find that, as well as I can determine, the average period of stay of a surgical patient in the hospital, in 1844-5, was  $28\frac{1}{2}$  days in the female wards, and  $29\frac{1}{2}$  days in the male wards; whereas, in 1883, it was about 26 days for the female, and 21 days for the male patients, this latter smaller ratio being due to the disproportionate number of simple fracture occurring in the male sex. Too much stress, however, must not be placed on these figures; since the total number of cases is not sufficient to neutralise the effect of important differences in the severity of the cases, whether in kind or in degree.

Partly on a similar ground, but also on account of the different value assigned by different persons to the terms "cured," "relieved," and "discharged as incurable," I refrain from recording, in regard to such general results, figures which would be unreliable, or actually misleading. For example, in the older records, cases of caries of bone, stricture of the urethra, epithelioma, and scirrhus, are entered as having been "cured," and in the later set, as being only "relieved" by operative treatment.

Even the ratio of mortality is deceptive, although it shows an advantage on the side of the later period, the percentage of deaths in 1844-5 being 7.5 for the males, and 6.5 for the females; whilst in 1883, these were about 5.75 and 5.74 respectively. But here, the fatal cases of the two periods are not commensurable, and a single accidental death, as for example from a burn, completely vitiates the result. Hence, a comparison of the treatment and its consequences in distinct classes of injuries and diseases will be found much more just and more instructive.

(a) The chief point to be noted in regard to differences in the management of simple fractures consists in this: that those of the leg and thigh were formerly retained longer in McIntyre's or Desault's splints, before they were put up in starch apparatus, of which Liston was a great advocate. Patients so injured were, therefore, detained longer in the hospital than now. The introduction of the plaster-of-Paris treatment has still further abridged the time, during which a bed is occupied with a case of broken leg, patella or femur. Wiring of bones was not attempted. Compound fractures proved to be very prolonged cases, and those of the lower limb were often fatal, with or without amputation.

(b) Injuries not involving a breach of the surface of the body, simple inflammations consecutive to these, or so-called idiopathic local inflammations which come under the care of the surgeon, such as sprains, simple dislocations, synovitis, orchitis, and other cases, were not less satisfactorily treated in 1844-5 than in 1883, and the progress of the patients towards recovery was quite as rapid. Venesection is not mentioned in Liston's case-books, but cupping and leeching were in the ascendant. A patient with disease of the hip-joint, requiring at the time only the application of Liston's famous leather splint, informed her dresser that she had previously had 141 leeches applied around her hip in the course of three months. A man with acute synovitis of the knee was ordered eighteen leeches over the joint on the day of his admission, eighteen more on the day after, eight on the tenth day, and ten on the twentieth day, and a week afterwards was discharged convalescent. For a condition described as "mania" from head-injury, a cupping to twelve ounces was ordered to the back of the neck, followed by two sets of leeches, twenty each time, to the temples, and, five days later, by a blister and the administration of calomel, and so was cured. Inflammatory urethral stricture, prostatitis and supposed cystitis were relieved by free cupping on the perinæum, and so in many other diseases. Whether these sanguinary proceedings were necessary or ever beneficial, and whether the local abstraction of blood is now too much neglected in cases of acute inflammations, especially of important organs, are problems which I cannot here discuss.

(c) In comparing the older and the more recent management of inflammations which end in suppuration, ulceration, or gangrene, or in combinations of these morbid processes, we meet with facts more or less unfavourable to the older practice, and unmistakably cumulative in support of the advantages of modern, that is, of aseptic, surgery.

Acute abscesses were treated by very free incisions with ultimate success; but suppuration continued for many days, and the abscess-cavity was filled up slowly. Nor were there wanting instances of more serious evils. Erysipelas and further abscesses often supervened. A patient with successive abscesses in the abdominal walls, due presumably to caries of the ilium, is recorded to have left the hospital on the thirty-second day, and to have died a few days afterwards. An acute abscess in the head of the tibia, opened with the trephine, was 77 days in healing. Abscesses and sinuses around, but not communicating with, the hip-joint, are men-

tioned as not having become closed when the patient was discharged from the wards after the expiration of 83 days. Lastly, an acute abscess in the knee-joint proved fatal, from distinct pyæmia, on the forty-seventh day, purulent deposits being found in the lungs after death. It is hardly necessary to state that poultices, and not antiseptic dressings, were employed; and, although counter-openings were freely practised, no drainage-tube was in use; and the abortive treatment of moderate-sized abscesses by aspiration and the injection of morphia, carbolic acid, or iodoform, was unknown.

Ulcers of the integuments, which usually are not prone to allow infective absorption, were very well managed in Liston's wards. Rest, elevation, and his favourite water-dressing, consisting of wetted lint, covered with oiled silk, cured most cases. All greasy applications were rigorously forbidden, for against these Liston waged an angry war. A spreading ulcer with fœtid discharge was treated with a lotion of chlorinated soda, or a weak solution of iodine, both strongly antiseptic and germicidal agents. Red wash, which probably acts in both these ways, as well as a local stimulant, nitrate of silver and sulphate of copper were used as now. Strong nitric acid was applied against phagedæna; solutions of chlorine and iodine against slight sloughings and actual gangrene.

Periostitis, osteitis, caries of bone and necrosis, were treated successfully, as now, by subcutaneous incisions, trephining, the extraction of sequestra, and scooping. In one report, the dresser mentions an instrument under the name of a "proper scoop," which, I assume, was really a "sharp scoop."

Venereal diseases were treated without mercury, or with as small doses as possible, in accordance with views which had then been ably propounded; and, as no distinction was made between the hard and the soft sores, so far as their possible consequences were concerned, whilst the majority of those taken into hospital were evidently soft chancres, followed by bubo, the non-specific or almost non-specific treatment was very successful. Iodide of potash was becoming a favourite remedy; but it is curious to observe that a common formula in the notes was one grain of blue pill and one grain of iodide of potash, combined in one mass, to be taken three times a day. When the iodide was administered alone, the usual dose was three grains three times daily; very seldom did it reach to four or five grains. In deep syphilitic ulcerations, and in sloughing gummata, a weak solution of iodine was commonly ordered as a lotion. Numerous cases of syphilitic caries and necrosis were admitted, and one of extensive disease of the parietal bone ended fatally, with abscess in the corresponding part of the brain.

(d) Wounds. — Passing by burns, scalds, and injuries from caustics, I proceed to consider the cases of wounds of greater or less severity, 28 in number, which were received into Liston's wards in the year in question. Four of these occurred to women. One only healed within a week, and, as stated in the notes, "by the first intention"—namely, a wound in the palm, involving the superficialis volæ and another small artery. A cut down to the patella granulated and suppurated, and healed favourably in 17 days; an abrasion over the shoulder led to erysipelas and axillary abscess, the patient leaving the hospital on the eighteenth day; the fourth and last case, a punctured wound in the foot, became complicated with abscesses in the foot, leg, and thigh, and was detained in the ward for 55 days. Of the 24 examples of wounds happening to men, four only healed, presumably by the first intention, in from five to nine days; these were wounds affecting, respectively, the ear, eyelid, scalp, and scrotum, the last one laying bare the tunica vaginalis. In

six other cases, very free suppuration, with accompanying fever, ensued—namely, in a wound of the scalp, a contused wound of the eyelid and eyebrow, a glass-cut of the forearm, a long split in the perinæum, a lacerated wound of the foot, and, lastly, a scalp-injury requiring counter-openings—in these cases, healing was deferred to from 15 to 28 days. In the remaining patients, still graver complications ensued; they may be briefly summarised thus: Punctured wound of thumb, erysipelas; patient, being in good circumstances, was sent out on the eighth day. Bite on the back of knuckle, erysipelas, abscess; discharged on the twenty-first day. Slight wound in butcher's hand, cellulitis, abscess in forearm and arm, 22 days; contused wound of leg, rigors, abscesses, 30 days; wound of ulnar and another smaller artery above the wrist, ligature, cellulitis, sloughing of fascia up the forearm, 32 days; lacerated wound of palm, abscess, sloughing, much fever, 34 days; punctured wound of thumb, suppuration, frequent rigors, 39 days; contused wound of ear and side of head, so-called "erythema," suppuration, 42 days; punctured wound of thigh, profuse hæmorrhage, suppuration, burrowing of pus, 45 days; attempted suicide, division of brachial artery at bend of elbow, cellulitis, sloughing of areolar tissue, severe fever, 54 days; gunshot wound of forearm without fracture, deep seated suppuration, with great fever, 58 days; lastly, two fatal cases, namely, a lacerated wound of the leg, erysipelas, rapidly spreading diffuse cellulitis, gangrene, and death on the eighth day; and a cut-throat dividing the trachea, followed by bronchitis and infective pulmonary abscesses, proving fatal after 61 days.

These cases, the only ones admitted, are surely sufficiently striking; but we have yet to consider the results of the cutting operations performed in the hospital during the twelve months of 1844-5.

(To be continued.)

## THERAPEUTIC PROGRESS.<sup>1</sup>

By JAMES SAWYER, M.D. Lond., F.R.C.P.,

Senior Physician to the Queen's Hospital, and Professor of Medicine in Queen's College, Birmingham.

*Comparative Backwardness of Therapeutics—Difficulty of Therapeutic Inference—Therapeutic Triumphs—Neglect of Therapeutic Teaching—Danger of False Theories—Right Relations of Science and Practice—Recent Therapeutic Progress—Scope of Therapeutics—Conditions of Therapeutic Progress—Physiological Research in Therapeutics—We must yet be Empirics—Progress proceeds by the Discovery of the Unknown and by the Perfection of the Known.*

GENTLEMEN,—It is my first duty to ask you to accept my hearty thanks for the honour you have done me to-day in my election to the presidency of our branch of the British Medical Association. I feel you have called me to a high responsibility in placing me, by your favour, at the head of one of the largest and most influential divisions of the largest professional society in the world. You have called me to succeed many distinguished predecessors. Let me assure you I appreciate your confidence and consideration to the full. I undertake the duties you have placed in my hands

<sup>1</sup> A Presidential Address delivered at the annual meeting of the Birmingham and Midland Counties Branch of the British Medical Association, held in the Birmingham Medical Institute, June 25th 1885.

with a sincere desire and with a single determination to do my best to justify your choice.

In choosing a subject upon which to address you, I remember that former presidents have most profitably engaged our attention upon a wide variety of topics. I can recall many brilliant addresses, some of which have not been without marked professional and public influence, and consequence of good, in the initiation and support of manifold improvements—of improvements in our relations, in our duties, in our powers, and in our practice. We have listened in succession to the able exposition of such important questions as the progress of ophthalmic surgery, the care and cure of the insane, the management of habitual drunkards, and our due relations to the sick poor, and to the benevolent public, through provident organizations and medical charities. We have heard, too, of the marvellous developments of surgery in our times, of the political duties of our profession, and of our moral and sanitary responsibilities. I am venturing to-day, gentlemen, to break other ground in asking you to return to a theme older, perhaps, than any of these; to one older, but to one which is ever new, for it touches us all in our daily work as practitioners, namely, the *therapeutics of disease*; the use of remedies for the cure and relief of our patients, and especially the remedial actions of medicines. The subject is a great one, and its adequate consideration is far beyond the scope of an inaugural address. I can only attempt now to take up a part of it. About the interest of therapeutics to us I can have no doubt. Let us regard to-day, gentlemen, if you please, the particular question of our therapeutic progress. Are we making real progress in the treatment of disease? How may we improve and quicken our advancement? What are the obstacles to our progress, and how may we hope to overcome them? I remember that a great medical authority, and a distinguished modern physician, the late Sir Thomas Watson, in his inaugural address at the foundation of the Clinical Society of London, in the year 1867, said:—"The greatest gap in the science of medicine is to be found in its final and supreme stage—the stage of therapeutics." And although, in the eighteen years which have passed since this declaration was made, the healing art has achieved many substantial and practical advances and developments, we must all of us still feel, I think, and often feel acutely as practitioners, in our daily application of remedies for the cure and relief of disease, that we want a knowledge more exact, a scope more enlarged, and indications more direct and more successful, of the means by which morbid processes may be prevented and extinguished. How can the art of "treatment" be placed upon a broader and sounder basis—upon a basis less shifting, less empiric, more demonstrable, more effectual, and more scientific? We thankfully rejoice in the advances of physiological and pathological science. These advances are good in themselves, and we welcome them with a hearty expectation that they may lead us to improvements in our practice. But we are disappointed that therapeutics lags behind. Why have these sciences of life and of death outstripped the science of healing?

There can be no doubt that the enormous difficulty of accurate therapeutic inference is the chief obstacle to the establishment of therapeutics as a scientific system, in the strictest acceptance of that term. This difficulty has never been overcome. It inheres intrinsically to the subject, and the subject is of unsurpassed complexity. In ages of scientific progress we have reduced this difficulty a little, and we shall yet surely reduce it still more; but shall we ever remove it? In a therapeutic inference we have to conclude about the action of a given drug upon

a living human body, in a state of disease. The question is easy, but we cannot complete the equation. We can cite the question thus clearly, but we cannot *state* the equation; for one reason, because we cannot state the great unknown quantity it includes. The terms are life, a disease, and a drug. In the whole range of human research there is no problem more difficult of exact solution than the question, which can be so simply stated, Does a certain drug cure a certain disease? To the uneducated the answer may seem an easy one; but the keenest logician of our time, John Stuart Mill, has put precisely this question as an illustration of the most intricate class of problems which the human intelligence can attempt to unravel, as the extremest instance he can imagine, when he "clothes in circumstances" the inherent and often insuperable difficulties which beset our reasoning when we have to deal with causes which are plural and distant, and with effects which are intermixed and many. But it is our business as practitioners to "treat" patients and the disorders that are in them, to preserve and restore to our patients their activity, to assuage their sufferings, and, if it be possible, to cure them. As faithful practitioners, in our daily dealings with the practical and the concrete, the considerations I have just adduced must not weigh upon us unduly. I have been speaking only of the difficulty of satisfying the severest canons of formal logic in a scientific inference about the cure of a disease by a drug. Outside the scope of such a demonstration, much of solid therapeutic achievement, much of priceless worth to our race, remains in the arts of medicine. Surely do we cure many diseases, and surely do we mitigate many more. Nor need we always cure their diseases when we save and restore our patients. Does the mariner cure the wind and the waves when he guides his ship in safety through a storm which would have overwhelmed her if he had been less vigilant and less skilful? And so we can have no doubt that in many diseases, the duration of which we cannot shorten, as in some of the specific fevers, we can so *manage* the patient as to make the issue for him recovery instead of death. But happily, also, we can have no reasonable doubt that we really cure many diseases; to feel sure of this we need not wait to satisfy the sterner requirements of logical proof. Paralyzing doubt melts into confident action without waiting for the later demonstration of final certainty. Can we doubt that we cure syphilis with mercury, or ague and its allied neuralgias with quinine, or many forms of anæmia with iron, or acute rheumatism with salicylate of soda, or some skin diseases with arsenic? And in diseases which we do not yet claim strictly to cure, are we not sure that their manifestations are largely within our control? Think of nitrite of amyl and nitro-glycerine in angina pectoris, of iodide of potassium in asthmatic dyspnoea, of the bromides in epilepsy, of digitalis in affections of the heart, and of venesection or of chloroform in convulsions. And again, the secretions and evacuations of the human body, if not wholly within our control, are largely under the influence of our therapeutic means. And is not pain, the commonest and the most urgent of all the expressions of disease, almost absolutely within our power?

But there is another great difficulty in the way of therapeutic progress. If we watch the current methods of medical education, we shall soon observe that the details of practical therapeutics are not, as a rule, sufficiently dealt with by our teachers. The examining bodies, in their curricula, unfortunately join *materia medica* and therapeutics to form the single subject of one short summer course, and present it to the student in his first year, when his acquaintance with disease and with patients has

scarcely begun. The art of treatment is now a neglected branch of medical instruction; its neglect is not often felt by the pupil until he becomes a practitioner. Now that medical students are no longer apprenticed, to learn in the practice of a surgery the art of *applied* therapeutics, but pass at once from the school desk to the hospital ward, they especially need long and careful training in the science of treatment and in the art of prescribing. The elaboration of the scientific details of the medical curriculum, as contrasted with the practical work amongst remedies required by the obsolete custom of apprenticeship (a system which had many practical advantages)—the prevailing elaboration of the scientific details of the medical curriculum has too often crowded therapeutics out of the cognizance of the modern student of medicine. The duration of the course of lectures on materia medica, as now required by most of the licensing bodies, is so short, and the period when these lectures are attended, namely, in the student's first summer session, is so inopportune, that justice is not done to the important range of practical subjects, such as pharmacy, pharmacology, the physiological actions of medicines, and the art of prescribing, which are huddled and hurried into this part of the current curriculum. Hence the young practitioner, when he has taken his diplomas and left his school, without sound training in the discrimination, combination, and application of remedies, too often finds himself imperfectly prepared for the practical responsibilities of his position, and he is in risk of abandonment "to the alternative of two great evils—a feeble and servile routine on one hand, or a wild and lawless empiricism on the other." In these difficulties, a clear head and a good conscience may still save him; but he may be tempted to a treacherous refuge by the easy charms and attractive nostrums of proprietary pharmacy, or seduced by one or other of those notorious therapeutic generalizations which can still captivate the ignorant, though they be tottering to their fall between the crutches of knavery and credulity.

It would be easy to gather from the history of our art abundant instances of how much an accurate knowledge of remedies has been obscured and retarded by superstition and by credulity, by scepticism and by caprice, by fashions in diseases and by fashions in remedies, and by false doctrines founded upon false theories of morbid processes, or upon false theories of the properties of medicines. In our times, with a sober yet hopeful temper in our judgments upon remedies, we may expect to escape many of the errors of the past, and to help forward a sounder therapeutic progress. We must seriously and patiently examine again our old remedies, and search for new ones, by the best resources of modern scientific precision; and we must set ourselves to do this with no superstition, and without too much credulity, and above all, without too much scepticism. It would be easy to point to a pedantic scepticism which, in our own days, has sometimes found disastrous expression in our schools, as an egotistic inflation of therapeutic ignorance, or as the premature offspring of our exacter pathology. Credulity has been well defined as belief without reason; scepticism is reason without belief; and history has generally shown that a race of credulous believers begets a generation of unreasonable doubters. But our history warns us that some of the most striking errors of our art have sprung from hasty and false generalisations as to the properties of remedies or as to the nature of morbid processes. Now, as ever, we must be watchful lest we gaze through glasses coloured by the deceitful hues of false theory and premature conclusion.

Possibly an unproved bacillary pathology may tempt us into premature bacillary therapeutics. As

therapeutists we have noted that medical science has lately presented one of its periodic revisions of the pathology of pulmonary phthisis. It has introduced to us a living and material germ, and labelled it the tubercle bacillus, and it has found this organism as a newly recognised concomitant of tubercular processes, or, as some would claim for it, as the characteristic, ultimate, and peculiar structural element of tubercle itself, or even as its infective, material and potential essence. It is now too soon to attempt to sum up the true value of the well-known and important investigations to which I refer. I may say, however, in passing, that I have a strong suspicion, which many of my brethren, doubtless, have also felt, that the tubercle bacillus will soon subside into obscurity, and that it will turn out, at the most, to be only an accident of tubercular processes. Of course, I am using the word accident, as opposed to essence, strictly in its well-known logical sense. Before long, possibly, our scientific brethren will have kindly found for us a special micro-organism, appropriately and specifically named, for every disease which presents an organic basis in which micro-organisms can flourish. Then will science once more react from error by proving too much, and the ætiological bacillus will be lost in its universality.

In view of this immediate and particular question of the structural ætiology and essential pathology of tubercular diseases, it is well for us, as therapeutists, if we would secure our progress, to realise our right attitude towards the sciences which underlie our art, and especially towards that great department of inductive knowledge which is distinguished as the science of medicine. The first test of inductive truth is the touchstone of practice. In medical practice we must prove the generalisations of medical science. Clinical experience is the balance which alone can weigh their value. As faithful practitioners we must always welcome new scientific truths, and reflect their due influence in our practice. We must ever watch and support the labours of those who are breaking new ground in the elucidation of morbid processes. We must watch them with an expectation which hopefully waits for clinical result, and with an interest which tends to action. But our experience has taught us to be cautious in the acceptance, not of new scientific facts, but of new scientific generalisations. We remember that fifty years ago the essence of phthisis was the tubercular granule. Twenty years ago the ingenious Niemeyer revised and developed the teachings of Addison, and elaborately worked out the catarrhal and broncho-pneumonic hypothesis of pulmonary consumption. Then, thereafter, came the "giant cell" of tubercle. And now Koch asks us to contemplate the tubercle bacillus.

Premature generalisation from particulars seems to be a very persistent tendency of the human mind, and it is a tendency which education and experience alike teach us to resist. Of all the errors which have retarded the progress of the science and art of medicine, premature generalisation is the chief. When we would ascend from particulars to generals, credulity is our bane, and scepticism our duty. And in medical science we must bring our conclusions face to face with particular and living cases of disease, and see if they be true then. While clinical medicine, to be progressive, must ever revise and recast its practice by the truth of medical science, the generalisations of medical science must find in the particular readings of clinical medicine the truest tests of their validity. If our science sometimes restrains us when our art is going astray, it is our art only which has often shown us when our science was falling into error. In medicine, as in morals, practice is the test of principle.

We shall brighten our faith in the possibilities of therapeutic progress when we recall the marvellous practical advances which the healing arts have achieved within the last five-and-twenty or thirty years. I cannot now attempt to cite these advances in detail, but I believe a critical examination of them would show that our power to cure and to alleviate disease has made more substantial progress within the time I have named than it has gained within any similar period in the history of medicine. Our remedies have grown in simplicity and in range, in number and in precision. I am sure many instances of such progress at once occur to your minds. We have developed the uses of some good old drugs, and we have learned the uses of some good new ones. Here are some prominent examples: The salicylates have become established beyond question as powerful remedies in pyrexial rheumatism. Thirty years ago, the use of the alkaline bromides in epilepsy and its allied disorders, now so familiar to us, was quite unknown. In nitrite of amyl and in nitro-glycerine have been found agents which can largely prevent, and which can markedly assuage the agonising paroxysms of angina pectoris. In chloral, in croton-chloral, in iodoform, we have found serviceable new drugs. In our time, too, the indications for the use of digitalis as a cardiac sedative, and as a cardiac tonic of marvellous power, if rightly employed, have been clearly worked out, and incorporated amongst the most reliable staples of our art. What may be called the local treatment of diseases of the respiratory organs by the use of inhalations has been largely developed in recent years. Think, too, of the therapeutic field which we owe to the hypodermic syringe!

And now, gentlemen, if you will kindly bear with me a little longer, let me invite you to look forward. Surely the prospect, the prospect of our remedial art, is encouraging. Here and there the haze obscures, and here and there it hangs thick and low, but the clouds are clearing, and we can see many a broadening gleam of bright blue sky. Let us remember the immensity of our prospect. The potentiality of our art is only bounded by the physiological possibilities of human life. Our art aims at the prevention and the cure of all disease. Towards this consummation, so devoutly to be wished, it is sure to grow. The lines of its development are plain, and we know them well. Only by slow experience, and only by the labours of many hands, can our progress be maintained. Little by little shall our knowledge surely grow, but only by the experience of reliable observations, infinitely multiplied, and laboriously compared. And from another aspect, and from one more immediately practical, we recognise the vastness of the scope of therapeutics. I need not remind my hearers that the art of therapeutics is not merely the administration of drugs. It is much more than this: it includes every agency and circumstance which can favourably influence disease. It includes dietetics—what a patient ought to eat, and what he ought to drink, and when and how; it includes balneology—an ancient therapeutic system which has a greater future; it includes climatology, it includes the physical resources of mechanics—a mine of boundless wealth, which in means for the evacuation of morbid collections, and for securing rest, immobility and support, has achieved such brilliant results; it includes electricity and other forms of gymnastics; it includes the regulation of occupation, pursuits and amusements; and it includes many details of practical education, in their physical and psychological bearings upon growth and stability. I wish the general mind of our profession were more clearly directed towards the pursuit of therapeutic progress. If the plainer conditions of such advancements were more generally

recognised, and more generally kept in recollection, we might soon reap some substantial improvements.

It is clear to us that we must know more, and a great deal more, of the causation of disease before we can construct a therapeutic science. Hence, as therapeutists, we must watch and welcome all investigations into the nature and origin of pathological processes. We must cultivate, too, the art of clinical observation, and especially the art of diagnosis, for it is obvious that an accurate discrimination of the character of a disease must precede, in any particular instance, its intelligent treatment. And here, too, I think we shall agree that there is a distinct danger from undue specialism in practice. While what is known as specialism in practice has done much to advance our remedial arts, and while specialism within certain limits is wisely accepted by our profession as a sound rule of conduct, I think we shall admit that there is an undue specialism against which we must guard, because it is a dangerous obstruction to real therapeutic progress. We must never forget that we cannot pursue therapeutics successfully to the exclusion of other branches of medical art and science. We cannot be therapeutic specialists! But our therapeutic progress cannot rest upon clinical experience alone. Physiological research into the precise details of the powers of remedies, and such research directed towards the perfection and discovery of remedies, has already yielded good fruit in practice, and is full of promise. The two broadest and directest lines of therapeutic progress lie in these two fields of work, in clinical experience and in physiological research. Each supports the other, and neither can stand alone. While clinical experience suggests specific wants which physiological research may endeavour to supply, physiological research supplies new agents which clinical experience may test in practice. Clinical experience reveals the therapeutic effects of medicines, physiological research discovers only their physiological actions. The therapeutic effect of a medicine is its remedial efficacy in disease. The physiological action of a medicine has no necessary connection with its therapeutic powers; it is an effect it produces upon a living and healthy body. We shall fall into error if we assume that there is always a necessary connection between the physiological actions of a medicine and its therapeutic effects. There are some agents which have marked physiological actions and yet are poor in therapeutic powers, and there are some remedies which have accepted therapeutic efficacies which exhibit scanty physiological manifestations. If we examine the matter closely, we shall find that in many instances the therapeutic effects of a remedy, and its physiological actions are, so to speak, two distinct, but not separate, sides of its character. But, however these things may be, we cannot doubt that the more we learn about the physiological powers of remedies the more likely we are to understand, the more likely we are intelligently to direct, their therapeutic employment in our practice. So, if we would make progress in our powers to cure disease and to relieve physical suffering, we must heartily help and patiently watch the physiological investigation of the actions of old and new remedies, and of old and new agents which may possibly become remedies. Our experience tells us that we shall often find that an agent which has particular and well marked physiological powers has also the capacity of a remedy with distinct therapeutic actions. In this way, physiological research suggests for us and for our patients new remedies, or new applications of old ones, and hands them on to clinical experience for test and for proof. Physiological research yields us a perennial spring of therapeutic progress, a spring in which our art may perpetually renew its vigour. Here is an

abundant source from which we may draw an exacter knowledge. Here shall the art of medicine become less empiric. Here shall our science become more practical, and our practice more scientific. There is another condition of our work in the treatment of disease about which there has been much misconception, but about which we can scarcely miss agreement if we weigh the case carefully. It is this: whether we like it or not, we must yet be mainly empirics in our practice. We must not be above being empirics. I do not mean empirics in any bad sense of the word. I do not even mean that there is any real opposition between true empiricism and scientific practice. The great bulk of our therapeutic knowledge is as yet empirical, and as empirics, though as rational and scientific ones, we must administer it. By this empiricism I mean, and mean only, a knowledge which is founded upon experience. I mean a knowledge which grows from and with experience, and which in this sense is empiric, however scientifically it be applied. In much of our therapeutic work it is experience which prompts our action, while experience alone can test our results. Much of what we do we cannot explain, in the scientific meaning of the word explanation, so we lean upon experience, and trust with an empiric faith much that we know to be true, though we cannot understand it. We expect much of further gain to our art from the discoveries and developments of physiological research into the actions of medicines, and such research has already found us some valuable remedies, which an *a priori* reasoning has applied in practice, and which experience has confirmed. But, in our time, experience must yet be our chief guide in therapeutics. Here is a specific question which we have to answer every day. Why do I give this medicine to this patient? Not because it has such-and-such physiological effects, and I expect, therefore, that it will do good, but because I have *before* found its administration attended with advantage under similar circumstances, and this experience *satisfies* me, and gives me confidence in using it again, until I know of a better remedy.

Progress has two sides. It advances with a double front, by the discovery of the unknown, and by the perfection of the known. What the unknown has in store for us we cannot say, but surely a mine of therapeutic progress lies ready at our hands in the perfection of the remedies we already know. The discovery of the unknown is reserved as a rare and great reward, as the guerdon of the few. Towards the perfection of the known we all can work, and none shall miss his prize. The discovery of the unknown bears fruit late, seldom, never, and splendid; the perfection of the known bears fruit at once, always, continuously and in bushels. Many good remedies are not fairly tried. A remedy has not failed when it has only been employed improperly. Let us study again, and more closely, and by modern scientific methods, many a good old drug, such as arsenic and antimony, mercury and hemlock, sulphur and turpentine. Let us watch, too, the marvellous developments of modern chemistry in their bearings upon our medicines. With a wide eye let us watch the sciences which are ancillary to ours, that we may translate their advances and resources into practical therapeutic utilities. Let us be reading, and reading old books, as well as doing other work. If we turn to the therapeutic literature of the past, we shall find not only that the fittest remedies have not always survived, but that some of our most striking modern curative triumphs have been gained by old remedies which had long been forgotten, as, for instance, in the treatment of pyrexia by the affusion of cold water, a revival and not a survival, a revival of the therapeutics of Currie, of Liverpool, at the beginning of this century, and of others before him.

Venesection is worthy at least of partial revival, and is sure to come into vogue again. We might, too, give point and precision to much that we know if we revived a little of the evacuant treatment of our predecessors—a treatment which, although based upon a superseded humoral pathology, was often sound in its practical results—and, casting aside much of the modern tonic rubbish which so easily besets us, studied the unloading of the viscera, and cultivated a robust therapeutics, based upon an accurate survey of the vital individuality of our patients.

## POSTURES IN SCHOOLS, AND THEIR INFLUENCE UPON THE FIGURE.<sup>1</sup>

By NOBLE SMITH, F.R.C.S. Ed.,

Surgeon to the All Saints Children's Hospital.

LED to enquire into the first causes of various deformities in young people, and more especially the causes of curvature of the spine, I have traced them in a great number of instances to the regularly repeated assumption of bad postures during school occupations. Last year I was invited to give expression to my observations upon this subject at the Congress upon School Hygiene at the International Health Exhibition; and since then I have, under the auspices of a very active and enthusiastic member of the School Board for London, visited several of the board schools, and carefully noted the prevailing bad postures assumed by the boys and girls whom I saw there. At the invitation of the Works Committee of the School Board, I met them and read a report of my observations. Desks and seats and children were provided at the meeting, and I demonstrated the bad postures and explained the faults in construction of the desks and seats, pointing out how the evils might be counteracted. I subsequently devised a modification of the former seats and desks, which overcomes to a great extent the evils complained of.

At my visits to the schools I found that a good posture was a rare exception among the children, and I will now call your attention to the positions which were commonly assumed. Stooping over the work was the most noticeable, and in writing and other work carried out upon the desk this posture was almost universal.

At the schools at Lisson Grove, Limehouse, and Carlton Road, I made sketches of the more general positions in which I found the children. The first sketch shows a child leaning over the desk (which was flat), bending the spine very much and holding the right shoulder forward. In one case I measured the distance between the eyes and the copybook and found it to be only  $2\frac{1}{2}$  inches. Among the 46 children in this class, 23—exactly half the number—were very much in the same position. The second sketch represents another favourite position, and the third shows how some of the pupils bend the upper part of the body to the left, and forwards. Fig. 4 shows a somewhat different posture seen in profile. Fig. 5 represents a girl holding her slate up while she is resting her back for a time against the rail of the seat. This posture twists the left shoulder forwards while the back is curved.

These positions are the result of the desk being too low, and removed too far from the body of the pupil. They all tend to produce permanent roundness of the

<sup>1</sup> A paper read before the Medical Officers of Schools Association, July 22nd, 1885.

back, and curvature of the upper part of the spine to the right. Now we know that even in adults (in whom the bones are more solid and much less liable to give way to pressure than in young people) trades which enforce constrained positions give rise to deformity. The round shoulders of the engraver, the curved spines of those who carry heavy weights, and the knock-knees and flat feet of waiters—are examples which are familiar to us all. We ought, therefore, to realise that bad postures at the school desk are productive of curved spines in accordance with the curved positions which are so commonly assumed.

In children the spine is, as you well know, to a great extent cartilaginous. The repeated assumption of a curved position cannot but influence the ultimate formation of this important structure. An independent observer, who has had much experience of girls' schools, states that 25 per cent. of girls at school have more or less curvature of the spine. And in these he refers to decided cases of curvature.

Some observers have thought that a slight lateral curvature is a natural condition, but although its frequency entitles the deformity to be considered common, we surely cannot look upon it as a normal state. I must own to being one of those who cannot admit that the spine should be otherwise than straight as regards symmetry.

As to the importance of preventing the development of these deformities, it is hardly necessary for me to say much here. I assume that the desirability of such prevention is recognised by all my hearers. The tendency of such conditions to increase when once produced, their deleterious effect upon the general health, their interference with free growth, their evil influence upon the functions of the body, and especially upon the chest, and their disfiguring effects ought to be sufficient to induce us to do all in our power to prevent their occurrence.

It is perhaps necessary to remark here that in considering posture as an influence in the development of deformity, we must always bear in mind the various other conditions which may act as causes. Such are congenital irregularity of the spine, inequality in the length of the limbs, or in the two sides of the pelvis, general debility, rapid growth producing an unnatural flexibility of the spine, paralysis, lameness, wry neck, &c.

But whatever may be the cause, there can be no doubt that habitual bad postures exercise an immensely harmful influence upon curvatures of the spine, and sitting postures are probably the worst. Sitting on chairs or forms is not natural to human beings, and few children would adopt the position by choice. A young child much prefers sprawling upon the floor; and I think it is a pity that they are not allowed more freedom in this matter. Nature dictates a frequent change of posture which is generally considered inelegant, but it allows growth to take place more regularly than when too much strain is imposed upon the figure in one or other direction. Girls are more interfered with in this respect than are boys, and consequently girls suffer most from the consequences. It is doubtless desirable that restrictions should be placed upon the dictates of Nature in this matter; but it is of great importance that every possible means should be taken to prevent these restrictions from producing such serious evils as I refer to. It would be a great relief to the delicate spines of young girls if they could lie in a prone position upon a sloping bench to learn their lessons and to read. However, seats and desks must be used, and it is to the proper construction of these that our attention must be drawn.

There are two points in the arrangement of this school furniture which especially require attention, and these are—1st. That the desk be sufficiently high

to obviate stooping. 2nd. That the desk be sufficiently near the body of the pupil to allow writing to be done while the back of the individual rests comfortably against the back of the seat. To effect the first requirement the edge of the desk should be on a level with the junction of the lower and middle thirds of the arm, *i.e.*, just above the front angle of the elbow. It has been advised that the height should be such that the forearms should rest evenly, while the elbow is at the side, upon a desk of 15° slope, but I have found it better to make it a little higher as above described, so that the elbows are removed outwards to allow the arms to rest evenly on the desk, and the work is thus placed nearer to the eyes without being too near. The slope of the desk is also better for practical purposes at an angle of 12°, as if it is more slanting, books and slates are apt to slide off. To fulfil the *second* important requirement, the desk should very nearly touch the body, whilst the back of the seat is being used as a support; about one inch distance is very suitable.

Other points requiring attention are, that the back of the seat supports the loins of the pupil, and it is well also to have a support to the shoulders. The seat should by preference be wide enough to support most of the thigh, but it is not always convenient to provide this. There should be ample room for the legs so that they can rest easily upon a slanting foot-board, or be moved about to relieve the pupil from a constrained position.

I cannot select any particular desk, but you will have no difficulty in choosing those which are suitable. I have found an adjustable table which can be adapted to any good chair, very useful for general purposes. If there is a flap which can be raised for resting a book for reading, it should be so arranged that the pupil can read easily without bending forwards. There is not due provision for this in the London Board Schools.

It is very desirable that large print be used in schools, not only on account of the eyesight, a most important matter, but also because it facilitates the adoption of an easy posture.

One great benefit which is conferred upon children at school is the inculcation of discipline, but even this discipline may be overdone. Some of the inspectors who visit the London Board Schools insist upon each child keeping its feet in one position, close together on the foot-board. Most of us know the irksomeness of such a constrained posture, even when enforced upon us at a theatre or other place of amusement for a couple of hours, and we can therefore realise the cruelty of imposing so unnecessary a restraint upon children. Another disciplinary rule which I discovered in my visits, and one which I believe is very general in schools, is the custom of twisting the body in writing. I believe it to be a most pernicious custom, and one which is probably answerable for many cases of curvature of the spine.

The order as I heard it delivered was to this effect: (1) "Stand for writing;" (2) "Turn to right," which consisted in turning sideways to the desk; (3) "Sit for writing." The effect of this plan is that the pupil sits with the knees directed to the right, the pelvis resting diagonally on the seat, the left arm resting upon the desk with the fingers upon the copy-book opposite the line to be written, and the head twisted to the left towards the left arm. If you will observe a child with its back naked, sitting at a table in this position, you will see that the spine is bent into the position of the commonest form of double curvature, the dorsal portion being bent to the right, and the lumbar slightly to the left, while the whole spine is twisted, the lower part from left to right, and the upper from right to left. I cannot but consider this practice a monstrous evil, for I think there can be little doubt that it leads to monstrous results. Why

is it taught, you will ask? The only explanation I could obtain was that it facilitates elegant writing. Some teachers consider that the direction of the pupils' knees should be in accordance with the desired slant of the writing. It would be far better to substitute upright writing if the slanting can only be attained at the sacrifice of the straightness of the spine.

Standing in class may be productive of bad results upon the figure, if prolonged for more than a quarter of an hour at a time (and even this period is too long for weak children); the muscles of the spine become tired, and the child is obliged to allow its spine to subside into curves, and these curves gradually become permanent. It is much better to allow children some latitude as to their position in standing. It is a most fatiguing posture to stand with the feet close together and both legs straight. The feet should be placed slightly apart so that a good base of support is afforded, and the pupils should be allowed to "stand at ease" as often as they like; but one leg should not be favoured in this respect. It would be a great help if a rail were provided for the children to lean against. Weak children, and especially those who show any symptoms of laxity of joints, whether associated with rickets or not, should be taken great care of, and allowed to rest as much as they like.

Girls, as I have already remarked, undoubtedly suffer from the effects of bad postures to a much greater extent than boys. I think this may be explained chiefly by the facts:—1st, that more strictness is observed with the former than with the latter; and 2nd, girls have less chance of counteracting the effect by energetic play. True it is that they have their calisthenic exercises, their regular and stately walks, or the more modern conceit of Swedish drill; but what are these in comparison to the free and unconstrained sports which are so heartily enjoyed by boys? But girls must be brought up, it is thought, in a genteel and lady-like manner; it is tom-boyish to be too energetic in action; their movements must be slow, deliberate and constrained, and the least attempt to indulge in Nature's craving for a childish romp, is too often repressed for fear of its engendering vulgarity.

For my own part, I am no believer in the refining effects of this pernicious system. I cannot but think that motherly care in early life, careful moral training and good example, will do far more to lead the child to grow up into an honest, truly refined and virtuous woman, than all the prim routine and unnatural restraint which modern civilization imposes upon girls.

When the actions of the body are quite free, as they are in boys when playing in the majority of their games, and I would especially mention that most English of all games—cricket, all parts of the body are severally brought into use, there is very little chance of one part being overworked at the expense of another. School-girls ought to be encouraged to play such games as cricket and tennis; instead of which they go for walks, marching along the streets or lanes in prim couples; and in many schools they have no other exercise.

To prevent the development of deformed figures is not merely a matter of appearance, it is a matter of health. A round back alone is a very deleterious condition. We all know that it produces a flattened chest—that a flattened chest indicates a small space for the lungs, and that then the lungs become much more liable to disease than when the chest is large and full; that the more fully our lungs can expand, the better chance we have of recovery from any lung disease; and that a full chest allows more room for the heart and stomach to do their work in properly. There was some truth in the remark which an old sportsman used to make to those of his friends who complained of indigestion, "It all comes from sitting

upon your stomach." If the spine becomes curved laterally as well as posteriorly, the evil effects are greater, and the condition a more difficult one to get rid of.

I have dwelt almost entirely upon the effect of posture upon *the spine*, and doubtless it is to this point that we should chiefly direct our attention. With regard to the legs, if there is plenty of room under the desk, the pupils may be allowed to change the position of the legs as often they like. At the schools already referred to I noticed many children who were obliged to sit with their feet crossed, or in other constrained positions, because a ledge beneath the desk interfered with their sitting with the legs upright.

The direction of the light is a very important matter; it should come preferably from the left and from above, so that it falls fairly upon the work on the desk and not glaringly into the eyes of the pupils. If the light is not well arranged the body has to be twisted or placed in some awkward position to allow it to fall upon the work, and not to glare into the eyes. It is not within my province to discuss the effect of a badly-arranged light upon the eyesight, but that we know is also a most important matter.

In conclusion, I would urge upon all those who have the custody of children the great importance of preventing the development of the serious deformities which may arise from, or at least be aggravated by bad postures frequently repeated. The rapid advance of education—the severe examination tests which both girls and boys have to undergo in the present day, necessitate most assiduous application to the school desk; and it will require the utmost vigilance and care on the part of teachers to prevent these bad postures from becoming habitual; and let it be thoroughly understood that the evils complained of cannot be prevented by simply making the children "sit up." I have elsewhere explained that no child can "sit up" straight for more than a few minutes at a time without proper support to the back, and that when they are continually urged, or I may perhaps justly say bullied into, "sitting up" they assume a comparatively upright posture without using their muscles—that is, they place the spine in a curved and fixed position, which when frequently repeated most assuredly causes the development of curvature.

If we consider the immense strain upon the spine to which in after life so many of us are subjected; if we consider the life of the clerk, or the seamstress, the governess, or the shop girl, how, hour after hour they have to sit or stand with little opportunity indeed of resting their weary backs, we shall realise the importance, nay, the imperative duty which devolves upon us of at least giving them a fair start in life. In every class of persons, the back is very liable to suffer in after life, but the stronger and straighter it is the better will it bear its work. Ought not as much care be bestowed upon physical as upon mental development? Should we not take care that while we are grasping at the attainment of superiority in mental culture, we are not losing the benefits of incalculable value which are almost peculiar to good physical development, and the good health which is its accompaniment?

---

UNION OF FRACTURED TEETH.—Dr. Wingate reports eight cases of united fractures in teeth from Carbondale, where there is a large class of miners amongst whom accidents are common. As these teeth were all extracted on account of the pain and discomfort caused by their distorted shape, it is probable that united fractures in teeth are much more common than has been supposed, for these teeth represent the failures only; the successful cases, not giving trouble, were never recognised.

# Medical Times and Gazette.

SATURDAY, AUGUST 8, 1885.

THE annual meeting of the British Medical Association was brought to a close on Friday, the 31st ult. Although the scientific aspect of these gatherings is not altogether satisfactory, still the Association is to be congratulated upon the large amount of useful work performed during the week. All the arrangements were carried out in the most admirable manner. Mr. Marshall's address in Surgery, on Thursday, attracted a large audience. It was practically a review of the cases which had been admitted into two wards at University College Hospital in the years 1844 and 1883. Mr. Marshall dwelt at some length upon the great benefits which had been derived from the use of antiseptics in the treatment of acute abscesses and amputation wounds, and upon the very marked diminution in the number of cases of cellulitis, erysipelas, and pyæmia. The third address, that in Public Medicine, was given on Friday by Mr. Dyke, of Merthyr Tydvil. It dealt mainly with local sanitary matters, and has already been published in the *Journal of the Association*.

At the third general meeting, Dr. Jacob, of Dublin, took advantage of the presentation of the Report of the Parliamentary Bills Committee, to move "That it be an instruction to the Council, in view of the approaching general election, to take immediate and active steps to organise the political power of the Association; to ascertain definitely the views of Parliamentary candidates upon those questions in which the Association and the medical profession are specially interested; and, so far as may be possible, to influence the members of the Association to give their votes for those candidates whose views are ascertained to be consistent with the policy of the Association and the good of the profession." Dr. Jacob asserted that just now was the opportunity, if ever, to lay the foundation of political influence on the part of the Association. At present the Association had no such influence, and the profession, according to him, was absolutely unrepresented in the House of Commons. The doctors now in the House of Commons were doctors by accident and politicians by profession. As an indication of what might be done, he said that while the British Medical Association would just now have great difficulty in securing two members to do its will in the House, the Irish Medical Association, by the judicious use of electioneering circulars and by extorting pledges, could at any time produce sixteen, while the Irish Medical Corporations had at one time secured twenty-five. Dr. Jacob found a seconder in Dr. Drysdale, of London, but his motion was not favoured by the Council, and an opportune stampede of members resulted in a "count out."

For the section of Medicine no subjects of greater interest and importance could have been selected than

the clinical aspect of Glycosuria and the treatment of acute Rheumatism. In connection with the former, Dr. Pavy gave a demonstration of the methods of testing urine for albumen, sugar, &c., which was very much appreciated. Dr. Markham Skerritt's rare case of Acute Febrile Glycosuria attracted much attention. Cases where fever has been an accident of the glycosuria, or where the glycosuria has followed upon an acute disease are not uncommon, but Dr. Skerritt's case falls into another category. The treatment of the case consisted in the administration of salicylate of soda and of codeia in combination with dietetic treatment. Professor Latham (Cambridge), going somewhat outside the question under debate, looked upon diabetes as the analogue of rheumatic fever, and acetonæmia as the analogue of hyperpyrexia. He endeavoured to explain on chemical grounds the formation of sugar through methylic aldehyde, the oxidized product of substances formed in muscles, &c. The outcome of the discussion on acute rheumatism, in which, among others, Drs. Bristowe, Latham, Pavy, and Wilks took part, was to disclose a general opinion that in salicin and its compounds the practitioner has now at his disposal for the treatment of the disease a drug almost as specific as is quinine for ague, but that the drug simply controls the manifestation of the symptoms, such as pain and high temperature, rather than cuts short the disease itself. Very beautiful microscopic specimens of ulcerative endocarditis and its results were exhibited by Dr. Byrom Bramwell.

IN the Surgical Section, after the opening address of the President on "Injuries to the Skeleton," and a discussion on bladder tumours, both of which we briefly reported last week, a very interesting paper was read by Mr. William Adams upon "Congenital Dislocation of the Hip." A recent dissection of a case of double dislocation was brought over from Dublin by Dr. Bennett. The capsule of each joint was complete, the round ligament present, and also a rudimentary acetabulum. There is no evidence to show that the labour-process is in any way a factor in the production of this so-called dislocation. Some speakers thought that the changes might result from an anterior poliomyelitis. The paper by Mr. Treves introducing the discussion on Operative Interference in Intestinal Obstruction, that by Mr. Bishop on Enterroraphy, and of Mr. Mayo Robson on Enterectomy for Intussusception, formed a very instructive series. The operation of enterectomy for obstruction, where the presenting part of the intestine is opened and stitched to the abdominal wall, which was upheld by Mr. Robson, was most severely criticized by Mr. Treves, who looked upon it as an operation which ought to be relegated to the past, and which was unworthy of a scientific surgeon.

IN the Obstetric Section, Dr. Playfair criticized the remarks, with reference to gynæcologists, made by Dr. Clifford Allbutt in his *Gulstonian Lectures*. He was not, however, successful in removing from the minds of his hearers the notion that a great deal of

mischief had been done by the unnecessary manipulations of some gynæcologists. Dr Playfair's remarks upon "ulceration of the cervix," "displacements of the uterus," and "intra-uterine medication" are deserving of attention. He strongly deprecated the frequent cauterisation of the cervix; the limit of time for intra-uterine applications in suitable cases of endometritis should not be more than two or three months, one or two applications in the week following menstruation. There should be no necessity for more than one or two visits after the application of a pessary to support a uterus deviated from its proper position. He hoped that the phrase "ulceration of the cervix" would be banished from use. Mr. Lawson Tait advocated the early removal of the ovaries in cases of uterine myomata. He brought forward cases of great interest in support of the treatment which he advocated. In the discussion on Antiseptic Midwifery, Mr. Tait strongly deprecated excessive antiseptic precautions. In the near future he would not be surprised to find the whole process of impregnation carried on antiseptically. Dr. Berry Hart, of Edinburgh, showed some very beautiful preparations—microscopic sections of uteri which had been removed by Cæsarean section, &c., and also several very interesting photographs. Dr. Hart's paper was devoted chiefly to the anatomy, histology and physiology of the uterus in the later stages of pregnancy.

THE Section of Pharmacology and Therapeutics promises to become one of the most important and instructive of the departments of the Association. In addition to his very interesting address, dealing with the history of pharmacology and therapeutics, and the methods of studying them, Dr. Fraser, the president, introduced the discussion on the action and uses of the digitalis group. He was convinced that we had found a most valuable addition to our therapeutic agents in strophanthine, a glucoside derived from the *Strophanthus Hispidus*, which was a safer drug in the treatment of heart disease than digitalis. Dr. Buxton's paper dealt very exhaustively with "Anæsthetics" from a physiological standpoint. It was felt by some members that sufficient attention had not been given to anæsthetics from the practical side. Dr. Buxton had hoped that this aspect of the subject would have been developed in the course of the discussion. Dr. Long Fox opened a discussion on the action of Diuretics, and Dr. Norman Kerr read a most interesting paper entitled, "Ought Alcohol to be prescribed, and how?" Members attending this Section were very much pleased with the demonstration of the action of the Digitalis Group upon the frog's heart, given by Dr. Stockman, of Edinburgh. In the Section of Public Medicine, Dr. Paine delivered an interesting address on the cholera epidemics in Cardiff, illustrated it by a very large and elaborate map, which was greatly appreciated by the members attending this Section. A paper was read by Dr. Vacher upon Summer Diarrhœa. There was but little unanimity amongst the members on the question of the causation of this interesting malady. In the same Section there was an interesting discussion on Provident Dispensaries, and it was suggested that a deputation should wait upon the

President of the Local Government Board to request his support in the formation of a Royal Commission to enquire into the present position of medical aid generally throughout the country.

LUNACY legislation was the most important topic of debate in the Psychological Section. Dr. Tuke, in his paper, remarked that the practical question before them he took to be this—"What ought we to strive for when a bill is brought in next Session, whether we have regard to the interests of the patient or of the medical men?" With regard to the intervention of the magistrate, he submitted that while recognising magisterial action in private as well as in pauper cases, stringent clauses should be introduced guarding medical men against improper interference on the part of the magistrate. Medical men and also superintendents of asylums should be well protected from the vexatious actions brought by discharged lunatics. They should be allowed the same free and unfettered action in the examination of lunatics that was accorded in other surgical and medical cases. It was only right and proper that private patients should be visited as soon as was convenient, either by commissioners or by medical visitors. If Justices of the Peace were to provide accommodation for private patients, separate buildings and separate superintendents should be introduced. The proprietors of private asylums should be equitably dealt with in case any future bill affected their prospects by depriving them of their patients. It was a question whether hospitals might not receive State aid or local help rather than that pauper asylums should be devoted in part to private patients. The majority of the speakers agreed as to the necessity of having private asylums for high-class patients.

ONE of the most interesting features of the meeting of the Association was the Museum, located in a large public hall, a short distance from the Town Hall. A most admirable collection of instruments formed the central feature of the Museum. The exhibits of food, drugs and chemicals, were numerous, many being supplied by local manufacturers. Section D contained several very interesting appliances, amongst them a hand ambulance, constructed by John Peck & Co., Wigan, weighing 29 lbs., and supplied at a cost of 50s. The patent automatic dry-gas regulator of the Bromhead-Tester Co. was at work; this simple contrivance increasing the illuminating power, while regulating the consumption of gas, deserves greater attention. The exhibition of pathological specimens was extremely meagre.

THE social attractions of the Cardiff Meeting will not be readily forgotten. The reception by the President and the South Wales Branch, on Wednesday evening, was of a brilliant character. The large public hall in Crockherbtown had been beautifully decorated for the occasion. Running hard by the hall is a stream, which had been gaily illuminated with numerous Chinese lanterns, arranged in festoons along the banks. A Venetian gondola richly decorated, containing a

group of singers, served to convey the visitors up and down the stream. An extensive promenade had been constructed outside the hall. The first part of the entertainment consisted of a concert in which several Welsh artists of great repute and a well-known Welsh choir took part. Dancing to the strains of the Artillery Band began at eleven, and was continued into the early hours of the morning. About 1,500 people were present. The reception by the Mayor of Cardiff was of a similar character. Five garden parties were given during the week: the first on Wednesday by the High Sheriff of Glamorgan, in the beautiful grounds of Rookwood, a short distance outside Cardiff; three on Thursday, by the President, Dr. Taylor and Dr. Edgar Jones; and the fifth on Friday, by Lord Windsor, at the Penarth Gardens. The weather was perfect, and everything passed off most successfully.

THE dinner on Thursday was worthy of the occasion—according to some old frequenters of these meetings, one of the best. The President, relieved from a considerable amount of worry and anxiety, was peculiarly happy in his speeches. After dinner the Llandaff Glee Party, in the intervals between the speeches, enlivened the proceedings with some well-selected and appropriate glees. Private hospitality was shown on a most liberal scale; in short, nothing was left undone that could make the visit to Cardiff one which will in future be remembered with pleasure. During the week the extensive docks were visited by a large number of people; various manufactories were thrown open to the members of the Association, as were also the museums, picture galleries, college, infirmary, castle and castle grounds. In addition to the excursions on Saturday, members availed themselves of the numerous opportunities during the week of visiting the places of interest in the neighbourhood, and of interviewing some fine scenery. On Saturday a large number of the members with their friends joined in the various excursions to Tintern for the beautiful scenery of the Wye, to Glastonbury and Wells Cathedral, and several other places of note. Lord Bute placed a special train at the disposal of those visitors who desired to visit Penylan, a mountain in the centre of the South Wales Coal Basin, from which a magnificent view is obtained of the Beacons of Breconshire, the Bristol Channel and parts of Monmouthshire, Gloucestershire and Carmarthenshire. Returning to Caerphilly Castle, the visitors partook of a most sumptuous luncheon as guests of the Marquis. The afternoon was spent in visiting the ruins; a very pleasant dance on the green and in the old banqueting-hall brought the day to a close.

THE Medical Relief Disqualification Removal Bill passed easily through Committee in the House of Lords on Thursday last week; not altogether, indeed, without some word-fencing, but happily the buttons were carefully kept on the foils. Lord Balfour of Burleigh moved to amend the Bill by limiting its operation to two years. The amendment met with as little support from the Lords as had been given to a similar proposal in the House of Commons, namely, it it was not even seconded; but it gave Lord Milltown

an opportunity of speaking in support of the measure more directly and strongly than he had done when he filched the moving of the second reading of it from Lord Granville, and it gave the last-named the opportunity of effusively thanking his noble brother Earl for having, at last, really argued in favour of the measure. Several peers spoke against the amendment, and the Marquis of Salisbury gave it the *coup de grace* by observing that it seemed to him that the effect of it would be to require that the Houses of Parliament should consider the question again two or three years hence. He, however, did not think that the Houses had so distinguished themselves on the present occasion that that would be a desirable result. The amendment was withdrawn, and without more ado the Bill passed through Committee; and next day it was read a third time, and passed without blessing or ban.

THE Criminal Law Amendment Bill, which has all but passed, important as it is, is not a Bill which it falls within our province to discuss, except perhaps to point out that from a hygienic point of view, the prevention of precocious sexual relations and of premature maternity is an end well worth striving for. But the ill-advised proposal of Mr. Stansfeld on Monday, to make the examination of women for certain purposes by medical men a criminal act, demands some comment at our hands. The proposal was, of course, the corollary of Mr. Stansfeld's faith in the baseless assertions of the *Pall Mall Gazette*, which we censured, we think with sufficient severity, soon after their publication. The discussion drifted off into a heated talk about the journal in question, but the House showed its comparative good sense by rejecting the clause by a majority of 115 against 50, after Mr. Mitchell Henry had protested against the slur proposed to be cast on the profession to which he belongs, and Sir W. Harcourt had pointed out that if the clause were carried no medical man could safely examine a woman in the course of his professional duty. But that even fifty M.P.'s should be found willing to vote for a clause which was the outcome of anonymous slander, and which, if passed, would have roused a tempest of righteous indignation throughout the medical profession, shows how the hysterical excitement of the last few weeks has influenced even those to whom we look for calm and sober judgment. We have not seen the text of the rejected clause, and so cannot tell whether Mr. Stansfeld meant it to apply to his *protégées*, medical women, as well as to medical men.

WE hear that the statement made last week in the House of Commons during the discussion on the annual grant to the Queen's Colleges in Ireland has already caused a good deal of uneasiness in educational circles there. The pledge given by the present Government that, if in power next session, they would frame a measure which would please the Irish members, shows clearly that the lamentable feeling of unrest and disquietude on university education in Ireland, of which we spoke in a recent number, is fully justified. We do not hesitate to foretell that if

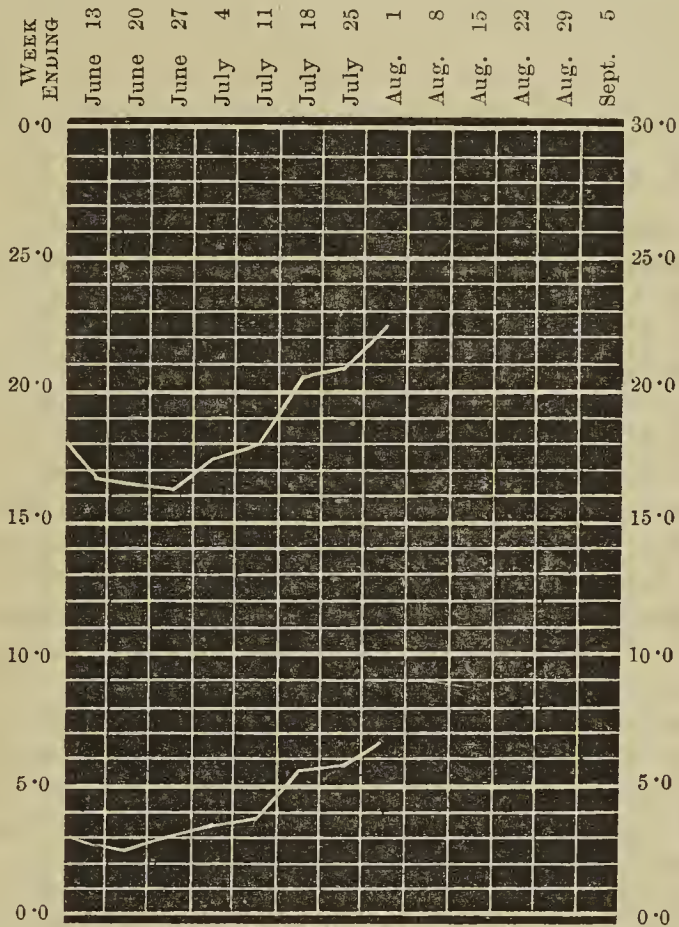

legislation be undertaken solely with the view of pleasing any section of the Irish members it must be a failure. Upon all hands, however, it must be conceded that legislation is absolutely necessary, and we have little fear that the lamentable mistake made by the Government which passed the Royal University Act will be repeated by either political party in years to come. The question must be fearlessly taken up by the next Parliament and settled. Hitherto in England we have only heard of the dissatisfaction of the Roman Catholic party, but by nearly all the graduates of the late Queen's University, and by none more so than by the medical graduates in the North of Ireland, the Act was keenly felt to be a cruel injustice. It must appear to everyone who has studied the difficulties of the question that both parties in Ireland will have to accept unpalatable compromises if the ruinous period of uneasiness is to be brought to an end. If Cork or Galway be handed over to the majority, it will not be sufficient to permit Belfast to remain as it is. Ulster requires, and the North of Ireland has long been entitled to, a university of its own. We only hope such a university will be established upon the broadest non-sectarian lines, to meet the requirements of the large medical school which has grown up in the North of Ireland during the last twenty years, and which, we regret to learn, has been seriously affected by recent legislation.

A ROYAL Commission has been appointed to investigate and report upon the condition of the blind in the United Kingdom, the various systems of education of the blind, elementary, technical and professional, at home and abroad, and the existing institutions for that purpose, the employment open to and suitable for the blind, and the means by which education may be extended, so as to increase the number of blind persons qualified for such employment. The only representative of the medical profession on the Commission is Dr. Armitage, who many years ago had the misfortune to lose his sight. Without wishing to deny that the objects with which the Commission has been appointed are admirable, we cannot help feeling that it would have been much more advantageous if the Commission had been made to extend its labours, and include a study of the causes of blindness, with especial reference to its prevention; possibly it is even now not too late to remedy this defect, and in that case we should feel that the presence of Sir William Bowman, and perhaps of one or two other prominent members of the Ophthalmological Society on the Committee, would be a guarantee that not only would everything be done to endeavour to alleviate the condition of those already blind, but that there would be a more widespread knowledge of the preventable causes of blindness, a knowledge for lack of which many an eye is now lost.

IN London last week both the general and zymotic death-rates experienced a rise, due mainly to the increased prevalence of summer diarrhoea. There were 348 deaths during the week from diarrhoea and dysentery, and 13 from cholera and choleraic diarrhoea. Of

these figures all but seventeen represented children under five years of age. In spite of this mortality the total number of deaths, 1,750, was still 57 below the ten years' average, though the zymotic deaths, in number 540, were six above the average. The deaths from small-pox were 16, and the epidemic is steadily declining, though there were still 614 cases in hospital on Saturday last. The 71 deaths from measles ex-

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past eight weeks.

ceeded the average by 24; while, on the other hand, the 18 deaths from scarlet fever were 33 below the average. There were during the week 23 deaths from diphtheria, *i.e.*, twice the average, and 8 deaths from enteric fever, or exactly half the average. Sunstroke was credited with the death of a child of 7. The temperature of the whole week was 2.5° above the twenty years' average, and the sun shone on an average seven hours a day.

THE cholera epidemic in Spain is daily assuming more fearful proportions, each day's return being worse than the previous day's. Four thousand cases and 1,500 deaths a day scattered over a score of provinces represent the latest returns. During the month of July the cases numbered 61,320, and the deaths 26,839, and it is to be feared that the present month will witness a much more serious prevalence of the disease. The extension of the epidemic during the past week has been chiefly northward into the provinces bordering on the Pyrenees, but it is also spreading through the provinces of Granada and Seville. The province and city of Saragossa are still suffering severely; at Madrid there has been no great increase, but the populace are mad with panic. There is great distress throughout the country, and in some of the remoter parts, where the doctors and local authorities have suc-

cumbed to the disease, the sick are said to be lying untended and the dead unburied. The event of the week, however, has been the general recognition of the fact that cholera prevails at Marseilles. There has been and still is great reluctance on the part of the authorities to admit the presence of the foe, a reluctance accounted for by the entire neglect of all sanitary improvement during the months that have passed since last year's epidemic. The French Minister of Commerce, however, has visited Marseilles with Drs. Brouardel and Proust, and it is to be hoped that the visit will result in some decisive measures. The epidemic, meanwhile, is increasing very rapidly, and in a very virulent form.

OUR Paris Correspondent writes: Neither official reports nor the independent press admit that the cholera has definitely appeared at Marseilles; but rumours are abroad which point to its outbreak both in that city and in Lyons and Bayonne, the latter a frontier town on the very borders of Spain, the former a place which till last year had been thought a perfect stronghold against all attacks of that epidemic. What the real truth may be we must wait to know. It seems likely enough that cholera, like small-pox, will become a naturalized citizen of Europe, in which it had already made its appearance ages ago in the comparatively mild form of cholera nostras. Dr. Doyen, a distinguished pupil of Professor Cornil, has maintained this view in a paper read before the Academy of Medicine, and embodied in his Thesis. In this production M. Doyen professes himself a decided follower of Koch; he openly adopts the comma bacillus, which, he says, is identically the same in cholera nostras and in Asiatic cholera, and states that after due cultivation it produces the unquestionable symptoms of the disease in animals after inoculation. Whether M. Doyen has really solved the problem, as he claims to have done, time will show.

A CRIMINAL prosecution has been commenced against a medical man of the south of France, Dr. Estachy, who is charged with an attempt at poisoning a rival practitioner, Dr. Tournatoire. This latter gentleman received a present of game from an unknown hand. Mme. Tournatoire and one of the servants having partaken of two of the birds, were seized with symptoms of severe poisoning, which nearly proved fatal. It was afterwards found that the birds had been stuffed with belladonna. The insidious present was traced to Dr. Estachy, who at first acknowledged the fact, but contended that it was a mere practical joke. The joke was considered a decidedly bad one by the judicial authorities, and the doctor is at present on trial under a charge of poisoning. The verdict has not yet been issued. An undoubted case of poisoning occurred quite lately at the Hôpital St. Louis. Two patients, who had been ordered to take a table-spoonful of a strong drastic purgative known as "Eau de vie allemande," were served with a preparation of nuxvomica, which settled their business in a very short time. The error was traced to the apothecary, who, by all accounts, is an able and promising young man, but who seems to have lost his wits on the occasion. Judicial proceedings have of course been initiated.

ONE of the leaders of Science, the Nestor of French naturalists, M. Henry Milne-Edwards, died on Wednesday week, at the age of 85, and has been buried with due solemnity. Henry Milne-Edwards and his brother William, the celebrated physiologist, were both Englishmen by extraction, although born at Bruges (in Belgium), and long ago naturalized in France. Both Henry and William were Members of the Academy of Sciences, and the son of Henry, M. Alphonse Milne-Edwards, is a member of the same scientific body, and of the Academy of Medicine. Henry Milne-Edwards was for a long time the prince of French zoologists, and his enormous work in fourteen volumes, on the structure and physiology of animals, is a monument of the old orthodox doctrines which reigned from the days of Cuvier down to the time of Darwin. His innumerable discoveries as a naturalist cannot of course be noticed here.

AT its last meeting, Dr. Javal, a Member of the House of Deputies, was elected a Member of the Academy of Medicine, in the sections of Physics and Chemistry. Dr. Javal's researches have been directed principally to the science of Optics, and he is well known for his researches on astigmatism.

AT the annual graduation ceremonial at Edinburgh on Saturday, the M.D. Degree was conferred on 58 candidates, eight of whom—viz., Harry Drinkwater, England; John Lockhart Gibson, Australia; Edwin Hyla Greves, England; Charles Kennedy, Scotland; Alexander McCormick, Scotland; Ernest Frederic Neve, England; Diarmid Noël Paton (B.Sc.), Scotland; and Johnson Lymington, England—obtained gold medals for the excellence of their respective Theses. The Degrees of M.B. and C.M. were conferred on 188 candidates who had successfully passed the required examinations. Of the candidates who took these degrees seven passed the examinations with First-class Honours, and 14 passed with Second-class Honours. Of these 21 honours' candidates only six are natives of Scotland, while as many as 10 are of English birth. The Ettles Medical Scholarship of £40 was awarded to H. J. Stiles, M.B., C.M., as the most distinguished Bachelor of Medicine and Master in Surgery of the year. The Goodsir Prize of £60 for the best essay containing results of original investigations in anatomy and physiology, was awarded to E. F. Neve, M.D. Various other prizes were awarded, after which the annual address to the graduates was delivered by Dr. Greenfield, the Professor of General Pathology.

THE Summer Session at Glasgow University closed on the 30th ultimo with the ceremony of graduation and the distribution of medals. Principal Caird presided. Nine Bachelors of Medicine received the degree of M.D. Of these John Yule Mackay, the Demonstrator of Anatomy, was highly commended for his thesis on "The Origin and Development of the Larger Arteries"; and William Macvie was commended for a thesis on "Atrophic Infantile Paralysis." The Bachelors of Medicine and Masters of Surgery were 37 in number, of whom Andrew Wilson, Archibald S. Alexander, and James R. R. McCrindle

received high commendation. The Brunton Memorial Prize of ten pounds, awarded to the most distinguished medical graduate of the year, was gained by Andrew Wilson. At the close of the distribution of medals and prizes, Professor Leishman addressed the graduates, and in a sensible and yet eloquent speech, counselled them to continue to be students while intellect and vigour remained to them, urging that the school in which they had mainly to learn, with energy, patience and humility, extending over many a year, was that of Nature, in which for the most part they would have to discover guidance for themselves.

THE festivities which brought the branch meeting of the British Medical Association at Aberdeen to a close the other day, afforded Dr. Angus Fraser the opportunity to speak his mind on the subject of the management of the Royal Aberdeen Infirmary. His charge against the managers of that institution is their neglect to carry out certain changes which some time since were declared to be desirable, and for which the necessary powers have long been in their hands. It appears that more than a year ago various alterations and improvements in regard to the nursing staff were promised, but the chief defect appears to be in the bath-room accommodation, which is admittedly insufficient and bad of its kind. The staff would seem to have agreed to refrain from public protest on the understanding that the managers were really going to take the matter in hand; but now that they have so long neglected their duties, Dr. Fraser has been fully within his right in publicly calling attention to their shortcomings.

AFTER seven months of imprisonment upon a conviction which all those who examined into the facts must have felt to be illogical, Dr. Bradley has been released by order of the Home Secretary. Now that this is an accomplished fact, we learn that the judge (Lord Coleridge) who tried the case was satisfied in his own mind that a wrong had been done, though no doubt a contrary impression had prevailed in the profession; under these circumstances the persistent refusal of the late Home Secretary to reverse the verdict is more unintelligible than ever. We congratulate Dr. Bradley upon the tardy justice which has been measured out to him, and are glad to learn that a subscription list has been opened to indemnify him for the pain and loss which he has suffered. Dr. Jackson, of Sheffield, is the Secretary, and Dr. Jeffreys, of Chesterfield, whose efforts on behalf of Dr. Bradley have been unceasing, is the Treasurer.

PROFESSOR BAMBERGER, writes our Vienna correspondent, has recently been elected Rector Magnificus of the University of Vienna. This post, which is held for one academical year, is the highest dignity which the University can bestow. He was not elected without some opposition, the ballot having to be taken five times before he obtained a clear majority. The delegates of the faculties of medicine and philosophy voted for him unanimously, but those of the faculties of theology and law gave their votes to Prof. Zhishmann, of the last-named faculty. Dr. Bamberger's election has been received with the most complete satisfaction, not to say enthusiasm, and it may be

safely said that he is about the most "sympathetic" Rector that the University could possibly elect. With all his learning, he is modest and kind-hearted, and his career both as a teacher and a private citizen has been irreproachable. The students were delighted by the election, and took a speedy opportunity of showing it, for when Prof. Bamberger entered his lecture-room the day after his elevation, they received him with a round of applause. In answer to this ovation, the new Rector said he hoped to rise to the dignity of his new position, though he was not quite sure that he was equal to it. He relied, however, greatly on the support of the students, who would greatly facilitate his labours by their industry and good behaviour. On his part he would contend with all his power for the interests of the students, whom he had always loved with his whole heart.

RECENT occurrences at Truro in connection with the appointment of a physician to the Royal Cornwall Infirmary, suggest strongly that the time has now come for a reform in the matter of hospital appointments, in the country at any rate. This is the age for the removal of disqualifications of all sorts, and it is high time that physicians to county hospitals and infirmaries should not be debarred from midwifery practice; there is no corresponding disqualification on the surgical side, and except in the interests of the surgeons themselves we can see no sort of reason for maintaining what is after all a serious restriction on a man's success in private practice. Putting aside those towns which can boast a medical school, we do not believe that there are half-a-dozen towns in the kingdom where a young man could earn enough to pay his way out of his practice as a pure consulting physician, and if this be the case, what a farce it is to encourage the keeping up of such a system. Within the last ten years there have been a number of physiciancies going a-begging in our leading towns throughout the country, and all because intending candidates learnt that they would not be allowed to compete on equal terms with their future professional brethren. With a fair field and no favour, many good men will be found to come forward for the now neglected physiciancies, and much unpleasantness between colleagues in their semi-professional relationships would be avoided.

THE case of *Neave v. Hatherley*, which was brought to a conclusion on Saturday last, is claimed by some of our lay contemporaries as affording yet another instance of the need for a reform of the existing lunacy laws. It may with much more justice be said to demonstrate the need for a reform of the system of trial by jury. The facts of the case were unusually simple. Dr. Hatherley, the family medical attendant of many years standing, was consulted by Mrs. Neave in reference to her daughter's state of mind; he found that the lady in question believed that all the servants were engaged in a Jesuitical conspiracy against her, that they had tried to poison her drinking water and tea, that the nurse had caused her nephew to have a fit of partial paralysis by hanging on his cot poisoned handkerchiefs, and that her mother was suffering from softening of the brain due to a prescription of his own

containing small doses of sulphuric ether. These and many like delusions were stoutly maintained by the patient in more than one interview with Dr. Hatherley, and on the strength of them he signed a certificate of insanity, and the jury have declined to impugn his *bona fides* in doing so. The above constitute a train of symptoms as suspicious as any that could be mentioned, and no one could foretell that they might not be the precursors of suicidal or homicidal tendencies, and yet the jury seem to have had no hesitation in deciding that the lady who was possessed of these absurd and absolutely unfounded delusions was nevertheless of sound mind. We have heard a good deal of late of the necessity for some provision by future legislation for the protection of medical men from such actions as these, and the present is certainly a good instance in point; the opportunity of proving to the world, as Dr. Hatherley has been able to do, that his conduct was scrupulously honourable and honest throughout the whole transaction, is, after all, hardly sufficient compensation for the worry and expense of a big lawsuit.

THE Apothecaries' Society have issued a list of the Licentiates added to their body in the seventeen months ending December 31st, 1884. They number 448, and the list bears witness to the fact that the Apothecaries' Society is not likely to find its examining function gone for some little time to come. It would have been interesting to know what proportion of the whole number of candidates the above 448 young apothecaries represent, and also how many of them had been previously plucked by other examining boards. If the Royal Colleges get their power of granting a degree, and persevere in keeping up the standard of their examinations, the Apothecaries' Society will probably have plenty to do in the future in passing men who wisely prefer the leniency of Blackfriars to the rigours of the Thames Embankment.

---

#### M.D., ANGL.

THE question of providing an accessible medical degree for London students has been rapidly ripening during the summer months, but that dread of precipitate action which forms one of the most notable features of the political character of the English has now dictated a pause. The holidays are upon us, and the opportunity is favourable for laying the matter on the shelf for a time, in the trust that when it is taken up again it will be a little more seasoned. It is a mistake to suppose that questions can only be advanced by public discussion and letter-writing. Often, like pears laid up in straw, they ripen the better for being deliberately left in the dark. Such a rest gives time for the working of that slow and silent process, which, whether we term it unconscious cerebration or the crystallisation of opinion, is a powerful factor in reconciling human minds to inevitable changes which at first sight they detest or dread. One of our statesmen, Lord Melbourne we believe, made a "practice of leaving his

letters unanswered, on the plea that in time most of them answered themselves. The same is more or less true of political problems. Left alone they settle, or tend to settle themselves. Difficulties disappear; opposition cools down; and the continued dread of change at length fascinates men into desiring it.

Such, we believe, will be more or less the future history of this "title of Doctor" question. The proposal of the Royal Colleges to give a medical degree is, at present, distasteful to two classes of men, first, to those graduates who regard their own degree, earned with some effort, as a vested interest the value of which will be seriously compromised by the broadcast conferment of a new M.D.; and, secondly, to those who, like the committee of the Teaching University Association, honestly believe that it is undesirable "to sever the machinery for granting degrees in London from academic influences," whatever that may mean. Well, we live in hope that quiet thought, untroubled by discussion, will do much to mitigate the hostility of both classes of objectors. The London medical graduates, led by Mr. Savory, have distinctly declared that they are opposed to any lowering of the standard of the degrees of their University, and have thus put themselves out of court, if they wish to oppose the institution in London of a less arduous degree. This declaration of theirs has done more perhaps to smooth the way for the Colleges than any other single incident of the discussion; for if the London University had been willing to give an accessible degree, the ground would have been at once cut from beneath the feet of the Colleges. As it is, the large and influential body of hospital teachers who are eager to secure a degree for the average student, as the due incentive and reward of his labours and their own, have only two possible avenues left open to them, viz.: on the one hand, the Colleges; and on the other, an association still in the clouds, and not unlikely to remain there. This being so, it is not difficult to see which opening they will incline to. We do not think that much opposition to the scheme of the Colleges need be feared from Oxford and Cambridge graduates, and as for the possessors of Scottish and other degrees, we hope we may fairly anticipate that the cool reflection of the recess will mitigate any selfish jealousy they may cherish in regard to the proposed degree, and allow their more generous feelings to prevail.

Some of these graduates, no doubt, hold with the Teaching University Association, that degrees ought only to be given by a University, and such views deserve, and at our hands will receive, the most respectful consideration. Indeed, the fact that the opinion of the above Association has been officially endorsed by an ex-President of the Royal College of Surgeons, serves to show that those views will find, and have probably already found, adequate expression and deliberate consideration within the Council of the College itself. For our part, we fear that if by "academic influences" the Association mean to imply such influences as are usually associated with life at a University, their expression of opinion is a mere counsel of perfection. Nothing at all comparable to such a life can ever be possible, and we

even doubt if it is desirable, for the London student of medicine. If, on the other hand, they mean that degrees ought only to be given by a University such as they contemplate, a University comprising all the Faculties, governed mainly by teachers, and itself perhaps undertaking a subsidiary share in the teaching, we may admire their ideal, but we must admit that it is hardly worth while waiting the long period that will probably elapse before its realization, when we have as an alternative a tangible proposal like that of the two Colleges. Should the London University adopt those reforms which would bring it into harmony with the notions of the Teaching University Association, and so rob the latter body of its *raison d'être*, its future medical undergraduates would not come one whit more under academic influences than they do now; and they do not now come under any academic influences worthy of the name which are not equally shared by their less ambitious or less able fellow-students. If coming under "academic influences" is synonymous with being legislated for by a senate of overworked statesmen and emeritus professors, we are inclined to think that the London student has little reason to complain of his independence of such influences. The plain fact seems to us that education at a well-found medical school is, or might easily be made, quite sufficiently redolent of academic influences to satisfy anyone but a pedant. An ordinary medical education is quite as worthy of the name of a liberal education as the course which an arts passman goes through at Oxford or Cambridge; and the relation of the Royal Colleges to the Medical Schools is a passable imitation, and might easily be made much better than an imitation, of the relation between the older Universities and their constituent Colleges. Were a new University to be started in London to-morrow, no one could fairly contend that the Royal Colleges were not fully competent to take their place in it as its Medical Faculty; and this being so, we think it would be unreasonable and pedantic to lay it down that they shall not act as such, and give degrees as such, until the Faculties of Arts, Laws and Science shall be able to organise themselves. Why should Medicine, with its completely organised curriculum and examinations, wait to receive the status it may fairly claim until that very indefinite period when the other Faculties shall be found worthy to take their places by its side?

---

#### FACTS AND FANCY ABOUT CHOLERA.

Two papers of widely different character and value on the subject of cholera are to be found this month in the magazines. Dr. Cameron, M.P., discourses in the *Nineteenth Century*, on Anti-cholera Inoculation, and Professor Burdon Sanderson, in the *Contemporary*, gives his views on the cause and prevention of the disease. The first of these articles is disappointing to those who might with reason have looked for a piece of learned and unbiassed criticism. It is throughout a defence of Dr. Ferrán's statements and his practice of inoculation, of which the public has heard so much and scientific men so little. Though, on the

face of it, it has all the clearness and plausibility of the speech of an able advocate, it cannot be said to do much, if anything, to rehabilitate the cause of Dr. Ferrán; nor will the evidence which the author has collected be held sufficient to justify the conclusion with which he sums up, viz.:—That Ferrán has discovered a hitherto unknown form of the cholera microbe, and that in that form it can be used as a vaccine hardly less potent against cholera than cow-pock is against variola.

The theoretical basis of Ferrán's teaching is that Koch's bacillus, or rather an earlier stage of Koch's bacillus, which he alleges he has discovered, is the cause of cholera. The position that the non-production of spores by this bacillus, and the failure hitherto to induce cholera artificially, militate against this view, is turned by this new statement, and by the further allegation that a virus has been found which is poisonous to guinea-pigs and to some extent to human beings. The proof of the production of spores by the so-called comma-bacillus is of course of vital importance to Ferrán's contention. This Dr. Cameron admits, for he says that on this assumption only can the phenomena of cholera-propagation be reconciled with Koch's belief that his bacillus is the cause of the disease. But in view of the many failures to find any spore-production in this case, and the extreme rarity of spore-producing bacilli, only two or three being known, the scanty evidence brought forward by Dr. Cameron cannot be said to settle this question. Dr. Cameron quotes in support of the accuracy of these observations an appendix to a recently published work by Dr. Van Ermengem, "*Le Microbe du Cholera*," where a description of Dr. Ferrán's method occurs. It appears from this that if a pure cultivation of the comma-bacillus be left to grow for a while in a sterilized soup at a temperature of 101° F., and then be removed to a similar solution at a temperature of 58° F. to which some bile is added, new forms of the microbe appear, and that a pure liquid cultivation of these, exposed to the influence of oxygen, is the anti-cholera vaccine. In further support of this statement, the Barcelona Commission is quoted as having verified and controlled the experiments of Ferrán. The same commission witnessed the effects produced on human beings by the inoculated virus, and came to the conclusion that probably a means of averting cholera had been discovered. It is, however, obvious, especially in view of the general reticence of Dr. Ferrán, which has not been denied, regarding his methods of procedure, that much more evidence is wanting before a scientific observer can admit that the spores have been found which develop into bacilli, or that the guinea-pigs which died and the human beings which recovered were suffering from cholera; and we want to know more of the composition of the Barcelona Commission and its ability to follow and check such delicate experiments, open to so many fallacies from contamination and other *contretemps*, before we accept its conclusions, which appear to be the sole external support of Dr. Ferrán's allegations.

With respect to the practical results of the inoculations in a cholera district, there is a similar want of conclusive evidence. Even taking the statistics as accurate, which is a great admission in the case of a

country like Spain, where the official census of population is often under-stated, and where scientific precision is not to be too confidently assumed, it is not at all clear that the vaccinated and non-vaccinated classes were, as Dr. Cameron says, "under precisely similar conditions and exposed to precisely the same causes of disease." It is likely, on the face of it, that those who would submit to vaccination would not be the poorest and most ignorant; and that in Alcira, as in all other towns, there are some people who live carefully and are better situated than others, and some who from their circumstances are exposed to almost every morbid influence. It would have to be shown that inmates of houses in all parts of the town were chosen for the experiments, some of each family being taken for inoculation, and the others left. Such a procedure may have been followed; but the opposite method of inoculating in batches would be more expeditious, and was more probably employed considering the shortness of the time over which the whole experiments extended. This same shortness of time, again, is an important element in the insufficiency of the data on which these important conclusions are based; and for this reason, as well as those above alluded to, the comparative statistics of this recent inoculation for cholera, and the long-established evidence in favour of vaccination for small-pox are not in very telling conjunction.

Dr. Cameron further deals, but not satisfactorily, with the obvious objection that cholera is not a self-protective disease, and that therefore protective inoculation in a modified form is not to be thought of as likely. He quotes Surgeon-Major Murray's statistics of five years' experience of cholera in the Agra Gaol as tending to prove that cholera is self-protective: nearly half of the whole number of prisoners having been attacked, while out of 857 recoveries, only one in 13·6 suffered again. But no mention is made of the relative severity of the epidemic in the different years; and it is certainly to be expected that in the later years, as is generally the case, the virulence of the affection would subside. These Agra statistics show, moreover, that nearly half of those who suffered a second time died—a fact out of keeping with Ferrán's allegation, that inoculation reduces the severity of the cases when it does not prevent them. But this difficulty is evaded by the suggestion that it does not follow that the cholera-virus falling on organs damaged by a previous natural attack will prove as little dangerous as when the first attack has been artificially contrived to fall on a totally different portion of the system. These are only some of the points which seem to us to give to Dr. Cameron's paper the appearance of somewhat biassed advocacy, or at least of premature publication. It is not of course impossible that Dr. Ferrán's teaching may be true, and his practice sound; but both are based on the theory of the causative nature of Koch's bacillus, which has been more than shaken; and of the superstructure which Dr. Ferrán has raised thereon we have as yet had no full and accurate account. There is a strong *prima facie* case against him, but no definite decision can be arrived at till precision and outspokenness take the place of rumour and reticence on the matter.

In Dr. Burdon Sanderson's paper we have an admirably clear summary of what is known for certain about the modes of propagation of cholera, and the practical aspect of this certain knowledge is set forth with a definiteness that gives great value to the article. Dr. Sanderson points out that the unbiassed intelligent reader of cholera history sees that the spread of cholera follows certain general laws: it loves great rivers, and particularly their deltas and estuaries; it can be conveyed over sea and land, and follows for the most part the lines of commercial intercourse. He declines to enter fully into the question of contagion or spontaneous origin; but teaches that it is specific in the sense of having a cause peculiar to it, which, though diligently searched for, has not been found. It is a tangible something, which can act at a greater or less distance, but remains an unknown quantity. This contagium, whatever it is, has a power of multiplying outside the body, rather than in the tissues (the disease is not directly catching from person to person), and the most important element in its production is the nature of the environment. The chief condition of its appearance in an epidemic form is probably a peculiar state of the soil, the cholera growth depending on certain physical characteristics and seasonal changes. Want of drainage is one great factor, and subsequent heat and drought another. The contagium may be swallowed or perhaps inhaled as cholera-dust, but of the latter there is no proof. The whole of this article, as being one of the clearest and most scientific expositions of our present knowledge of cholera that has yet appeared, we most warmly recommend to the perusal of those interested in the subject. To abstract it would be to spoil it.

---

#### A THIRSTY LAND.

IF Royal Commissions were but half as fruitful in practical results as they are imposing in their composition and inception, the question of the national water-supply—its sources, management and waste—might fairly claim the consideration of such a body, with an urgency scarcely inferior to that of the Dwellings of the Poor, or the Depression of Trade. There are, indeed, good grounds for thinking that such a question would be more satisfactorily and profitably treated by submitting it to a powerful and despotic central authority, which could and would legislate for the country as a whole, than by relinquishing it to the tender mercies of local corporations too often influenced by mutual jealousies, always swayed by topical selfishness, and necessarily blinded to the true proportions of the whole problem. So long as the supply of a commodity is practically infinite in amount and uniform in quality, and while it is equally obtainable by all, it matters little by what means and to what extent the individual satisfies his needs. Waste, which is always a relative term, can scarcely be said to exist under such conditions, and extravagance may even be a virtue. Unfortunately these conditions do not apply to the supply of water, hygienically suitable for drinking and domestic purposes, which is now-a-days available for the length and breadth of this country. Year by

year as population has increased, the demand for a supply of pure water, ample for all emergencies and continuous under all conditions, has grown with a rapidity only equalled by the lessened facilities for meeting it. The exigencies of commerce, the waste products of un-natural manufacturing operations, and the depurative methods adopted by crowded humanity, have most effectually fouled the waterways which once served to bring man's natural beverage pure and limpid to the lips which need only stoop to drink in safety. And in the efforts to find an equivalent for the supply which their own acts have poisoned, it is only too obvious that permanent good has been often sacrificed to present advantage. Local needs have been satisfied at the expense of more distant neighbours, or by means which merely provided a temporary stop-gap with a prospective increase of future difficulties; while no sufficient thought has been given to the maintenance of the natural reservoirs which are thus being drawn upon, and no special care taken with regard to ensuring their regular replenishment. At least we may say that when these questions have of late received, or been forced upon, the consideration of thinking men capable of judging them fairly, the result has been astonishment that a recklessly ignorant waste has so long escaped its inevitable penalty, together with ominous forebodings as to the future, unless the magnitude of the problem be realised at once, and earnest endeavours made to cope with it *as a whole*.

It is no credit to Englishmen that the climate which their country enjoys is one—despite all its detractors may say—which makes a national water-famine appear a contingency almost impossibly remote. Famine is perhaps a specially unfortunate word to apply to a condition whose essence is thirst. The physiological needs expressed by hunger can be satisfied by bread; and this bread may be of very varying quality. But there is only one quality of water recognised by the sanitarian as suitable for quenching thirst—for which purpose all other kinds of water differ only as do the Dead Sea and the City Sewers. However large a man's income may be, he will be penniless if it be all squandered before it can come into his pockets; and though the yearly rainfall of this country may be more than ample for washing all the bodies of its teeming population, both inside and out, with an abundance of pure water, statistics of this sort will not fill the cistern, or flush the sewers. While the showers are hurried from the surface of the over-drained soil into ditches and streamlets, and carried off-hand to the sea by rivers suddenly flooded with storm water, the deep wells of water companies, breweries, factories, and private owners are lowering foot by foot and year by year the water-level of the great natural subterranean reservoirs. Hence it is that last year's drought was felt so severely and so widely; hence the fact that a comparatively dry winter and spring failed to fill the deep wells of the country—whose water-level indicates that of the deep strata which they tap—as was needed; and hence the threatening of a "water-famine" of at least equal severity during the present autumn.

So long as it is only country districts, always largely

dependent upon surface-pools and wells, which suffer, we might afford to regard the matter with selfish indolence. But the imminent peril incurred by such populous centres as Manchester and Bradford last autumn, was a warning that ought not to have been overlooked. At the present time the stock of water in the Liverpool reservoirs is calculated to last only a few weeks; and the new supply from Vyenwy will not be available for several months to come. It has been officially stated that Newcastle-on-Tyne can reckon upon barely another fortnight's supply from its reservoirs, and the necessity for pumping water from the Tyne itself for domestic purposes has to be considered. Many other towns must be in a scarcely less enviable plight; for Fortune never comes with both hands full, and the absence of the thunderstorm, which might have laid the farmers' corn, has at the same time withheld even that precarious moisture from the parched meadows and dried-up ponds. We would be no alarmists, though, at the present time, no one could think of one or more of our great sea-ports being absolutely deprived of its usual water-supply without feelings of the gravest apprehension. Even if we had not reason to remember that England stands before Europe as the champion of home and personal cleanliness *versus* sanitary cordons and protective inoculations, we might well be humbled that such things can be, and anxious for a remedy. The latter, to be of real and permanent efficacy, will perhaps imply the reversal of some of our present procedures. Certainly the source of the country's fresh water supply should be carefully studied; the method and the *locale* of its natural storage need to be better understood, and, as far as possible, mapped out for the whole country; care should be taken that these natural reservoirs are not tampered with or unduly drawn upon, and that their adequate and regular replenishment is not interfered with. The storage of rain-water should be encouraged, and in towns be made to a certain extent compulsory. And every large community, unless possessed of an adequate *permanent* water supply, should be compelled to provide itself with reservoirs of a certain capacity in proportion to its population, so as to allow of a supply ample for all probable emergencies, and the proportion of water-reserve to population should be subject to quinquennial revision. The matter should, in fact, be recognised as one of national importance, and it should be managed as such by a central authority, with the assistance of skilled local representatives. Water-works would then be less likely to fail at the very time when they are most needed; the river-water, which was regarded as dilute sewage during the winter floods, would not have to be resorted to as a beverage in the summer drought; and we should be spared the spectacle of a city in danger of thus drinking itself to death.

---

#### THE GLASGOW SOUTHERN HOSPITAL.

It was announced a short time ago in the Glasgow newspapers that the Committee who have charge of the erection of this hospital have decided to commence building operations at once. The decision to erect a new hospital on the south side of Glasgow was taken at a public meeting, held

in April, 1881. It was stated at that meeting that considerable sums of money had already been promised for the building. A legacy was left for the same purpose by the late Mr. Cowper, of Cathcart. It would appear, however, that verbal support has been more freely given towards the project than pecuniary assistance; for, after more than four years, only 7,000*l.* have been accumulated to meet the requirements which, if the original proposal of a hospital of from 100 to 120 beds be carried out, amount to not less than 30,000*l.* In face of this, however, the Committee are taking plans for the erection of a part of the hospital capable of accommodating 60 patients, and mean to proceed with the work. The outlay involved in building the part contemplated, including the purchase of the site, is estimated at 20,000*l.*, but the Committee hope that the actual progress of the building will stimulate public interest, and cause the necessary money to flow in.

We venture to doubt whether the Committee are drawing the true lessons of time from these past four years. One would naturally be tempted to conclude that, if the public interest needs stimulating by the sight of a hospital rising up for the payment of which there is at hand only a third part of the money, and for the maintenance of which nothing is yet provided, the call for the hospital cannot be so great as was declared at the public meeting in 1881. Whether there is any great call for it, at least on the part of the public, we are not convinced. Glasgow has already two large hospitals on the north side of the river, the Royal and the Western Infirmaries, having between them 932 beds. The Western Infirmary has to-day 50 beds more than it contained in 1881, that is to say, half of the addition proposed to be made by the south side hospital. And since that date, the Hospital for Sick Children, containing 57 beds, has been erected. Thus, since April, 1881, an addition to the hospital accommodation of Glasgow, amounting to 107 beds, has been made. If the added accommodation of the proposed southern hospital was supposed to be sufficient to meet the requirements of Glasgow, and this was practically said at the public meeting, then that accommodation has been already provided without it. This does not, however, exhaust the total beds available. The Eye Infirmary, the Ophthalmic Institution, the Institution for Diseases of Women, and other smaller institutions have to be taken into account. Among them they contain altogether upwards of 1,100 beds. It must also be remembered that each one of these institutions has connected with it a dispensary for out-door patients. Between in-door and out-door patients it will be found that the number of cases receiving the benefit of medical charities in Glasgow scarcely falls short of 100,000. The population of Glasgow and suburbs, at the last census, was 704,436. In these figures no account is taken of the Corporation hospitals, the Belvedere Fever Hospital, for example, nor of the arrangements of the Parochial Boards.

If the question is looked at from the financial point of view, the propriety of proceeding with the new hospital seems still more dubious. In 1884 the ordinary income of the Royal Infirmary was 18,810*l.*, and the ordinary expenditure was 24,907*l.*, an excess of expenditure over income of 6,097*l.* This excess had, of course, to be met out of the extraordinary income, consisting of legacies, &c., and intended for the endowment of the hospital. The same tale is told by the Western Infirmary treasurer. The ordinary income was 13,359*l.*, and the ordinary expenditure 18,589*l.*, showing a deficit of 5,230*l.*, also met out of the legacies of the year. The only conclusion to be drawn from these facts is that the establishment of a third hospital is likely

still further to reduce the annual income of the two existing infirmaries, while it is not likely itself to be in a position to meet its expenditure. This is more than admitted by one of its promoters, who in 1881 said, "Existing infirmaries were greatly indebted to the gentlemen of the southern districts, not only for large contributions to their building funds, but also for their endowments and annual support. To go no further than last year, he would remind them that the late Mr. Dixon bequeathed 10,000*l.* for the sick poor on the south side of Glasgow, and that that money went to the existing infirmaries, because they at present attended to the sick poor of the southern districts." How Dr. Duncan, who made these remarks, conceived they were an argument in favour of the proposed southern hospital we do not understand. To our mind they afford a strong reason for refraining, at least in the present condition of affairs, from pressing forward the proposed new infirmary. Indeed it seems to us that, in view of all these facts, the wisdom of the committee is open to grave question. If additional hospital accommodation is required, and if an additional building can be maintained, we do not dispute the claim of the south side to have it erected in their midst. But we do object to a hospital being erected in the hope that the public will be stimulated to pay for it, when it can count on "no visible means of support," and when there seems no necessity for its establishment.

We would suggest, and we should be glad if the suggestion received some consideration from hospital managers and directors, that the time has come for some organization of medical charities in Glasgow and similar large cities. At present two or three persons only require to put their heads together and straightway establish an institution for the treatment of some disease or other, appealing to the public for funds. In large cities like Glasgow there are a multitude of medical charities working independently of one another, and often in antagonism. If some sort of co-operation could be arranged, and if all such charities could be brought under one central superintendence, the public would be more thoroughly, and at the same time more judiciously, served.

## REVIEWS AND NOTICES OF BOOKS.

---

*The Middlesex Hospital Reports of the Medical and Surgical Registrars for 1883.* London: H. K. Lewis, 1885.—This volume is decidedly late in appearing, but that is a fault not peculiar to the registrars of the Middlesex Hospital, and possibly if the matter were investigated it would be found that they were not at all behind their fellows in this respect. Dr. Pringle, the medical registrar, has expended his energies chiefly on a full and elaborate report on the epidemic of typhoid fever which prevailed in the year in question. During the progress of this epidemic, 115 cases were taken into the hospital, 62 males and 53 females; of the former 4 and of the latter 14 died; of 21 cases occurring in children under 10, none proved fatal; whilst of 42 cases in persons between 30 and 40, as many as 10 died. The Middlesex Hospital may be regarded at present as the home of the bath treatment of typhoid fever—at any rate, so far as the general hospitals are concerned—and Dr. Pringle devotes a considerable amount of

space therefore to an examination of the results of this treatment. His conclusions, which are put forward with all due caution, are decidedly in its favour; a table is appended containing a detailed report of the individual cases. The medical registrar also appends tables of the cases of acute tuberculosis, and of the more interesting of the cases of disease of the nervous system that presented themselves during the years. One of these illustrates the caution that is necessary in dealing with the *succus conii*; a man with spasmodic torticollis, who had suffered much at the hands of the surgeons without any permanent benefit, was being treated with this drug with somewhat heroic doses; 4 ozs. daily had been reached, when a sudden loss of power in the limbs necessitated the suspension of the drug for a few days; it was resumed in diminished doses, when, a week later, having taken his daily dose of 2 ozs. at 5 a.m., at 5.15 a.m. he called out that he was dying. "His face was pallid, beads of perspiration stood upon his forehead, the spasmodic movements of his head and arms were very violent. In ten minutes he became cyanosed, respiration ceased, his heart continuing to beat for a minute afterwards." The cause of death was recorded as doubtful. The Surgical Registrar's report is mainly taken up with tables of the various forms of cancer, sarcoma and other malignant growths of which the special beds at the hospital afford such an enormous number. This portion might, however, have been somewhat curtailed without any diminution of its scientific value; for instance, on page 245 there is a list of the previous diseases from which 37 patients with cancer of the uterus said that they had suffered, from which we glean the deeply interesting information that one of these unfortunate persons had previously been afflicted with dyspepsia, whilst another had had the misfortune to suffer from bronchitis. On the same page there is an equally valueless list of the cause of death of the father in 29 of the cases; and as if for the sake of spinning out his material, Mr. Williams makes a distinction between head injury and accident. It would be ungracious, however, not to recognise that the detailed reports of the cases in the several tables represent an immense amount of hard and good work, which will probably prove useful to some subsequent investigator of this subject. Dr. Fowler's pathological report, with which the volume closes, deals with 294 *post mortems*, and certainly does not err on the side of diffuseness, but it does not call for special comment at our hands.

*Tracheotomy in Laryngeal Diphtheria; After-Treatment and Complications*; by ROBERT WILLIAM PARKER, second edition. London: H. K. Lewis, 1885.—This is a very valuable little book on a most important subject, and we infer with great pleasure from the appearance of a second edition, that the public have realised the truth of these two facts. The book being mainly directed to one point in reference to the disease, the author is necessarily brief in dealing with the nature of diphtheria; but the chapter relating to this portion of his subject, which has been entirely remodelled, contains a clear and concise statement of current opinions. Of course, the chief part of the book is taken up more or less directly with the operation of tracheotomy. The reasons for the operation, the indications for it, and the contraindications to it are minutely discussed. The time for its performance and the several steps of the operation are separately detailed. The after-treatment, which, as the author shows, is of such extreme importance in helping to a successful issue, is fully considered, as well as the various complications that may arise, and the mode of dealing with them, especial reference being made to the difficulty sometimes experienced in removing the tube permanently. Mr. Parker's aphorisms on pp. 32 and 33 will meet with the entire approval of those who have had any experience of the operation. The printing and binding deserve a passing word of commendation, nor can we close this notice without referring to the very effective manner of emphasising important passages which Mr. Parker has borrowed from the Germans.

*Nouveau Dictionnaire de Médecine et de Chirurgie*. Sur la Rédaction du Dr. JACCOUD. Paris: J. B. Baillière et Fils. Vols. XXXVI., XXXVII. 1884, pp. 847, 906.—The regularity with which the volumes of this huge dictionary make their appearance is something to be recorded. Notwithstanding this regularity, a long time has necessarily elapsed since the work was commenced, but those who have been subscribing from the first will doubtless now begin to feel that there is every chance of a speedy completion of the work. Dr. Jaccoud and his many collaborateurs are to be congratulated on the near termination of their arduous labours. The first of these volumes is largely surgical, and contains articles on the trachea, tracheotomy, tumours, transfusion, and on the trephine and trephining. This volume likewise contains a very long detailed account of typhoid fever. The subjects dealt with in the second volume are even fewer than those in the first. The uterus occupies more than the concluding third of the volume; the urine in health and disease and diseases of the urinary passages taking a somewhat larger portion out of the middle of the book. These are preceded by a somewhat lengthy article on the urethra and its diseases, whilst articles on typhus fever and uræmia practically conclude the list of contents of the volume. It is impossible in the space at our command to attempt any critical analysis of such a series of monographs as is contained in these volumes. We need only say that each is written by an able author, who has spared no pains to enter fully into the "spirit" in which the dictionary was started, viz., that it was not to be a mere compilation, but "rather an analysis of the best French and foreign 'masters,' impressed with the critical yet enlightened individuality of the author." We may add in conclusion that the volumes are sold separately at 10 francs apiece.

*Surgical Delusions and Follies*; by Dr. JOHN B. ROBERTS, Philadelphia: Blakiston, Son & Co., 1884, pp. 55.—This is a revised reprint of an address in surgery delivered before the Medical Society of the State of Pennsylvania. The author, in a few short paragraphs, discusses "under the caption 'Surgical Delusions,' his personal appreciation of some of the doctrines held and taught by surgical practitioners of the day." Chloroform, value of styptics, delay in operating in strangulated hernia, in malignant disease, and a host of kindred subjects are discussed from a very original standpoint, and divested of the halo of tradition. To mention only one—the dose folly; our author says, "I should, perhaps, term it the *small* dose folly, for I refer to the practice of administering insufficient doses of medicine. . . . If any medication at all is required give that which will do the work and do it promptly. A few large doses will dispel the symptoms and cure the patient, when months of nonsensical drugging with emasculated remedies will bring nothing but discredit to the practitioner and obloquy to medical science." This quotation is a fair sample of the author's criticism on what in many instances, he is quite justified in styling "delusions and follies." We recommend this little book to our reader's attention.

*Modern Pessimism: its Cause and Cure*; by CHARLES WILLIAMS, Physician. Bodmin: Liddle & Son, 1885.—This is a well meant little treatise, and we hope it may do some good. Dr. Williams is mistaken in his belief that he is the first to call attention to the modern growth of the disease of pessimism, as he may convince himself if he will consult an article entitled "The Age of Melancholy," published in the *Medical Times*, January 12th of the present year. A still earlier account of the matter, however, may be found at p. 199 in Cheyne's "English Malady," published in 1733. According to Dr. Williams, the treatment of the disease properly comes within the province of the cleric rather than of the medical profession, and it would therefore be out of place to discuss it in the present notice. As the author has himself suffered from the symptoms he describes, and successfully recovered, his description of its symptoms may be read with interest.

## ABSTRACTS AND EXTRACTS.

### NEAVE *versus* HATHERLEY: OPINIONS OF THE LAY PRESS.

THE *Times* thinks that the action is not without its lessons in reference to the alteration of the Lunacy Laws, long promised, which cannot be much longer withheld. The law requires two certificates, signed by medical men who must examine the patient separately, and who ought not to be connected with the asylum to which he or she is to be consigned. In some of the actions against doctors which have lately been tried there have been facts suggestive of negligence or of collusion from which it was impossible to escape; and, under the present system, such instances must now and then arise. In the great majority of cases there is nothing of the kind. . . . It may be a question whether, if the medical certificate in some form is to be retained in future legislation, some protection ought not to be afforded to the doctors who are called upon to sign. Unless something of this kind be done, none but raving maniacs will be placed under restraint; and hundreds of so-called temper cases, with or without delusions, will be suffered to lapse into incurable insanity.

The *Daily News* says:—In all respects, except the Jesuit and some other crazes, Miss Neave appears to have been a person at least of ordinary prudence and intelligence. "Don't send her yet to a lunatic asylum, because it might topple her over," said Dr. Hatherley to Mrs. Neave some weeks before he signed the certificate. The very fact that Miss Neave did not "topple over" in consequence of her imprisonment among lunatics, idiots, and imbeciles, says something for the strength and soundness of her mind. The very worst that might be said of Miss Neave was that she stood somewhere on the border line between eccentricity and lunacy, and ran some risk of transgressing it. She was still on the right side when Dr. Hatherley warned Mrs. Neave against doing anything which might "topple" her daughter over; and the jury are of opinion that she was on the right side weeks afterwards, when the doctor formally certified her unsoundness. Yet the jury have acquitted Dr. Hatherley, from whom Miss Neave claimed two thousand pounds damages. We do not see how the jury could have done otherwise. There is not the ghost of a shadow of evidence to show that Dr. Hatherley could have profited by his testimony in any way whatsoever; or that he acted otherwise than honourably and according to the best of his judgment.

The *Standard* admits that, so far as the evidence went to prove, there was not the slightest ground for believing that in granting the certificate which deprived Miss Neave of her liberty, Dr. Hatherley was actuated by any motives of an unprofessional character. He believed, to the best of his judgment, that the lady before him was of unsound mind, and certified accordingly. As a matter of fact he was, in the opinion of the jury, wrong; but all the evidence adduced tended to show that he acted with due care, and could not, therefore, be held guilty. Any other decision would render the duties of a physician under the Lunacy Act too dangerous to be undertaken. The result would be either the abrogation of the present system altogether, or the certainty that the signing of the certificates necessary in these cases should fall into the hands of a class of medical men whose interference in such delicate matters is far from desirable. The first contingency, no doubt, is earnestly sought by the Lunacy Law reformers, and we are not prepared to say without good cause. But as the latter is the only one with which we have to deal at present, the acquittal of Dr. Hatherley, though to the non-legal mind somewhat illogical, was sound in law. . . . Mental disease is a specialty cultivated by a few practitioners, whilst the particular points to which they usually direct their attention come just as readily within the province of a shrewd lawyer or a common-sense layman as of a medical man. To shut up a sane person among madmen is a frightful responsibility to incur. It is a fate worse than death to the victims, and is very likely to precipitate what it is intended to cure. In the interest, therefore, of all

parties concerned, such a momentous decision ought to be relegated to a broader tribunal than two doctors, who, with the best of intentions, may be extremely unfitted for the task they have undertaken, or who, though nothing of the kind was suggested in the present case, may be unwittingly lending themselves to a criminal conspiracy.

The *Daily Telegraph* says:—Nobody can tell that at some time or other he or she may not in the eyes of some relative or some medical practitioner develop a strangeness of conduct which, unless the safeguards we have spoken of be sufficient and be rigidly applied, may be used as the ground for lifelong confinement. It is not in the least degree surprising that a great amount of public feeling hostile to private asylums, and condemnatory of the means taken to fill them, should exist, or that the public should be crying out for additional precautions to make sure of the lunacy of persons branded as insane. It is, of course, highly desirable that physicians should not rely on the reports of relatives, but should themselves make impartial and prolonged investigations; yet, after all, the public will never be satisfied until this duty of mental examination be thrown upon physicians of eminence who have made the brain a special study, and until the opinion of lunacy so formed be confirmed by the judgment of some impartial Board, consisting of shrewd men who are not doctors. The law of private asylums must also be radically changed, and the inspection of the insane must be frequent and thorough, while every possible opportunity must be given to patients to prove their sanity. Medical science is confessedly ignorant of the precise line separating sanity from insanity, and doctors cannot be offended when the public demands that the very strongest barricades be erected at the entrance gates of asylums, public and private, to prevent all but the really diseased in mind from having a chance of being admitted.

The *St. James's Gazette* hopes that the fate of Miss Neave may warn eccentric people who have been locked up in madhouses that mere proof of their sanity is not enough to entitle them to compensation from the doctors who signed certificates against them. Doctors are human, and we cannot ask more of them than that they should be reasonably skilful, thoroughly careful, and completely honest. If, as will inevitably happen from time to time, while fulfilling all these requisites, they make mistakes, it is a misfortune, but one which cannot be avoided. We are sorry for the victims; but we must not on that account compensate them at the expense of those who have done no wrong. For, if we did, the result would be that no doctor would sign a certificate, and that all lunatics would go at large; which would be a much greater evil than even the temporary undeserved imprisonment of such persons as Miss Neave.

THE SURGICAL TREATMENT OF CYSTS OF THE PANCREAS.—Of all abdominal organs the pancreas has been least frequently subjected to surgical treatment, for which the anatomical location of this organ, and the obscurity of its affections, furnish a sufficiently satisfactory explanation. Situated high up in the abdominal cavity, and hidden behind such important organs as the stomach, omentum, and transverse colon, it is the least accessible of all abdominal organs, and on this account its affections, wrapped in obscurity, have for the most part constituted objects for empirical medication. The relation of this gland to the surrounding organs, and its great distance from the anterior wall of the abdomen, the only point of approach, necessarily offer serious obstacles to diagnosis and direct treatment. From a diagnostic point of view another great difficulty is our want of positive knowledge concerning the physiological functions performed by this gland in the process of digestion. As the symptomatology of all affections of the pancreas is always obscure, and a probable diagnosis can only be made in cases where the gland has become considerably enlarged by disease, it is apparent that our present clinical knowledge is limited to diseases which increase the size of the organ to a sufficient extent to permit its detection by palpation. Primary malignant disease of the pancreas, when it has advanced to such an extent that its presence can be diagnosticated with

certainty by physical signs, will have invaded the adjacent tissues to such a degree as to preclude the advisability of an operation, consequently the efforts by the surgeon, for the present at least, must be directed exclusively toward the recognition and treatment of benign affections of this gland. Clinical experience does not extend beyond an imperfect knowledge of cysts of the pancreas. The pancreas, like other secretory organs, is prone to become the seat of cystic tumours, the result of obliteration or obstruction of the common duct, or one or more of its branches. Cysts originating in this manner are true retention cysts, containing the physiological secretion from the distal portion of the gland tissue, with perhaps accidental products, such as altered secretions, blood, and the products of inflammation. In a very valuable paper on the surgical treatment of cysts of the pancreas, Dr. N. Senn, of Milwaukee, in the July number of *The American Journal of the Medical Sciences*, presents a full report of a case of retention cyst of the pancreas which has recently come under his observation, and, at the same time, summarizes, in a compact form, the clinical history of similar recorded cases which serve as a basis for some general remarks. In recapitulation, Dr. Senn submits the following conclusions:— (1) Cysts of the pancreas are true retention cysts; (2) cicatricial contraction or obliteration of the common duct or its branches, and impacted calculi are the most frequent causes of cysts of the pancreas; (3) a positive diagnosis of a cyst of the pancreas is impossible, a probable diagnosis between it and some other kind of cysts amenable to the same surgical treatment is adequate for all practical purposes; (4) the formation of a pancreatic fistula under antiseptic precautions recommends itself as the safest and most expedient operation in the treatment of cysts of the pancreas.

**LATERAL INCISION FOR THE PREVENTION OF RUPTURE OF THE PERINEUM.**—Drs. Credé and Colpé, of Leipzig, are the authors of a paper on this subject which appears in the *Archiv für Gynäkologie* (Band XXIV., Heft 1). They discuss the practice of incising the perineum laterally in order to prevent its tearing centrally. The objections brought against it are these: (1) That the incision becomes an ulcer, and disturbs the healthy course of the lying-in. This they prevent by bringing the edges of the incision together by suture, with the result that primary union almost invariably follows. They have devised an ingenious method for applying this suture, but without the assistance of diagrams it is difficult to make this understood; we must therefore refer our readers to the paper, where they will find illustrations that make it perfectly clear. (2) That germs of disease may enter through the wound. In this respect the prospect is no worse than that from a torn perineum. Injury to the perineum only to a slightly appreciable extent increases the lying-in woman's chance of disease or death. Out of 2,000 deliveries in Leipzig, among those with uninjured perineums the death-rate was .954 and the morbidity 2.94 per cent.; among those with torn perineums the mortality was .934 and the morbidity 3.24 per cent. (3) That the incisions do not invariably prevent perineal rupture. To meet this the authors give a table of the percentage of cases in which lateral incisions were made, and of those in which rupture of the perineum occurred, in the practice of five different assistant physicians; and the table shows that the frequency of incision and the frequency of rupture stood in inverse proportion to one another. They also state that since incision has been practised, not a single case of complete perineal rupture has occurred. (4) That the cutting is painful; to which the authors reply, that it is done when the patient is already in much pain, so that she does not notice it. (5) That it leads to subsequent gaping of the vulva. This our authors deny. They believe, in short, that the lateral incision is extremely useful and absolutely harmless. We may add, in order to give an idea of their practice, that in primiparæ, lateral incision was practised in 25.9 per cent., spontaneous rupture took place in 10.4 per cent., and rupture in spite of incision in 2.9 per cent. In multiparæ, the corresponding figures are: lateral incision, 1.2 per cent.; spontaneous rupture, 2.4 per cent. They give figures also which show the influence of perineal

ruptures in causing illness during the lying-in period. The percentage of primiparæ, whom it was necessary to keep in the hospital longer than a fortnight, was 23.1 among those with perineal cuts or tears, 11.4 among those in whom the perineum was uninjured. In multiparæ it was only 6.8 per cent. The authors recommend that the incision should be made just after the acme of a pain, *i.e.*, just as it is beginning to pass off.

**HYPODERMIC INJECTIONS OF ETHER.**—In adynamic pneumonia, when there is considerable depression of strength and the ordinary means having been exhausted, while the patient is menaced by asphyxia, Dr. Barth injects hypodermically a Pravaz syringeful of sulphuric ether, repeating it a second, third, or even a fourth time in the day in bad cases. These injections render the cough easy and allow the bronchi to clear themselves. They may be inserted at the external side of the thighs, the back or sides; and they give rise to a sharp burning sensation which, however, soon subsides. Dr. Féréol employs these injections whenever he has to do with excessive debility consequent on hæmorrhage, typhoid fever, &c. He regards them as a valuable means of restoring life to patients who are exhausted and threatened with speedy death. Dr. Moutard-Martin has used them with success in the algidity and cramps of cholera.—*Union Médicale*.

**THE PNEUMO-COCUS.**—It having been questioned whether the capsule surrounding the pneumo-coccus is constant, Foà and Rathone (*Giornale Intern. d. Sc.*, No. 4) have made a number of observations on the subject by means of injecting cultivations into the serous cavities and subcutaneously. They find that the coccus is invested by a capsule, which is capable of being stained while the coccus itself is not. They also found that the cocci were conveyed to distant parts of the body by the lymphatics, that meningitis was produced by infection of the Schneiderian membrane with a sterilised needle, and that abortion followed injection of the gravid uterus with abundant development of the cocci in the uterine sinuses.

**PARTHENIN IN MALARIAL NEURALGIAS.**—Neuralgias of malarian origin will, according to Dr. Esperon, writing in a Habana medical journal, often yield to a medicine named *parthenin*, extracted from an indigenous plant called *escoba amarga*, bitter broom. He describes cases in which all the ordinary drugs were useless, or produced only temporary benefit, while parthenin, as soon as it was given, gave great relief, and was followed by a lasting cure. The mode of administration is in pills, of which twelve contain two grammes of the drug, one being ordered every two hours. The cases mentioned include ovarian neuralgia, coccygodynia and facial neuralgia.

---

## NOTES ON FOREIGN HEALTH RESORTS.

---

### "NASSAU" (NEW PROVIDENCE).

A CHAIN of islands, Cays and rocks 600 miles in length, stretch from the coast of Florida, as far south as St. Domingo. They separate the waters of the North Atlantic from the Gulf of Mexico, and form a barrier to the mainland. They barred the passage of Columbus on his first voyage of discovery, and one of the Bahama group was the scene of his landfall. They are now English possessions, having long ago been wrested from the Spaniards, by whom they were reconquered, to be restored again. Their history is a very curious one, and not very edifying, as in the olden time the islands were the resorts of the pirates of the West Indian seas, and in late days they furnished a safe harbour for the "blockade runners" who availed themselves of the misfortunes caused by the great war between the Northern and Southern States of America. The formation of all the islands is the same, calcareous rocks of coral and shell, hardened into limestone, honey-combed and perforated with innumerable cavities, without a trace of primitive or volcanic rock. The surface is hard

as flint, and emits sparks when struck with steel. The shores are generally low, and the highest hill in the whole group is said to be only 230 feet in height, and it is remarkable that, with the exception of one island, no stream of running water exists, the inhabitants being supplied by wells which are sunk to a depth, where the rain filtering through the surface rests upon salt water, the contents of the well rising and falling with the tide upon the neighbouring shores. The timber of the Bahamas is valuable, and includes mastic, lignum vitæ, and mahogany. The fruits are abundant, in particular the pineapples equal any grown in any part of the world, and the fertile, although thin soil, will furnish crops of vegetables with extraordinary luxuriance. Tobacco flourishes as a link between food stuffs and medicines, and among the latter are to be found castor oil and cascarilla. The animal life throughout the Bahamas is restricted. When the Spaniards first arrived, they found no animals excepting a race of dogs that did not bark, and a small kind of coney. The birds of the islands are mostly birds of passage; they include wild geese, ducks, flamingoes, pigeons, hawks, green parrots, doves, and the beautiful humming-bird. As for the waters, they swarm with fish, and the turtle of the Bahamas is considered super-excellent. The reptiles of the sea or land are not numerous, and consist of the monstrous-looking lizard, "the Guana," and an occasional alligator sometimes found on the shore of some desolate Cay. In spite of the ugliness of the Guana, justice must be done to its good qualities, for it furnishes a pie of excellent flavour. Insect life is very busy, and the climate is very suitable to the tastes of spiders, chigoes, centipedes and mosquitoes. Of the Aborigines little is known, and none now remain, as the Spaniards coaxed all they could to be carried away to work the gold mines of St. Domingo, and those they could not coax they hunted down with bloodhounds.

Of all the Bahama islands, there is but one which can be noticed as "a health resort." It is the island of New Providence, and Nassau is the capital of New Providence, and of the Bahamas generally. It gained its position by accident, for it has no particular merit of its own, and it kept it by the lucky circumstance of having a long low bank stretching for three miles along its northern face, leaving a strip of harbour, from half to three-quarters of a mile in width, with an opening at either end, by one of which a pirate vessel could escape should a Government cruiser enter at the other. And at Nassau government was first established when the pirates were exterminated, and all that there is of commerce and of trade centres in the pretty little town. Not that there is very much of either. The islands might have been well-named the Unfortunate islands. Nature has done much for them, but somehow man has never been able to make use of her gifts. Cotton and sugar growing failed even in the old days of slavery, and although great efforts have been made of late years to introduce fresh industries, they have not been remarkably successful. Fruit preserving has not paid well. The sponge trade has not flourished of late, and the salt manufacture has not been remunerative. It is said that America looks with no favourable eye on the produce of the Bahamas, and puts a heavy duty on their exports, and this may be possible, for during the great war between North and South, the Northerners are credited with the threat that they would come down and shovel New Providence into the sea. It would have been difficult, for New Providence, which lies in 25° 29' North and longitude 76° 34' West, extends 21 miles from east to west, and measures 7 miles in breadth from north to south. It is not a beautiful island by any means, for it is nearly covered with pine trees and brushwood, intersected by marshes and lagoons, and traversed by a central chain of hills some 80 feet in height; but Nassau, the capital, is a bright and pretty little town. It is a quiet "sleepy-hollow" sort of place, with a bright sun always shining on its pure white streets, and the blue sea for ever sparkling and dancing in their front, and the harbour is generally alive with pretty little schooners just back from one wreck, or starting for another.

Nassau proclaims its maritime character unmistakably. Its stores are full of rope and pulleys, tar, red-herrings, and tinned provisions, while the street trade consists in the sale of sticky confectionery, pine apples, and sugar

cane, conducted by dusky-coloured women, wearing the brightest of turbans and the gaudiest of cotton prints. Towards evening the city brightens up; the one road along the harbour front, three miles in length, is gay with every variety of the "one horse shay," and the waters are studded with pleasure seekers, rowing or sailing, until sunset, for the night dews render it dangerous to take the air in the delicious moonlight. The population of New Providence in 1881 was 11,653, and as to race, 94½ per cent. were returned as natives, 3 per cent. as Africans, and the remaining few mostly either of English or American birth. The population of the whole of the Bahama group in 1881 was only 43,521, and the ratio of births per 1,000 was 36.44 and of deaths, 21.75.

The claims of Nassau to be reckoned as a "health resort" date from long ago. The first reference to the salubrity of the islands was made by Peter Bruce in 1732. He wrote: "The Bahama Islands enjoy the most serene and the most temperate air in all America; the heat of the sun being greatly allayed by refreshing breezes from the east, and the earth and air are cooled by constant dews which fall in the night, and by gentle showers which fall in their proper seasons, so that they are free from the sultry heats of our other settlements. They are as little affected with frost, snow, hail, or the north-west winds, which prove so fatal both to men and plants in our other colonies. It is therefore no wonder the sick and afflicted inhabitants of those climates fly hither for relief, being sure to find a cure here." And as it was when America was ruled by England, so is it now, and Nassau is the health resort of a goodly number of our cousins of the United States. The visitors are chiefly those who suffer from or have cause to fear pulmonary disease. Statistics were formerly rather loosely kept at the Bahamas, but there is no doubt that among the natives the proportion of deaths from lung disease has been always much smaller than in England, although the proportion of all deaths to population is unfavourable to the Bahama islands. There is one remarkable exception, in the fact that the African troops of the West Indian regiment suffer terribly from pulmonary disease, while serving in Nassau during the winter season. Staff-surgeon Watson noticed this as long back as 1827, and many medical officers have since referred to it. Some have attributed the disease in part to the faulty dress of the troops, but the principal cause is probably to be found in the habits of the African soldiers. When a black Zouave asks for a pass, it is pretty sure to be a night pass, and the night is passed in the slums of Grant's Town. For Grant's Town and Nassau, although adjoining, are two very different places, and have distinct climates. A second low range of hills divides the two townships, and civilisation occupies the northern portion, which is but narrow and bounded by the harbour, while Grant's Town is the home of the dusky races, half or wholly African, who herd together on the southern side in wretched hovels, huddled together on a swampy soil, poisoned by decaying vegetable matter, and rendered more impure by absence of drainage, and water contaminated by sewage. In Grant's Town, intermittent fever has its home and immorality is rife. But if there are two climates in New Providence, so also are there two seasons, and it is only during the winter that Nassau claims to be considered a health resort. If we examine the subjoined table, we can understand why Nassau may be a delightful place during four or five months

Month.	Thermometer at 9 A.M.			Wind at 9 A.M.				Rainfall on ground in month.
	max.	med.	min.	Four chief points in order of prevalence.				
January ...	75	70	66	N.E.	E.	S.E.	N.	2.4

Heavy rains

in the year, and intolerable during all the rest. The table shows the temperature, the prevailing winds, and rainfall in each month, being the mean of daily observations on week days for ten years.

Sir J. Clark, when comparing the climate of Nassau with that of Barbadoes, remarked that the winter of the former is nearly 6° and the spring 2° colder than the same seasons in the latter island, while the summer of the Bahamas is 2° warmer than that of Barbadoes, the autumn temperature at both places being about the same.

The following observations with regard to the winds and clouds at the Bahamas are taken from Governor Rawson's reports. He observed, first, that the highest winds usually prevail in November and January, and the average from October to March inclusive considerably exceeds the average of the remaining six months. Secondly, that the differences between the observations as to the direction of the wind taken in the morning and afternoon are not of sufficient importance to disturb the calculations based on those of the earlier hour. Thirdly, that north-easterly and easterly winds are the most prevalent from September to February, during which months they blow during one-half or two-thirds of the whole time. Northerly winds seldom blow except during those months, and then only for three days in a month. In June to August, the average is less than a day. Easterly and south-easterly winds prevail chiefly from March to August; south-westerns are most prevalent in February and March, to the extent of two or three days in a month, and during the rest of the year of less than a day monthly, and from November to March about two days in a month. The density of clouds does not vary much throughout the year, but is rather greater from May to October than during the other six months. In the autumn, fogs in the mornings and evenings are common. The mean annual degree of humidity was recorded by a medical officer on the staff as 73.3 during the year that he was stationed there, and the mean height of the barometer for a series of years is given as exactly thirty inches. What curative effect is caused by a winter residence at the Bahamas is still a matter of doubt. Sir J. Clark said, "The climate is not suited for consumptive patients, on account of the rapid changes of temperature, and the prevalence of winds, often of a dry cold character." At the same time, he remarked, "Persons for whose cases a warm climate is indicated, may pass the winter in the Bahamas safely; and residents in the West Indies might derive considerable benefit by a change to these islands for a few months during the season."

A medical practitioner of high standing, long resident at Nassau, insists strongly upon the advantages afforded by the equable temperature and small rainfall of the winter months, and describes the general variations of temperature as little more than 10°, the absence of the land winds reducing the difference of day and night to less than four degrees of temperature. In former days when white troops were stationed at Nassau, they suffered terribly at times from malaria during the summer months, but were healthy during the winter season. However, no one would dream of selecting Nassau as a health resort, excepting during the winter months, and the balance of the evidence as to its value then is altogether favourable. The hurricane season lies between the beginning of August and the end of October, before the commencement of the winter season. The visitors may depend during November, December, January, February, and March, on fine weather and a warm and even temperature. The Americans know this well, and return year after year to kill the winter in the soft perpetual summer of Nassau. It is no wonder that English people so seldom visit the Bahamas, for it is a troublesome business to get there. It is easy enough for the Americans, for Nassau is only about 900 miles from New York, but there is no other steam communication excepting with Cuba, about 300 miles away. The journey from England to New York, and then to Nassau, is rather a serious undertaking, and few can afford to take a trip to the Bahamas, as Lady Brassey did in the "Sunbeam" in 1883. It is not likely either that a sojourn at New Providence would be very agreeable to people of moderate means. There is little to do on shore. There are no theatres or concerts, no walks, only one drive, and few

excursions to be made. There is, indeed, a very capital library, and the residents are very hospitable, and used to be renowned as whist-players. There is but one hotel, called the Victoria, worthy of the name, which is opened only during the winter season. At a certain date, the mail steamer brings from New York a manager, a band, and all sorts of stores, and they are soon followed by the invalids from America, who are then excellently catered for. Provisions in New Providence are plentiful enough, although the cattle of the out islands are of inferior quality. To those fond of the sea and able to indulge their taste, a winter at the Bahamas would be a delightful memory for ever after. The sponge and coral fishing, the hundreds of Cays and islands that might be visited, the curious insight to be gained into the ways of a semi-civilised African population, would be of interest, and if the lucky traveller could sketch what he saw, or write what he heard, we should get a book about the Bahamas which might prove to be the book of the season.

## GENERAL CORRESPONDENCE.

### AN APPEAL.

[To the Editor of the Medical Times.]

SIR,—The following case has come under my notice as treasurer of the British Medical Benevolent Fund within the last week. A medical man in practice in Australia lost his life through an accident. His widow and two daughters came to England expecting to find friends, but these were on the point of returning to Australia. Being without advisers here they were robbed of nearly all they had by a fraudulent trustee, and have had to strive for a maintenance by letting their house out in apartments, and by teaching. The mother, however, has been suffering for 18 months from gastric ulcer, and requires the constant attendance of one of the daughters, so that only one can go out to teach, and their resources have consequently run down to the point of exhaustion. A grant of 20*l.* has been made from the Fund, the maximum that can be afforded to any single case, 10*l.* of which has been given at once, while the remainder is to be distributed in monthly instalments. But this just falls short of what is required to give these poor ladies another chance. Twenty or thirty pounds more would redeem a valuable pianoforte which would enable the girl kept at home in attendance on her mother to earn something by giving music lessons, and this would probably suffice to maintain them. Under such circumstances I have felt justified in departing from my rule of not asking for aid for individual cases, and in placing the facts before the profession. I shall be happy to take charge of anything which may be sent for these ladies. At the same time I trust that the fund will not suffer, relieving as it does more than 150 deserving and urgent cases yearly, besides giving over 50 annuities to aged members of the profession.

I am, Sir, yours, &c.,

W. H. BROADBENT, M.D.

34, Seymour Street,  
Portman Square, W.

## MEDICAL NEWS.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Thursday, August 6th. After confirmation of the minutes of the preceding meeting and the transaction of some routine business, the Report, dated the 24th ult., of the Building Committee of the Royal Colleges of Physicians and Surgeons was approved, adopted, and entered on the minutes; it was further ordered that authority be given to the Building Committee to carry out the proposed plans, that the College Seal be affixed to the documents, and that no alteration in the plans be permitted after signature of the contracts, without the sanction of the College. The Report, dated the 7th ult.,

from the Committee of Delegates appointed by the Royal College of Physicians of London and the Royal College of Surgeons of England, to consider the question of the advisability and practicability of granting the title of "Doctor" to persons who have received the Diplomas of the two Colleges, was then read. It suggested the desirability of granting the title of Doctor; but its further consideration was referred to a special meeting of the Council, to be summoned in October for the purpose. In order to give effect to the resolution of the Council of the 11th of June, 1885, it was determined that a meeting of the Fellows and Members be held on Thursday, the 29th of October, at 3 o'clock p.m., and that notice of such meeting be given to the Fellows and Members by advertisement in the medical journals and two London daily newspapers, not less than thirty days before its date.

Mr. Marshall then moved, Sir Spencer Wells seconded, and it was carried unanimously, "That, in recognition of the time and thought devoted by Sir James Paget, during many years past, to the revision and completion of the Catalogue of the Pathological Collection of the Museum, and of his many other important services to the College, he be requested by the Council to sit for a marble bust to be placed in some suitable position in the College Buildings, and executed at the expense of the College; and that the President and Vice-Presidents be asked to communicate with Sir James Paget, and to take the necessary steps to give effect to the foregoing Resolution."

The Council then adjourned until October 15th.

**VICTORIA UNIVERSITY, MANCHESTER.**—The following are the results of the examinations just held:—

Final Examination for the Degree of M.B. (Part I).—

First Division—O. J. Kauffmann; Second Division—J. M. Clarke. Distinguished in Pharmacology and Therapeutics—O. J. Kauffmann.

Final Examination for the Degree of M.B. (Part II).—

J. M. Clarke, E. Gordon.

Intermediate Examination for the Degree of M.B.—

First Division—G. F. W. Braide; Second Division—H. Sidebotham, J. H. Thompson. Distinguished in Materia Medica and Pharmacy—G. F. W. Braide.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—The following were admitted members on July 30th, 1885:—

John Anderson, M.D. St. Andrews, 105, Gloster Place, W.; Richard Hingston Fox, M.D. Brussels, 43, Finsbury Circus, E.C.; William Dobinson Halliburton, M.D. Lond., 135, Gower Street, W.C.; Arthur Shadwell, M.B. Ox., Brighton; St. Clair Thomson, M.B. Lond., 18, Gloster Walk, W.; Leonard Charles Wooldridge, M.B. Lond., Guy's Hospital, S.E.

The following were admitted Licentiate on July 30th, 1885:—

James Hugh Brodie Allan, M.D. McGill, 56, Gore Road, E.; Thomas Matthews Angior, Bootle, Liverpool; Herbert Ward Austin, Stoke, Devonport; William James Townsend Barker, General Hospital, Bristol; George Bent, 26, Charlwood Street, S.W.; Andrew Alexander Brockat, St. Thomas's Hospital, S.E.; Aubrey Durant Chapple, Leigham Court Road, S.W.; Thomas Hillier Chittenden, Whitwell, Welling; Frank Cecil Clarkson, Grove Road, Surbiton; Frederick John Clendinnen, 32, Calthorpe Street, W.C.; John Sadler Curgenvin, 12, Craven Hill Gardens, W.; Trevor Augustus Dagg, 36, Granville Square, W.C.; William Francis Dearden, Portland House, Bolton; Walter Henry Dodd, Sirhowy, Tredegar; Edward William Du Buisson, 46, Nelson Square, S.E.; John Morgan Evans, 89, Turner Street, E.; Alexander Grant Russell Foulerton, 16, Norland Square, W.; John Harley Gough, St. Mary's Hospital, Manchester; Duncan Gow, M.D. Toronto, 7, Nicholas Street, E.; William Habgood, Wimborne; Harry George Standish Hore, Guy's Hospital, S.E.; Alfred William Hunton, Royal Infirmary, Manchester; Habeeb Jabboor, London Hospital, E.; Hanna Jabboor, London Hospital, E.; Thomas Brander Jacobson, Guy's Hospital, S.E.; John Jarvis, Bury St. Edmunds; Arthur Jervis, St. George's Hospital, S.W.; Perceval Allen Lloyd, Manor House, St. Mark's Road, W.; George William Augustus Lynch, 48, Minford Gardens, W.; Walter Henry Bernard Moore, 5, St. Paul's Road, N.W.; John Oliver, 259, Friern Road, S.E.; Archibald Thomas O'Reilly, 24, Huntley Street, W.C.; Harry Compton Parsons, Hampton Wick; Frederick Arthur Pring, 47, Endell Street, W.C.; Joseph James Gauler Pritchard, Ferndale, St. John's Park, S.E.; Herbert Edward Rayner, 33, Great Charlotte Street, S.E.; Thomas Rushbrooke, 22, Rutland Street, N.W.; Gerald Schofield, Guy's Hospital, S.E.; Harry Winstanley Shadwell, 167, Hammersmith Grove, W.; George Francis Smith, 11, St. Anne's Terrace, N.W.; John Smith, 29, Cassland Road, E.; Walter Oliver Steinthal, 7, Rudall Crescent, N.W.; Thomas Hindle Sykes, Southport; John Philip Wagstaff, 61, Aere Lane, S.W.; Henry Secker Walker, Elms, Wakefield;

John Welpton, 81, St. Mark's Road, Leeds; Frank Faulder White, 35, Sussex Gardens, W.; Daniel Flockton Whiteley, 29, Great Percy Street, W.C.; Campbell Williams, 99, Gower Street, W.C.; Edward Lloyd Williams, 2, James Street, Buckingham Gate, S.W.; Albert Wilson, 131, Railton Road, S.E.; George Justiu Woutersz, 1, Rankeillor Street, Edinburgh.

**THE SOCIETY OF APOTHECARIES, LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Thursday, July 30th, 1885:—

Josiah Beddow, M.R.C.S., Upper Clapton; Percy Reeves Traer Harris, Bethune Road, Amhurst Park, N.; Charles Gower Lermite, Sheen Park, Richmond; John McLachlan, M.B. & C.M. Edin., Lothian Street, Edinburgh; Edward Thornton, M.R.C.S., Shrewsbury.

On the same day

Francis William Jollye, Spalding, Lincolnshire, passed his examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise.

**UNIVERSITY OF ABERDEEN.**—During the past year, the following candidates received Degrees in Medicine and Surgery:—

The Degree of M.D.:—

William Barron, Letham, Forfar; Clarence William Haig Brown, Godalming, Surrey; Alexander Campbell, Dundee; Robert John Collie, Aberdeen; William Cooper, Bellhelvie; Herbert William Tolver Crow, London; Francis Carteret Gayton, Surrey County Asylum, Woking; Alfred Hodgson, Rochdale; Andrew Hosie, Inverness District Asylum; James Leith Leslie, London; Alexander Macgregor, Aberdeen; Alexander MacLean, Deputy Surgeon-General, Thurso, Caithness; Thomas Marsden, Bridgewater; William Adam Michie, Cove, Aberdeen; James Thomas Mitchell, Port Adelaide, S. Australia; Charles Louis Isidore de Seilan, Bedale, Yorkshire; William Simpson, Buckie; William Henry Stewart, H.M.S. "Clyde," Aberdeen; William Stuart, Stratton, Cornwall; George Vincent, Worksop, Notts.

The Degrees of M.B. and C.M.:—

Alfred William Alcock, Bombay; Charles Spencer Anderson, Aberdeen; John Anderson, M.A., Marnoch; Matthew Ferguson Anderson, Dundee; William Robert Cheves, Longside, Aberdeenshire; John Christie, M.A., Old Aberdeen; David Macdonald Brown, Banchory-Ternan; Charles Alexander Butchart, Aberdeen; Alexander Gray Connan, Aberdeen; Andrew Hunter Cowan, Aberdeen; John Stuart Davidson, Mauritius; Edward Greaves Wooding Deane, Barbadoes, West Indies; John Duncan, M.A., Aberdeen; John Francis Scott Fowler, St. Helena; Frederick Arthur Foy, Cawnpore; David M. Gill, Grantown; Henry William Godfrey, Hornchurch, Essex; James William McKenzie Gunn, M.A., Reay, Thurso; Herbert John Hargrave, Hoveton, St. Peter; Albert Edward Henderson, Sheffield; George Nicol Henry, Macduff, Banffshire; John Watson Hutcheon, Aberdeen; John Charles Davidson Irvine, Udry; James Eddington Jefferis, Sydney, N. S. Wales; Francis Grice Jones, Denbigh, North Wales; John Marshall Lamb, M.A., Aberdeen; John Mackenzie, Ardersier, Fort George; John Marsden, Banff; Alexander Milne, Huntly; James Black Milne, Huntly; James Shaw Milne, Laurencekirk; William Vincent Morgan, Narberth, Pembrokeshire; Thomas George Paterson, New Galloway; Arthur Edward Patterson, Aberdeen; Patrick Whyte Rattray, M.A., Aberdeen; George Scott, Aberdeen; David Simpson, M.A., Alva, Banff; William Bulmer Simpson, Bedale, Yorkshire; John Rutherford Skinner, Ryde, Isle of Wight; Arthur Greatorex Smith, Marlborough; William Gordon Stott, M.A., Bonavista, Fyvie; Alexander James Stuart, Buxburn; Peter Alfred Sullivan, Carlisle; David Taylor, Cove, Kincardineshire; Andrew Whyte, Fraserburgh.

The following Candidates received their Degrees in Medicine and Surgery with Highest Academic Honours:—

John Marshall Lamb, M.A.; Alexander Milne; Patrick Whyte Rattray, M.A.; Arthur Greatorex Smith.

The following Candidates received their Degrees in Medicine and Surgery with Honourable Distinction:—

Alfred William Alcock; John Stuart Davidson; Henry William Godfrey; George Nicol Henry; Francis Grice Jones; James Black Milne; Thomas George Paterson.

The following Candidate received the John Murray Medal and Scholarship as the most distinguished graduate of his year:—

Patrick Whyte Rattray, M.A.

**UNIVERSITY OF GLASGOW.**—The degree of Doctor of Medicine has been conferred on the following graduates:—

William F. Gibb, M.B., Scotland. (Thesis: "General Paralysis of the Insane.")—John Glaister, M.B., Scotland. (Thesis: "An Enquiry into the necessity for Legislative Reform in Scotland in regard to Uncertified Deaths.")—Edward F. S. Green, M.B., Newfoundland. (Thesis: "Report of two cases of Cerebral Tumour, with an enquiry into the value of the Symptoms as to Diagnosis.")—James C. Herbertson, M.B., Scotland. (Thesis: "Typhoid Fever with five consecutive cases.")—John Yule Mackay, M.B., Scotland. (Thesis: "The Origin and Develop-

ment of the Larger Arteries.")—Peter Maclean, M.B., Scotland. (Thesis: "Cases of Epilepsy, with remarks.")—Donald Macleod, M.B., Scotland. (Thesis: "Alcohol; its effects.")—†William Macvie, M.B., Scotland. (Thesis: "Atrophic Infantile Paralysis.")—James Parker, M.B., Scotland. (Thesis: "The Testicle; its arrestment in its migration through the inguinal canal, the diseases it is subject to in that situation, and the method suggested for its restoration to its natural situation.")

The one marked thus \* was highly commended for Thesis, and marked † commended for Thesis. The degrees of Bachelor of Medicine and Master of Surgery were at the same time conferred on the 87 successful candidates whose names appeared in our last issue.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the July sittings of the examiners, held in Glasgow, the following gentlemen passed the final examination for the triple qualification, and were admitted L.R.C.P. Ed., L.R.C.S. Ed., and L.F.P.S. Glasgow:—

Andrew Alexander, Berwick; Henry Wm. Bryant, Edinburgh; Edward Clarkson, Darlington; Wm. W. Clegg, Leeds; James Blair Donaldson, Edinburgh; M. M. Gandevia, India; Thomas J. G. Garrett, Manchester; Walter Macgibbon, Edinburgh; Arthur R. Oust, Blackheath; H. N. Rademeyer, South Africa; David Sturrock, Edinburgh; John T. Winter, Manchester.

The following were admitted L.R.C.P. Ed. and L.F.P.S. Glasgow:—

G. C. Bezbaroa, Glasgow; Robert Kerr, Glasgow.

THE Library of the Obstetrical Society will be closed from August 17th to September 17th.

GUY'S HOSPITAL.—The library of this hospital will be closed on Saturday, August 8th, at 3 p.m., and re-opened on Tuesday, September 1st, at 9.30 a.m.

DR. GOODHART has chosen "Morbid Arterial Tension" as the subject of his Bradshawe Lecture, to be delivered before the Royal College of Physicians on Tuesday week.

THE Summer Medical graduation ceremony at Aberdeen took place on Thursday week, Principal Pirie presiding. The list of graduates "capped" is given above.

IT is interesting to note that of the 87 students who recently took the M.B. and C.M. degrees of the University of Glasgow, 65 or just three-fourths are described as of Scotland, 10 as of England, 3 as of Wales, 2 as of Ireland, 1 as of the Isle of Man, while one came from each of the following countries: Australia, India, Jamaica, Portugal, Singapore and Tasmania.

A SAD OCCURRENCE.—On Wednesday last an inquest was held respecting the death of Dr. Maurice James O'Connor, late medical officer of the Infirmary attached to the St. George's-in-the-East Workhouse. The deceased had been much upset about an official inquiry that was taking place, and committed suicide by taking strychnia. A verdict was returned of suicide whilst of unsound mind.

VIVISECTION IN AUSTRIA.—A circular is about to be issued to the Austrian medical faculties restricting and regulating the practice of vivisection. The chief points in the decree are that vivisection is only to be performed in State establishments, and by properly qualified surgical practitioners, or by students acting under their supervision and responsibility. Anæsthetics are to be used whenever the nature of an experiment will allow of their adoption.

THE PARIS NIGHT SERVICE.—In his report for the quarter ending June 30th, Dr. Passant states (*Gazette des Hôpitaux*, July 21st) that there were 1,799 night-calls, 590 (33 per cent.) being for males, 916 (51 per cent.) for females, and 293 (16 per cent.) for children under three years of age. The visits averaged 19.77 per night, while in the same quarter for 1884 they averaged 19.10.

THE LATE PROFESSOR HENRI MILNE-EDWARDS.—This distinguished *savant*, whose death after a long and painful illness we briefly recorded last week, was born at Bruges in 1800. He repaired to Paris as a medical student, and obtained his diploma in 1823. After having practised a short time, and produced several works of an elementary character, he gave himself up exclusively to the cultivation of natural science, and in this he attained the highest position. In 1833 he succeeded Cuvier in the Académie des Sciences, and three years later was elected Professor of

Entomology in the Muséum d'Histoire Naturelle. In 1843 he was made Professor of Zoology and General Physiology at the Faculté des Sciences. He was also an Associate of the Académie de Médecine, Member of the Institute and Grand Officer of the Legion of Honour. The author of an immense number of memoirs and communications to learned bodies, his fame will chiefly rest upon his great work, "Leçons sur l'Anatomie et la Physiologie Comparées de l'Homme et des Animaux," in fourteen volumes, which, commenced in 1833, was only completed in 1881.

TECHNICAL INSTRUCTION IN PLUMBING.—We are glad to observe that the resolutions passed at a recent Conference of metropolitan and provincial plumbers, with the view of improving plumbing work in dwelling-houses, is likely to result in the adoption, by the trade, of such regulations as will tend to secure good, sound work. Bad, defective plumbing has been a serious public evil. A report was read at a meeting, held at the Guildhall on the 31st ultimo, to consider certain recommendations of the Plumbers' Company, which stated that they had decided to recommend the establishment of a system of registration of plumbers in London and seven miles round; and that the persons registered should be required to satisfy the Court of their competency and experience in the trade. Technical instruction was strongly urged by Mr. P. Magnus (Director of the City and Guilds Technical Institute). The recommendations were agreed to.

MR. ERICHSEN'S CANDIDATURE.—There has been issued to the members of Council of the Universities of Edinburgh and St. Andrew's a circular, signed by Professor Douglas Maclagan, of Edinburgh, and Professor T. S. Baynes, of St. Andrew's, as chairmen of Mr. Erichsen's General Committee. It states that for more than a third of a century Mr. Erichsen has devoted himself to the cause of science, and, as a surgeon, has risen to the front rank of his profession, and after enumerating the main facts in his career, continues:—"From these facts it will be seen that Mr. Erichsen's professional training, life-long experience and familiarity with most academic and educational subjects, render him in all respects singularly well fitted to enter Parliament, and to represent efficiently, not only the great interests of science, learning, and education, but more especially the great medical schools, upon whose future fame and progress the prosperity of the Scottish Universities so much depends." The chairmen have every reason to believe that his sound judgment, great experience, and judicial habit of mind will be of the utmost service to the Universities, and that their highest and best interests will be safe in his hands. A list annexed to the circular contains the names of about 450 graduates resident in Great Britain and Ireland, many of whom are men of great eminence in their several professions. With this circular there has been sent to the medical graduates a letter signed by Sir James Risdon Bennett, as chairman of the London committee, who remarks that Mr. Erichsen's career, character, and position in the profession are so well known and appreciated that it would be unbecoming to adduce any special proofs of his eminent fitness to represent medical science in Parliament. As upwards of 3,600 members of the General Council of these Universities—more than one-half of the constituency—belong to the medical profession, it is to them that they venture to appeal and to suggest that, on the present occasion, feelings of party politics should be made to give place to the higher considerations of the national advantage to be secured by the return to Parliament, as the representative of these Universities, of one so capable to represent science, especially in its medical aspect, as Mr. Erichsen.

THE ARMY MEDICAL SCHOOL.—The session of the Army Medical School at Netley Hospital was closed on Monday last, the prizes being distributed by Sir Arthur Hayter. Mr. S. Hickson gained the Herbert prize of 20*l.*, with the prize in pathology, and also the prize presented by Sir Joseph Fayrer. Mr. R. G. Thompson gained the Martin memorial gold medal; Mr. S. Powell gained the Parkes memorial bronze medal and the Montefiore second prize; and Mr. H. J. Dyson, of Her Majesty's Indian Medical Service, gained the Montefiore medal and prize of 20

guineas. The following is a list of surgeons on probation in the Medical Department of the Army, who were successful at both the London and Netley examinations. The marks shown are those which were gained at the London examination; the order of position is not affected by the marks gained at Netley in the first half session:—S. Hickson, 2540; H. J. Fletcher, 2480; S. H. Lindeman, 2445; E. Davis, 2430; S. Powell, 2410; F. W. C. Jones, 2335; J. Meek, 2320; A. E. Morris, 2310; E. Cormack, 2300; J. F. M'Millan, 2290; C. O'Donel, 2275; W. A. Carte, 2270; A. O. Fitzgerald, 2270; F. D. Elderton, 2260; E. N. Sheldrake, 2230; R. E. Molesworth, 2220; J. W. F. Long, 2215; C. L. Josling, 2210; J. F. Bateson, 2180; W. T. Swan, 2180; J. Bulfin, 2175; R. L. R. M'Leod, 2145; J. H. Curtis, 2140; G. G. Adams, 2130; J. M. F. Shine, 2120; W. B. Day, 2110; D. R. Hamilton, 2100; R. G. Thompson, 2080; C. T. Blackwell, 2070; R. J. Power, 2070; C. R. Kilkelly, 2065; W. H. Bean, 2020; N. C. Ferguson, 2010; S. R. Wills, 1980; M. L. Hearn, 1960; S. L. Deeble, 1950; R. H. Hall, 1950; W. H. Bennett, 1940; J. H. Greenway, 1921; R. G. Hanley, 1880; W. H. Bell, 1875; G. Cree, 1850; S. C. Philson, 1850; J. M. Nicholls, 1830; F. W. H. D. Harris, 1800. Second half session:—J. F. M'Millan, 2290; S. G. Allen, 1863; J. S. Green, 1847; G. H. Symes, 1840; C. A. Lane, 1775; P. C. H. Gordon, 1770; L. T. M. Nash, 1770; J. H. Brannigan, 1755; M. O'Halloran, 1745; C. S. Sparkes, 1740; W. H. Pinches, 1720; H. F. Horne, 1720; J. H. Daly, 1710; G. J. A. Tuke, 1710; P. de B. Skerrett, 1700; H. C. Dent, 1680; F. J. Greig, 1630; C. Hayden, 1630; H. D. Rowan, 1630; H. Carr, 1625; H. G. Hathaway, 1620; A. L. H. Dixon, 1610; C. G. Woods, 1610; P. J. Minnerly, 1600; B. A. Maturin, 1580; H. V. Dillon, 1570; T. Daly, 1550; M. J. Sexton, 1540; H. T. Baylor, 1530; H. E. Cree, 1520; F. L. Carter, 1520; W. H. Starr, 1500; A. A. Sutton, 1500; A. P. H. Griffiths, 1460; W. S. Boles, 1450; H. L. G. Chevers, 1440; F. J. W. Stoncy, 1430; J. F. G. Burke, 1360; H. N. Kenny, 1350. In the course of his address, Sir Arthur Hayter said there had been attacks made upon the medical arrangements in connection with the Expedition brought to such a successful close at Tel-el-Kebir. These attacks were unjust. If there were any defects at Ismailia it was because the military hospitals were separated from the troops, and everything had to be sacrificed to the rapid advance, without even information being given to the principal medical officer, Sir James Hanbury. The experience gained, however, enabled them to place the more recent campaign under General Graham, in all its medical details, on a basis which seemed to him unassailable even by the most hostile critics.

**THE WASHINGTON INTERNATIONAL MEDICAL CONGRESS.**—The resignations by distinguished American practitioners of the places that had been assigned them in connection with the Medical Congress of 1887 still continue. The practitioners of Cincinnati who had been appointed to office by the Chicago committee have followed the example set them in Philadelphia, Boston, Baltimore and Washington, and have declined to accept office in the Congress. Dr. W. A. Hardaway, of St. Louis, has declined the Presidency, and Dr. J. Nevins Hyde, of Chicago, the Vice-Presidency, of the Section of Dermatology and Syphilis in the new organization of the Congress; Dr. E. Williams, of Cincinnati, declines the Presidency of the Section of Ophthalmology; and Drs. T. A. Reamy, of Cincinnati, and J. C. Reeve, of Dayton, Ohio, have declined Vice-Presidencies in the Section of Obstetrics and Gynecology. Drs. George M. Sternberg and R. W. Shufeldt, U.S. Army, E. Van de Warker, of Syracuse, N.Y., and William Lee, of Washington, J. M. Keating and George E. De Schweinitz, of Philadelphia, have also declared their intention to decline office. Dr. N. Senn, of Milwaukee, has resigned from the General Committee. At the annual meeting of the American Ophthalmological Society held at New London last week, the following resolution was adopted: "That it is the sense of the American Ophthalmological Society that the action of the American Medical Association at its late meeting in New Orleans, and of the enlarged Committee appointed at that time to make arrangements for the International Medical Congress, in overturning much of the carefully

planned work of the Original Committee appointed at Washington for the same purpose, was unwise and not to be defended, unless, possibly, upon technical grounds; and this Society hopes that none of its members will endorse the action of the enlarged Committee by accepting official positions at its hands."

**MEDICAL POLITICS IN THE UNITED STATES.**—A correspondent having asked us for information as to the celebrated code dispute which has caused so much heartburning to the profession in America, we cannot do better than reproduce the following cutting from a New York lay journal. It is the most concise and correct account of the fight we have yet seen. "The new code consists in a resolution adopted by the New York State Medical Society a few years ago, permitting its members to consult with any *legally qualified* practitioner of medicine, including of course homeopaths and eclectics who are recognised and certified by law as physicians. Nobody under the new code is *required* to do anything of the sort. The resolution is permissive simply. It merely makes the physician the custodian of his own professional honour. If he thinks that duty requires him in any case to consult with a homeopath, he may do so without being stricken from the list of his brother physicians. The new code is an affair of New York exclusively, no other State having taken up the question, except in the way of showing incidentally sympathy with or repugnance to the New York resolution, as in the present case." "It would be erroneous to assume," continues the same journal, "that the distinguished physicians of Philadelphia, Boston, and Baltimore were governed in the action they have taken altogether or mainly by a feeling of sympathy with the new code. It is most probable that they have looked upon the doings of the American Medical Association as simply unwarranted, irregular, and impertinent. The International Congress at Copenhagen appointed its own committee, as it had an undoubted right to do. It selected a committee, consisting of most eminent men, who performed the duty assigned to them without reference to the code question, but with strict regard to professional merit. The attempt of the American Medical Association to undo the action of this Committee and to subordinate the interests of medical science to their own notions of punctilio—practically, in this case, the notions of a majority of sawbones from Texas and Arkansas—might justly be considered by the physicians of the East as an intolerable usurpation, and this regardless of their individual opinions on the code question. It will be most regrettable if the proposed meeting of the International Medical Congress in 1887, the first one held in the United States, should be frustrated and turned into a laughing stock, as it now seems likely to be. There is still sufficient time, it appears to us, to save the profession and the country from such a disgrace. Let Dr. Billings and his committee go on under their original authority, carry out their own programme, ignoring all codes and eliques, and appeal to the public for the funds needed for the entertainment of their foreign visitors. It will be very strange indeed if they do not find a generous response to their call."

**THE LATE GENERAL GRANT.**—So much interest has been expressed in medical circles in the fatal illness of the late General Grant, and the reports of his condition, telegraphed over from time to time, have seemed to some so conflicting, that the following brief account of his case, which we have good reason to believe is entirely correct, will probably be appreciated by many of our readers. In June of last year, General Grant first felt a lump in the roof of his mouth and found swallowing painful. Being away from home he consulted Dr. De Costa, of Philadelphia, and was advised to see his own medical adviser, Dr. Fordyce Barker. When he consulted Dr. Barker in the following October, the trouble in the throat had increased to such an extent, that he found great difficulty in sleeping or eating, and Dr. Barker at once advised him to place himself under Dr. J. H. Douglas, a specialist in throat diseases. Some decayed teeth were extracted and the General was induced to give up smoking; he improved steadily till December 16th, when he had again to consult Dr. Douglas for acute pain in the throat. The gland at the right angle of the jaw was then found much enlarged

and very tender. There was a slight ulceration on the right tonsil, and at the junction of the hard and soft palates, the epithelium was very much thickened in three warty patches each a quarter of an inch in diameter. Muriate of cocaine was applied twice a day, and gave almost instant relief from the intense pain, and the ulceration in the tonsil was kept in a healthy condition by the application of iodoform. Under this treatment, combined with that of Dr. Barker, which was mainly constitutional, the trouble in the throat was relieved, so that by January 13th, of the present year, the General was able to eat and sleep with comparatively little difficulty. The patches in the roof of the mouth, however, refused to yield, but they were not painful, and the physicians, while fearing the disease to be malignant, had great hopes at this time of prolonging General Grant's life for a long time to come. A month later, however, their fears were confirmed; with the view of making a more satisfactory investigation of the nature of the disease, the throat was sprayed with a 4 per cent. solution of cocaine, and Dr. F. C. Riley removed from the ulcerated edge of the posterior pillar of the fauces a piece about as large as a small pea. This, on microscopical examination, was found to be largely composed of epithelial elements with a tendency to arrange themselves in concentric "nests." The conclusion reached by Dr. Elliott, who made the microscopical investigation, was that the more or less lobulated appearance of the epithelial mass, the actual existence of some cell nests, the great diversity in the shape of the cell elements, the marked evidences of epithelial proliferation, and the peculiar appearance of the stroma warranted the diagnosis of epithelioma of the squamous variety. On February 19, a consultation was held, and although the result of the microscopical examination was not then known, it was decided that the General was suffering from epithelioma, and that no possible good could result from an operation to remove it. From the time of that consultation the certainty of General Grant's death from the cancer was accepted by the doctors, and by such of the public as knew of its result. After that General Grant sank slowly but steadily, losing flesh rapidly. On March 8th, another consultation was held, when it was found that the ulceration of the posterior pillar fauces on the right side had extended, and that the perforation at the base of the anterior pillar which had been previously noticed had increased, so that its internal edge was converted into a small bridle of tissue. The entire soft palate was uniformly red and swollen, and the right posterior border of the tongue was indurated from a point just in front of the anterior pillar of the fauces as far back as could be reached by the finger. The most grateful local application to the throat, next to the cocaine spray, was hot salt and water, five parts to the thousand, used occasionally as a gargle. After the consultation, the ulcerative process in the anterior pillar extended to the adjoining side of the tongue, and the bridle of tissue bounding the perforation of the anterior pillar internally gave way. On March 15th another consultation was held with a view of discussing the expediency of a surgical operation for the removal of the cancerous growth. The operation would have involved the division of the lower jaw in the median line, the extirpation of the entire tongue and the greater part of the soft palate, together with the removal of the ulcerated and infiltrated fauces and the indurated glandular structures under the right angle of the lower jaw. This was decided to be mechanically possible, but the surgeons did not feel inclined to recommend the operation, as there would be no guarantee that the limits of the disease could be reached without immediate risk to life by severe shock to a constitution already much enfeebled. At a consultation held a week later, it was decided that there was no fear of any sudden failure of the vital powers, or of any encroachment of the ulcerative process on the neighbouring blood vessels, and that the death of the General might by proper treatment be postponed for some little time. For the next two months the local affection remained comparatively quiescent, though there were occasionally severe fits of choking from the accumulation of secretion, and on one occasion a fatal result was apprehended. On April 7th there was an attack of hæmorrhage from the

throat, which, however, appeared to relieve him. He began to work again at his book, and to drive out, but by the beginning of June the epithelioma had greatly extended and his voice was almost lost. In the third week of June, by the advice of his physicians he was moved into the country, and from that time his strength steadily failed until his death.

**COTTON SEED AS FOOD.**—M. Sacc, in a recent communication to the Académie des Sciences, calls attention to the result of his researches on the composition of the seeds of the cotton-plant. They contain a notable quantity of dextrine, sugar, fibrine and starch, which result in a nutritious flour of a yellow colour, which he believes is destined to play an important part in human alimentation. At present it has been used only for the production of oil and the feeding of cattle.—*Annales d'Hygiène.*

**BATHS OF LAURVIK, IN NORWAY.**—Dr. J. C. Holm has published a small pamphlet, recommending the baths of Laurvik, a town on the Laurviks Fjord, on the Skagerak, 5 hours by rail from Christiania. The baths are sulphurous and ferruginous, the soil dry and sandy, the water-works excellent. The sulphur is said to be twice as much in quantity as in the water at Aix-la-Chapelle. There are complete hydropathic departments with sea-weed baths, as well as sulphur and ordinary baths; from the pictures given, the place would seem to be very pretty and picturesque, and the terms appear very moderate.

**SECRET REMEDIES IN PRUSSIA.**—According to the Berlin correspondent of the *Allgemeine Wiener Medicinische Zeitschrift*, the Prussians are suffering as much from the prevalence of the use of secret remedies, as we are from patent medicines. The profession has taken up the question seriously, and has formed a joint committee of the Medical and Apothecaries' Societies in order to devise a remedy. This does not seem a very easy matter, and various suggestions were made, such as increasing the stringency of the present mild laws on the matter, and the application of a tax, &c. The resolution come to at last was mild enough, for it determined upon the presentation of a petition to the President of Police, requesting that his deputies should be requested to draw up instructive treatises on the subject for insertion in the daily newspapers, in imitation of what has been done in Frankfort, Carlsruhe and other towns. Feeling, however, that this is but a means of doubtful efficacy, the joint committee adjourned to consider what more may be done to abate a grievance which is doing much harm to professional interests and the public welfare.

**THE INSENSIBILITY OF DECAPITATED HEADS.**—Dr. Bonnafont, writing in the *Revue de Thérapeutique*, No. 12, observes that after every decapitation which takes place in Paris the question is raised whether sensibility is not retained by the head one or more minutes after its removal; and that many writers on the subject have, from imperfect observations, maintained the reality of the occurrence. He thought that he had settled the point 50 years ago; for in a communication addressed to the *Académie des Sciences* in 1834, he narrated the observations which he had made with every possible precaution for the express purpose of testing his prevalent opinion. These were made on a marabout and a sheik who were beheaded in Algeria (no rare occurrence in those days), and the results were entirely negative—no effect having been produced by the voice conveyed through a speaking-trumpet, or by punctures made with a pointed instrument. He is not aware of any experiment of the kind having been since conducted with all the care which surrounded his own.

**POISONING BY PETROLEUM.**—In the *Gazette des Hôpitaux* for June 16th, Dr. Duguet, of the Luciboisière, relates the case of a woman, aged 48, who was brought into that hospital, 8th May, having just swallowed about a pint of the ordinary petroleum of commerce with suicidal intentions. She at once felt a strong sensation of oppression along the œsophagus, and especially at the stomach, together with a sense of burning, and was in a very agitated condition. She exhaled a powerful odour of petroleum, and on vomiting being excited by ipecacuanha, with large quantities of milk, a good deal of petroleum floated on the ejections as it did in those produced from the bowels by a

glyster. All the urine of the patient was carefully preserved, and that passed just before the emetic was given contained a floating layer of petroleum, 2 or 3 centimeters in thickness. On the next day after her admission the floating petroleum in the urine amounted to 21 cubic centimeters, but by the next day had diminished to 5 centimeters, and then gradually disappeared. Some albumen, which at first was present, disappeared with the petroleum. During the first four days the petroleum enabled the urine to be preserved without undergoing decomposition for ten days. No other feature of interest is recorded.

PRIZE QUESTIONS OF THE ACADÉMIE DE MÉDECINE DE BELGIQUE.—(1) Prize of 1,500 francs: Determine, by new researches and new applications, the degree of utility of Spectrum Analysis in investigations in Legal Medicine and Medical Police. (Essays to be sent in by the 1st April, 1886.) (2) Prize of 1,500 francs: The physiological action of abstraction of blood, whether local or general; and the indications and contra-indications for this treatment of diseases. (31st December, 1885.) (3) A prize of 600 francs: A critical exposition of the various methods of antiseptic dressing and antiseptic treatment of wounds and surgical affections. (15th January, 1887.) (4) A prize of 605 francs: A study on carbuncular (*charbonneux*) erysipelas, or the *rouget* of the pig, as to its causes, manifestations, lesions, prophylaxis, and treatment; finally, establish its relation to carbuncular and bacterial affections. (15th January, 1887.) For the first prize the essays may be in Latin, French, German, English, or Italian, and for the others in French only. For information, applications may be made to the Secretary of the Academy, Palais des Académies, Brussels.

ARE THE DOCTOR'S HORSE AND BUGGY HIS TOOLS?—In reply to this query, the *Boston Medical Journal* (June 11th) gives the judgment of a court in New Hampshire, in a case in which the horse and buggy of a physician, having been seized to satisfy the claims of creditors, he pleaded that as the "tools of his occupation" they were exempt from liability to seizure for debt. The following is the decision under which the jury restored the property: "The Court cannot say, as a matter of law, that a wagon or a harness is a tool of a physician's calling, and so exempt all physicians; nor can they say it is not such a tool. The most that can be said is that it may be a tool of his profession if, in this particular case, it is reasonably necessary for him to use it as a tool. If it should appear that his practice was confined to his office, or that he was a physician or surgeon in an hospital, attending to no cases outside of the institution, or that he was a surgeon on ship-board, or that he went on foot or on horseback, or on the cars, to visit his patients, a wagon and harness would not be exempt under the statute, because they would be of no use to him as tools in his practice. They might be of use to him in other respects, as in going to church, or carrying his children to school, or as a means of recreation and pleasure; but these uses are manifestly not within the legitimate scope of the technical duties of a physician. But if it should be found that the physician claiming exemption could not practise his profession with reasonable success without a team with which to visit his patients; that he was located in a country town, for example, where it was necessary for him to ride a large part of the time, in order to accomplish anything professionally, a wagon and horses might properly be found reasonably necessary for him as tools of his occupation. But the finding would be one of fact, so far as the reasonableness of the act is concerned; and it could not be said that these articles are exempt to every physician, or to physicians generally, but only to the debtor in the particular case. If there is any doubt whether an article claimed as exempt from attachment is a tool under the statute, the question must be submitted to the jury."

AN ENORMOUS GALL-STONE.—At a recent meeting of the College of Physicians of Philadelphia, a gall-stone was presented which had been removed from the body of a woman who had died of colloid cancer of the omentum, in her 63th year. The cancer had been recognised, but the presence of the gall-stone had not been suspected. The gall-bladder was firmly contracted around the stone, and a small fistula at the fundus communicated with its cavity

and that of the peritoneum. The stone weighed 394 grains (or 25·6 grammes), and was 3½ inches (8·5 centimetres) long. The largest circumference measured 7·9 cm., the small end measuring 5 cm. and the large one 7 cm. — *Boston Medical Journal*, July 2.

ADVENTURE OF A FALSE TOOTH.—A lady in South Bend, Indiana, who had a false tooth, set on a pivot, sneezed it out one day while feeding chickens. An old hen thought that it was a grain of corn and swallowed it as soon as it struck the ground. After a long chase the hen was captured, beheaded, and its crop opened; the tooth was found and restored to the mouth, where it afterwards helped to masticate its rash devourer.—*New York Medical Record*.

FOUNDLING AND DESERTED INFANTS IN PARIS.—The *Gazette Hebdomadaire*, July 10th, produces some extracts from an essay by M. Leon Lallemand, to which a prize has just been adjudged by the Académie des Sciences Morales et Politiques, as illustrative of the wretched condition of these infants in the 17th and 18th century as compared with our own times. In 1670, 423 infants were brought to the Maison de la Couche, of whom 302 were sent to nurse (great numbers of them dying), and of the 121 remaining 118 died, so that only three survived. Of 5,012 infants received in 1758 1,470 died while awaiting the arrival of nurses, 2,278 died at nurse, and 124 were sent to the General Hospital. Of 42,750 children received during 6 years and 4 months, terminating in 1775, there died in the house 13,431, or nearly one-third every year—thrush being the disease through which the great bulk perished. According to M. Lallemand's tables, the deaths of these infants were 56·53 per cent. in 1504; 63·49 in 1751; 92·13 in An. V and 68·05 in 1818. In 1877 this mortality had become reduced to 33·55. Deaths under the first month occurred in the An. V in the frightful proportion of 3,129 out of 3,406 infants; while from 1877 to 1881, of 6,374 infants only 1,525 died—the mortality thus sinking from 94·30 to 35·67 per cent.

PREMATURE PREGNANCY.—Dr. Kinney, of Greensboro', Vermont, relates in the *New York Medical Record*, June 13th, the case of a young girl to whom he was called while she was in labour. The labour going on slowly, he delivered her with the forceps of a fairly well-developed child weighing seven-and-a-half pounds. Both mother and child went on well. The girl is rather large for her age, and would weigh probably not far from 110 lbs.; and the only point of interest in the case is her extreme youth, she being at the time of her delivery but twelve years ten months and sixteen days old.

EXAMINATION OF POTABLE WATER.—The method recommended by J. W. Gunning (*Chem. Centr.*) for the chemical examination of water consists in adding to a litre of the water enough ferric chloride to correspond with about 5 mgrms. of iron. The ferric chloride should be as nearly neutral as possible. Under these conditions, ammonia, nitrites and nitrates are left in solution, whilst other nitrogenous substances are carried down with the precipitate of ferric hydroxide. By heating this with soda-lime the nitrogen of these compounds is obtained as ammonia. By this treatment cloudy water is completely clarified and yellow moor-water decolorised. The process has been applied with success on a large scale in Holland for the purification of drinking water, especially during diarrhoea and cholera epidemics. In the bacteriological examination of water, the author prefers to develop a pure culture in a liquid medium rather than in the solid medium recommended by Koch. The water to be tested is mixed with a clear sterilised yeast decoction. By sterilising this again, certain bacteria are either killed or rendered inactive, while the others from their superior vitality survive and develop. By a process of progressive sterilisation, beginning at low temperatures and gradually ascending, pure cultures are obtained.

LEPROSY.—Dr. Beaven Rike's report on the Leger Asylum at Mucurapo, Trinidad, during 1884 shows that the beds there, especially on the male side, have been in great demand. There were 23 deaths, eight of which were due to some form of gangrene or ulceration, and a like

number were attributed to phthisis or kidney disease; swarms of the bacillus lepræ were found in the tubercles after removal. Gurgun oil was given as a matter of routine in nearly all the cases, but Dr. Beaven Rake does not think he has seen much real benefit from it; in the only instance in which any softening of the tubercles occurred the patient was taking chaulmoogra oil, and had not had any gurgun oil. Any good results that were obtained he is inclined to attribute to the careful dieting and nursing; in two cases, however, he found arsenic to be very beneficial. Twice amputation was performed for leprosy gangrene, both cases ultimately doing well, though in each there was some sloughing of the flaps.

**THE REFRACTION OF THE HUMAN EYE.**—Dr. B. Alex' Randall, of Philadelphia, presents in the July issue of *The American Journal of the Medical Sciences* a critical study of the statistics which have thus far been obtained by examinations of the refraction, especially among school children. The results of his investigation seem to fully uphold the following conclusions:—(1) Myopia is almost unknown in infancy and very infrequent before the beginning of school-life. In the earlier school-years its percentage is still low, and it is only in the advanced classes, especially of the German schools, that it ever attains to a preponderance. It has been found in not more than 39=2.54 per cent. of 1,534 eyes of infants, in not more than 28=7.86 per cent. of 356 eyes of children under the school-age, and in only 1,582=6.79 per cent. of 23,315 eyes of children examined during the first three school-years—figures which more accurate methods might have made lower. Among 3,052 eyes of young men, upon whom the school influence had not been excessive, it was found in 347=11.4 per cent.—a percentage which probably oversteps the maximum which it is likely to attain outside of the schools. (2) Hypermetropia is the enormously preponderating condition in infancy and early childhood, and the first years of school life witness little reduction in its proportion. Outside of the schools it remains by far the most frequent refraction throughout life, and in the schools it is decreased by the change of eyes to the myopic refraction in a degree apparently varying according to the circumstances calling into existence that defect. It was found in 1,400=91.26 per cent. of the 1,534 eyes of infants examined, in 291=81.75 per cent. of the 356 eyes of young children, and in 2,564=76 per cent. of the 3,358 eyes of children in the elementary school years, among whom it was sought with adequate care. So also in the higher schools, it constituted at least 56 per cent. of the whole number of eyes studied by competent methods, being found in 5,587 of the 9,965 examined. (3) Astigmatism has been rarely sought with care, and the data with regard to its frequency are not sufficiently wide to justify definite conclusions. The findings of the studies where it has been well looked for, concur with the clinical work in indicating a measurable degree of astigmatism (0.5 D. or more) in the majority of ametropic eyes. (4) Emmetropia in a mathematically strict sense has probably no existence. Approximate emmetropia (Am.  $< \pm 0.5$ ) is infrequent in all ages, probably at no epoch exceeding 10 per cent. Its apparent proportion is swollen by the array of eyes *not proven* ametropic, and we have but few studies where the accommodation has been with certainty set aside and its existence fairly well known. Cohn among 299 atropinised eyes proved in no single instance its presence. Under homatropine Hansen found it in but 26 of 1,610 eyes, and Durr in 30 of 414 eyes; it constituted at most 60=2.6 per cent. of these 2,323 eyes. Among the infants and young children 135=7.36 per cent. of the 1,834 examined under atropine may have been emmetropic; and Roosa's brief study indicates that it is probably as rare in adult life, even when perfect function apparently proves its presence. (5) The question of what is the *normal refraction* of the human eye is still an open one, and further material on the subject and closer study of the data in hand will be necessary before drawing conclusions as to it. Much light will be thrown upon the question by studies like Risley's of the relations of normal vision, intraocular health, and functional comfort, to the refraction. For the present the conclusion of this author, whose work stands almost alone,

may be accepted. "The emmetropic is the model or standard eye, since emmetropia is shown not only to remain nearly constant in percentage throughout the school life, but that it is also the condition of health, and withal enjoys the highest acuity of vision and the greatest freedom from pain." Yet hypermetropia is the prevailing—almost the exclusive—condition of the refraction among most animals, among children, among uncivilised peoples, and among all eyes uninjured by the educational process.

**ANTIPIRYN IN PHTHISIS.**—M. Rollet, an *interne*, furnishes to the *Lyon Medical*, Aug. 2nd, an account of the results obtained by Dr. Mayet's trial of this substance in cases of phthisis during the last four months. These are (1) That the medicine is well borne in half gramme doses to the extent of from two to four grammes per diem; (2) that in spite of its manifest anti-thermic power it exerts scarcely any influence on the general condition of tuberculous patients arrived at the last stage of the disease, in whom all the other symptoms then continue to increase in intensity; (3) it is especially indicated, and may lead to a certain amount of amelioration, in tubercularisation that is but little advanced, when fever is the principal cause of the debility.

### APPOINTMENTS.

- BARTON, GEORGE HENRY, M.R.C.S. Eng., L.R.C.P. Edin.—Medical Officer to the Tealby District, Caistor Union, *vice* Mr. H. H. Turnour, deceased.
- BRUNSKILL, ROBERT DOVER, L.R.C.S. and L.R.C.P. Edin.—Medical Officer to the Cornforth District, Sedgefield Union, *vice* Dr. H. Clark, deceased.
- DYSON, W., B.A., M.D. Lond.—Physician to the Sheffield General Infirmary, *vice* H. F. Banham, M.D., resigned.
- FIRMAN, CHARLES GEORGE, L.F.P. and S. Glasg., M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Caistor District, Peterborough Union, *vice* Mr. F. M. Brown, resigned.
- HAW, W. H., M.R.C.S., L.S.A.—Resident Obstetric Officer to the Charing Cross Hospital, *vice* W. T. Wallington.
- HEYCOCK, F. R., M.D., M.C., F.R.C.S.—Honorary Surgeon to St. Peter's Hospital for Stone, *vice* W. F. Teevan, F.R.C.S.
- HOOKE, CHARLES PAGET, L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the South District and to the Workhouse, Cirencester Union, *vice* Mr. C. W. Wilson, resigned.
- JONES, J. H., M.B., M.R.C.S.—House Surgeon to the Clinical Hospital for Women and Children, Park Place, Manchester.
- MACLAREN, M., B.A., M.B., C.M. Edin.—House Surgeon to the Bootle Borough Hospital, Liverpool.
- SHIRLAW, JAMES L., M.B., C.M. Edin.—Medical Officer to the Ferryhill District, Sedgefield Union, *vice* Dr. H. Clark, deceased.
- STEDMAN, F. O., M.R.C.S., L.S.A.—House Surgeon to the Charing Cross Hospital, *vice* A. R. Jolliffe.
- TEEVAN, W. F., F.R.C.S.—Consulting Surgeon to St. Peter's Hospital for Stone.
- WILDING, WILLIAM A., L.K.Q.C.P. Ire., M.R.C.S. Eng.—Medical Officer to the First District and to the Workhouse, Church Stretton Union, *vice* Mr. T. J. Hughes, resigned.

### VACANCIES.

- ATCHAM UNION.—Medical Officer for the Pontesbury District, in succession to Mr. A. A. Gillittle, deceased. Area, 12,171 acres. Population, 4,275. Salary, £58 10s. per annum.
- COTON HILL LUNATIC HOSPITAL, STAFFORD.—Assistant Medical Officer. Salary, £100, with board and furnished apartments in the Hospital. Candidates must be duly qualified and registered. Applications, with testimonials, to be sent to the Medical Superintendent on or before August 8th.
- LINCOLN COUNTY HOSPITAL.—House Surgeon. Salary, £100, with board, lodging, and washing. Candidates must be unmarried, doubly qualified, registered, and under 40 years of age. Copies of testimonials to W. B. Danby, Secretary, on or before Aug. 15th.
- MARTLEY UNION.—Medical Officer for the Holt District, in succession to Mr. Hilary Hill, deceased. Area, 11,407 acres. Population, 3,345. Salary, £85 per annum.
- ROYAL BERKSHIRE HOSPITAL, READING.—House Surgeon. Salary, £90, with board and lodging in the hospital. Candidates must be members of one of the Royal Colleges of Surgeons of Great Britain and Ireland, and Licentiates of the College of Physicians or of the Apothecaries' Company, and be able to produce testimonials of good character. Applications, with testimonials, to be sent to the Secretary by August 15th.
- SROCKTON-UPON-TEES HOSPITAL AND DISPENSARY.—House Surgeon (non-resident). Salary, £200 per annum. Candidates must be doubly qualified. Applications, stating age, with recent testimonials or copies, to be sent to the Secretary not later than August 24th.
- TRURO UNION.—Medical Officer for the St. Just District, in succession to Mr. G. W. Hill, resigned. Area, 5,730 acres. Population, 2,351. Salary, £20 per annum.
- WHITBY UNION.—Medical Officer for the East District and for the Workhouse, in succession to Dr. E. M. Taylor, resigned. Area, 9,901 acres. Population, 5,921. Salary, £25 per annum. Salary for Workhouse, £25 per annum.

## DEATHS.

- CHAPMAN, RICHARD, M.D., F.R.C.S.—At Kirbymoorside, on July 28th, aged 83.  
 FRENCH, JOHN GAY, M.D., F.R.C.S.—At Ballygar, County Galway, on July 23th, aged 46.  
 HILL, HILARY, M.R.C.S.—At Worcester, suddenly, on July 25th, aged 64.  
 MILLIGAN, JOHN LAIDLAW, M.D.—At Hayfield Thornhill, Dumfriesshire, on July 26th.

## COMMUNICATIONS RECEIVED—

Dr. NORMAN CHEEVERS, C.I.E., London; Prof. MCKENDRICK, Glasgow; Dr. CHOLMELEY, London; Prof. MACLAGAN, London; Dr. GOODHART, London; Dr. W. H. BROADBENT, London; Mr. W. J. SANBURY, London; OUR BELFAST CORRESPONDENT; Dr. WILLOUGHBY, London; Dr. RHYS GRIFFITHS, Cardiff; Dr. DONKIN, London; THE SECRETARY OF THE SOCIETY OF APOTHECARIES, London; THE REGISTRAR-GENERAL FOR IRELAND, Dublin; THE REGISTRAR OF THE UNIVERSITY OF ABERDEEN; THE BEDELL OF THE ROYAL COLLEGE OF PHYSICIANS, London; Mr. J. T. W. BACOT, London; Dr. CLIFFORD BEALE, London; OUR GLASGOW CORRESPONDENT; Dr. MAXWELL, Woolwich; Mr. NOBLE SMITH, London; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; Messrs. BING & SON, Canterbury; The Rev. G. HOWARD WRIGHT, London; THE SECRETARY OF THE OBSTETRICAL SOCIETY, London; Dr. A. FOXWELL, Birmingham; Mr. J. H. MORGAN, London; THE REGISTRAR-GENERAL FOR ENGLAND, London.

## BOOKS RECEIVED—

Pepper's Practice of Medicine, Vol. II.—Abstract of the Licensing Laws Amendment Bill of the Church of England Temperance Society—Speech delivered by John Eric Erichsen to a meeting of the Electors of the Universities of Edinburgh and St. Andrew's—List of Persons having obtained Certificates to Practise as Apothecaries from August, 1883, to December 31st, 1884—Die Neueren Fortschritte in der Therapie der Hautkrankheiten, von Dr. P. G. Unna—Observations on some changes in Form of the Prostate and Floor of the Bladder, by Reginald Harrison, F.R.C.S.

## PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Gazette Hebdomadaire—Nature—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medizin—Philadelphia Medical News—Weekblad—Le Progrès Médical—Berliner Klinische Wochenschrift—Centralblatt für die Medicinischen Wissenschaften—Deutsche Medicinische Wochenschrift—The Hospital Gazette—New York Medical Journal—Louisville Medical News—Boston Medical and Surgical Journal—Philadelphia Medical Times—Revue Médicale—West Briton and Cornwall Advertiser—Sunday at Home—Boys' Own Paper—Girls' Own Paper—Leisure Hour—Biographical Series, No. 22—Friendly Greetings—Veterinarian—Archives of Pediatrics—Monthly Homœopathic Review—City Press—Brain—Vaccination Inquirer—Once a Month—Archives Générales de Médecine—Canada Medical and Surgical Journal—Daily Free Press, July 27 and Aug. 1—Glasgow Medical Journal—Analyst—American Eagle—Sammlung Klinischer Vorträge—Edinburgh Medical Journal—An Ephemeris of Materia Medica, etc.—The Australasian Medical Gazette—Birmingham Medical Review—The Maloja Chronicle—Revista de Medicina.

## HOSPITAL OPERATING DAYS.

- Friday.—Metropolitan Free, 2 p.m.; St. Mark's Hospital for Diseases of the Rectum, 2 p.m.; Royal London Ophthalmic 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Hospital for Women, 2 p.m.; Royal Orthopaedic, 2 p.m.  
 Tuesday.—Guy's 1½ p.m.; Westminster, 2 p.m.; West London, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; Royal South London Ophthalmic, 3 p.m.; St. Mark's Hospital, 9 a.m.; St. Thomas's (ophthalmic operations), 4 p.m.  
 Wednesday.—Middlesex, 1 p.m.; St. Mary's, 1½ p.m.; St. Thomas's, 1½ p.m.; St. Bartholomew's, 1½ p.m.; University College, 2 p.m.; London, 2 p.m.; Great Northern, 2 p.m.; King's College (ophthalmic operations), 1 p.m.; Samaritan, 2½ p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.; St. Peter's Hospital for Stone, 2 p.m.; National Orthopaedic, Great Portland Street, 10 a.m.  
 Thursday.—St. George's, 1 p.m.; Central London Ophthalmic, 2 p.m.; University College, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Hospital for Diseases of the Throat, 2 p.m.; Hospital for Women, 2 p.m.; Charing Cross, 2 p.m.; London, 2 p.m.; North West London, 2½ p.m.; Chelsea Hospital for Women, 2 p.m.

Friday.—St. George's (ophthalmic operations), 1½ p.m.; Guy's, 1½ p.m.; St. Thomas's (ophthalmic operations), 2 p.m.; King's College, 2 p.m.; Central London Ophthalmic, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal South London Ophthalmic, 2 p.m.; Royal Westminster Ophthalmic, 1½ p.m.

Saturday.—King's College, 1 p.m.; St. Bartholomew's, 1½ p.m.; St. Thomas's, 1½ p.m.; London, 2 p.m.; Middlesex, 2 p.m.; Royal Free, 2 p.m.; Royal London Ophthalmic, 11 a.m.; Royal Westminster Ophthalmic, 1½ p.m.; Central London Ophthalmic, 2 p.m.

## ON MEDICAL EDUCATION.

AN ADDRESS DELIVERED AT THE UNIVERSITY OF EDINBURGH GRADUATION CEREMONIAL ON AUGUST 1ST,

By W. S. GREENFIELD, M.D., F.R.C.P. Lond.,  
Professor of Pathology in the University.

DOCTORS IN MEDICINE,—Many of you have already achieved success, and now, as always, the University is proud of her sons, and wishes them well. As with so many distinguished graduates of the past, may the work embodied in your theses be only a foretaste of what you are yet to accomplish. But I turn to those whose studies here have just ended, who have to-day received the final stamp of approbation upon their labours, and are about to leave the Alma Mater which has given them intellectual nourishment and training during the past four or five years. For my colleagues and myself I congratulate you on the well-merited degrees which you have attained. Some slowly and wearily, with prolonged pains and struggle and privations only known to themselves; some better endowed by nature or education, or more fortunate in their circumstances and time, with an easy, rapid, and brilliant march—you have all reached the goal,

and we rejoice with you in your success. There have been times when, face to face with intricate problems or puzzling questions, we have seemed to you to be bent on barring your road. But you see now that these apparent obstacles have been stimuli to exertion, and that they serve to enhance your merit. If you do not as yet perceive it, you will some day, on looking back at your studies, recognise the fact that our one object has been to teach and help you, and to ensure that your attainments and capacity for professional work shall be in no respect inferior to those of any other medical graduates, and that so far as you may be capable, you shall be superior to most.

Far be it from me to make this the occasion for conveying to the world in general my views on the subject of University reform and University legislation. You have probably heard wholesale condemnations of the entire system of medical education and examination in this University. This is not the place or time to meet these charges. The statements which have been made, whether by those within or without the University, are made in a profound, and in large measure, I fear, a wilful ignorance of the actual conditions under which medical study is carried on here by teachers and taught. I have had large opportunities of observing the state of medical education in England, and I venture to say that nowhere is the instruction so thorough, so systematic, and so personal as in this University. I speak with all the prejudices of an Englishman, with the affection engendered by years

of study and work in London; yet I can honestly affirm that apart from the personal attachment and veneration which I entertain for my old teachers, if my student life were to begin again, I think I should prefer Edinburgh to London. For, apart from other advantages, nowhere is the teaching, viewed as a whole or in its several parts, so thorough as here; nowhere do the teachers devote so large an amount of time, energy, and pains to the development of all the methods and appliances of teaching, or take upon themselves so large a burden of work; and nowhere can a student become so completely trained in every branch of medical science. Gentlemen, it is not pleasant to say, even in self defence, so much, which may seem like undue laudation of my colleagues and predecessors who have made this University what it is. If I do so, it is only because I can speak, as it were, as an outsider, and can see and compare the merits of this and other schools; can see, too, how great have been your advantages. To those who would disparage the degree here, or, by assailing us, would injure your reputation, we say that all we desire is the calm and dispassionate judgment of those who have no interests of their own to serve, and who are capable of forming a sound opinion. Speaking to you who know us, and not through you to those who neither desire nor have the means of knowing us, we are content to stand approved or condemned in your judgment, and yet more in the results of the teaching as they develop in your future life-work.

If one attempts to define the quality which has distinguished this University in the past, I think one may say that it is the tendency to practical application of all learning and science, and the desire for progress. And especially will you find that in the history of medical science, a very remarkable proportion of those who have been eminent in discovery and in practical advance have been either professors or students of this University. I believe that a part of this has been due to the reaction of the various Faculties upon each other, to the practical interchange of ideas in all that is most advanced in literature and art, in science and philosophy, in theology and law; and to the varied academic training which many of the most distinguished graduates have received. But still more has it been due to the recognition of the essential necessity of a thorough scientific training as a basis for practice. It is this which has given to the world such men as Cullen, Gregory, Alison, Bright, Addison, Hughes-Bennett, Marshall Hall, and Murchison, Monro, Goodsir, and Sharpey, Christison, and Simpson, Charles Bell, Liston, Syme, and Ferguson, and the many others whose names are memorable in the past, or who still live to carry on the fame of the University. Addressing you, then, as graduates of this University, in which, as I have said, the scientific training is hardly equalled, and nowhere surpassed, in Great Britain, one may well express the hope that you will maintain and increase its scientific reputation. You have passed through your studies at a time when the teaching appliances of the University have undergone an enormous development, and you have enjoyed, as none of your predecessors did, the advantage of a thorough equipment for practical instruction in all branches of medical science. If, as we believe, this advanced scientific teaching is essential to the complete training of the medical man, those who enjoy it in the greatest perfection should be the most fitted for practice. There are many who view with mistrust or dislike this extension of scientific teaching, who long for the good old times, when the skilful compounding of pills and potions, and the aiding of a parish doctor to bleed, leech, and blister his poorer patients, constituted the portal to medical studies. Others, less sweeping in their condemnation, would

fain combine the new and old systems, and by working at once at the roof and the foundation, would ensure the stability and unity of the building. It is not for me to say that we have reached the perfect system or perfect curriculum. It is of the essence of advance that new systems and new methods of teaching should be developed with the progress of science. We may think that the present curriculum gives disproportionate time to certain preliminary branches of study to the detriment of those more intimately connected with practice, and that there is a tendency to become too technical in these earlier studies, and to fail to impress upon the student their direct bearing on the study of the human frame in health and disease. Yet, I have no doubt that in the future, the earlier training of all highly-qualified medical men will tend to become even more scientific, and that a more intimate knowledge of physics and chemistry, of comparative anatomy and physiology, and of botany will become essential with the further evolution of medical science.

But I must not linger on this topic, or endeavour now to rearrange the medical curriculum. You have profited by the application of this scientific training at a period in your mental evolution when the formation of habits of observation is of the greatest value. You have acquired some knowledge of important branches of science which you could not well have mastered at any other period of your lives, nor with such facilities for their study. You now go forth to put these studies into practice, and to begin to apply them to the personal investigation and treatment of disease. And if you would know in what respects we would have you to excel, and how you may best apply the training you have received, I should say that it is by becoming examples and exponents of the scientific method in medicine. For I take it that it is not the mere acquisition of knowledge, however extensive and varied, which will be of greatest value. It is the care and accuracy of your observations and practices, the sagacity of your inferences, the soundness and balance of your judgment which will alone enable you to use your knowledge to advantage. In other words, it is the application of scientific methods and a scientific mind to the problems of disease. Nor is this all, for one very important result of a scientific training of the medical man is to produce a capacity for advance, and for the assimilation of new discoveries. It may have seemed to you for a time that you had arrived at ultimate truth, solid and immovable, when you had gained a knowledge of certain chemical reactions or physiological laws. But you have long ago discovered that even as regards observation of facts of structure or function our knowledge is only provisional, and that the fact of to-day may be revolutionised to-morrow by some new appliance for research, or some fresh experiment. So that, whilst the old may remain true, it is so altered in its relations or importance that you no longer recognise it as the same. And if this is the case with regard to those physical properties which can be directly observed, how much more with those "laws" which result from inference and deduction? In all departments of medical science this truth holds good, and more especially in those more complex ones which deal with the nature and treatment of disease. A small discovery, or what seems at first a small one, in physiology may upset a score of explanations of the action of a drug, nay, may make that appear baneful which we have been regarding as inevitably beneficial. Yet we may say, with almost absolute certainty, that in twenty years we shall have a new physiology, a new pharmacology, and a new pathology. Why, then, you say, have we thus entered upon scientific study? Why, if the facts of to-day are to be the errors of a year hence have we

so laboriously acquired them? Why beckon us to what seemed solid ground, only to find it sliding away and carrying us with it? Because it is only by thus entering the stream of advance, that you can progress with it, or rather by allowing it to enter into your mental life that you can grow with its growth, and strengthen with its strength. If you have not begun to grow, I fear there is little hope of further development. But if you have begun, let me beg of you to continue to develop. And to do this you must retain a youthful and enquiring mind. The greatest men have always been the least fossilised. Take any man you please, who justly maintains a high position in the esteem of his professional brethren, and you shall find that his mind is open to advance with the progress of the times; that he is the keenest to follow out any new line of research, and the most ready to utilise new discoveries. The moment a man ceases to grow, he begins to degenerate. And, as you know, when proper repair and vitality diminish, there may be more than degeneration. The main periods of morbid growth are those of development and of commencing senility. And one sometimes sees painful examples of men who have in early life been active scientific workers, who at the age of senescence develop peculiar crotchets and hobbies, which not only use up and misdirect what vital energy is left, but form painful and unsightly excrescences, spreading acrid humours amongst the body medical.

But it will not suffice that you shall be open to the reception of new discoveries. It is for you to progress with the development of medical science, and to be capable of judging, testing, and applying the law. The marvellous discoveries which have been made of late years, although ultimately very beneficial, perhaps do more than anything else to encourage in the majority of people an unscientific habit of mind. The anticipation and desire of novelty make anything new credible. Probably in no age has there been greater credulity, more readiness to accept speculation for facts, or to jump at conclusions on the most imperfect data. This is true not only of medical science, but more or less of all science. Hence in no age has quackery been more successful. Do not be surprised if persons of high social position and great intelligence on many other matters crowd the consulting rooms of charlatans of all sorts who trade upon the discoveries of science to palm off their own counterfeits. The realities are so marvellous that it is not to be wondered at that those who have not had your advantages should be unable to distinguish the counterfeit from the true; and whilst we may pity those who imperil their life and health by an ungrounded trust, we may well ask if the attitude of the medical profession to scientific discovery is always a thing to boast of. For there is too often a strange lack of judiciousness in the acceptance or rejection of discoveries. A fact is discovered, which, if verified by future observations, may revolutionise medical science. It may chance to gain immediate acceptance, without enquiry, and to be made the basis of a new doctrine of disease of the most far-reaching import. As likely as not, it may receive the cold shoulder and have to endure years of uphill work. At the present time the tendency is to accept everything at first with the greatest facility, and afterwards to reject it with equal promptitude and as little reason. It is for you to correct this tendency by the cultivation of the scientific mind, a mind receptive to truth from all quarters, capable of appreciating its importance and its relations, and of testing it by research and by practical application. I have spoken of the discoveries of others; let me say a word as to your own discoveries. For it is you who are in the future to carry on the work of discovery and invention, to remodel our science and practice

and to make new conquests over disease. In one sense every man who works diligently and honestly is a discoverer. For by his observations he must extend the basis of certainty of present knowledge, and extended experience must modify and may entirely recast the presently ascertained truth, and lead to new views and new practice. But we expect even more than this from you. Every new generation clarifies the knowledge of the old. Starting where our predecessors left us, we may have risen after years of struggle to a certain point, and our time of strength fails us just at the crucial point of exertion which is needed to attain the result. Youth often sees the truth as it were of instinct. You receive certain ideas or groups of ideas or ascertained facts from different men who, each in his own sphere, has worked them out, and these, coming into contact in your minds, react as inevitably as two bodies having chemical affinity. That they do not so combine in our minds may be because the two sets of ideas never come into mutual contact, or because they are encrusted by habits of thought or scientific prejudice, from which very few are entirely free. If you have such ideas or discoveries germinating in your minds, on no account neglect or discard them. Many discoveries are really made when a man is young, although it may take years of patient experiment or observation before the seed truth develops into proved and accepted fact. Only do not let the combination of ideas take place with too great evolution of light and heat, far less with explosive violence. The product will be none the less stable for a quiet and governed reaction. It is of no advantage to a man that his discovery of a truth, however important, should for him destroy or overshadow all other truths, or shake to the foundation his hold of eternal verities. Do not be too hasty to promulgate half-established discoveries, nor expose your delicate growing plant too soon to the cold winds of opposition and criticism, lest you should find that your time will become occupied in embittered controversy which should be devoted to maturing your observations. Much harm is done to science by haste for distinction and priority. Few discoveries are made by one man alone, and scarcely any discovery is in the truest sense original. The discovery is the product of the time, and whilst it may be that he who is quickest, or most fortunate, or most popular, wins the credit, yet the palm is usually awarded to the one who combines the greatest ability with the greatest earnestness and diligence. If you will read the history of discovery in any branch of science, you will find that often simultaneously, and at the most distant places, the same discovery is made. Out of a multitude of instances of the kind, I cite such trite examples as those of Adams and Leverrier in astronomy, Virchow and Hughes Bennett in pathology, Priestley and Scheele in chemistry, and if there is no real rival, one is sure to be found or invented. Even the illustrious Harvey shall not rest in peace as the discoverer of the circulation of the blood, but literature in nearly all the languages of Europe shall year after year be poured forth to uphold the claims of one or other rival. Now, it is one thing for future ages to interest or amuse themselves with the investigation of these rival claims, quite another for a man to be so greatly concerned to establish his own priority. It is a most curious study of human weakness to observe how constantly this is done; how even for some most trivial modification of an instrument a man claims, as it were, a scientific patent, and demands that all the world shall pay him homage as an inventor. The smaller the matter the more need apparently that he shall blazon forth his merits, forgetful of that wise saying—"Let another man praise thee, and not thine own self." By all means let a man maintain and

promulgate that which he has discovered, which is for the good of humanity. That in so doing he shall have to encounter painful opposition and unkind criticism, is one of the bitters in the cup of that joy which must come to a man who makes a great discovery which is to benefit mankind. But let a man rejoice in the promotion of truth, whether of himself or by another. True science is ever humble, and the truly great discoverers, such as Newton and Faraday, have been amongst the humblest of men. Those who demand the acceptance of hypotheses as facts, of theories as discoveries, are in greater or less measure dogmatic, self-assertive, and devoid of humility, seeking by loudness of asseveration to cover the weakness of their case.

If I would bring before you for your imitation a living example of the medical discoverer, I could not do better than instance the name of one whom we all regard as one of the greatest discoverers of the present day, a man whose worth and reputation are indissolubly connected with this University, whose discoveries have revolutionised surgery, and conferred incalculable benefit on his race. Only those who have watched the slow acceptance of the antiseptic system, and who have seen the dead weight of prejudice and hostility which it has had to encounter during the past fifteen years, can appreciate the labour and self-sacrifice and the mental and moral trial which its discoverer has had to bear. And to those who know Sir Joseph Lister, the greatness of the man is increased tenfold by the magnanimity with which he has borne the attacks made upon him, and the infinite pains which he has taken to correct defects of detail, to establish every point upon a scientific basis, and to perfect to the utmost the practical application of his root idea.

I have said enough of the relation which you should maintain to the progress of discovery. And if it is well to be open to advance, be also reverent to the past. There may be a tendency to regard with compassion, if not with some disdainful sense of superiority those whose knowledge is not so recent or so scientific as your own. You may be brought into close relations with men who may be unacquainted with the terms you use, and who perhaps do not even know the names of diseases or remedies which are to you as household words. But beware of considering that they are behind the age, or have neglected their opportunities. Very possibly they are far abler and more scientific than you, although they have not had your more modern advantages. Certainly, they know far more than you of disease and its treatment, and if when you are fifty you, so learned in the wisdom of the moderns, are as skilled in practice as they, you may congratulate yourselves. Be quick to learn from them the practical lessons of their ripe experience, and communicate to them in return your new green fruits. Nor is it only to living ancients that you should respectfully listen; you will do well in the leisure of your early years to study the works of those great men of the past, whose marvellous sagacity in the observation of disease affords lessons for all time.

And if you would utilise the training you have received, carry with you into your practice that thoroughness and exactness of observation which you know to be essential to all experiment and research. If patient investigation, laborious work, and minute accuracy of record are needed for the elementary studies, far more are they requisite for the advanced study and complex study which fall to your lot in practice. If you do not continue to train to the utmost your eye and ear and touch, and acquire the use of the various aids to diagnosis, your training will have been largely thrown away. And if you do not acquire scientific habits of thought, and train your

reasoning faculties to the utmost, you will fall far short of what is required of you. No good work can be done in practice, medical or surgical, without some degree of scientific method.

But beyond and above all these we must place as the highest resultant of a true scientific training that capacity for observing and receiving truth, of perceiving its due relation and importance, and of acting upon it, which should be the outcome of all wisely directed study of nature. It is sometimes supposed that the study of science tends to materialism and to a rejection of religion. I cannot see how this can be so. The effect upon every open mind of studying the marvellous workings seen in nature, and especially in biology, should be to reveal the infinite mystery of life, and to impress the observer with the sense of his own extreme ignorance and littleness. Nor can I conceive a more unscientific attitude of mind than that of those who, professing to be humble observers of facts, and, so far as may be, interpreters of them, yet decline to observe or even see those facts in life which are more manifest than most physical phenomena, and more intimately connected with the welfare of the race than all discoveries in physical or natural science put together. Yet there are men who, because they think that some statement in the Bible is not in exact accordance with their views as to the modern physical sciences, will shut their eyes to all other statements, and will disregard the accumulated facts, teeming all around, of the effects of belief upon the life and character of individuals and races. What a strange spectacle to an unbiassed philosopher, of men professing to be seekers after truth, yet who will not see the light which is all around, because they are not sure whether their window is constructed upon strictly scientific principles. It is not true science which sneers at or rejects religious faith, but a parody of science; a one-eyed science and not a sound and healthy scientific mind. You have seen the effects of religious faith during your studies here, and I beg of you to observe and investigate with equal candour and openness of mind the facts of religion as you would of any other subject. For no man who humbly and earnestly seeks after the truth shall fail to find it.

It may seem to some of you that I have laid too much stress on the intellectual side of your work. If I have done so, it is rather because it is too apt to be neglected, not so much in words as in action. That there are many other qualities essential to success I am well aware. You will soon find that the race is not always to the swift, nor the battle to the strong. Nor is your future relative position to be gauged by class or University distinctions. Social ability and manners, business capacity, influence, money, and health will have much to do with determining your lot. And far beyond these, moral character, which is the most powerful agent for good or evil. Circumstances, acquirements, learning, and distinctions are but integuments, the framework is character, and it is that which mainly governs a man's career. And even if it does not ensure fortune, it makes the difference between happiness and misery, between honour and usefulness and the reverse. But remember that it is not of yourselves or your own success that you are henceforth to think first or chiefly. You take upon you to-day the character of medical men, and in so doing you take vows of self-denial and consecration to the relief of suffering. You take a position which demands and deserves your self-devotion, and which requires of you that you should seek to cultivate all that ennobles and purifies the character and life. Your relations to your patients will give to your character an incalculable influence over them and their friends for good or ill. Let it be such that they may not only experience your kindness, gentleness, and patience in sickness, and be

able to entrust to your confidence all that they hold most dear, but that your life shall react as an elevating power over theirs.

But it is time that we should part. Believe me that we cannot take leave of you without deep feeling. Your faces have become familiar to us in the lecture-room, we have worked with you in the practical classes, and you have given us invaluable aid in teaching. And, still more, you have with us entered upon the struggle with disease and death in the Infirmary wards, and we have been united by the common bond of sympathy with suffering humanity, and in efforts for their relief. To you we are indebted for that stimulus of contact with young and energetic and unprepossessed minds, which is essential for our mental activity and growth. We have watched your growth and development, a development not only of professional training and acquirements, but the unfolding of character and ability. Entering as many of you did, as mere lads, you have passed through one of the most critical periods of the formation of character, and you go out as strong men. We have formed with you a friendship which separation and silence will never break, and as we have rejoiced in your success in the past, so your future prosperity will be our happiness. We feel keenly the separation as with each returning year we part with those who have been our most familiar and intimate companions, who go to all the ends of the earth, knowing full well that on this side of the grave at least we shall see many of your faces no more. And at such a time no man need be ashamed of feeling—nay, he needs to be ashamed if he do not feel—what a solemn weight of responsibility rests upon him for the effect which his character and teaching may have had upon those from whom he is parting. No words can add to, nor regrets subtract from that; for good or evil it is done, and its effect will continue. Nor can we fail to entertain some solicitude for their future, for the honour or dishonour they may bring to their University, for the benefits which they may confer upon suffering humanity, and for their own peace and prosperity. At such a time one would, if it were possible, concentrate into one small word all the weighty councils and sage precepts of experience, so as to convey to each of you in parting that triple essence of wisdom, that nucleus of discretion around which all that is wise and right in thought and action should develop. But as one asks again that question, old as the ages, "Where shall wisdom be found?" there comes but one answer which satisfies the problem and has stood the test of generations. You know it well—"The fear of the Lord is the beginning of wisdom, and a good understanding have all they that keep his commandments." And commending that to you, I bid you "Farewell."

**CHLORIDE OF AMMONIUM.**—It increases the secretion of mucus from the alimentary canal, and is supposed to render the blood less plastic and coagulable, without impairing the structure of the corpuscles. Its habitual use causes emaciation, renders all the secretions freer and more abundant, and exerts an alterative and absorbent action, especially on the connective tissues, in hyperplasia and cirrhosis of many organs. It has even exerted some beneficial influence upon fibrous tumours of the uterus, and much more on chronic engorgement of that organ. Its slow but steady modification of the nutrition of the connective tissues has been seen in chronic enlargement of the liver, spleen, prostate, thyroid, &c. It cures many cases of gleet, and if any internal remedy will remove stricture of the urethra, this is the one most apt to do it. It cures some cases of neuralgia dependent upon thickening of the neurilemma, and is one of the best remedies in fibroid phthisis.—*New York Medical Record.*

## CLINICAL LECTURES

ON

### DISEASES OF THE URINARY TRACT IN THE YOUNG.

DELIVERED AT THE HOSPITAL FOR SICK CHILDREN,  
GREAT ORMOND STREET.

By JOHN H. MORGAN, M.A. Oxon., F.R.C.S.,  
Assistant Surgeon to the Hospital.

#### LECTURE III.

HÆMATURIA is a symptom of even wider signification in children than in adults. I have alluded already to some of those conditions under which it may occur, lithiasis, calculus, tumours or tubercular disease of the bladder. Speaking generally, hæmorrhage from the kidney is more profuse than from the bladder, and it may be caused by any of those affections which originate in that viscus. But besides these causes, blood may be found in the urine to be dependent upon general diseases. In purpura or scurvy, in addition to blood-cells, there may be found casts of the renal tubules, and the diagnosis is established by the presence of the characteristic hæmorrhages in other parts of the body, or from other mucous surfaces. In albuminuria the blood is seldom found in larger quantities than will give a slightly smoky tint to the urine, and the albumen exists in larger quantities than can be accounted for by the presence of blood. In intermittent hæmaturia or hæmoglobinuria, the blood corpuscles are destroyed and the symptoms appear after exposure to cold, and are usually ushered in by a rigor. These, then, are the causes of hæmorrhage which must be examined in the absence of any local indications.

Retention of urine in a child occurs only from impaction of a calculus in the urethra, or abscess pressing upon the walls of that canal. In most cases it is possible to pass a small gum catheter past the stone or even to push it back into the bladder, but should this not be readily possible it is necessary at once to open the urethra and to extract the stone. The small uric acid calculus which I here show you, was removed by lateral lithotomy from a boy aged 13, to whom I was called on account of retention of urine. The bladder was immensely distended, and the patient in very great pain. I succeeded in passing a catheter, and in doing so pushed the stone back into the bladder, from which it was removed on the following day.

With all those various sources of irritation which have been mentioned, it may be wondered that acute inflammation of the mucous membrane of the bladder, which is highly sensitive and vascular in children, is not more frequently met with. But though chronic cystitis may be induced by any of the causes which we have discussed, an acute condition is very rarely encountered. One instance occurred in a child under my care, upon whom I had operated for the cure of a spina bifida by the injection of Morton's solution of glycerine and iodine. Although there was no sign of constitutional disturbance, there was complete and obstinate retention, which persisted for over three weeks, during which a catheter had to be passed every few hours, and there ensued an inflammation of the bladder with mucopurulent urine and all the other symptoms of cystitis. These gradually disappeared, and a subsequent injection of the tumour caused its consolidation, and was not followed by similar symptoms. The child was aged eight months

and is now perfectly well. Before quitting this subject, I must mention one case of great interest which occurred here lately, under the care of my colleague, Mr. Owen, in which a tumour of the bladder was the cause of retention, for which it was necessary to perform cystotomy. The case is in some respects unique, and with his permission I give the notes.

R. S., aged three years, had always been noticed to strain in passing urine, but had done so to a greater extent during the last twelve months, and had complained of pain in the hypogastrium before micturating. He would often go sixteen hours without passing water. Blood had never been observed, nor had any stone or gravel been noticed. There was no family history of stone or of malignant disease. He was perfectly well until four days previous to admission, when complete retention set in which was relieved by the passing of a catheter on several occasions.

On admission he was fairly well nourished. The distended bladder reached up to the navel. He passed no urine, and under an anæsthetic a No. 4 silver catheter was introduced, not without difficulty, and pressure had to be made upon the walls of the abdomen in order to make the urine flow, showing the atonied condition of the viscus. Neither blood nor albumen were detected in the water.

On the following day Mr. Owen performed cystotomy on account of the increased difficulty of introducing the catheter, which caused acute pain and was followed by the passing of blood. The following day he developed a scarlatinal rash, and four days subsequently he sank with symptoms of peritonitis.

*Post-mortem Examination.*—The body weighed 26 lbs. In the peritonæal cavity flaky lymph was found on the peritonæal surfaces of the organs, the intestines were distended and considerably injected. Some creamy pus was loculated in Douglas' pouch by the adhesions formed around, but no communication was detected with the cellular tissue of the pelvis. The cavity of the bladder had about one-third more than its usual capacity, and its walls were flaccid. All the tissues around it and the rectum were easily broken down, and were infiltrated with thin purulent fluid, which seemed to spread upwards along the course of the vas deferens on each side. The track of the wound led into the bladder and admitted the index finger, and the parts about the neck were in a state of gangrene. On opening the viscus from above well-defined patches of a new growth came into view. It sprang from the region of the neck, and involved the inner aspect of the floor of the cavity as far back as the orifices of the ureters, each of which was surrounded by new growth, though neither appeared to be occluded. A better-defined and larger area of neoplasm arose from the inner wall behind the pubis. This was  $1\frac{1}{2}$  inches in diameter,  $\frac{1}{16}$  of an inch thick. The growth was soft and crumbling at the surface, but firmer in its deeper portions. Microscopically, it presented the ordinary characters of lympho-sarcoma in most parts; some of the superficial portions showed little fibrillar structure; in some portions round and spindle cells were massed, the whole exhibiting, therefore, the characters of a mixed celled sarcoma. There were no secondary deposits and no enlarged glands.

I give the particulars of this case as abridged from the careful record of our registrar, Dr. Chaffey, because it is the only instance to be found of a sarcoma affecting the bladder of a child. Tumour of this organ in childhood is indeed very rare, and the instances of it recorded go to show that it is generally innocent in character. In his work upon "Tumours of the Bladder," Sir H. Thompson alludes to eight cases of which specimens were preserved in London museums, and which had occurred in children. Of these six were in females, and most were examples of the simple mucous polypos

or myxoma. The growths are generally multiple, as in the case which occurred in a girl under Mr. Marsh's care in this hospital, and is described in the 25th Vol. of the "Pathological Society's Transactions." The child was aged two, and when one year old, a dark fleshy-looking growth projected from the vagina, which was tied and fell off. This happened to others, and when the case was seen by Mr. Marsh, six of these masses had been ligatured. Then came retention of urine, which was complete, with attacks of pain and straining, slight bleeding and offensive discharge. On examination under chloroform, a large bunch of growths like polypi were found just within the vulva projecting from the vagina and distending the urethra. They varied in size and in colour, some being pale and others darkly purple. It was thought advisable not to interfere, and death took place sixteen months after the disease had been first observed. On examination of the specimen, it was described as an overgrowth of connective tissue.

A somewhat similar mass of growth is shewn in specimen No. 2,000 in the Museum of the College of Surgeons, which was taken by Mr. Crosse from a boy aged  $1\frac{1}{2}$ , and is described and figured in his work upon calculus. The boy presented all the symptoms of stone, and the lateral operation was performed, when several small tumours protruded from the wound, some of which were removed. A case of great interest occurred in the practice of Prof. Billroth, where in a boy aged 12, with frequent painful micturition, a tumour could be felt in the region of the bladder, which was suspected to be connected with the back of the viscus. The lateral incision was made, and a tumour nearly the size of a fist, with an uneven surface, was found projecting from the posterior wall into the cavity of the bladder. Owing to its size it was found impossible to extract the tumour with the finger through the perinæum. A suprapubic incision was then made, both recti were cut across, and a transverse incision carried into the bladder. The tumour was then torn through near its base with the finger, and the pedicle dissected out. It appeared to take its origin from the muscular coat, and had not attacked the peritonæum. A drainage tube was passed into the bladder and drawn out at the incision in the perinæum. In a month the patient was discharged perfectly well. The tumour was principally a myosarcoma, and in some places a myocarcinoma. The case is quoted by Professor Humphry in a paper upon the successful removal, by the lateral incision, of a growth, about the size of an orange, from the bladder of a man aged 21.

Looking, then, at the great probability that a growth from the mucous membrane of a child is of an innocent nature, and remembering the position of the viscus in the young, which is mainly in the abdomen, I should be inclined at first to explore, by median urethrotomy, in the male, or possibly by dilatation of the urethra in the female, and if the growth could not be extracted by this means, to follow the example of Billroth and deal with it from in front, which would have all the greater chance of success from the ease by which the urine would be carried off through the lower opening.

Excepting that condition of dilatation of the pelvis of the kidney, and of the ureter to which the name hydronephrosis is applied, morbid conditions of the ureter rarely come under the observation of the surgeon. Occasionally, however, hydronephrosis is found in children to result from malformation of the ureter, and this may give rise to a fluctuating tumour which requires to be emptied, and the same condition has been the result of a blow upon the loin. The diagnosis of even so rare an affection is not so difficult as might be supposed, the question generally lying between cystic tumour and abscess in or around the kidney. In either case aspiration determines the diagnosis, and

the treatment of abscess should not be delayed, lest the contents should find an exit for themselves by way of the bowel, or as has on one occasion been noticed by the sheath of the psoas muscles. Free incision and drainage from the posterior part of the collection should lead to a good result, where the mischief has originated around the kidney, and where the gland itself is not materially injured. In hydronephrosis, removal of the ureter and kidney should only be attempted where the state of the urine warrants the assumption that the opposite kidney is sound, and capable of performing all its excretory functions.

The remaining conditions of the kidney under which operation may be undertaken are: calculus in the pelvis, tubercular disease and new growths in or invading the gland. To this subject attention has of late years been frequently directed, and it is probable that much success may attend future efforts. In all these conditions the great difficulty is to determine the state of the opposite gland, and upon this depends entirely the chance of success of removal of the faulty organ. But experience is gradually showing with what impunity an exploratory incision can be made to ascertain the state of the viscus to which symptoms are referred, and this is especially successful in cases of renal calculus, because when a stone exists in one kidney there is little probability of the other being affected. The new growths which affect the kidney are almost invariably sarcomatous, and generally originate in the tissue of the gland itself, although some interesting specimens have been shown by Dr. Abercrombie in which the growth commencing outside went on to invade the gland. The difficulty in dealing with them lies in the fact that it is not until they have attained considerable size that they can be detected, nor do they at first show any symptoms either by the urine or by swelling in the region of the loin. Later both these symptoms are evident, but by that time the growth has attained considerable size, and the glands or internal organs are probably affected. Add to this the extreme vascularity of these tumours and the loss of blood which their removal entails, and it may be doubted whether nephrectomy, under these circumstances, can ever be much resorted to. Still the operation has been successfully carried out, and if the diagnosis can be arrived at sufficiently early, it is only proper to make the attempt. The kidney has also been successfully removed in children for tubercular disease, but here, again, the great obstacle to success is the fact that when disease is advanced in one gland it is never entirely absent from the other, and exists probably more or less in other viscera. Still there are a few cases in which operation may bring relief, and we must wait for more experience on the subject to enable us to determine the points which should guide our action. Better results appear so far to have been obtained by the lumbar than by the abdominal incision, but the former in children allows so very little space that the latter must almost necessarily be resorted to if there be expectation that the parts to be removed are of any magnitude. The whole subject is one of the greatest interest, but here I am compelled to leave it for the present.

---

**INJURIES TO BLOOD-VESSELS IN DISLOCATIONS OF SHOULDER.**—The *New York Medical Journal*, June 12th, contains an elaborate paper by Dr. Stimson, Professor of Clinical Surgery in the University of the City of New York, which was read at the New York Surgical Society. Its precise title is "Injuries to the Main Blood-vessels in the Axilla, caused by efforts to reduce Dislocations of the Shoulder." It gives a very exhaustive criticism of all recorded cases, but is much too long for our pages, while it does not admit of abridgement.

## ADDRESS IN SURGERY,

DELIVERED BEFORE THE BRITISH MEDICAL ASSOCIATION  
AT CARDIFF.

By J. MARSHALL, F.R.S., F.R.C.S.,

Late Professor of Surgery, University College, London; Consulting Surgeon to University College Hospital.

(Concluded from page 177.)

**OPERATIONS.**—Five cases of lithotomy, four of herniotomy, and one of perinæal section for laceration of the urethra, all successful, afford evidence of Liston's skill as an operator; and, as regards the duration of the cases, three of the lithotomies were cured within the month; one on the thirty-third day; and the remaining one, an elderly patient with large stone, on the fifty-third day. One of the hernia cases was discharged cured on the ninth day, one on the twentieth, another on the thirtieth, but one not until the forty-seventh day. The perinæal section was closed on the twenty-eighth day. A case of phimosis, in a boy required twenty-four days to cicatrise; and another, in an adult, was followed by erysipelas, severe rigors, and bubo, and was healed only after thirty-nine days. *Fistula in ano* behaved as now; but one patient thus afflicted died, on the seventh day after the operation, from pulmonary complications. Two cases of extravasation of urine were unavoidably fatal, in one of which minute abscesses were found in both kidneys.

For the removal or excision of new growths, twenty-one operations were performed in the year 1844-5, eight upon men, and thirteen on women. They may be thus briefly detailed. Male cases: three—namely, a small epithelioma of the tongue, epithelioma of the lower lip, and a small thyroid cyst, healed by first intention, by the end of a week; two, namely, a larger thyroid cyst, and a broad epithelioma of the lower lip, healed with granulation in nineteen and twenty days; three, namely, a parotid tumour, a cystic sarcoma of the testis, and a large lymph-cyst of the neck, all attacked by erysipelas, were cured in twenty-nine, thirty-four, and fifty days respectively. Female cases: five fatty tumours; the wound in four healed by granulation on the twelfth, eighteenth, twenty-fourth, and fifty-seventh days; in the fifth, a succession of rigors, on the first, third, and fourth days, with offensive discharges, the patient was sent out of the hospital on the fourteenth day, and died seven weeks later; five mammary tumours; one a cystic tumour, patient left the hospital doing well on the fourth day; the others, namely, a painful tubercle, two sarcomas with cysts, and a scirrhus, healed by granulation and suppuration, twenty-one to twenty-eight days; a large parotid tumour, followed by abscess and profuse suppuration, thirty-two days; and lastly, a large thyroid body, seton inserted for ten days, suppuration, intense fever, fifty-seven days. To these cases, I must now add that of a very large ovarian tumour, of three years' duration, tapped once before; operated on, in the words of the case-book, "in Mr. Liston's usual manner," that is, "by a previous incision into the abdomen," and "the introduction into the cyst of a large trocar and canula"; "thirteen quarts of a dark-coloured glutinous fluid" evacuated, some more afterwards squeezed out, wound closed, next day pain and vomiting; on third day decided peritonitis; treatment by leeches, fomentations, opium, calomel, hydrocyanic acid, and creasote; incessant vomiting, exhaustion and death on the twenty-second day. *Post-mortem*: peritonæal cavity

contained "three pints of purulent-looking fluid, with portions of badly-formed lymph floating in it"; "cyst partly refilled," with "soft adhesions to adjacent parts." In Liston's "Elements of Surgery" (edition 1840) ovariectomy is denounced, from contemporary experience, as an "unjustifiable piece of butchery!" How this has all been changed by cautious, and, if I may coin a word, *precautious* surgery!

In two subcutaneous operations, one for a contracted toe, and another for displacing a loose body from the knee-joint into the areolar tissue outside the capsule, the wounds healed at once, without suppuration; but in a third, for directing the proper extensor tendon and the long flexor tendon of the great toe, abscesses and ulceration detained the patient 69 days in the ward. Of plastic operations, Liston's great pride, a divided hare-lip united before the end of a week, and an example of webbed fingers healed in a fortnight; but four operations on the face, for pendulous upper eyelids, cancerum oris, partial destruction of nose and upper lip, and complete loss of the nose, required for the healing process 33, 42, 43, and 66 days respectively. An operation on the scrotum, designed to cover a testis, exposed by gangrene, necessitated treatment for 50 days. Ten amputations and one excision of a joint are also recorded. First, four female cases: compound dislocation of finger, erysipelas, abscess in axilla, 30 days; diseased phalanges and joint of finger, erysipelas, abscess in axilla, 29 days; excision of elbow-joint, ends of humerus and ulna removed, abscesses and extensive burrowing of pus up and down the limb, eventual good result, 93 days; large "bleeding sarcoma," or "fungus hæmatodes," springing from integuments of the forearm, three or four years' duration, lately rapid growth, axillary glands sound; amputation above elbow, rigors on seventh day, discharges very offensive, abscess in axilla with similarly offensive pus, sweatings, emaciation, jaundice, made out-patient on sixty-ninth day, death one month afterwards. Male cases, seven: compound fracture of finger, healed in 16 days; badly crushed finger, so-called "erythema," abscess in palm, patient discharged on twentieth day; comminuted fracture of finger, cellulitis, deep sub-fascial suppuration along the forearm, 59 days; disease of tarso-metatarsal joint of great toe, removal with internal cuneiform bone, prolonged suppuration in foot, 92 days. There remain three major amputations, all fatal. First case, a buffer accident, compound fracture of tibia, and fracture of head of fibula into the knee-joint on the right limb, fracture of tibia with lacerated wound of leg on left limb, primary amputation of right limb above the knee; progress favourable for three days, then some hæmorrhage, left limb became much discoloured, rapid exhaustion, followed by death on the eighth day; *post-mortem*, collection of pus around cut end of femur, and extending as high as great trochanter, yellow line of demarcation on left leg; internal organs not examined. Second case: sarcoma of leg, originating in a cicatrix from burn; amputation above knee, profuse suppuration, separation of flaps, hæmorrhage, general oozing, death on the sixth day. Third case: sarcoma springing from front of tibia, amputation through knee-joint, patella and cartilage on end of femur left, good progress for five days; on the sixth day a slight rigor; on the ninth day severe rigors; on the eleventh day another rigor with profuse sweatings, discharges foetid, flakes of loose cartilage coming away; on the thirteenth day another rigor, subsequently several others less severe, and death on the seventeenth day. No *post-mortem* examination, but the case was typically pyæmic.

In the case of aneurysm of the femoral artery, in which the temperature of the two limbs was registered by aid of a thermometer, as the tumour reached above Poupart's ligament, it was necessary to tie the external

iliac artery. On the third day, swelling, and so-called "erythema," appeared around the wound; the patient had dyspnœa, a rapid pulse, restlessness, and delirium; the temperature between the toes of the affected limb, which became dusky, was gradually lowered to 84°, 72°, and 64°, as compared with 93°, 97°, and 78°, between the toes of the sound limb, the temperature of which, however, also fell; the patient succumbed, apparently septicised, on the sixth day.

The picture thus finished of the results of the surgical practice in Liston's wards in 1844-5 is full of instruction. The separate mention of individual cases, all of which I have read from beginning to end, serves to enforce the lessons they teach. In the light of present knowledge, the frequency of grave inflammatory complications must be attributed to removable or corrigible conditions, which would have been prevented or minimised by more effectual sanitary arrangements, by the isolation of infective disease, and by strict antiseptic precautions.

It will have been noticed that, in cases of injury or disease not involving a breach of surface of the body, and in cases in which, as in operations in the perinæum or ischio-rectal fossa, antiseptic dressings are not available, the results of the older practice are quite upon a level with those of modern experience. Even in regard to ulcers, this is also true. But in the case of recently opened abscesses, and especially of open wounds, whether accidental or intentionally inflicted by the surgeon in his operations, in which the delicate walls of divided and exposed blood vessels, the cut or lacerated surfaces of the interstices of the areolar tissue, and the torn and irritated lymphatics are helpless to resist the entrance into the system of infective fluids and organisms, we find that prolonged suppuration, erysipelas, cellulitis, lymphangitis, pyæmia, and septicæmia, as it were, dogged the footsteps and foiled the handiwork of the most skilful operator of his time.

We have seen that all abscesses, when opened, continued to suppurate freely; whilst in four cases (14 being the total number), grave complications arose, one case ended fatally. Again, of 27 cases of accidental wounds, only 5 healed quickly by the first intention, 7 by granulation and free suppuration, and 13 after prolonged suppuration, cellulitis, or erysipelas, whilst two terminated in death. Lastly, of 54 wounds made in operations, 8 only united by the first intention, 26 closed after granulation and free suppuration, 14 were cured after the occurrence of erysipelas or cellulitis, with secondary abscess, and, excluding two unavoidable deaths from extravasation of urine, four died of septicæmia or pyæmia.

It must be within the experience of every living hospital surgeon that no such calamitous results follow his own practice. It is unnecessary to quote here, in detail, the number and kinds of cases treated in my wards in the year 1883; but the facts relating to those cases, which are carefully reported, show indisputably that abscesses, both acute and chronic, treated by incision, proper drainage, and antiseptic dressings, heal with much less subsequent suppuration, and in less time, than under the open treatment; that accidental wounds, maintained in an aseptic condition, are far less frequently followed by serious complications than formerly happened; and that operation-wounds of all kinds heal more quickly and kindly under antiseptic treatment. By way of illustration, it may be mentioned that in 24 operations for the removal of new growths, the wounds were healed in five cases between the seventh and tenth days, in seven cases between the fourteenth and twentieth days, in seven cases between the twenty-fifth and thirty-fifth days, and in four cases between the forty-third and fifty-fifth days, and in one only, a case of a double operation on a cancerous penis, on the seventy-third

day. It must also be added that in no case was there more than a show of suppuration, and that no case of erysipelas, infective cellulitis, septicæmia, or pyæmia, arose, during the year in question, in the wards under my care; yet these diseases were not absent from the hospital, for three cases of pyæmia, one of septicæmia, and five of erysipelas originated in other wards, whilst sixteen cases of erysipelas, or infective cellulitis, were admitted from outside into the proper erysipelas-wards. It must, in justice to the older period when there were no isolation-wards, be granted that some of the cases of injury complicated with erysipelas were already so affected on their admission; but most of those cases, and all those following on operation-wounds, arose within the hospital, making a total of at least 24 cases of septic disease arising in Liston's wards in 1844-5, as against none arising in my wards in 1883. It is easy to trace, in these older records, that frequent and long acknowledged co-existence of endemic and hospital erysipelas, to which a recent joint Franco-German Surgical Commission of Enquiry into the effects of that disease has directed attention; and, indeed, it may be said that in Liston's time not only did inflammation, which, like fire, may be a good servant but is a bad master, attack every wound, and free suppuration, which, if not a combustive is an exhaustive process, run riot in the wards: but the demon of erysipelas, which so often gained an entrance therein, if it did not strike all the patients, at least hovered over every bed. Its vagaries were well understood; its advent took no one by surprise, and there was one bed in particular, in the corner of a certain ward, in which it most frequently seized its victim. This familiarity with it in hospital practice explains perhaps the promptitude, and, judging from the number of recoveries which followed it, the success with which it was treated when it occurred. But neither it, nor other septic diseases, nor the tendency to undue suppurative inflammation were efficiently prevented.

On general principles, every surgical patient was subjected, almost *in limine*, to the inevitable purge, consisting of the nocturnal dose of blue pill or calomel, with colocynth and henbane, and a choice between castor-oil or a black or white saline draught in the morning. Subsequent fever was met with salines, often combined, even in the later stages, with antimonial wine, and sometimes with the then new remedy, acorite; rigors, sweatings, and exhaustion were combated with ammonia or mineral acids, administered in bark. In the meantime, complete purity of the surroundings, absolute surgical cleanliness, and the exclusion of all noxious substances, were not strictly aimed at, or attained. Sanitary vigilance was dormant, or did not exist; and the dressings, the famous water-dressings, alas! were doubtless the constant innocent, but not innocuous vehicles of infection. Liston, as is well known, denounced all resinous plasters as "dirty applications," and all ointments as "greasy abominations," prefixing to these appellations a strong characteristic epithet. Isinglass plaster, wet lint, and oiled silk, were no doubt neat, and to the eye cleanly; but they were not aseptic. Lint "stuffed" into open abscesses, sinuses, and carious cavities, or placed for a few hours between the flaps, after an amputation, would certainly contain organised or unorganised extraneous particles; and the water with which it was moistened, surely not previously boiled, would also contain them. The heat and moisture of the living tissues, and of the exudations from them, would favour the development of germs, as well as the formation of lifeless but injurious chemical compounds. To us, the consequences are clear. No change of dressings, however frequent, and no occasional use of chlorinated lotions, or iodised solutions, would cleanse effectually the

microscopic but Augean recesses of the injured tissues. Hence, more or less suppurative action ensued, and more or less deadly agents of infection gained an entrance into the vessels and the blood. Asepticised air, hands, instruments and sponges, together with all the varieties of aseptic ligatures, sutures, and dressings, form a remarkable contrast to Liston's means of treatment. It would be untrue, and calumny against Nature, to say that these and other antiseptic agents are everywhere and at all times indispensable necessities of surgical practice. As narrated to me by a French surgeon, an eye-witness to the facts of an African campaign, an Arab's cheek, all but sliced off and hanging down, may be stitched up in its place, and bandaged with strips from his own cotton garments, and then unite by the first intention, with scarcely a drop of exudation; and I have been told of a gentleman colonist in Australia, who cut open his knee-joint in felling a gum-tree, sewed up the wound himself, and put on a back-splint, before the nearest surgeon, who resided 60 miles off, could arrive, and was cured "straight off" without suppuration, preserving a perfectly useful limb. Union by the first intention occurred long before the antiseptic system was devised; and it occurs still without its aid. But in formidable operations anywhere, and in most operations in hospital, it is a safe and therefore an incumbent provision to adopt. In this view adequate hospital expenditure for antiseptics is fully justified. Their employment shortens the period of cure, limits the amount of suppuration, diminishes the drain upon the bodily strength, lessens the risk of complications and the chances of future organic degenerations, and thus contributes to a more rapid, complete, and lasting recovery.

As anæsthetics encourage patients to submit more frequently, willingly and hopefully to more and more serious operation, so antiseptics have emboldened surgeons to attempt, and enabled them to succeed in enterprises formerly considered hopeless and unjustifiable. When I remember Liston's grave and despairing looks at his too frequent disappointments, I welcome the confident glance and triumphant expression of many a modern operator.

Of the three great cavities of the body, the abdomen, with its membranous coverings, the one least protected and most accessible, containing parts less immediately essential to life, and yet, from its size and the extent of its lining membrane, the most prone to a rapidly fatal inflammation, was the first to be entered by the properly aseptic hand; next, the thorax, with its half-bony and half-membranous walls, and therefore better protected and less open to access, containing parts more immediately necessary to life, but lined by a membrane of smaller extent, and subject to less formidable inflammatory reaction, yielded entrance to the antiseptic method of procedure; and, lastly, the cranio-spinal cavity, the smallest, the most perfectly enclosed, the best protected, enclosing organs of vital essentiality, and yet lined by a membrane of moderate proclivity to disease, has been invaded by the new surgery, under the guidance of an improved diagnosis, in search of removable disease. Even the cervical region, which, though not designated a cavity is, nevertheless, a specially adapted part of the general cavity of the body, has become the field for the employment of aseptic methods.

It might thus seem as if surgical enterprise and skill, applied to the trunk as contrasted with the limbs, had reached their utmost attainable limits; but it cannot be so. Already, the cry is for still greater security against the consequences of irritant and septic influences. That this will be obtained in the future, no one can doubt.

Forty years since, Liston was deprived of our present advantages, and suffered accordingly; but his dexterity and fame as an operator, his desire to simplify all surgical proceedings, his lasting devotion to and sound knowledge of anatomy, and his interest in the then opening science of pathology, require no vindication at my hands. May the next forty years witness as great advances as have been realised since his death; and, in that future, may the reputation of British surgeons, and the triumphs of British surgery, be maintained by our successors with undiminished lustre.

## PRACTICAL NOTES ON THE ORDINARY DISEASES OF INDIA.

By NORMAN CHEVERS, C.I.E., M.D., F.R.C.S. Eng.,

President of the Health Department, Social Science Association.

(Continued from page 112.)

### DISEASES OF THE EYE.

My remarks will be almost exclusively confined to the chief of those peculiarities which distinguish Ophthalmic Disease in India.

It appears in the Report of the Sanitary Commissioner for 1881 that the admissions for Eye Diseases during that year were, among the European troops throughout India 14.1, and among the native soldiers 25.9 per mille. Among the jail population, the ratio was 13.7. The highest rate was among the women and children of European troops, of whom 30.2 per mille were treated for ophthalmic disease.

*Orbit.*—In December, 1880, Baboo Devendra Nath Dey brought before the Calcutta Medical Society a case of epithelioma of the orbit disorganizing the eye. On excising the eye, the growth was found to be attached by a broad and rugged base to the orbital plate of the frontal bone.

*Eyelids.*—The *Blepharitis* of the present day which I used to know as *ophthalmia tarsi*, being especially a disease of fair complexioned and strumous people in cold climates, is not common among the dark races of the plains of India. I watched for many years the cases of two aged gentlemen suffering from *Entropium*. They deserve notice for the benefit of those who may refuse to submit to cure by excision of skin. One of these individuals always wore a strip of black sticking-plaster which slightly everted the lid. The other, a medical man, who had suffered greatly from facial neuralgia and from *ophthalmia tarsi*, experienced years of mental torture from what he conceived to be malignant disease of the antrum, the inverted lashes occasioning great conjunctival irritation extending downwards through the nasal duct. All trouble ceased when the plan of keeping the lower lid free from ingrowing hairs, by the use of tweezers, was adopted.

Mr. Macnamara removed an *epithelioma* from the skin of the inner angle of the left eye of a clergyman in India, whose father was considered to have died of cancer of the face. No reproduction of the disease had occurred when the patient died of fever five years subsequently.

*Warts* growing from the skin of the lid and from its tarsal margin are frequent in India. I have usually twisted them off, but they generally disappear spontaneously when left alone.

Mr Albert Leahy<sup>1</sup> removed a *dermoid cyst* from the

upper eyelid of a Brahmin, aged 33. It had grown with his growth. It lay mainly beneath the orbicularis palpebrarum. It projected backwards for about half an inch beneath the supraorbital ridge, and was attached to the periosteum at the margin of the orbit. It contained a quantity of dark green fluid loaded with albumen, and of the consistency of castor oil. The cyst wall was about a quarter of an inch thick, and was composed of layers of white fibrous tissue. Lying loose at the bottom of its cavity was a coil of hair about the size of a shilling. The coil was regular and the hairs composing it were about 2½ inches long.

I have noticed, at p. 400 of vol. ii, for 1884, the case, by Dr. Chatham Gray, of a native boy of 12 suffering from *molluscum*. The eyelids were especially affected. One eye was lost, the other was almost disorganised.

*Functional Ptosis* occasionally results in India from imprudently sleeping in the open air. In the following case ptosis was clearly an early symptom of rapidly destructive brain mischief. At the time of the Mutiny I saw too much of an intemperate officer in the prime of life, who gradually fell into a state of mental degradation which appears not to have been considered such as to justify his removal to the lunatic asylum. One very hot day I met him in a shop looking unusually clean and sharp; at a second glance, I saw that he had ptosis of one eyelid. In a day or two it was reported that he had died suddenly.

I treated for some time, but not to its termination, the case of a native suffering from paralysis of the seventh pair, resulting from exposure. The loss of contractile power of the orbicularis palpebrarum led to conjunctivitis, but the cornea escaped while he was with me. On a heatstroke-day, just after I had joined a new station, a native gentleman, born a Brahmin, residing two miles off, sent to me requesting that I would immediately visit his wife who "was attacked with disease of the eye." I went at once and told her that she had a *sty*. She replied that she was perfectly well aware of the fact, and gave me the Bengali name of the disease which, perhaps out of spite, I have always failed to remember.

In the work quoted above, Sir Joseph Fayrer has given a very instructive case of destruction of the eyeball and impetiginous eruption of the face in a Hindoo goldsmith. The lesions were attributed to peripheral irritation of the fifth nerve excited by a spark which flew into the external corner of his eye.

Valuable contributions to our knowledge of *Herpes Zoster Ophthalmicus* have been made by Dr. H. Garden<sup>2</sup> and by Mr. Scriven.<sup>3</sup>

Dr. Garden says that of six cases in his list the nasal branch was implicated in two: in one the eye was affected, in the other it was not. Of the remaining four cases, in which the eruption did not extend to the nose, the eye was also affected in one. In both these cases the patients were old and debilitated. In the first there was iritis and in the other conjunctivitis. Hence Dr. Garden infers that Hutchinson's law<sup>4</sup> as it is far too absolute; for not only does inflammation of the eye, &c., occur frequently when the nasal branch is not affected, but also when the first division of the fifth itself is untouched; though it may be accepted as a fair inference that the chance of serious damage to the eye is greater when the nasal nerve is affected than when it is not.

Mr. Scriven gives the case of a Hindu, aged 40, treated in his Medical School Hospital, Lahore, the only example of this affection which he had seen in India. At first there was periodic fever, occurring at night only.

<sup>2</sup> Reprint from the *Indian Medical Gazette*, 1874.

<sup>3</sup> *Ibid.* *Indian Medical Gazette*, Vol. iv., p. 139.

<sup>4</sup> "The eye scarcely ever suffers much when the nose is not affected, and the severity of the eruption on the one part is in direct relation with the severity of the inflammation on the other."

It was followed by severe left frontal headache, and, after a time, small vesicles appeared in clusters, at first on the forehead only, but within two or three hours on the side of the face also. There were two or three spots on the lower lip. On the fourth day of observation there was a good deal of swelling of the left upper eyelid and slight inflammation of the conjunctiva with chemosis. On the following day there was a small phlyctenula at the upper and outer margin of the cornea, and a little opacity near it. He was discharged on the twenty-first day, the report being "Cornea almost clear, vision perfectly good, no pain, slight vascularity of the conjunctiva." Mr. Scriven remarks that the case afforded an additional instance of the implication of the superior maxillary nerve. It also illustrated Hutchinson's observation that the side of the nose may show vesicles to its tip, and yet the eye may be only transitorily inflamed. He noted it as a point which he had not seen mentioned, that the eruption may extend to the cutaneous branches of the third or inferior maxillary division of the fifth, and show itself on the lower lip.

*Conjunctivitis Excited by Mechanical Irritation.*—At Cairo, I was called to see a fellow-passenger said to have been attacked with Egyptian ophthalmia. When I reached his hotel, the conjunctival irritation having passed off, he was quite well and dining heartily. Leaving in absolute darkness, I got upon broken ground where extensive building was going on, and was in great peril. At Bombay, I was summoned in haste to see an officer's child with an inflamed eye. The mother appeared frantic with terror, and desired me to recommend the best oculist in the place. Merely finding a little conjunctival inflammation of an hour's standing, I said that to take the child through the town in the heat of the day would do more harm than good, and recommended that the eye should be closed by a pledget of raw cotton, and that the little fellow should be allowed to go to sleep. This was done, most reluctantly. His recovery before evening brought me an elaborate apology and more than due credit.

The *ophthalmia of Egypt* has been attributed to dust and sun-glare. These excitants are only too prevalent in the Delta of the Ganges; but, there, the great atmospheric humidity probably exerts a counter-influence. At the station of Bellary (Madras Presidency), the marked prevalence of ophthalmia among the European troops was attributed<sup>5</sup> to the extreme dryness of the atmosphere, to the excessive glare and reflection from the numerous large masses of granite in the lower fort, the light colour of the ground and numerous white-washed buildings, and to the fine white sandy nature of the soil. The disease commonly appeared as a mild purulent ophthalmia, but occasionally the deeper structures of the eye were involved and the cornea became opaque. Rarely the organ became disorganised. Nitrate of silver and sulphate of copper were the usual applications.

In Paulghaut the "country sore eye" was noticed as being very prevalent in April and May, amongst Europeans as well as natives. In Dindigal, ophthalmia occurred annually as an epidemic during July and August, especially among children, the conjunctiva becoming highly inflamed with tumefaction of the eye-lids, and a purulent discharge. It was generally attributed to the effects of the hot winds. The best application was considered to be solution of lunar caustic<sup>6</sup>.

In his "Medical Memoir on the Plains of the Indus,"<sup>7</sup> Dr. Perceval Lord observed that the sandy and

saline deserts towards the south at once suggest the idea of ophthalmic affections, and he found them so common that he scarce met a man whose eyes were not more or less inflamed. At Khaispin, where he saw on an average a hundred patients a day, he examined more cases of pterygium, opacity of cornea, obstructed lacrimal gland, and other external affections of the eye, during the week he remained there, than a London hospital would present in several months.

In his valuable account of the "General and Medical Topography of Ajmeer," Dr. Robert Hamilton Irvine spoke of ophthalmia as very severe and common in the province. He considered that it is caused by the "hard particles of dust impinging on the eyes during the frequent high winds." He did not regard it as being epidemic or contagious. It was very amenable to treatment, but the natives frequently aggravated it into a severe lingering complaint.

In his report on the diseases of Ladak, Dr. Cayley notices that conjunctivitis is very common there, hardly ever appearing in the acute purulent form; but being generally of a very chronic character, the result of a low form of muco-purulent inflammation of the conjunctiva, and lasting weeks, months and even years, leading to great thickening and oedema of the lids, and extreme vascularity and roughness of their mucous membrane, causing opacity of the cornea, and often producing entropion, of which affection he cured several cases by operation. He found that treatment by astringent lotions, the application of sulphate of copper to the inner surface of the lids, and nitrate of silver painted on outside, was often effectual; but, in many cases, the disease was too confirmed for rapid amendment. He attributed many of the cases to exposure to the intense glare and dust, and to the heat of the sun in the barren sandy deserts which extend over so much of Ladak.

In the *Madras Medical Journal*, vol. iv, p. 333, Mr. Bucke published a report which may still be consulted with advantage on ophthalmia, as it existed in 1834, among the boys at the Military Orphan Asylum, Madras. Five hundred and seventy-two cases were admitted in eighteen months. The disease appears generally to have commenced as mild conjunctivitis, but, many of the boys being in weak health, there was a tendency to sloughing of the cornea. There was sometimes purulent ophthalmia with granular lids, at others pustular conjunctivitis. Corneal ulcers "were often factitious, from the application of *uchunam*" (lime) "or caustic."

It was reported, in 1842, that improvement in the ventilation and cleanliness of this asylum, the inmates of which were mostly Indo-Britons, had, in the two years ending 1838, reduced the cases of ophthalmia to 293, the admissions during the two preceding years having amounted to 1,057. Here we find a clue to the origin of most of the conjunctivitis which prevailed in military buildings for Europeans in old times.

Conjunctivitis used to cause a great deal of suffering among the European men, women and children cooped up in the ill-ventilated and often over-crowded barracks which existed before my time in the North-West Provinces of India. Perhaps those who attributed this to the practice of lime-washing the floors were partly in the right. It was a well-known practice of the regimental urchins to irritate their eyes that they might avoid going to school. Confinement in a cell containing a heap of quicklime has been mentioned as a torture practised in India.

Mr. Macnamara speaks of muco-purulent conjunctivitis occasioned by an insect finding its way into the eye. There is especially one insect, "the flying bug," which appears to be gifted with a large share of the venom of the *mylabris cichorei*, or blistering fly of India,

<sup>5</sup> "Madras Topographical Reports, Ceded Districts," p. 76.

<sup>6</sup> *Ibid.*, Southern Division, p. 143.

<sup>7</sup> *Calcutta Medical and Physical Transactions*, Vol. viii., part ii., Appendix.

the contact of which produces a sensation like a knife-stroke through the eye, and a good deal of subsequent conjunctivitis with œdema of the lids. As it is black and large, it is easily removed.

There is still a great deal of "ophthalmia" in the armies of India. Bryden's tables show that, in ten years, there were admitted 17,561 men, of whom 569 were invalided; 2,181 women and 7,221 children. No deaths.

A medical officer in Fort William lost the sight of one eye, with considerable deformity, in opening a bottle of liquor ammoniæ. In very hot weather, a lady had fainted in a room near his dispensary. In his haste, he did not take care to hold the bottle, the stopper of which had struck, at arm's length; there was an explosion straight in his face. A similar accident, attended with far less serious results, occurred to my late friend Joseph R. Bedford.<sup>8</sup> Whilst on his passage to India, he was endeavouring to remove the glass stopper from a bottle of muriatic acid. It resisted, he applied force, holding the bottle incautiously too near his face; on a sudden the stopper was removed, the fumes rushed out. He experienced a sharp pain in both eyes, and made up his mind for life-blindness. Sweet oil was at once applied; and, on opening his eyes in about a quarter of an hour, he found to his intense joy that vision was unharmed. A slight conjunctivitis continued some days. I do not think that I have ever been more shocked than I was to see an old gentleman apply a strong Goulard lotion, mistaken for a zinc wash, to both his eyes. At first, the pain and redness were intense, but they soon abated under warm water sponging. No lesion followed.

I know of more than one case in which surgeons have been blinded by venereal matter in opening buboes, &c. Mr. J. D. O. Wild reported<sup>9</sup> the case of a Bengal hospital apprentice of irregular habits who, six days before coming under treatment, contracted inflammation of both eyes which he attributed to the accidental introduction of venereal matter while dressing sores. There was severe purulent ophthalmia of both eyes. Right much distended, its structure disorganised, sight gone. Left inflamed and swelled, but with a clear cornea. There was a tendency to delirium and coma, but, on being roused, he spoke coherently. Previous to the attack he was suffering from quotidian fever. He died in fifteen days with symptoms of meningitis. The *right* eye was totally disorganised. Meninges red and congested. A large patch of "ulceration" coated with pus occupied the surface of the *left* hemisphere.

My friend, Dr. Samuel Brown, showed me, before I went to India, many cases of *pustular conjunctivitis*, as it used to prevail among unhealthy-looking factory girls at Belfast. He used to cure it by a dexterous application of the stick of nitrate of silver. I never saw it in London or in Bengal, and Macnamara does not say that it occurs in India, but it used, as I have stated above, to prevail in the Madras Orphan Asylum. My friend Dr. Henry Cayley, in charge of the Calcutta Eye Infirmary, informs me that the "strumous" ophthalmia of children is not uncommon among natives and Eurasians in India. He thinks he has seen it in European children also, but of this he is not quite sure as he has not seen it, among them, in its most characteristic stage. European children, in India, are not generally of the class that are most liable to that form of ophthalmia. Judging from hospital experience, his impression is that scrofulous ophthalmia is much more common in large English cities than in Calcutta.

I watched very marked *Leprous conjunctival deposit* in an East Indian woman for some weeks and in a

*mheter* (sweeper) for many years. I could not perceive that it made any progress in either case.

*Pterygium*, in every one of its forms, is very common among the natives of India. Mr. Brudenell Carter observes<sup>10</sup> that "pterygium is especially apt to occur in persons who have lived in the tropics."

In a report on the medical topography of Orissa<sup>11</sup> Dr. Shortt mentions that pterygium is so very common throughout that province that, in almost every village, he met with two, three, or more cases. The growth extends over the cornea, producing blindness. In several cases he dissected away the corneal portion. A few drops of the solution of argenti nitras for a day or two completed the cure.

The number of pterygia successfully operated upon, in four years, by my late friend Mr. Martin at the Calcutta Eye Infirmary, was 58 in 44 individuals. I saw *epithelioma* of the conjunctiva, beginning at the outer canthus in an English officer. At a meeting of the Calcutta Medical Society held, in December 1880, a case of Dr. Cayley's was brought forward in which a growth, considered to be papillomatous, originated, like a pterygium, at the outer canthus. This, after ablation re-formed, spread, and extended over nearly the whole of the cornea, abolishing vision. The eye was removed, the growth was confined to the sclerotic and cornea, not penetrating the eyeball.

*Diseases of the Cornea.*—In 1858, my friend Dr. W. coming home one afternoon from a long round of visits in Calcutta, sat upon the edge of his low bed and opened a bottle of soda water. Slipping from his fingers the cork flew upwards and struck his cornea with its angular outer margin, producing a most painful shock and denting in the cornea as if the edge of the thumb nail had been strongly pressed vertically across the axis of vision. It appeared as if the superficial layers of the cornea yielding, the inner ones had been fractured. The sight of that eye was lost; the dent remained visible for years, a small opacity occupying the axis of vision.<sup>12</sup>

Mr. Macnamara gives an interesting case of a Hindoo boy with characteristic malformation of the incisors, suffering from congenital syphilis and *keratitis* of both eyes.

Extremely marked *arcus senilis* frequently occurs in India. I was consulted in the case of an English gentleman in whom this condition was regarded as a bar to life insurance. Another very active and healthy-looking Scotch gentleman had, in middle age, a singularly pronounced arcus. He lived for about 15 years after his return from India. A very remarkable case was brought into my ward and taken out again so quickly that I only saw him once. He was a respectable European who, although not much over 50 years of age, had an aspect of extreme senility. He had much the look of an albino, but I think that he had been a very fair red-headed man. His hair was snowy white and he had the arcus excessively developed. His feet were gangrenous; but, in the legs the anterior tibial muscles only appeared to have mortified up to their origins, showing lividly through the pale integument.

I have already described *Sloughing of the Cornea*, as it occurs most extensively among the native poor in Bengal, as a form of malarious cachexia (*vide* vol. ii for 1883, p. 736). Undoubtedly scorbutus is, in many cases, a factor in the causation of this tendency to sloughing of the cornea. I have already alluded to the fact that this death of the cornea precisely resembles

<sup>10</sup> "Holmes's Surgery," 3rd Edition, p. 705.

<sup>11</sup> "Indian Annals of Medical Science," No. 10, p. 508.

<sup>12</sup> A few years ago it was reported that a man was struck in the eye by a ginger-beer cork; the blow did not cause much pain at the time; but, after a time, he began to suffer so much in the eye that he was admitted to the Bristol Infirmary, where he died from "cerebral congestion."

<sup>8</sup> "Chemical Injuries to the Eye," *Finch's Indian Journal of Medical and Physical Science*, Vol. ii, p. 481.

<sup>9</sup> "Indian Annals of Medical Science," No. 8, p. 661.

the state produced by Majendie in dogs, by dividing the fifth nerve or by feeding them exclusively upon non-nitrogenous food. In an excess mortality in a native jail, attributed to a diminution in the dietary, which occurred in 1853, my friend, the late Mr. Bedford observed<sup>13</sup> cases in which the corneæ ulcerated and sloughed away previous to death. In the chapter on Scorbutus I have cited the narrative of my friend, Mr. Alexander Grant, to the effect that, in the expedition of 1840 to China, the 37th Madras Native Infantry, being ill-fed and miserably lodged, became thoroughly scorbutic; and then sloughing of the corneæ was rife among them.

In Lower Bengal, this destructive corneitis occurs frequently in patients worn out by jail diarrhœa, perishing from sheer inanition, often without any very manifest evidences of a scorbutic taint, although the presence of such a condition generally may be expected. When the Andamans were first occupied as a place of transportation for criminals engaged in the Great Mutiny, the malarial influence was intense and most destructive; and, nearly all food having to be brought in ships from Calcutta, scurvy became rife among the prisoners at Port Blair. Dr. Gamack observed, "Sixteen deaths are recorded amongst the patients admitted under Diseases of the Eye. These occurred from scurvy or diarrhœa, and it frequently happened that the scurvy patients became blind some time before death. A patient, in the advanced stage, would complain of violent pain in and around the eye; and, on examination, nothing could be detected but a slight haziness of the cornea; but inflammation would proceed so rapidly that, in 24 or 36 hours, the globe of the eye would become filled with pus; and, if both eyes were not affected at first, the other was almost sure to become affected after a few days. The sign was looked upon as fatal" (it is too often so in Bengal); "but two cases which occurred towards the end of the monsoon are still alive, and the men, although quite blind, are now well and have become exceedingly stout."

In those who survive, all the results of penetrating ulcer of the cornea *anterior synechia*, *prolapsus of iris*, *staphyloma*, &c., may occur. Mr. Macnamara recommends iridectomy in spreading eccentric ulcers of the cornea.

Mr. William Martin operated, at the Calcutta Eye Infirmary, upon fourteen cases of *staphyloma* in four years—not a large number considering how great is the prevalence of ulceration of the cornea in Bengal.

*Syphilitic and Rheumatic Iritis* occur in India nearly as in Europe. Dr. Robert Bird relates<sup>14</sup> the very noteworthy case of a European in whom daily attacks of feverishness with pains in various parts of the body, lasting from two to three hours, was followed by conjunctivitis and characteristically marked iritis of one eye. Being in a weak state of health and not improving under treatment, he went on a sea voyage to the Straits, and returned to Calcutta in five weeks as ill as when he started. He was very lean and weak, and, to all appearances, the sight of the eyeball was destroyed. Suddenly he was seized in the middle of the night with fever and ague, and, from this time, he steadily mended. Pain and morbid sensibility left the eye, which gradually recovered.

I was shown a patient who, having had solution of atropia applied to the eye, had marked symptoms of belladonna poisoning, and I know of two instances in which native patients, under the same influence, made their way out of the windows of an upper ward, but happily were not killed.

When I first went to India, I found *Chronic Glaucoma*, confined to the crystalline, in its first stage,

so very common among natives of Bengal beyond middle age, that I was in the habit of looking for it in men who did not complain of eye disease. The form of glaucoma most frequent among natives appears to be this first stage, which Mackenzie used to describe as often remaining stationary for a great part of life. Mr. Odevaine has recorded some valuable remarks in the *Indian Medical Gazette* for July, 1877, on the importance of making an accurate diagnosis between glaucoma and cataract.

Mr. Macnamara remarks, after giving illustrations of the syphilitic form, that non-syphilitic opacity of the vitreous commonly arises (excluding cases depending on disease of the choroid) from an impoverished state of the blood induced by malarious influences.

My late colleague, Mr. Cutcliffe described<sup>15</sup> the case of an East Indian, æt. 55, who was treated in our hospital for exophthalmos of both eyes due to syphilitic disease of the base of the skull. He died convulsed.<sup>16</sup>

(To be continued.)

## APPOINTMENTS FOR THE WEEK.

Tuesday, August 18.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 4 p.m.—Dr. Goodhart, Bradshawe Lecture, "On Morbid Arterial Tension: a Review."

# Medical Times and Gazette.

SATURDAY, AUGUST 15, 1885.

CHOLERA is still making fearful ravages in Spain, as the subjoined figures will show. During the first week in August the total number of cases was 29,612, with 10,832 deaths, and since then the daily figures have been:—

	Cases.	Deaths.
August 8th .....	4,338	1,638
"   9th ....	4,151	1,504
"  10th .....	4,688	1,690
"  11th .....	6,464	2,109
"  12th .....	4,433	1,648
Totals ....	24,074	8,589

The epidemic is spreading north and east, and showing signs of decline in the south, except at Granada. Up to the present, more than 610 different places have been attacked and sixty large towns. The province of Saragossa contributes about 1,000 cases a day, with a mortality exceeding 25 per cent., whilst the province of Teruel supplies the next largest number of cases, viz., from 400 to 500 a day, with upwards of 160 deaths a day. Of the large towns Granada, with a death-rate of between 30 and 40 per cent., has had over 100 deaths a day lately. Up to the end of the first week in August the total number of cases in Madrid is stated to have been 865 with 529 deaths; but it is believed

<sup>15</sup> *Indian Medical Gazette*, Vol. vii., p. 276.

<sup>14</sup> *Indian Medical Gazette*, Vol. i., p. 56.

that many cases amongst the upper and middle classes are concealed, whilst amongst the lower classes many cases are put down as cholera which ought rather to be called cholérine.

It is stated by a Barcelona paper that Dr. Ferrán has been ordered by the Spanish Government to perform all the cholera inoculations with his own hands. The medical practitioners have taken offence at this, as implying that they are not competent to perform so simple an operation as the giving of a hypodermic injection. The Government has sent a commission with instructions to see Dr. Ferrán operate. Meanwhile we learn that the populace are losing faith in his inoculations, and in Albacete, Alicante and Saragossa the authorities and the people have refused to have anything to do with him. They are of opinion, doubtless, and so are we, that before any further experiments are tried some statement of the results hitherto obtained ought to be made. From France and Italy we hear a great deal of stringent quarantine regulations, of the futility of which we had abundant proof last year, but as yet the cholera has only obtained a footing at Marseilles, where some thirty deaths from it are daily recorded, in consequence of which the Pharo Hospital was re-opened last Monday as a special cholera hospital. We have no reason to be boastful, but we have every reason to believe that our sanitary authorities have done, and are doing their best to meet the cholera bacillus with a chilling reception whenever it wends its way to this country. The Paris Municipal Council is apparently of the same opinion, as it has sent a commission composed of its President (M. Michelin), M. Robinet, M. Straus and others to study our sanitary and general precautions against the disease.

OUR Paris Correspondent writes:—The existence of cholera at Marseilles having at last been officially acknowledged, the Minister of Trade, accompanied by Professors Proust and Brouardel, paid a visit to that city. The results of their investigations are contained in a report read by Professor Brouardel before the Academy of Medicine. The first case of death by cholera occurred on the 25th of June, the second on the 26th. No other cases took place till the 13th of July. The figures up to the 3rd instant are the following: July 14th, 1; 15th, 1; 19th, 1; 20th, 2; 22nd, 2; 23rd, 1; 24th, 3; 25th, 3; 26th, 2; 27th, 4; 28th, 8; 29th, 5; 30th, 15; 31st, 21; August 1st, 15; 2nd, 17; 3rd, 11. The death-rate of Tuesday marks 19 deaths from cholera in Marseilles. This is not a large figure for a population of nearly 400,000 souls. Still it seems that an epidemic has really sprung into existence. The low quarters of the city are in a lamentable state of filth and neglect. No water-closets exist in the houses, and the excreta of the population are either thrown into the streets, or collected in large open tubs, which generally overflow, and fill the neighbourhood with an intolerable stench. In some places the excreta are merely deposited on the stairs, and removed when large heaps have thus been collected. In a girl's school, situated behind the *Mairie*,

or Mansion House, a large court-yard receives through the windows of the house the fæcal matter of all the inhabitants, besides other kinds of refuse. The school-room is, of course, infested by a strong and penetrating odour.

THE old Port is the receptacle of all the sewers, and its waters are constantly black, and emit bubbles of foetid gas. Some of the sewers are open. This state of things, of course, prevails in the dirty and poor quarters of the town, which, in its better parts, contains some of the finest streets in Europe. But an epidemic raging in similar conditions has evidently strong chances of becoming exceptionally severe. Professor Brouardel demands an improvement in sanitary legislation, which will make improvements compulsory, and this in a limited space of time. Under present conditions a landlord who chooses to resist the operation of the law can argue the matter in court for months—nay, years: in one case the legal proceedings lasted seven years. Dr. Leroy de Méricourt is of opinion, like Professor Brouardel, that the sanitary condition of Marseilles ought to be the object of immediate attention on the part of the authorities. Still he contends that filth has no influence upon the outbreak and development of cholera. Marseilles is, and has been for centuries, in the condition described, yet cholera never broke out there before 1830. Nearly all the cities of the East are in a worse condition, yet cholera is infinitely less frequent there. On the other hand, cholera has often been known to break out on board a ship, in which all proper hygienic conditions had been observed, and in which, of course, not a particle of fæcal matter was retained on board. Although the doctrinal questions which concern the origin and dissemination of cholera cannot be solved by similar investigations, one point is clear, viz., that the largest port of France, and one of its most important and wealthiest cities, cannot be allowed to remain longer in the infamous state of contamination which has disgraced it for centuries. Plenty of work will be found, no doubt, for sanitation to achieve in other cities, French and foreign; but the state of Marseilles is a stain upon the civilisation of modern Europe.

THE Criminal Law Amendment Bill has now passed through both Houses of Parliament and received the Royal Assent. There is little to be noted about its final stages except that members of each House had the opportunity of giving vent to their private views in regard to the action of the *Pall Mall Gazette*, and availed themselves of the opportunity. A few alterations were made in the House of Commons before the third reading, the only one of importance being the following proviso:—"Whereas doubts have been entertained whether a man who induces a married woman to have connection with her by personating her husband is or is not guilty of rape, it is hereby enacted and declared that every such offender shall be deemed to be guilty of rape."

ON Friday last a Bill was introduced into the House of Lords, entitled "An Act to consolidate with amend-

ments certain Acts relating to nuisances, infectious diseases, and other matters concerning public health in the Metropolis," or more shortly, the "Public Health (Metropolis) Bill." It was not intended of course to proceed with it at so late a stage of the session, but it was introduced in order that its provisions might become known, and be subjected to public criticism before being seriously taken up next year. The Bill deals with the law relating to nuisances, infectious diseases, hospitals and mortuaries, &c., and gives power to local authorities to proceed in a summary manner against all persons who fail to abate any common or public nuisance; it also gives additional powers to medical officers of health with regard to the inspection and condemnation of unsound meat. In reference to infectious diseases, the Bill gives the local authorities additional powers to proceed against persons exposing others who have contagious diseases, and makes stringent provisions for the disinfection of houses where any such diseases may have existed. The Local Government Board is to have the power, when necessary, to prevent the spread of epidemic diseases; to alter its existing regulations, first with regard to the speedy interment of the dead, secondly with reference to house-to-house visitation, and lastly, with regard to the provision of medical aid and accommodation for the promotion of cleansing, ventilation, and disinfection, and guarding against the spread of disease.

THE controversy which was started on the occasion of the distribution of the Hospital Sunday Fund has opened up a question of paramount importance. The correspondence which has appeared in the *Times* has largely related to the merits or demerits of the present nursing system at University College Hospital, a matter which those in authority are quite competent to deal with, and with which we have no intention of interfering. The real question is, as was pointed out in a well-timed letter by Dr. Sieveking, are the authorities of the Hospital Sunday Fund to be allowed to exercise any control over the manner in which the nursing is carried on in hospitals which receive a share of that fund. If this question is not answered at once, and decisively in the negative, there is no detail of internal hospital management which the Sunday Fund Committee may not in time claim to alter. The money is subscribed by the public unconditionally, and must be handed over to the hospitals without any restriction on some generally accepted principle in proportion to the amount of work done. Many will be of opinion that State control of Hospitals would be preferable to their being subject to a self-elected and irresponsible body like the Hospital Sunday Fund Committee.

At the meeting of the Third International Otolological Congress at Basle, a prize of 3,000 florins was offered by Baron Léon de Lenval, of Nice, for the best instrument (easily carried), constructed according to the principle of the microphone, for improvement of hearing in cases of partial deafness. We are sure that our readers will join in our hope that the result of this competition will be an invention which will still further contribute to the alleviation of one of the

most cruel ailments to which mankind is liable. The instruments intended for competition must be sent before the 31st of December, 1887, to one or other of the following, who compose the jury, viz.: Professor Hagenbach-Bischoff, Basle; Dr. Benni, Warsaw; Prof. Burckhardt-Merian, Basle; Dr. Gellé, Paris; Prof. Politzer, Vienna.

THE Annual General Meeting of the Medico-Psychological Association was held at Queen's College, Cork, on the 4th August, under the presidency of Dr. J. A. Eames. After a vote of thanks to Dr. Rayner, the retiring President, Dr. Savage, of Bethlem Hospital, was elected President for the next year. The Association considered and approved of a scheme for the granting of certificates in Psychological Medicine, and a paper was read by Dr. Hack Tuke on a case of Moral Insanity. At the adjournment for luncheon, a visit was paid to the Cork District Lunatic Asylum, which contains nearly one thousand patients, and which includes, among other well-ordered arrangements, a very complete system of Turkish baths. At the afternoon sitting an address was delivered by Dr. Eames, and the members of the Association afterwards dined together at Queenstown, which rising place, it was stated, had never before been chosen for a scientific association's meeting. On the following days excursions were made to Killarney and other places.

THE complete programme of the 58th Congress of German Naturalists and Physicians, which is to be held at Strasburg from the 18th to the 23rd of next month, has recently been published. The first general meeting will be opened on the 18th by Prof. Kussmaul, and in addition to general business, Dr. Rühle, of Bonn, will deliver an oration in memory of the late Prof. Frerichs. At the second general meeting Prof. Virchow will give an address on "Acclimatisation"; and Dr. Pechuel-Lösche, of Jena, will speak on the cultivation of tropical countries. There will be 24 sections, 14 of which deal with branches of medical science. The Section of Internal Medicine, under the joint-presidency of Drs. Kussmaul and Wiegner, has by far the fullest programme. Erb, Eichhorst, Eulenburg, Adamkiewicz, Jürgensen, and many other well-known clinical observers, will contribute papers. In the Gynæcological Section there are several interesting papers put down, including one by Dr. A. Martin, of Berlin, on Operations for Prolapse; and one by Dr. Bayer, of Strasburg, on the Ophthalmoscopic Appearances in Septicæmia. Dr. Zweifel, of Erlangen, will discuss the important question whether putrefactive germs exist in the healthy organism. In the Section of Pædiatrics, there are papers on Tracheotomy, its Results (Ranke), and Sequelæ (Jurasz), on Cerebral Paralysis in Children (H. Ranke), and on Tumours of the Spinal Cord (Kohts). In the Section of Ophthalmology, Dr. Ellinger will discuss the influence of writing on the eyes and the figure. In the Section of Hygiene, in addition to several papers of interest, three questions of great practical importance will be discussed, viz., Educational Over-pressure, the Causation of Cholera, and the measures of Sanitary Police which should be recommended in order to prevent the Cholera from

crossing the German frontier. In the Pathological Section, presided over by Von Recklinghausen, we notice a paper by Dr. Roy, of Cambridge, on the Pathology of Asthma. We have not space to give even the briefest details of the remaining sections, but all except that of Laryngology appear to have a full programme. There will be no Section of Dermatology and Syphilis, unless a sufficient number of members declare their intention to take part in it; but several papers dealing with subjects that would properly come under that section are distributed through other sections. We have only to add that a Museum of Instruments and Specimens is being formed, and that a variety of entertainments will be provided. As we have said before, no effort will be omitted to make this, the first visit of the Society to the conquered provinces, a striking success.

THE deaths in London last week numbered 1,720, being 30 less than last week. So far for the present quarter the death-rate is 20·8 per 1,000, as compared with 22·0 during the corresponding period of the previous nine years. Diarrhoea was not so fatal as in the preceding week, 309 deaths having been attributed to it, of which 251 were of infants under one year of age. There were 58 deaths from measles, a lower figure than has been recorded for three months past, whilst the 20 deaths from scarlet fever show an equally decided increase. The epidemic of small-pox is, we

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past nine weeks.

may hope, dying out, as only 14 deaths were recorded as due to it. There were no fatalities attributed to the weather, which is not to be wondered at, seeing that there were but 98·8 hours sunshine out of a possible of 105·9 hours. In the provincial towns

Leicester and Preston head the list with a general death-rate of 32·2 and 31·2 respectively, and zymotic death-rates of 12·3 and 13·0; in these towns diarrhoea caused 26 and 22 deaths, and from the same cause there were 40 deaths in Liverpool, 35 in Leeds, 28 in Birmingham, 28 in Salford, and 25 in Sheffield.

THE quarterly return of the Registrar-General for Ireland for the second quarter of the present year has just appeared. The death-rate was 20·5 per 1,000, which compares unfavourably with that for the same quarter during the previous five years, the average for which was 0·6 lower. The deaths of children under one year of age were at the rate of 11·7 per cent. of the whole. Zymotic diseases proved slightly more fatal than in the corresponding quarter of previous years, measles being chiefly responsible for the rise. There were 704 deaths registered as due to this cause, of which no fewer than 427 occurred in the Belfast Union, whilst there were only 21 in the whole of Connaught. The deaths from typhus, numbering 169, show a marked and satisfactory diminution. After an immunity of nine months, 4 fatal cases of small-pox have occurred. The price of provisions, so far as bread, potatoes, and beef are concerned, has been on the whole below the average, and the number of persons who received indoor relief shows a distinct falling off. As usual, in the special reports of the different registrars, the deaths of several centenarians are recorded, one person being stated to have attained the age of 107 and two others that of 104.

AN outbreak of diphtheria, which occurred in the early part of the present year in the Cheshunt Urban Sanitary District, has been the subject of a report to the Local Government Board,<sup>1</sup> by Mr. R. D. R. Sweeting. The outbreak occurred in two groups, separated by an interval of nine days. In the first group, 12 families and 30 persons were attacked, 25 of them being in children between the ages of 3 and 15; in the second group, 6 families were attacked, 11 persons suffering. In the first group there were 8 deaths, none of the cases in the second group proving fatal. A careful enquiry showed, that in the first group there was no common condition of sanitary circumstances, or of milk supply, but that the same school was attended by members of all the families invaded. Mr. Sweeting's investigations were naturally directed towards this school, but no local condition was discovered to which the diphtheria could fairly be attributed; it was ascertained that, after the closing of the school, no cases occurred for the above-mentioned interval. It was further ascertained, that during December and January (*i.e.*, about a month before the outbreak of diphtheria), several cases of simple sore throat (as they were termed) had occurred amongst the school children, and that several children thus affected had attended the school in various stages of their malady. In the second group no common cause could be found, and the cases all seemed traceable to personal communication, either

<sup>1</sup> These reports may be obtained from Knight and Co., 90, Fleet Street; Shaw and Sons, Fetter Lane; Hadden, Best, and Co., West Harding Street, Fetter Lane, E.C.; and P. S. King and Son, Canada Building, King Street, S.W.

with cases of their own or the previous group. The fatality of the cases in the first group, as compared with the second group, was evidently due to the former having so much more largely attacked children.

DR. PARSONS has lately made a report to the Local Government Board on the sanitary condition of the borough of Newark. This report is the outcome of an investigation instituted on account of a serious outbreak of typhoid fever during the summer and autumn of last year. The chief sewerage defects discovered were that the main sewers were mostly unventilated, the drain inlets of faulty construction, and the sink pipes often untrapped. In a considerable part of the town water-closets had been provided; but where this was not the case, the arrangements for disposing of the excrement from the midden privies and tub-closets left much to be desired. The water supply is partly derived from a company and partly from shallow wells; that supplied by the company was on the whole found to be good and free from contamination, whilst that taken from the shallow wells, whilst colourless and pleasant to the taste, was found to be loaded with chlorides, nitrates and phosphates, and other products of sewage decomposition. To this contamination of the water and to the defective sewerage arrangements Dr. Parsons attributes the epidemic of typhoid fever, and he reports that the authorities are taking steps to remedy the various insanitary conditions which he has pointed out.

A REPORT has just been made to the Local Government Board by Mr. R. D. Sweeting on the Sandal Sub-district of the Wakefield Registration District in reference of the prevalence there of scarlet fever, diphtheria, and "fever." The population of the sub-district in question is one-fourth of the whole district, but the mortality from scarlet fever and diphtheria during the five years ending 1884 was almost exactly the same as that in all the other sub-divisions taken together. The area reported upon included the towns of Normanton, Altofts and Sandal Magna. The chief defect that Mr. Sweeting found was the existence of the ashpit midden system for the disposal of excrement, especially in the case of the Normanton division, the arrangements for the regular emptying of the middens being of the most unsatisfactory kind. No proper provision for the ventilation and efficient flushing of the sewers has been as yet provided, and no hospital accommodation exists either at Normanton or Altofts for infectious cases. Mr. Sweeting was unable to trace the cause either of the scarlet fever or the diphtheria epidemics, but the latter appeared to him to spread owing rather to direct exposure at school than to any insanitary conditions in the houses of those affected.

AT a recent meeting of the Society of Physicians of Vienna, writes our Correspondent in that city, Professor Rosenthal showed two interesting cases which had been under his treatment as out-patients at the "Allgemeines Krankenhaus." The first case was one of lead poisoning, produced by the long-continued

painting of the face. The patient, an actor aged 37, had long noticed an emaciation of the fingers of his right hand. Professor Rosenthal found, on examination with the electric current, a loss of power and of Faradaic irritability in the common extensors of the fingers, and in the lumbricales as well as in the fourth interosseous; galvanic contractility was not lost. The supinator longus was not affected, but the irritability of the radial nerve was much diminished. The left hand was normal except that the power of abducting the thumb was somewhat impaired. The idea that it was a case of paralysis caused by pressure was abandoned in view of the slow development of the case, the implication of the fourth interosseous muscle, and the normal state of the supinator. Progressive muscular atrophy was also excluded, as the development and reaction of the muscles of the thumb were normal, and there was no muscular atrophy of the arm, though the irritability was diminished. The whole complex of symptoms, however, induced Professor Rosenthal to diagnose lead-poisoning. He therefore had the grey and red paint that had been used examined by Professor Ludwig, who found that both contained a considerable proportion of lead.

THE second case, which Professor Rosenthal declared to be unique, was one of hemi-paresis and hemi-anæsthesia following diphtheria. The patient, a girl aged 15, had suffered some weeks previously from an inflammation of the throat which got better after the use of a gargle without other medical treatment. The third week after her recovery she felt pains in the right arm and leg, the right hand was powerless to grasp anything, and she could not double her fist. About this time she began to talk through the nose, and the fluids which she took returned by the nostrils; even water could only be sipped occasionally. Diplopia was also complained of. Recently pains in the left leg also appeared, and the fingers of the right hand became insensible. When the patient was examined by Professor Rosenthal in the sixth week there was paresis of the right arm, the mobility of which was impaired, the grasp of the hand was feeble, and there was loss of power in the right leg. The Faradaic reaction was anywhere normal, and the tendon reflex was also unaffected. The skin on the right side of the body was insensible to electrical as well as mechanical stimulation. The application of the Faradaic brush to the arm, the mamma, the abdominal wall, the nates, the thigh and legs, the nape of the neck, and the back produced no pain, and the same was true of heat and cold. The palatine arch was displaced towards the left side, and both its right half and that of the pharynx, and, according to Dr. Chiari, who had examined the patient with the laryngoscope, the right half of the epiglottis as well suffered from impaired sensibility; besides which there was paresis of the right vocal cord. In the nerve plexus of the arm, and in the course of median and radial nerves on the right side, there were points which were tender on pressure, and the same was to be observed in the case of the peroneal nerve. The excitability of the fifth nerve and the sense of taste were impaired on the

right side. There was no symptom of hysteria; and menstruation was regular. All the symptoms pointed to a conducting anæsthesia in the region of the right spinal roots and posterior branches which had been preceded by a condition of irritation. Pierret and Déjerine had found an infiltration of the nerve nucleus and proliferation of neuroglia in the nerve roots and nerve trunks after diphtheria.

DR. BLUMENSTOCK, the Professor of State Medicine in the University of Cracow, has been appointed Dean of the Medical Faculty.

AMONG the many critical opponents of Dr. Koch's views with respect to the causal importance of the comma bacillus in the ætiology of cholera, Professors Finkler and Prior, of Bonn, have been the most determined. They succeeded, a year ago, in persuading themselves and some others that the comma-bacillus was not peculiar to cases of Asiatic cholera, but was to be found to an equal extent in the disease which they dubbed "Cholera Nostras." By means of the familiar methods of cultivation they were also able to reproduce it in forms capable of setting up intestinal irritation in the lower animals. By publishing the results of their labours in a lay journal, however, they called down no small share of professional abuse upon themselves and their doctrines alike. Mindful, perhaps, of the storm of unkindly comment to which they were then exposed, they have lately taken the precaution to publish their most recent views upon the subject of the bacillus in the columns of a professional *Centralblatt* to which no exception can be taken. As the result of a series of investigations made during the cholera epidemic in Genoa last year, they are able to confirm the presence of Koch's bacillus in the intestinal tissues and contents in cases of true Asiatic cholera. They found the comma-bacillus also in the excreta in cases of cholera nostras. Both these comma-bacilli they affirm to be vibriones which represent true spirilla. In cultivation, the two forms show but little variation. Relative, but not absolute, differences exist between them, and especially in the greater rapidity of growth and vitality of the vibrio of cholera nostras. Koch's vibrio, on the other hand, would appear to show greater pathogenic activity. The symptoms which they both set up in the lower animals bear a certain resemblance to those of cholera in man; but they are not specific, and, in guinea-pigs, can be brought about by other forms of inoculation or by chemical irritants. The causal connection between the comma-bacillus and Asiatic cholera is rendered most probable by the constant occurrence of the micro-organism, but cannot be looked upon as confirmed by experiments upon animals. The causal connection between the bacillus of Finkler and Prior and cholera nostras is probable on the one hand by the discovery of the micro-organism, and on the other by the extensive correspondence of the symptoms of cholera nostras and cholera Asiatica, and of the biological and pathological properties of the two forms of bacilli themselves.

CHOLERA enquiry formed the subject of Surgeon-General Cornish's address when retiring from the presidential chair of the South India Branch of the British Medical Association. Koch and the German Commission, in his opinion, fell into the error of forming hasty conclusions and drawing deductions from their experiments unwarranted by the evidence at their command; in like manner the work of Drs. Klein and Gibbes was too hurried and incomplete to settle the questions at issue. The difficulty hitherto experienced of proving anything definitely as to the communicability of the disease lies in the fact that the lower animals are not susceptible to it, and experiments on them are futile. Dr. Cornish holds that the question can only be settled by direct experimentation on human beings, and urges that condemned criminals should be utilised for the purpose, their own consent being first obtained; this is of course no new suggestion, and so far as we can judge of the tendency of modern ideas is less likely to meet with public approval now than it has been in the past, though so far as we know there is no argument of any real weight to be brought forward against it. Surgeon-General Cornish is unable to accept Dr. J. M. Cunningham's views on the causation of cholera by atmospheric conditions or some unknown force, and he contends that when such views are submitted for our acceptance the principal facts on which belief in them is based ought also to be given. Dr. Cornish has not made up his mind on the subject himself, but he considers that the question—whether anything given off from the bodies of cholera-affected persons will produce symptoms of cholera in healthy persons subjected to such emanations, either by contamination of their air, food or water—is one that ought to admit of a definite answer, and he holds that it is the duty of the State to supply the answer.

WHILE others quarrel the wise man acts. "The title of Doctor" continues to be an ever-suggestive theme of discussion; its recognition as a right, its bestowal as a courtesy, its assumption as a flourish, are all questioned, attacked, defended. This man values it as a reverend distinction: that decries it as a convenient but intrinsically worthless trade-stamp. And, behold! while disputants cover reams of foolscap and immortalise their opinions in pages of print, the practical country practitioner evolves order out of chaos, advertising himself in the columns of a daily paper as "A Medical Doctor" in search of a pupil; we may take it that the specific adjective was not intended merely to mark the distinction between himself and his brethren of Divinity and Law, since that is indicated with sufficient clearness by a statement of the advertiser's willingness to "give certificates in pharmacy, midwifery, and vaccination."

It has been pointed out that an important distinction is to be made between the Vomiting of Pregnancy and Vomiting in Pregnancy. Perhaps the Vomiting of Pregnant Women is a term which may serve conveniently to include both classes of cases. The affection is so common as to be within the cognisance of the mere medical tiro in some one or other of

its phases. Its course is often so severe and its results so serious as to tax the resources of the most experienced practitioner to the uttermost, and sometimes even to exhaust them. Since every organ of the body is more or less concerned in the underlying process of gestation, it is not surprising that almost every organ has, separately or conjointly, been held responsible; and, *per contra*, all sorts of remedies applied in all sorts of ways have been found sometimes satisfactory, and too often useless. The subject is one which may be recommended to the Collective Investigation Committee of the British Medical Association as worthy of their attention. We may be able to regard this and kindred puzzles from a stand-point more strictly scientific than any possible to our forefathers, but probably the actual state of our knowledge of the matter is pretty accurately indicated by a discussion lately held on the subject, in the course of which the following remedies were each and all stated to have proved successful in the experience of the several speakers:—small doses of ipecacuanha; hydrochlorate of cocaine: oxalate of cerium in two-grain doses (“You might” once said a distinguished British gynæcologist, “as well give oxalate of mud”); tincture of iodine applied within the cervical canal; calomel, in doses of one twentieth to one-tenth of a grain every hour; and the rectification of malpositions of the uterus by suitable pessaries.

ENGLISH practitioners and their patients owe a good deal to the conservatism with which the former are now-a-days often twitted. It is true that we have not yet altogether forsworn the use of chloroform in favour of that of ether; and most of us still think more of saving the life of our patient than of destroying all the micro-organisms with which he may be encumbered. We do not forget the case of the unfortunate German surgeon who was convicted on a criminal prosecution because his patient died from the effects of a slight wound which had not from the first been treated with what are understood to be strict antiseptic precautions; but we have no desire to be perpetually reminded of it in the routine of private practice. A recent American writer lauds the “popular enlightenment” which made such a verdict possible, and trusts that ere long public opinion will be sufficiently educated in his own country to make a minute observance of a rigid antisepticism obligatory upon all his professional brethren. Meanwhile, we note incidentally that Fränkel has reported fourteen deaths during the employment of corrosive sublimate on wounded surfaces; and Dr. Peabody, induced by this report to investigate the subject, found evidence of corrosive sublimate poisoning in eleven cases on the records of the New York Hospital during the last eighteen months, including seven deaths from this cause; the strength of the solution used was 1 in 1,000, and the wound surface was ordinarily large. On the other hand, a zealous Paris *pharmacien* the other day treated a little girl who was brought to him with a wounded finger by encasing the injured digit in absolute phenol, with the result that the finger was ultimately lost by gangrene. Certainly it would seem desirable that before committing ourselves to the unvarying

practice of antiseptic formalities as legally requisite in all cases, we should be better agreed as to what antiseptics are, how they act, how far they really secure asepsis—which is what we want—and how they are to be used effectually without detriment to the patient. One human life is worth those of a good many bacteria.

THE medical men of Boston, U.S.A., are disquieted at the increasing frequency of scabies. Dr. Greenough states that the percentage of scabies amongst the cases of skin diseases noted in the dispensary case-books stands thus: for the year ending June 30th, 1879, about 0.4; for 1880, a little over 1; 1881, 0.8; 1882, 2; 1883, 5; 1884, 8.5; while for 1885 it reaches nearly 18! During and just after the war, scabies was by no means uncommon; but the cases gradually diminished in frequency, and in the decade 1870–1880, a case of itch was exceptional enough to be of especial interest, even in skin practice. The disease, in fact, became so comparatively rare as not to be generally recognised; to this cause, and to natural contagion by contact in crowded centres, the spread of the disease is to be attributed. It is not due (primarily at least) to importation, as only a very small number of the patients are recent arrivals from abroad. It is seen, for the most part, in children who get infected at school, and amongst mechanics, with whom it is quite common for two young men to share a room together, besides coming into frequent mutual contact in the workshop. There is also increasing evidence that it is not confined to the lower strata of society; and it is suggested that school-teachers, police-station captains, and the visitors of the various benevolent and religious societies should be so instructed that all suspicious cases may be recognised and examined, and thus be subjected to prompt and efficient treatment if found to be infected.

It was not to be expected that the Professors of the University of Edinburgh would look with favour upon the recent movement on the part of the two Royal Colleges, in reference to giving their licentiates an M.D. degree, and the following observations by Dr. Greenfield at the commencement of his address, the rest of which we print elsewhere, support this foregone conclusion: “The growing number of those who seek the degree of M.D. is, I take it, a proof of the value of the degree both in the eyes of the profession and the public. At the present time, as you are aware, it is seriously proposed to give the title of Doctor of Medicine to all who succeed in attaining the diploma of the conjoined Corporations of Medicine and Surgery, whose examinations represent the minimum qualification. I do not know what will be the fate of this extraordinary movement, but I am very sure that the public will not be slow to distinguish between a degree which represents an academic training of high order and difficult attainment and one which is merely a common title to practice. When all are M.D.’s, the relative degree of estimation will depend upon the prestige of the body which confers the titles, and the thoroughness of the training

which they represent ; and I have no fear that the degrees of this University will cease to maintain their present high position. Much more might be said upon this subject—will indeed be said before such a scheme can be allowed to reach maturity. From the historical standpoint nothing could be stranger than the proposal to confer a title which is in all countries, and has been from all time, a University degree by such a body as two conjoined corporations, however important or powerful they may be, which, though nominally colleges, have no strictly collegiate function.”

THE Medical School of Westminster Hospital, under the influence of its present zealous staff, will enter this autumn into more active competition with its hitherto better-found rivals. The new school-buildings in Caxton Street, close to the Westminster Town Hall, are rapidly approaching completion, and Mr. George Cowell, the Senior Surgeon, will deliver the introductory address there on October 1st. The new series of Westminster Hospital Reports, the appearance of which is announced in our advertisement pages, provides another sign of the earnest intention of the Staff to give fresh impulse and solidarity to their medical school.

#### THE DISSENSIONS IN AMERICA.

THE present medical situation in the United States has received less attention on this side the water than it deserves. But we may assure our American readers that all here who have mastered the question sympathise most deeply with them in the trouble that has befallen them. A disagreement like the present is, for many reasons, taken more to heart by our American kinsmen than it would be in England, assuming for the moment such a schism to be possible here. The American temperament differs perceptibly from ours. It is less insular and phlegmatic, more sensitive, we fancy, to the opinion of other countries, more concerned to make a good appearance before the world. Then the position of the medical profession in America is somewhat different from that which it holds in this country. Here we take a comparatively inferior place in the social hierarchy ; we are overshadowed by estates and professions of higher importance and prestige in the nation's estimate. Our organization too is more oligarchical ; there is more reverence amongst us for authority. Our leaders do lead, and if they are unanimous in any undertaking, as in the case of the London Congress, being able to count on the support of Royalty, and the City, and South Kensington, and other depositories of power, they can afford to be indifferent to the support of the mere privates in their army. Even if the Editor of the *British Medical Journal* and all his Council had made up their minds to control the London Congress or to wreck it, they would only have made themselves ridiculous. But in the United States the position of the profession is entirely different. There is nothing to overshadow it there. It holds a position as important and honourable in the State as that of any other calling ; so that an International Medical Congress in America may be expected to enjoy a higher dignity from a national point of view than it can

claim in older countries ; but, at the same time, it must depend far more largely for its ceremonial success on the harmonious co-operation of the medical profession itself. Now in the United States, the organisation of the profession is purely democratic ; there is no common link like that of our Royal Colleges, no recognized headship like that of our President of the College of Physicians, or our President of the College of Surgeons. According to the very political theory on which the State is founded, every man has as good a right to lead as any other, if he can only get that right admitted by his fellows, and for that purpose one vote is as good as another. Distinction in science and reputation abroad supply no reason to a practitioner in Texas or Colorado why he should follow a Wendell Holmes or a Weir Mitchell, in preference to a Shoemaker or a Beverley Cole. Hence a revolt of the “rump” in the United States threatens to prove a much more disastrous affair than it would be in England, and hence we especially ask our readers' sympathy for those well and widely known American practitioners, whose title to lead their profession is admitted everywhere except in the ruder and remoter States of their own country.

We have had an opportunity of seeing several letters from distinguished American practitioners, and they all concur in expressing the most bitter grief and disappointment at the pass to which their profession has been brought. In these letters we have met with scarcely one word of anger against the dissidents who have rudely torn up the first programme of the Congress. Indeed, if we may say so without impertinence, the spirit in which the “leaders” of the American profession, for we will still venture to call them so, have met the recent crisis is one which reflects the highest possible credit upon them. We hardly know which to praise most, their patient suspension of action until the Chicago meeting had confirmed the spirit of the proceedings of the meeting at New Orleans, or their swift and unanimous protest and withdrawal from the Congress when definite action was at length called for. The only hope for the Congress—the only possibility of maintaining the dignity of the profession—lay in such firm and united action on their part, and the effect of this action has been so favourable that there already appears to be a much more hopeful feeling in the States as to the prospects of a peace with honour. The organizers of the revolt are meanwhile making frantic efforts to prevent further resignations, and are even said to contemplate throwing over Dr. Shoemaker, on the score of his supposed unpopularity. But we may take it that no concessions on their part will be accepted short of unconditional surrender and full recognition of the authority and acts of the original Committee. These are the essential preliminaries to the holding of any International Congress at all, and every day increases the prospect of their general acceptance. The sooner they are accepted the better. There will then be still two years in which to bury the hatchet, two years in which to prepare a Congress which shall “whip creation.” We had all made up our minds for that, and shall be disappointed with anything less.

## THE DIGNITY OF DIET.

THE address delivered by Dr. Roberts at Cardiff usefully attracts attention to a subject which suffers habitual neglect simply because it is so constantly brought under our notice. If it be true that an army "fights upon its stomach," it is at least equally certain that the present and the future of a nation is most closely dependent upon the how and the what its forefathers and their descendants have learned to eat and drink. There is nothing which mankind has done for so long, so often, so persistently, and so successfully as—eat. In a sense even higher than that commonly allowed, the successful peoples of the earth have eaten to live; and now-a-days—when the Goddess of Reason, recrowned with the titles of Intellectual Culture and Educational Progress, threatens to claim her victims as well as to reward her votaries—it is not amiss to be reminded that the nations who stand highest in the scale of a boasted Western Civilization have literally eaten and drunk themselves to that proud pre-eminence. "To be a good animal" is still the groundwork of a successful manhood, and even, we would venture to say, of a successful womanhood. And man would be, indeed, a despicable organism, from the evolutionary point of view, if the most successful specimens of his race had not by this time, after the lapse of countless ages of experiment, achieved something like practical success in managing the greatest essential of his material existence. It may be admitted, then, that the food-customs of the mass of civilized humanity are very admirably adapted to their needs in health; and when dealing with those suffering from the various degrees of ill-health, we may take it that some modification of the accustomed dietary is usually preferable to any complete and sudden change. Nor should we be too hasty in condemning usages which confront us as the outgrowth of æons of accumulated individual experience, hallowed with a fathomless antiquity, even though the physiological knowledge of to-day hesitates to sanction, and perhaps condemns them. There is more in the vital mysteries of our living body than the physiologist can pretend to know or his book to tell us of. For instance, before we conclude that a long-established customary article of diet is really pernicious, although pleasant to the taste, we should be able to understand why one simple kind of food agrees with this man and is prejudicial to his equally healthy neighbour. The facts of experimental physiology at present known are too rigid in themselves and too isolated to serve as a perfect chart amidst the shifting currents of clinical experience. The human body is not an inflexible machine working with mathematical precision, it is rather a collection of elastic force-generators. No one would dream of loading a hungry man with a meal as accurately apportioned as the shot which fits, air-tight, the tube of a Whitworth gun. And for the sick we must have regard to the same elements of variety in quality, quantity, kind and method—following the same general plan with an allowance for the same unknown quantity which is found to be essential for the healthy. His experience and customs in health are constantly appealed to when regulating a patient's

dietary during sickness. And, in broader fashion, the accustomed usages of healthy nations afford the student of dietetics a standard which, if not absolutely ideal, is eminently serviceable for purposes of practical utility.

It is, of course, in the severer degrees of illness that the greatest difficulty is found in modifying the ordinary diet of health in accordance with the decrease in digestive and assimilative vigour. No name is better known than that of Dr. Roberts in connection with therapeutic dietetics, and few have done so much as he in teaching how to provide food for the invalid which shall be at once nutritious, palatable and easy of absorption. It would be vastly better for the young practitioner's patients and much less puzzling to himself if a course of lectures on "Kitchen-Physic" were a recognised item in the medical curriculum. A person really ill needs to be dosed with food quite as regularly and as carefully as he is with drugs; and it is equally important that the ingredients of his food, their action and their amount, their suitability to his physiological needs and his digestive capabilities, should be clearly comprehended. Too often the "light, easily digestible food" recommended by the medical attendant is translated into an infusion of sapid extractives known as strong beef-tea, and a delicate glue called calves-foot jelly, at the bedside of the patient. A patient once remarked that he did not much believe in jelly until he found by experiment that a small cube supported a four-ounce weight, when he became convinced that it "must be very strengthening." Probably nothing would have shaken his faith in this *argumentum ad unciam*. And, despite the repeated exposure of its pretensions, there is probably no reputation so over-blown, so firmly believed in, and so little deserved, as that of domestic beef-tea as ordinarily prepared for the sick room. Though most valuable as a stimulant, and as a peptogenic adjunct to other proteid foods, its "refreshing effect" is an indication of strength drawn from the patient's reserve of potential force rather than a proof of vigour introduced into his system from without. Even when recourse is had to any of the numerous "foods," "juices," and "extracts" supplied by the purveyors of dietetic novelties, it is often extremely difficult to make sure that one is better off, and the purchaser is generally more influenced by considerations of convenience, added to the pleasant appearance of the article and the vendor's recommendation, than by any knowledge—or indeed, any power of knowing—its real suitability for the patient. A paper lately published by A. Stutzer in the *Berliner Medicinische Wochenschrift* is of interest in this connection. In all, nine varieties of meat-extracts were examined by him, four being of American manufacture, three English and two German. The *nutritive value* of these preparations is compared in terms of the easily digestible albumen and peptone which they were severally found to contain; and the list is headed by Reed and Carnrick's beef peptonoids, of which 100 parts by weight contain as much albumen and peptone as 178 of Johnson's fluid beef, 285 of Kemmerich's meat extract, 482 of Murdock's liquid food, 745 of Brand and Co.'s essence of beef, 764 of Savory and Moore's fluid meat, 898 of Liebig's meat

extract, 902 of Benger's peptonised beef jelly, or 966 of Valentine's meat juice. In this comparison Liebig's extract, for instance, takes a subordinate position, because it is found to be mainly an appetising and scarcely a nutritious substance. If, on the other hand, the same preparations be compared as regards the flesh-bases contained in them, it is found that 100 parts by weight of Liebig's extract contain the same amount of nitrogen (in the form of creatin and carnin) as 126 of Kemmerich's meat extract, 537 of Valentine's meat juice, 558 of Johnson's fluid beef, 1,844 of Benger's peptonised beef jelly, 4,161 of Murdock's liquid food, 5,053 of Brand's essence of beef, or 7,782 of Reed and Carrick's beef peptonoids. From the above interesting analysis it is seen that such "medical comforts" possess a far different value according as they are regarded as nutritive or as appetising and peptogenic; and the indications in each case need therefore to be carefully considered before they are prescribed. Although we must cordially sympathise with Dr. Roberts in his objections to patented foods of secret constitution, we cannot imagine that preparations of this class, if good of their kind and of known composition, can ever be entirely replaced by home-made equivalents. The claims of portability and convenience will prevail as against the expenditure of time and trouble needed for preparing small quantities at home, to say nothing of the numberless cases of emergency and of those slighter ailments and less fortunate patients for whom the requisite attention is not necessary, or not obtainable. Of course there are many instances in which the use of a reliable pancreatic ferment is advisable; and our grateful thanks are specially due to Dr. Roberts for having simplified and popularised the methods of employing these agents with but little trouble and so as to secure excellent results. He has done real service, too, in now laying down the broad principle that as a healthy body is the same body still when ill, though working under altered conditions, so the diet of the sick should be founded on the same general principles, specially modified in detail in accordance with the changed circumstances, and even to some extent involving the same puzzles and apparent contradictions, as have been proved by the perfected experience of ages to be essential to the welfare of the best men in the best of health. "All knowledge begins in doubt, and much of it ends there." Until the finite *scientia* of man has blossomed into omniscience he must still be content to modify, and sometimes even to correct, his scientific conclusions by the results of a genuinely successful empiricism. The reflection that each meal we take is an element in the evolution of a perfected humanity as well as of a perfect dietary, confers a chaste dignity upon the pleasures of the table which may well content both the physiologist and the philosopher. But, whether in the sick room or at a civic feast, we cannot afford to forget that to "live well" is, in every good sense of the term, quite as much a matter of the cook as of the chemist.

---

THE Library and Museum of the Royal College of Surgeons will be closed for the usual cleaning and repairs, during the month of September.

## REVIEWS AND NOTICES OF BOOKS.

### GOWERS ON THE DIAGNOSIS OF DISEASES OF THE BRAIN.<sup>1</sup>

IN this volume of less than 250 pages a really first-rate summary will be found of what is known concerning the anatomy, both normal and morbid, of the brain, and its relations to physiological function and the symptomatology of disease. The writer has set himself the task of guiding the student to a conclusion, in any case of presumable cerebral disorder which comes before him, as to whether it is cerebral or not, and, if so, as to what is its probable seat and cause. This task Dr. Gowers has performed in a manner which makes his book invaluable from its clearness and small compass not only to students of medicine in the narrower sense, but also to most of those who teach and practice. There are few who do not often stand in need of some handy book of reference on the application of the very considerable body of physiological facts of which we are now fairly certain, to the diagnosis and prognosis of cases of brain disorder and disease; and it requires a very extended and constant experience of such cases, however well the principles of diagnosis may have been learned and understood, to deal satisfactorily with each one as it comes before us. There are few, then, who will not have cause to thank Dr. Gowers for his very able *résumé* of this confessedly difficult and complicated subject. He is thoroughly equipped for the task he has performed so well, showing here, as he has done in all his previous work, an extensive and accurate acquaintance with the literature of his subject. But he has shown more than this—and perhaps even more markedly here than in his former books, he has made the subject especially his own by a wide experience and reflective criticism. The book is not a mere *résumé*, but is characterised throughout by remarks and cautions which can only be the outcome of thoughtful clinical work, and of knowledge far beyond the special subject-matter which gives it its title.

The plan of the work is to give first an account of the structure and functions of the brain; then of the symptoms produced by its diseases; and, lastly, of the relation of these symptoms to the seat and nature of the morbid change or disorder. In the first section, clear and succinct throughout, we would especially point out the account of the visual path from the retina to the convolutions, where what is known, and what is at present merely probable, is set forth perhaps better than in any other text-book. It is to be noted that Dr. Gowers states with great certainty, that there is no complementary decussation of the visual fibres at the corpora quadrigemina, as was suggested by Charcot. We are glad to observe Dr. Gowers' caution against the use of the word *paresis*—a term we have long regarded as of more than doubtful value—pointing as it does generally, in the student mind, to something different in kind from paralysis. It is altogether unjustifiable, as Dr. Gowers says, to assert that partial loss of power is not paralysis. Certainly the word is always superfluous and most often misleading. Another welcome instance of the author's dislike to the nebulous language which is popular with those to whom thought is an unpleasant labour, is his implied condemnation of the term *neuræsthenia*, "at once more alarming," he says, "and more gratifying to the weakened mind, than the older equivalent, nervous weakness." Speaking again of the numerous "sensa-

<sup>1</sup> "Lectures on the Diagnosis of the Diseases of the Brain." By W. R. Gowers, M.D., F.R.C.P. London: J. & A. Churchill, 1885.

tions" complained of by those of neurotic inheritance, and of the infinite number of impressions which must be always reaching the brain from the activity of various parts and processes, Dr. Gowers makes the remark that the conviction on the part of the patients of the existence of a grave organic cause for some of their sensations is easily to be understood. Examples of these are known to be extremely common; and it is equally well known that diversion of attention will cure many cases. How to effect this often puzzles the physician; but no one who tries can fail to be sometimes rewarded with success. Some, however, Dr. Gowers goes on to say, find it profitable to pander to these morbid tendencies by a diagnosis of some actual disease in harmony with the patient's fancy, such as congestion of the base of the brain; and he points out that there is a current manual in which the symptomatology of congestion of the brain has been largely written from such cases as are here alluded to. These are only a few examples out of many of this author's useful warnings. Every one expects from Dr. Gowers accuracy of knowledge and statement regarding the physiological explanation and symptomatology of cerebral disease; we therefore deem it unnecessary to enlarge on the excellence of the book from this point of view, or to quote examples of his erudition. It is rather the evidences which are so frequent of what may be called common-sense and extensive experience, that being comparatively rare in books of this kind seem more especially noteworthy in a review. Thus in his pointed and useful remarks on headache, worth in themselves many of the padded volumes of verbiage that have been written on this symptom, Dr. Gowers does not disdain to teach, what indeed most really practical men know, but is rarely enough taught in speech or in writing, that a not uncommon cause of headache is cough. He quotes a patient who came for treatment on account of headache, and complained of nothing else, when the headache was the result of cough, and the cough of phthisis. Anyone with a large experience of out-patient practice will recognise the truth of this remark; and will remember, too, how often headache is to be attributed directly to chronic bronchitis. The true physician is he who least often falls into a well while gazing at the stars, and this book, which is full of hints and reflections, such as we have quoted, owes no little of its value to the evidence it contains, that its author, while ably cultivating a certain class of affections, has, owing to his wide field of experience, successfully avoided the fatal error of over-concentration on one subject.

There are many useful remarks made in passing as to the import of certain symptoms in children with regard to possible brain disease. Thus in cases of vomiting, we are reminded that when indigestion causes this symptom, the child is usually ill; and that, when vomiting takes place frequently, the child not seeming otherwise indisposed, the assumption of indigestion must not be rashly made. Again, it is well for all to remember that a child may suffer from fever, headache, and vomiting, which may for a time simulate meningitis, but will soon pass away, and are often due to what is probably migraine. The early history of a migraine, as is well known when carefully enquired into in an individual case, is often lost in the obscurity of the years of childhood. We would quote, too, still under this head, the evidence that the author brings forward for thrombosis of a vein being a common cause of infantile hemiplegia and convulsions which may or may not persist. It is well known that children dying with such symptoms are often found to have thrombosis of the longitudinal sinus. Dr. Gowers, after fully discussing the question from the pathological stand-point, comes to the conclusion that in the cases which do not die, there is thrombosis in one of

the veins which ascend to this sinus. These cases are not infrequent; and the author teaches that such thrombosis is probably the cause of most cases of sudden cerebral disease in childhood, and of many instances of one-sided convulsions which date from infancy. In calling attention, lastly, to the useful and much-needed advice recorded towards the end of the work, that due consideration of the nature of the lesion of the nerve-elements in any given case of syphilitic brain disease should take place before recovery is promised to patients "if they are properly treated," and the consequent avoidance of discredit on the part of the medical adviser, we cordially commend to our readers this most recent work of a well-known authority, as one which will be studied with profit and pleasure by teacher and learner alike.

*The Climate of Canada and its relations to Life and Health*; by WM. H. HINGSTON, M.D., D.C.L. Montreal: Dawson Bros., 1884. Large 8vo. Pp. 266.—Believing that in emigration, State-aided, is to be found one means of relieving the present over-crowded condition of the market for unskilled labour, we have read this book with care, and notwithstanding some glaring faults of style and matter, with much interest. The first part, consisting of 94 pages, is devoted to a consideration of the climate or meteorology of British North America, which is essentially continental, though the vast extent of inland waters, the heavy rain and snow-falls, the interminable forests, and the absence of any wide area of subtropical continent to the south, render it more equable than that of the corresponding latitudes of Asia, and even the extreme cold is less destructive than elsewhere. Labrador is almost arctic, but the climate becomes less inhospitable as one proceeds westwards and even northwards in the interior, and on the western shores spring and autumn can scarcely be said to exist; in the short hot summer wheat has been reaped nine weeks after sowing, while the winter, though intensely cold, is clear and dry, and makes labour a pleasure, and out-door exercise a luxury. Not only for the strong is winter the healthiest season of the year, but throughout the whole Dominion the mortality is less than in summer, and in Montreal it is actually less than two-thirds of the summer rate. It seems almost incredible, though a well known fact, that the hardy *voyageurs*, and the Scotsmen in the service of the Hudson's Bay Company, will sleep out under a canvas tent or a canoe, or even in a single blanket, when the thermometer stands at  $-40^{\circ}$  or  $-50^{\circ}$  F., without seeing a fire for a whole winter! Except in some classes of the population in the larger towns where the habits and vices of American cities prevail, the extraordinary improvement in the height, strength, and physical development of every nationality alike, in each successive generation, is most conspicuous; while well attested feats performed by giants, where all are athletes, almost take away one's breath. The most interesting point in connection with the French Canadians especially, so vastly superior in physique to their cousins in the old country, is, that they marry at an unusually early age, and are extremely prolific, six children being the *average* of each family. In 1763 their number was but 60,000 or 70,000, now they are not fewer than a million and a half in Canada, and half a million more who have migrated to the States, and this notwithstanding a fearfully high infant mortality, 60 per cent. under five years, due to imprudent exposure. But the Herculean build of the *habitant*, as well as of the descendants in the second and third generation of English, Scotch and Irish settlers, effectually disproves the theory that early marriages *per se* tend to the degeneration of a race. Their longevity too, so far as we can judge from imperfect statistics, is high. Dr. Hingston discusses the probable effect of further clearing of the forests on the climate, and shows from various classical quotations that that of Italy, in the time of the Romans, was far colder in winter than it is now, and that the Seine, the Rhine, and the Rhone in ancient days were, like our Thames, frequently frozen. But we cannot conclude our favourable notice without some strictures on a style which is at once in-

flated and slipshod, and occasionally ungrammatical. We are also surprised, not to use a stronger term, that an M.D., D.C.L., &c., should talk of *motion* being essential to putrefaction, and cold preventing motion, of stimulating gases in the air, and above all, that he should imagine that air is a definite compound subject to the law of combining proportions, so that "any excess of oxygen must exist as an addition to, and not as a constituent part of the atmosphere;" or that Nature's lines of female beauty are "the same as we see in the new-born," the waist wider than the haunches and "forming the base of a cone, the apex of which is at the shoulders"! We should fancy that any boy in the modern side of our public schools, and many in our elementary schools, would smile at such ignorance of the first principles of chemistry.

*De la Coqueluche et de son traitement par la Résorcine;* par le Dr. MONCORVO. Paris: O. Berthier, 1885.—This is the second memoir from the author's pen on this subject, the former having been mainly devoted to supporting the view that whooping-cough is a local affection primarily attacking the entrance to the air-passages. Amongst the points on which he relies as telling in favour of his view he observes that there is an entire absence of any relation between the frequency, duration and violence of the paroxysms and the extent or intensity of the bronchial catarrh. This paroxysmal cough may be manifested without any sign of bronchial inflammation. It may be induced by emotion, fright, crying, or difficulty in swallowing; this does not occur in other affections of the respiratory tract. The absence of fever, its transmission by contagion and the immunity against a second attack provided by a first, all help to differentiate it from ordinary affections of the respiratory organs. Dr. Moncorvo altogether rejects the theory which would classify whooping-cough amongst the neuroses, and declares it to be a definite specific disease due to the presence of a germ which he holds will soon be identified. The results of treatment have, he contends, brought material support to his view on all points. Résorcine, whose use in whooping-cough it is one of the objects of this pamphlet to proclaim, is an aromatic substance closely allied to carbolic acid, but possessing certain advantages over the latter. It was first introduced by Dr. Andeer of Munich; it is an antiseptic of the highest order; it has no odour, and a taste pleasing to children, and has no tendency to provoke irritation of the pharyngo-laryngeal mucous membrane. The mode of using it is to apply a two per cent. solution to the orifice of the glottis by means of a camel's hair brush. Just at the first application it produces a paroxysm of coughing, but this effect soon passes off, and complete tolerance is very soon obtained. The author has adopted this line of treatment in a good many cases, and in every one with a good result.

## ABSTRACTS AND EXTRACTS.

### COMMENTARY ON SHAKESPEARE'S MEDICAL KNOWLEDGE.<sup>1</sup>

By WILLIAM WADD, F.L.S.

SHAKESPEARE has been allowed by every commentator and critic from Rowe to Douce the meed of a matchless knowledge of human nature; but while all agree in giving credit to the unrivalled power of his genius, some have questioned his learning and attainments.

<sup>1</sup> On the appearance in the *Medical Times* some months ago of a review of Dr. Chesney's laboured work on "Shakespeare as a Physician," one of our contributors called our attention to an interesting article on the same subject, published many years ago in Brande's *Quarterly Journal of Science*, No. X., and suggested that we should republish it. Space could not be spared at the time, but now that the vacation of the Societies leaves our columns more free, we think that our readers will be glad to make acquaintance with an article which, though not written by a medical man, deals with the subject in a far more satisfactory manner than the volume to which, in some way, we owe our knowledge of it.

Yielding to no one in my admiration of our great dramatic bard, and fully sensible of the services these interpreters have rendered him, I would crave leave to notice one point which seems to have escaped their observation, or if they have alluded to it in the abstract I do not recollect any practical illustration: I mean his decided knowledge of abstruse sciences. Let us take that of medicine, in all its branches, as an exemplification of this remark. One can easily understand how an intuitive knowledge of mankind might enable a genius like his "to hold the mirror up to Nature," and even to kindle into life new beings and new worlds:—

"Each trait of many-coloured life he drew,  
Exhausted worlds, and then imagined new."

Or further, that his nice discrimination might render him a faithful delineator of human passions and human actions; but that he should be versed in all "the thousand ills that flesh is heir to," and understand the proper treatment of those ills, and the niceties of medical and surgical practice, with which he exhibits in his writings so intimate an acquaintance—this is beyond what professional faith can allow to intuitive genius alone. If he did not indeed study medicine and surgery, we must agree with Pope, that "he gives ground for a new opinion, that the philosopher, and even the man of the world, may be *born* such, as well as the poet." The medical profession has undoubtedly furnished some geniuses of the first order; but it would be a grand acquisition to identify a doctor in our immortal bard. We should be proud to hail him as a surgeon; the Apothecaries Company and the general practitioners would probably be equally anxious to prefer their claims. The history of Shakespeare's life, however, does not give us any reason to believe that he was otherwise connected with the medical profession than by having a medical son-in-law (Hall). Whether he profited by this connection or not, we cannot tell; but we have as little ground to imagine that Hall was of use to Shakespeare by his medical talents as we have that Shakespeare assisted Hall, and yet the intimate knowledge displayed by "the bard of Avon" in physic and surgery, pharmacy and physiology, leads to the conclusion that he must have acquired his medical notions from practical experience. With singular felicity and discernment, he hits upon the particular point on which a medical or surgical argument would turn; it does not appear that he ever *walked the hospitals*; yet I can hardly conceive that the ordinary *walks of life* would furnish means for describing symptoms, as he does, with the technicality of Warren. He might challenge Sir Henry Halford to define with greater accuracy the type of febrile exacerbations, and so nice is his discrimination, that with the correctness of a clinical lecturer, he notices an intermittent fever passing into a continued form, and makes a quotidian tertian and delirium tremens end the life of Sir John Falstaff, whose nose (as in such cases) became as sharp as a pen."—*Henry V.*, act 2, scene i.

With hyper-critical acumen, he makes a distinction between *distemper* and *disease*. In using the latter word, it is always applied to malady, or deadly sickness—

"What's the *disease* he means?  
'Tis called the evil."

Again—

"We're all *diseased*,  
And with our surfeiting and wanton hours,  
Have brought ourselves into a *burning fever*."

When, on the other hand, he uses the former word, it is lightly touched as—

"Little faults proceeding on *distemper*."—*Henry V.*

And in *Henry IV.*—

"'Tis but a body yet *distempered*."

Concerning hysterics, there is another practical refinement in *Lear*, act 2—"Oh, how this mother, &c."—by which application of the term he evinces a belief that this affection was not peculiar to women, but common also to men: a doctrine entertained by the best medical authorities of that period. What modern physiologist could give a more correct representation of the relative conditions of the organs of circulation than he does, where he describes the phenomena which they present in the gasps of mortal

agony, when the blood, for the last time, has retreated to its citadel?

"Oft have I seen a timely parted ghost  
Of ashy semblance, meagre, pale and bloodless,  
Being all descended to the labouring heart,  
Who, in the conflict that it holds with death,  
Attracts the same for aidance 'gainst the enemy,  
Which, with the heart there cools, and ne'er returns  
To blush and beautify the cheek again."

Sympathies he understood as well as Kenelm Digby; and how well he comprehended the influence of the mind upon the body is demonstrated by that masterly scene in which Henry VIII. hands over some papers, of no very agreeable import, to Cardinal Wolsey: "Read this, and this, and after, this—and then, to breakfast with what appetite you may." Abernethy could not have put it more pithily! Here was a touch upon the gastric nerves, with whose effect on digestion he was well acquainted, as also that produced upon the faculties by gross feeding; he knew how uncongenial *gastronomic* and literary pursuits must ever be—

"Fat paunches make lean pates, and grosser bits  
Make rich the ribs, but banker out the wits."

And, for this reason, he invariably abstained from composition when he retired to aldermanic fare at Stratford. Then, again, how ably and beautifully does he delineate the effects of suppressed mental emotions—

"She never told her love,  
But let concealment, like a worm i' th' bud,  
Feed on her damask cheek."

And in the same tone in another place—

"To keep it from divulging, let it feed  
E'en on the pith of life."

Nor was he ignorant of idiosyncrasies, or constitutional peculiarities—

"Some men there are, love not a gaping pig;  
Some that are mad, if they behold a cat,  
— for affection,  
Master of passion, sways it to the mood  
Of what it likes, or loathes."

When he asks whether the doctor can—

"Minister to a mind diseased,"

and evinces in mental aberrations his want of faith in physic, he only acts according to the opinion of his contemporaries; it is no proof of ignorance, for in other places he shows an intimate acquaintance with many of the leading features of the distempered mind, particularly the increase of muscular strength—

"My limbs, enraged with grief,  
Are thrice themselves."

*Henry IV.*, part 2, act i.

Now let us look to his surgical pretensions, and we shall find strong symptoms indicative of a minute knowledge of anatomy and surgery. Take, for instance, his repeated reference to the *pia mater*, and his notice of the epidermis. How honestly does he admit the impossibility of curing scrofula, when he describes those affected by it as—

"Strangely visited people,  
All swollen and ulcerous, pitiful to the eye,  
The mere despair of surgery."—*Macbeth*.

And from the manner in which he sneers at the rubbers and thumbers, we may conclude he would not have been a subscriber to modern quackery. His contempt for charlatanry seems proportioned to his scientific knowledge of surgery: indeed, he was fully informed of the use of the lancet and cautery. "We do lance diseases in our bodies," says he; and in *Timon of Athens*, act 5, scene iii., actually speaks of "cauterising the root of the tongue"; and cicatrice, a technical term, is of frequent occurrence. Podagram and Chiragram he also speaks of; and what has jocosely been designated *hipagram*, he correctly calls *sciatica*—*Measure for Measure*. And who out of an hospital ever heard such a list of surgical diseases as Thersites runs over to Patroclus?—*Troilus and Cressida*. In numerous instances, he seems giving a prognosis. "This apoplexy will certainly be his end!"—*Henry IV.* act 1,

scene ii. Sir Astley Cooper could not be more positive, nor could he describe it more appropriately, than by the words in *Coriolanus*: "A very apoplexy-lethargy, muddled, deaf, sleepy, insensible;" and there is no doubt that when in *Othello* he states that, "My lord had fallen into an *epilepsy*" (act 4, scene i), he could, had it been necessary, have defined that extraordinary disease with equal accuracy, for even such as result from sedentary occupations did not escape him, as he unequivocally states that "universal plodding prisons up the nimble spirits in the arteries."<sup>2</sup>—*Love's Labour Lost*, act 4, scene iii. Or had he studied the chylopoietic doctrines of our times, could he have given a more decided touch of practical experience than the following remark in *Coriolanus*: "Your affections are a sick man's appetite, which most desires what would increase the evil"? His knowledge of the liver is evinced in many instances, and in *Love's Labour Lost* he speaks of "the liver vein," in allusion to the ancient notion of its being the seat of love. The "red plague," which Caliban so kindly wishes may seize upon Prospero, was another term for erysipelas. And when he speaks of *serpigo*, he distinguishes the *dry serpigo*—

"Now the dry serpigo on the subject."

*Troilus and Cressida*, Act 2, Scene iii. From these critical niceties, his remark on stewed prunes, *Henry IV.*, part 1, and some hints about the tub fast, it is clear that he had studied Master William Clowes's "Surgery." And although he does not use the modern term "morbid poison," perhaps thinking all poisons *morbid*, or some other reason, yet from his joke about a French crown, *Measure for Measure*, his equivocal use of the Corona Veneris, and the manner in which he alludes to the devouring power of the "goujeers," it is evident that he understood the action of animal, as well as vegetable and mineral poisons. He would have split a straw argument with John Hunter or Dr. Adams on yaws or sirvens, discussed the *pseudo* with Abernethy, and defined phagedena with the accuracy of Celsus. Of the sweating sickness, and the proposed remedies, he was perfectly master; there is abundant proof that he was equally versed in the symptoms of leprosy; and it is more than probable that he knew the difference between the cochin leg and the elephantiasis of Aretæus. How minutely he was acquainted with the paraphernalia of surgery is curiously exhibited in the quibble on the word "tent"—bring in the "surgeon's box or the patient's wound." And he gives to Dr. Caius a *boitier verd*, which is a truly technical term for a case of surgeon's instruments. Had he served seven years apprenticeship to an apothecary his acquaintance with the properties of chemicals and galenicals could not have been more correct. He evidently knew the effects of belladonna; the "insane root," he tells us, "takes the reason prisoner," and he was equally master of the properties and effects of sedatives, for he explains a case where "poppy nor mandragora" would avail not, and in mixing a dose for Othello, he makes it "as bitter as Coloquintida," act 1, scene iii. Many curious and rare substances in the vegetable world are critically treated. The nettle of India, the *Urtica Marina*, a zoophyte in the Indian Sea, is even noticed—

"Yon dwarf of hind'ring knotgrass made"

shows a knowledge of ancient notions, this herb being supposed to have the power of stopping growth, and fern seed, that of making people invisible, as well as curing the rickets. Then the "Cuckoo-buds of yellow hue" is a remark of one skilled in botany. Gerard calls it, *Flos cuculi cardamine*.

In *All's Well that Ends Well* he makes Parolles notice Galen and Paracelsus in a manner that clearly proves he understood their different systems. He applies the term *learned* to Galen and *authentic* or *fashionable* to Paracelsus; and when he speaks of all the learned and authentic fellows, he uses the very words of the diploma, *authentic licentiatus*. He may be said to have been *bon Galeniste*, *et très bon Paracelsiste*. He seems to have considered the doctrine of Galen as *non mesprisabile pour la pathologie, et propitable pour les boutiques*; while that

<sup>2</sup> The system of physic of those days gave to the *arteries* the office now given to the *nerves*.

of Paracelsus was *bonne à suivre pour la subtilités l'épargne, te pour la thérapeutique*. From the familiar manner in which he alludes to certain pharmaceutical operations, it is evident that he did not consider the apothecary the mere "Culler of Simples"; and when he states the courses quicksilver takes (*Hamlet*, act 1, scene v.) he proves himself acquainted with all the subtleties of its application, for though out of fashion now, the time has been when it was as common to take a drachm of quicksilver with a dish of coffee as it is now to take a *chasse café* in the shape of a dram of Maraschino. Then his observation about "the toad, ugly and venomous," and the "precious jewel in his head," shows that he was acquainted with the notion of the early naturalists, that the head of an old toad contained a wonder-working medical stone; and although a modern apothecary would not look there for a "most souveraine remedy to repulse poysons," yet Master Edward Fenton, 1589, tells us that "there is founde in the *heades* of old and great *toades* a stone called borax or stelon" (*As You Like It*, act 2). That he was skilled in comparative anatomy could be easily proved; and that he was abundantly stored with materials of natural history is equally true; even the building of the swallow's nest in a favourable aspect did not escape his observation. That he was also deeply read in Tuberville's book of hunting, and the noble art it treats of, cannot be disputed; and from the manner in which he alludes to the "stagers," as "the horse's apoplexy," and other diseases, it may fairly be inferred that he was not ignorant of the veterinary art. After all this evidence in proof of the medical attainments of Shakespeare, we are at a loss to reconcile such an unprofessional speech as "Throw physic to the dogs;" and that still more injurious one—

"Trust not the physician,  
He kills more than you rob."

It must be confessed that, having uttered such opinions, he could not, however qualified, have had the assurance to take out his M.D. diploma. As, however, in no one instance can he be accused of giving offence to *Surgery*, we may be allowed to indulge a hope that, had he not been contented with being one of the most renowned of that bright galaxy of genius who paid their court to the "Fair vestal crowned in the west," with being, in short, the pride of England to all succeeding ages, it was in his power to have been (as Hunter now is) the glory of the Royal College of Surgeons.

## MEDICINE.

**MALIGNANT PUSTULE.**—Surgeon A. P. Hart, M.B., records the following case of this disease in an appendix to the Army Medical Report for 1883. On the afternoon of July 24, 1854, Private H——, age 26, a healthy and temperate man, belonging to the Royal Inniskilling Fusiliers, came to the Station Hospital in Penang with his left ear red, swollen, and very painful; his ear sticking out, the result of considerable œdema behind the ear. On the upper edge of the ear was a black eschar from  $\frac{1}{2}$  to 1 in. in diameter, surrounded by the tissues in an acutely inflamed state, and behind the ear were two bullæ. He stated that two days previous he had been bitten on the ear by a small black fly, and that the next day it began to be painful, but he did not think it of sufficient consequence to come to hospital. He was ordered a purgative, and poultices were applied. July 25th.—Ear very painful; the œdema behind the ear still present. Ordered diaphoretic mixture, and put on milk diet. July 26th.—Temp. 103.6°, pulse 140. Ear not so inflamed and less painful. He had two 10 gr. doses of quinine, which reduced the temperature. July 27th, at 4.30 a.m.—His groaning woke a patient up, and he was found to be unconscious. Temperature was then 102°, pulse 120, skin very hot and dry, unable to speak, but partly conscious on being roused; head turned over to the right side, and it seemed to cause him pain if it was forcibly turned. The left side of the neck was hard, with brawny œdema. He swallowed with great difficulty, and had a little froth coming from the mouth. The pupil of the right eye was dilated and insensible to light. He was

ordered 5 grains of calomel and 10 grains of quinine, and had fomentations applied to the left side of the neck. At 11 a.m. his temperature was 103°, and remained at this till the time of his death. His bowels were opened after the calomel, and he was sensible enough to make a sign when he wanted to pass his excreta. He sent for a paper and pencil to write, but he was not collected enough to do more than make a few random strokes. At 7 p.m.—Low muttering delirium set in, with picking of bedclothes. There was a red, erysipelatous blush over the left neck. His head still turned to the right, and he was conscious enough to feel it if we put it straight. He was given Tinc. Ferri Perchlor. in half drachm doses, and had flour sprinkled over his neck, and also two drops of tincture of aconite every two hours with a hope of reducing the temperature. July 28th.—Very restless all night and no sleep. Quite unconscious, head in same position. Temperature 103°, pulse 130. The pupil of his right eye was normal and acted to light. Skin very hot and dry. Had his head shaved and applied ice; mustard poultice applied over region of heart, as there seemed some cardiac disturbance, but no murmur. 10.30.—Began to suffer from dyspnoea, and became cyanosed; temperature went up to 104°, and his pulse became irregular, and he died at 1.30. No *post mortem* allowed. Rigor mortis set in within an hour. Hypostatic congestion very marked all over body. Blood taken from the femoral artery was found to be very dark, tarry, and viscid; numberless bacteria were found, but Dr. Hart could not say whether they were the bacilli anthracis. If on admission he had made a correct diagnosis, he believes this man's life might have been saved; but he looked at this eschar on the ear as caused by the bite of some insect aggravated by irritation from picking or applying something to the spot, and not as a malignant pustule, and so failed to excise and cauterise the place, and the man was put on a milk instead of an animal diet, which is recommended. At one time the case was judged to be one of erysipelas. The paralysis of the right eye was peculiar, as no other part of the face was affected, and this entirely disappeared within 24 hours. It was due probably to some local hæmorrhage or exudation in the brain which afterwards became absorbed, such appearance being very common in *post mortems* on bodies of persons who have died from this disease. As regards the ætiology of the case, it was probably caused by indirect inoculation through the medium of the insect which bit him. Large herds of cattle frequent the extensive grazing grounds around the barracks, and though Dr. Hart was not able to discover that any animal had died from this disease, it seemed most likely that the insect conveyed the virus from a diseased carcass. Investigations by Pasteur seemed to show that these bacilli contain such an extraordinary amount of vitality that the ordinary burial of a carcass is not sufficient, and that there is a possibility of their being brought to the surface by means of earth worms, and so contaminating the pasture on which cattle might afterwards feed.

**PARACENTESIS PERICARDII.**—In a communication read before the Medico-Chirurgical Society of Edinburgh, Professor Grainger Stewart described a case in which this operation had been performed. The patient was 17 years of age, in whom pericarditis had supervened upon inflammation of the lungs. Aspiration was performed in the fifth intercostal space towards the left margin of absolute dulness, and two ounces of a reddish blood-stained serum withdrawn. Two days later it was again found necessary to tap him, and four ounces of fluid were withdrawn. The patient made a rapid and complete recovery. Professor Stewart analysed all the recorded cases of this operation, finding 38 successes and 59 failures. He then gave the following answers to the question, What are the indications for its use? "1. It should be tried wherever life is imperilled by the copiousness of the effusion. 2. It should be tried, even if pericarditis be not in itself dangerous, in any case of considerable pericardial effusion in which the pulse threatens to fail, whether it be due to inflammatory or degenerative changes in the cardiac muscle, or to general debility from severe or prolonged disease." As to the best rules for operative procedure, he said: "1. Exploratory puncture should be made by means of a Wood's syringe or

other fine perforated needle, the needle being cautiously introduced at a point where there is absolute dulness and least likelihood of injuring the heart. 2. If serous fluid be found, the fine needle of an aspirator should be introduced at the same point and the fluid drawn off. 3. If purulent fluid be found, either aspiration, or what is probably better, free incision should be resorted to and the pus evacuated. The splendid results obtained by the latter plan of treatment by Dr. West and by Professor Rosenstein of Leyden must satisfy any one who reads their papers of the value of this method. 4. As to the quantity to be drawn off, opinions are somewhat contradictory. If the fluid be purulent, it is obviously desirable to remove the whole of it as speedily as possible: if it be serous, I think that this rule does not necessarily hold. While admitting that there is plenty of evidence to show that the pericardium may be emptied or almost emptied without danger to the patient, it appears to me that only a sufficient quantity to give relief should be removed. It is a sound principle that in dealing with vital organs only the minimum amount of interference acquired should be had recourse to, and especially in cases which threaten failure of pulse is this precaution necessary. It is conceivable that the sudden removal of considerable pressure from the surface of the heart might sometimes lead to a fatal syncope, while the removal of a small quantity of fluid would involve no such danger. You are familiar with the occasional occurrence of syncope when paracentesis of the pleura is being performed, and whatever may be the explanation of this fact, it seems quite as likely to occur in connexion with the pericardium. I therefore prefer, as at present advised, to draw off only a small number of ounces, and, if necessary, to repeat the operation rather than to adopt the method recommended by the majority of authorities, and draw off a large quantity at once. 5. At what point should the puncture be made? It is not very important what point is selected for puncture, so long as the operation is performed with caution. Obviously wounding the heart is to be carefully avoided, notwithstanding the fact that it has been wounded, and even penetrated, without seriously bad effect. I should insist upon the puncture being made where there is absolute dulness, and should prefer the fifth interspace as much to the left of the sternum as possible. By such a rule we must avoid risk of injuring the heart."—*Edinburgh Medical Journal*, August.

**OVER-PRESSURE IN SCHOOLS, NERVOUSNESS AND INSANITY.**—In the course of his presidential address to the Connecticut Medical Society, Dr. B. N. Comings attempted "in an unscientific and practical way to call attention to the extremely nervous condition of a large percentage of New England people, and to consider the cause." All medical men testify to the rapid and universal increase of nervousness: it is a condition that comes about from a great variety of causes that are often not dependent on any organic lesion. A great portion of our nervous patients are not insane, but they live very close to insanity at times, and in paroxysms of high excitement bear a close resemblance to lunatics. Nervousness is becoming more and more a characteristic of all persons whose health is generally below par, and complicates unpleasantly the symptoms of many real diseases. The cause is often to be found in heredity, and as New England stock is rapidly deteriorating and moving out, this is acting more powerfully. The children of great brain-workers are oftener below than above mediocrity—our best men generally come from sound stock in rather humble life—a parentage of good physical organisation, strong common sense, industrious habits, fair intelligence and a life free from excitement. Over-pressure in schools is a prolific cause of nervousness; from statistics specially obtained in relation to this subject, it appears that fully one-third of the children in the Connecticut graded schools suffer seriously from overstudy, become nervous and irritable at home, lose appetite, and run down in term time. Everything tending to overwork or unnecessary excitement should be pruned out. This necessitates giving up two factors now deemed essential, namely, competition and marking—with children under twelve one-half of the time now devoted to study should be given to physical labour or training. The speaker instanced the life-success

of noted men like Lincoln, Garfield, and Burritt, who acquired their education with a very large admixture of physical labour thrown in.—*Boston Medical Journal*.

**DIABETES IN ADVANCED LIFE.**—In a clinical lecture on this subject, M. Landrieux narrated five cases of glycosurie diabetes in persons over sixty years of age; three of whom were rheumatic, whilst none were gouty; they all had intermittent glycosuria. Were these cases of simple glycosuria or were they cases of intermittent real glycosuria? The lecturer was not inclined to admit the reality of any such distinctions. For him persistent glycosuria is glycosurie diabetes which may or may not be joined with other signs. The only indispensable accessory sign is a certain degree of polyuria. The distinction between glycosuria and glycosurie diabetes could only be made, then, if some organic lesion could be discovered belonging to diabetes and absent in glycosuria. The explanation which he offered of cases of intermittent diabetes, such as one of those he had detailed in his lecture, was that the organism was seized with a second attack of diabetes, before it had quite recovered from the former attack—that, in fact, there was a species of intercurrent diabetes. He concluded that there was no essential difference between glycosuria and glycosurie diabetes, that old age gave to glycosurie diabetes special characters, that senile diabetes usually presented itself in the form of intermittent or intercurrent attacks, that it was frequently associated with other disturbances of assimilation, and that these differences might be explained on the hypothesis of a sort of ataxy of nutrition.—*Progrès Médical*.

**BACILLUS OF SYPHILIS.**—At the Académie de Médecine, on August 4th, M. Cornil communicated the result of some work done on this subject in his laboratory by MM. Alvarès and Tavel. They arrived at the following conclusions:—(1) There exists in certain normal secretions of the human organism a bacillus which has not hitherto been noted; (2) this bacillus is identical in form and in colour reactions to that which Luskgarten has described as peculiar to syphilis; (3) it may be that the bacillus which Luskgarten has found in syphilitic secretions and sections of syphilitic products is none other than this bacillus; (4) our bacillus has a great resemblance in form to the bacillus tuberculosis, and presents several colour reactions hitherto considered peculiar to Koch's bacillus and that of leprosy. It is distinguished from the bacillus tuberculosis, apart from its lesser thickness and its less granular appearance (conditions difficult to appreciate in an isolated specimen), by its diminished resistance to alcohol after staining by fuchsin and treatment by nitric acid; and further, it is distinguished by the failure to stain it after Erlich's method with mythyl violet. (6) In the clinical diagnosis of tuberculosis made from histological examination of the secretions these facts should be borne in mind. As this bacillus has not yet been cultivated, one must still be very cautious about admitting that the bacillus of Luskgarten is in reality the cause of syphilis.—*Progrès Médical*, No. 32.

**A HEAT-CENTRE IN THE CEREBRUM.**—More than a year ago Dr. Isaac Ott announced the existence of a heat-centre in the vicinity of the corpora striata, which was subsequently confirmed by Aronsohn and Sachs. In a "preliminary note" (*Medical News*, July 4th), Dr. Ott describes some attempts to ascertain more accurately the precise position of this centre. The experiments were made on rabbits, not fastened down, in a room at about 75° F. The temperature in the rectum having been noted, the skull was trephined, and punctures made with a coarse needle through the cerebrum down to its base, and the increment of temperature observed. A rise of temperature commonly ensues after injury to various parts of the cerebrum, but disappears in a few hours. If, however, the needle strikes a certain point in the anterior inner part of the optic thalamus near the corpus striatum, then the rise is from three to four and-a-half degrees, and the temperature remains at this height until next day. The injury to the cerebral cortex has nothing to do with it, for removal of the cortex in different places gives rise to only a transient pyrexia. It is possible that injury at the point named calls vaso-motor influence into activity and causes the increase of temperature. A few observations made with D'Arsonval's

calorimeter showed an increased heat-production, but more extended experiments are necessary to decide this point. Nearly twenty years ago, Teschschichin found that section of the medulla oblongata where it joins the pons caused an increase in temperature, and concluded that physiological experiment and clinical facts pointed to a moderation-centre in the brain.

**RUPTURE OF THE AORTA.**—This occurrence is so rare in young persons that the following case, recorded by Mr. J. P. Bush in the *Bristol Medico-Chirurgical Journal*, No. 8, is worth quoting. A postman, aged 18, who had been rowing, but had ceased doing so for some considerable time, was noticed by his companions to be looking very ill, he lay back in the boat and appeared to sink. When landed a few minutes later he was found to be dead. He was not known to have been ill previously. At the *post-mortem* examination the heart and pericardium were found to be natural. A rupture through the internal and middle coats of the aorta was found starting from a point immediately above the anterior aortic valve; it had spread round the aorta in a somewhat spiral manner, terminating about a quarter of an inch higher than the level of its starting point; it had extended one complete circumference and a quarter. The rent passed through the elastic coats of the aorta, and dissected the fibrous coat to the extent of half an inch upwards, whilst downwards the separation of the coats extended as far as the origin of the aorta from the heart.

**A NEGATIVE SYMPTOM IN THE DIAGNOSIS OF GASTRIC OR INTESTINAL PERFORATION.**—Dr. Austin Flint has again drawn attention to a matter of diagnostic import which he originally noted in a paper published in 1882, "On the Physical Diagnosis of Perforation." He contends that persistent hepatic flatness on percussion in cases of diffuse peritonitis is a proof that perforation of the alimentary canal has not taken place. He has also demonstrated upon the cadaver that the injection into the peritoneal cavity of a small quantity of air causes the disappearance of flatness on percussion over the liver. The same thing occurs when, by perforation of the stomach or bowel, intestinal or putrefactive gases are liberated within the peritoneal cavity of the living. Dr. Flint does not claim originality in submitting this point for diagnosis, but he finds that it is noticed in scarcely any British or American works on practical medicine, although it has been referred to by some recent German writers.

## SPECIAL CORRESPONDENCE.

### INDIA.

(From Our Bombay Correspondent.)

*The "Break" of the Monsoon—Cholera—Assistant-Surgeons in Civil Hospitals—New Medical School for Bombay—Honorary M.B.'s—"Unemployed Pay"—Transactions of the Medical Society of Bombay.*  
July 20th.

AN annual advent of considerable moment in this country—the setting in of the *monsoon* or rains—may now fairly be said to have taken place. Those of your readers who are unacquainted with the meteorology of India, may be reminded that here, unlike that in Europe, we have the rainfall periodically confined to a certain season of the year, and this season is immediately after the scorching hot weather to which the people of India are now gladly bidding a happy adieu. Heavy moisture-laden clouds are brought to these shores with regular periodicity athwart the gigantic Indian Ocean by what are known as the *trade winds*. These pass onwards with the direction of the strong prevailing wind, generally of gale-like intensity, and accompanied with a good deal of thunder and lightning. The rains are most welcome, because they not only cool the stifling atmosphere, afford water-supply, play an essential part in agriculture, but above all make up so potentially for sanitary short-comings and neglect, by

washing away filth, cleaning and cleansing inhabited parts, diluting with pure water the contaminated potable waters of wells, tanks, &c. Hence, the sudden decrease of cholera and diseases of that class after the setting in of the rains.

I am glad to be able to record that the cholera which had been prevailing in Quettah and adjoining regions, has now abated to a certain extent, and it is reported that Mr. Hewlett is of opinion (as is your own correspondent, the present writer) that the cause is attributable to contaminated water-supply. In my duty as a journalist, I would urge the matter on the notice of the authorities at home and in India, and hope to see steps taken without delay, and remedial measures applied with promptitude.

The advocates of the scheme of employing honorary assistant-surgeons in the Bombay hospitals (which has so signally failed) had, it appears, appealed to Government against their resolution to the effect, that the system of employing them in the local hospitals cannot be expected to succeed in India as it does in England; with the result that the Government very rightly hold fast to their original decision, on the advice of the Civil Surgeon-General. The medical press may well congratulate Mr. Moore on his not being easily swayed by the pressure brought to bear on his view of the matter (which is the same as that of Dr. Beattie, his predecessor), by those personally and otherwise interested in the scheme, which is altogether unworkable. This resolution of Government came the other day before the local Municipal Corporation, when a medical member moved that he was sorry to see that the present head of the Medical Service had adopted his predecessor's view. He proposed that the Corporation should record the Government resolution, stating at the same time that they adhere to their opinion that the experiment had not had a fair trial. Another local practitioner, however, had the better sense to move an amendment, that the Government resolution "be recorded without any further comment from the Corporation." This was finally carried.

The agitation for the establishment of a new Medical School for Bombay, has continued since my last notice of the subject, and the *Bombay Gazette* has now closed its columns to the ventilation of the views for and against this proposal. I have already expressed the opinion that no necessity, so far as I can judge, has been made out to exist for a new school, though I allow that the present Grant Medical College needs to be enlarged, and its professional staff augmented. This would, I opine, meet the required wants, and should commend itself for adoption alike on utilitarian and on financial grounds.

I learn, on the authority of your contemporary, the *Times of India*, that the University of Bombay is introducing the degree of Bachelor of Medicine (M.B.), to be conferred on Senior Licentiates who had previously obtained the L.M. The degree of M.B. thus conferred by the Senatus is to be an honorary distinction and without examination. This certainly would appear unique, but, before criticising it further, we must await full details of the rules and regulations.

Owing partly to the exertions of the Indian Medical Service Defence Fund Committee, and partly to the matter being taken up by the medical and Indian press, and to a considerable measure to the powerful influence brought to bear on it by Mr. Ernest Hart, not merely in his capacity as a medical journalist, but as President of the Parliamentary Bills Committee of the British Medical Association, the subject of "unemployed pay," which was (and is to some extent) the bugbear of the Service, received some attention early this year from the India Office, which ruled that the junior surgeon, without any appointment, and doing the rough work of what is known as "general duty" with its liability of being shunted from pillar to post, should get, at least, the same rate of salary as his colleague in the Home Service in India. From the wording, however, of the original order, the rule would have applied to all officers—surgeons as well as surgeons-major—but the Government of India have now brought the pruning knife into operation, and have definitely stated that this apparent concession refers only to the rank of surgeon. This is all very well, so long as surgeons-major have permanent appointments, but directly they do not hold such the shoe

will begin to pine and they will not fail to agitate for their rights. An order is also issued to the effect that a medical officer transferred from one regiment to another draws, during transit from station to station, only the grade pay of his rank, except when the transfer is made solely in the interests of the public service. This is an anomaly, as not only is no such rule applicable to the combatant officers, but the medical officers of the Home Service draw a rate of pay which is not affected by any move, and, moreover, they get their travelling done at the public expense. I would commend this matter to the notice of the able editor of your contemporary, the *British Medical Journal*, and of Mr. Gibson, M.P. for the Dublin University.

I have before me a copy of *Transactions of the Medical and Physical Society of Bombay*, No. v, for the half-year ending 31st December, 1884; Education Society's Press, 1885. This interesting volume gives evidence of the amount of work gone through in the Bombay hospitals, and the abundance of material available for clinical research. Pressure on your space will hardly permit of a notice at any length, and all I can therefore do is to lay before your readers the contents. Most of the contributions, I note, are by that indefatigable scientific worker in the domain of dermatology and micro-biology, Dr. Vandyke Carter, and these decidedly are of the greatest value. He has "Clinical Contributions" on a case of large nævus of the tongue; on "Quickly-growing Cancer of the Abdomen," autopsy and remarks (illustrated); on "Strumous Disease of the Head of the Humerus." In "some recent cases of Spirillum or Relapsing Fever," he publishes notes of three cases, and says that in one there was no difficulty in the diagnosis, while the other two, though more severe, "could hardly have been verified without the aid of the microscope." He remarks also that it is noteworthy that these cases go to show "the continued presence in Bombay of this typical zymotic disease, notwithstanding the generally prosperous condition of the local population." Dr. Carter notices Bowkett's "Clinical Thermograph," but does not speak favourably of it. He next describes a case of "Recurring Remittent Fever," in which he made microscopic examinations of the alvine discharges, and ascertained them to contain rod-like bacterial growths of varied aspect, but with a large form distinctly predominating. He tells us "doubtless these organisms mainly belong to the group classed as 'putrefaction bacteria,' one of which constitutes the so-called 'microphyte' of typhoid fever." He has also found bacterial vegetation in "some seemingly healthy stools." These, I learn, are in the shape of visible "clumps and masses." But in febrile conditions the rod-like configuration would appear to predominate, whilst in diarrhæas the "micro-coccus forms" are the most common. To those of your readers interested in the subject, I would specially commend the study of Dr. Carter's work on the subject, and side by side with it these other interesting cases. Mr. W. K. Hateh, M.B. (whose address is Brench Candy, Bombay), is the Hon. Secretary, and will, I dare say, be glad to furnish copies of the *Transactions* on payment. The other papers are also of interest. There is one on a case of Traumatic Facio-brachial Monoplegia, by Mr. M. Collie, M.B.; on Ainhum, by Mr. W. W. Henderson; on Traumatic Cerebral Abscess, by Mr. K. R. Kirtikar, L.R.C.P.; on Vaccination, by Mr. Sakharan Arjoon, L.M.; on Cerebro-spinal Fever, by Mr. H. P. Dimmoek, and a few other papers.

## MEDICAL NEWS.

UNIVERSITY OF LONDON.—Intermediate Examination in Medicine.—Pass List.—Entire Examination.

*First Division.*—John Hill Abram, University College Liverpool; Evelyn Oliver Ashe, London Hospital; Percy Ashworth, B.Sc., Owen's College; Marmaduke Bannister, Owen's College; George Black, Guy's Hospital; Ernest Henry Brock, Guy's Hospital; Robert James Carter, King's College; Walter Stacy Colman, University of Edinburgh and University College; Samuel Bird Cook, St. Thomas's Hospital; Herbert Evelyn Crook, Guy's Hospital; Charles Percival Crouch, St. Bartholomew's Hospital;

Herbert Edmund Cuff, Guy's Hospital; Henry Percy Dean, B.Sc., University College; Edward Deanesly, University College; Horace Duncan, St. Thomas's Hospital; Frank Fawcett, St. Thomas's Hospital; Theodore Fisher, Guy's Hospital; George Taylor Gifford, King's College; Thomas Caspar Gilchrist, Owen's College; Cyril William Jecks, University College; Harold Johnson, St. Bartholomew's Hospital; Alfredo Antunes Kanthack, B.A., University College, Liverpool; George Herbert Lang, University College; Milton Prentice Ledward, Owen's College; William Job Maillard, Guy's Hospital; Hyde Marriott, B.Sc., University College; William Page May, B.Sc., University College; Brian Melland, Owen's College; Alfred Alexander Mumford, Owen's College; Geo. Hartley O'Reilly, King's College; Ernest Bidgood Randall, University College; George Edward Rennie, B.A. Sydney, University College; John Lloyd Roberts, B.A., B.Sc., Guy's Hospital; Harold Kennaway Roper, Guy's Hospital; Ernest Alfred Sadler, Queen's and Mason Colleges, Birmingham; Harry Arthur Sansom, St. Thomas's Hospital; Ramon Alexander Sawyer, Guy's Hospital; Arnold Scott, Guy's Hospital; William Arnison Slater, B.Sc., Guy's Hospital; Guy Bellingham Smith, Guy's Hospital; Reginald Vaughan Solly, St. Thomas's Hospital; Ernest Henry Starling, Guy's Hospital; William Percy Stocks, Owen's College; Henry Symonds, St. Bartholomew's Hospital; Frederick Howard Taylor, London Hospital; Alfred Herbert Tubby, Guy's Hospital; John Ogle Tunstall, University College; John Wilkie, St. Bartholomew's Hospital; William Griffith Williams, St. Bartholomew's Hospital.

*Second Division.*—Arthur Baxendell, Owen's College; James Thomas Bays, St. Mary's Hospital; Lewis Thomas Fraser Bryett, King's College; Solomon Bueno de Mesquita, Guy's Hospital; James Joseph Buist, St. Bartholomew's Hospital; Cyril Cecil Barrow Burt, Westminster Hospital; John Telfer Calvert, St. Thomas's Hospital; Henry Edward Leigh Canney, University College; Herbert Alfred William Coryn, Charing Cross Hospital; Rainsford Foster Gill, University College; Wilfred Thomason Grenfell, London Hospital; Nathan Charles Haring, Owen's College; Edwin Birchall Hastings, University College; Arthur Egerton Hensley, King's College; Henry Truman Keisall, London Hospital; Isabella Macdonald Macdonald, London School of Medicine for Women; Ludovic William Darra Mair, St. Bartholomew's Hospital; Enoch Moss, Guy's Hospital; Henry Alexander Lephairia Pope, King's College; Philip Nicholas Randall, Guy's Hospital; John Joseph Redfern, Queen's College, Belfast; Bernard Relton, St. Thomas's Hospital; Joseph Crofts Rossall, St. Mary's Hospital; Charles Frederic Routh, Guy's Hospital; Frank Percy Sarjant, Guy's Hospital; Ernest Hugh Snell, Queen's and Mason Colleges, Birmingham; Theodore Mayo Stiles, Bristol Medical School; Stuart Alexander Tidey, St. Mary's Hospital; Herbert Edmund Vincent, Guy's Hospital; Howard Percy Ward, King's College; Helen Webb, London School of Medicine for Women, and Royal Free Hospital; John Price Williams, Owen's College; Marcus George Yunge-Bateman, Guy's Hospital.

### Excluding Physiology:—

*First Division.*—Charles Frederic Manning Althorp, Leeds School of Medicine; Arthur Edward Giles, Owen's College; John Edwin Gould, University College; Frances Harris, London School of Medicine for Women; Berkeley George Andrew Moynihan, Leeds School of Medicine; John Alexander Shaw, University College; Christopher Peirson Spink, Leeds School of Medicine; Frank Arthur Spreat, St. Bartholomew's Hospital; William Elliot Tresidder, Guy's Hospital; Joseph Williamson Winterburn, St. Thomas's Hospital.

*Second Division.*—Frederic William Abbott, Charing Cross Hospital; George Barlow, Owen's College; Richard Oxley Bowman, Owen's College; Arthur Thomas Brown, Guy's Hospital.

### Physiology only:—

*Second Division.*—William Harry Kelson, London Hospital; Charles Pye Oliver, Charing Cross Hospital; William Newt Risdon, Guy's Hospital; Arthur Hastings Lanfear Stewart, St. Mary's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma were admitted Members of the College, at a meeting of the Court of Examiners, on the 30th ult., viz. :—

H. S. Walker, L.R.C.P. Lond., Wakefield, of University College Hospital; Hanna Jabboor, L.R.C.P. Lond., Beyrout, Syria, of London Hospital; Ashton Street, Mirfield, of Leeds School of Medicine; C. E. Oldacres, Leicester; W. Barltrop Featherstone, Birmingham, of Birmingham General Hospital; Albert Carless, L.S.A., Richmond, of King's College Hospital; F. J. Knowles, L.R.C.P. Lond., St Helens, Lancs., of Liverpool; A. N. Little, Bristol Infirmary; Herbert Lund, M.A., Cantab, Manchester, of Cambridge and Guy's Hospital; H. A. Haviland, B.A., Cantab, Cheltenham, of Cambridge and St Bartholomew's Hospital; George H. Dodd, Wallingford, of St Thomas's Hospital.

Four candidates passed in Surgery, and when qualified in Medicine and Midwifery, will be admitted Members of the College; 4 candidates was referred for 3 months, and 9 candidates for 6 months.

### Admitted on the 31st ultimo:—

Joseph Beddow, L.S.A., Upper Clapton, E.; Niell MacGillycuddy, L.S.A., Halsey Street, S.W.; and Raymond Johnson, Ladbroke Road, W., of University College Hospital; Benjamin Sumner, L.R.C.P. Lond., Crowdale Road, N.W., of Liverpool Royal

Infirmery; L. M. Gabriel, Gloucestee Gardens; Edmond F. Trevelyan, Bath; Philip H. Dunn Stevenage, and William J. Gow, Hampstead, N.W., of St Bartholomew's Hospital; John E. Panton, Horneastle, of Newcastle and St Bartholomew's Hospital; Samuel O. Prall, Reigate, and Francis R. B. Bishshope, Tunbridge Wells, of Guy's Hospital.

Two candidates passed in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College; 2 candidates were referred for 3 months, 11 for 6 months, 2 for 9 months, and 1 for one year.

Admitted on the 3rd of August:—

Frank F. White, L.R.C.P. Lond., Sussex Gardens, W., of St Mary's Hospital; W. G. Speneer, Bath, and E. M. Sympton, Lincoln, of St Bartholomew's Hospital; Leslie Powne, Swindon, of Middlesex Hospital; T. R. A. Harney, Victoria, Australia; J. H. A. Schade, Argyle Square, W.C., and Edgar H. Thane, Montague Street, W.C., of University College Hospital; William Rawes, Maer, Staffs., of the London Hospital; S. W. Owen, East Dulwich, S.E.; J. W. Washbourn, Gloucester, and F. W. Foster, Brixton of Guy's Hospital; A. F. Davenport, Hobart Town, of Edinburgh University.

Six candidates passed in Surgery, and when qualified in Medicine and Midwifery, will be admitted Members of the College; 3 candidates were referred for 3 months, and 5 for 6 months.

Admitted on the 4th August:—

E. Lycett Bond, Shrewsbury; Hubert Nicholls; Fernigh Stevenage, of Cambridge and St. Bartholomew's Hospital; A. R. S. Anderson, Sussex Place, N.W., of Cambridge and St. Mary's Hospital; E. C. Andrews, Hampstead, of Cambridge and Guy's Hospital; C. H. Upham, Kensington; T. M. Beale, Shepherd's Bush; H. B. Mathias, Minehead; and L. P. Shadbolt, Chislehurst, of St. Bartholomew's Hospital F. G. O. Martin, L.S.A., Commercial Road, E.; George Hart, Bolton; W. G. Dreaper, Old Trafford; Joseph Whittaker, Eccles; J. E. Parker, Scholes, Wigan; and H. L. Williams, Altrincham, of Manchester Infirmary; W. Ivens Watson, Rugby; E. P. Mourilyan, Deal; L. F. Childe, St. Leonard's-on-Sea, and A. M. Sutton, Tunbridge Wells, of Guy's Hospital; W. H. Smart, West Kensington, of Cambridge and St. Thomas's Hospital; W. P. O'Connor, Weymouth Street, of University College Hospital; A. Sharland, Sydenham, of Middlesex Hospital; G. L. Travis, Leeds, of Liverpool Infirmary.

Thirteen candidates passed in Surgery, and when qualified in Medicine and Midwifery, will be admitted Members of the College; 1 candidate was referred for 3 months, and 5 for 6 months.

Admitted on the 5th August:—

Charles G. Lermitte, L.S.A., Richmond; and H. B. Lavies, L.S.A., St. George's Road, S.W., of King's College Hospital; Aubrey D. Chapple, L.R.C.P. Lond., Streatham, S.W., and Trevor A. Dagg, L.S.A., Suttons, near St. Albans, of St. Bartholomew's Hospital; P. A. Lloyd, L.R.C.P. Lond., St. Mark's Road, W., of St. Mary's Hospital; Albert Wilson, L.R.C.P. Lond., Hnll, of St. Thomas's Hospital; G. W. A. Lynch, L.R.C.P. Lond., Minford Gardens, W., of Cambridge and St. Thomas's Hospital; H. A. Reed, L.R.C.P. Lond., Denmark Hill, S.E., of Guy's Hospital; Edmond Roghib, L.S.A., New Wandsworth, of Charing Cross Hospital.

Five candidates passed in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College; 3 candidates were referred for three months, and 11 for 6 months.

Admitted on the 7th inst.:—

H. R. Codd, L.S.A., Leamington, of University College Hospital; T. A. Collinson, L.S.A., Granville Square, W.C.; and E. Suter Hasell, L.S.A., Isleworth, of King's College Hospital; F. W. P. Holton, L.S.A., Kilburn, W., of St. George's Hospital; Sydney D. Ashley, L.S.A., Leytonstone, of the London Hospital; J. L. T. Jones, M.B. Durham, Tremadoc, N. Wales, of Newcastle and St. Bartholomew's Hospital.

One candidate was referred for 3 months, 9 for 6 months, and 1 for 12 months; 8 candidates passed in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College.

Admitted on the 10th inst.:—

Speneer Hurlbutt, L.S.A., Chippenham Road, W., of St. Mary's Hospital; J. Douglas Hughes, L.R.C.P. Lond., Folkestone, of Guy's Hospital; A. C. Waters, L.S.A., Bow, E., of the London Hospital; P. C. Scott, Blackheath Park, S.E., of St. George's Hospital; Percy D. Bray, L.S.A., Bognor, of Middlesex Hospital; R. II. Barrett, L.S.A., Dulwich, of St. Bartholomew's Hospital.

One candidate was referred for 3 months, 12 for 6 months, 1 for 12 months; 4 candidates passed in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College.

Admitted on the 11th inst.:—

Edward Thornton, L.S.A., Shrewsbury, of St. Mary's Hospital; W. H. Heffernan, L.S.A., Southsea, and A. E. Godfrey, L.R.C.P.

Lond., Northampton, of St. Thomas's Hospital; Charles Yeoman, L.S.A., Northallerton, of Cambridge and St. Thomas's Hospital; H. M. Morris, L.R.C.P. Lond., Percy Circus, of Charing Cross Hospital; H. G. H. Monk, L.S.A., Woburn Place, W.C., of King's College Hospital; Robert Wrigley, L.S.A., Glendow Place, S.W., of St. Bartholomew's Hospital; G. R. McIntosh Pollard, L.R.C.P. Lond., Clapham, of Guy's Hospital.

One candidate was referred for 3 months, 4 for 6 months, and 2 for 12 months; 11 candidates passed in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College.

Admitted on the 12th inst.:—

S. P. Alexander, M.B. Glas., Belham Terrace, Glasgow, of the Western Infirmary, Glasgow; J. R. Isaac Raywood, L.S.A., Thorne, near Doncaster, of Guy's Hospital; Isaac R. Cory, L.R.C.P. Lond., Clarendon Road, W., of St. Thomas's Hospital; R. N. Wallinger, L.R.C.P. Lond., Brighton, and G. A. T. Inman, L.S.A., Kew Gardens, of King's College Hospital; H. K. Bradbury, L.S.A., Putney, of the London Hospital.

Two candidates were referred for 3 months, 6 for 6 months, and 1 for 9 months; 11 candidates passed in Surgery, and when qualified in Medicine and Midwifery will be admitted Members of the College.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentlemen passed their examination in the Science and Practise of Medicine, and received certificates to practise, on Thursday, August 6th, 1885:—

Charles Denn Christmas, Weltye Road, Hammersmith; Henry Robinson Codd, M.R.C.S., Willes Road, Leamington; Richard Tanner Finch, M.R.C.S., Rochester; Speneer Hurlbutt, M.R.C.S., Chippenham Road, St. Peter's Park, W.; Angus Ross Kennedy, Glasgow; James Jesse Wm. Stevens, High Street, Strood, Rochester; Edward Reginald Tweed, 14, Upper Brook Street, W.

On the same day

Ferdinand Simeon Le Quesne, King's College Hospital, passed his examination in the Science and Practise of Medicine, Surgery, and Midwifery, and received a certificate to practise.

The following gentlemen also, on the same day, passed their Primary Professional examination:—

Arthur John Briant, Liverpool Royal Infirmary School of Medicine; Astley Brodie Crowther, Manchester Royal Infirmary School of Medicine; William Ellis, St. George's Hospital; Naunton Wingfield Walford Meadows, Guy's Hospital; Francis Silva White, University College.

GLASGOW ROYAL INFIRMARY.—At the meeting of Managers of the Glasgow Royal Infirmary on the 10th instant, the vacancies in the staff, caused by the retirement of Dr. Scott Orr and Dr. Ebenezer Watson, were filled up by the appointment of Dr. J. Wallae Anderson as Physician, and Dr. W. J. Fleming as Surgeon. Both gentlemen belonged to the Dispensary Staff, on which they were the seniors, having each served for a considerable term of years. The probabilities of the appointments have been the topic of conversation in medical circles for the last few weeks; and it has been rather loudly maintained that the only just course for the managers to take was to promote those of the Dispensary Staff who had "served longest." Indeed, to some extent the fight for the positions has been regarded by some of the younger men as a test one, and we suppose the election will be claimed as a triumph of the promotion idea, though we do not doubt that in the present election the managers found other reasons besides length of service to determine their choice.

ST. GEORGES' HOSPITAL MEDICAL SCHOOL.—The prizes were distributed in the Board-room of the hospital to the successful students, by Sir Preseott Hewett, Bart., F.R.S., on Tuesday, the 28th July. The list of prizes and prizemen is as follows:—(1) The William Brown (40*l.*, Exhibition, with an Honorary Certificate), Mr. George Francis Smith; (2) The Treasurer's Prize (10*l.* 10*s.*, with an Honorary Certificate), Mr. Arthur Vernon; (3) The Brackenbury Prize in Medicine (32*l.*, with an Honorary Certificate), Mr. G. F. Smith; (4) The Brackenbury Prize in Surgery (32*l.*, with an Honorary Certificate), Mr. De Nyssen; (5) Sir Benjamin Brodie's Prize (6*l.*, with an Honorary Certificate), Mr. Russell Coombe; (6) The Henry Charles Johnson Prize in Anatomy (10*l.* 10*s.*, with an Honorary Certificate), Mr. A. H. Ward; (7) Sir Charles Clarke's Prize (6*l.*, with an Honorary Certificate), Mr. Arthur Jervis; (8) The George Pollock Prize in Physiology

18l. 12s. 6d., with an Honorary Certificate), Mr. Lancaster; (9, 10, 11) Honorary Certificates for Proficiency in Anatomy, Mr. Lancaster, Mr. Parker, Mr. J. Wayte; (12) Three Years' General Proficiency Prize (10l. 10s., with a Certificate of Proficiency), Mr. De Neysen; (13, 14, 15) Certificates of Proficiency in Medicine, Surgery and Pathology, Mr. Remfry, Mr. Pereival and Mr. W. L. Dickinson; (16) Certificate of Proficiency in Surgery, Pathology and Midwifery, Mr. Vernon; (17) Certificate of Proficiency in Medicine and Surgery, Mr. Goodale; (18) Second Year's General Proficiency Prize (10l. 10s., with an Honorary Certificate), Mr. Lancaster; (19) First Year's General Proficiency Prize (10l. 10s., with an Honorary Certificate), Mr. Le Cronier; (20) Honorary Certificate of Proficiency, Mr. Cyril Ogle; (21) Extra First Year's General Proficiency Prize (10l. 10s., with a certificate), Mr. Herbert Higgins.

**SOCIETY OF APOTHECARIES.**—The following gentlemen have been elected Members of the Court of Examiners of the Society of Apothecaries of London for the ensuing year, viz.: Henry Bullock, F.R.C.S.; Henry R. Crocker, M.D. Univ. Lond.; Robt. Fowler, M.D. Univ. Edin.; F. de Havilland Hall, M.D., Univ. Lond., F.R.C.P. Lond.; Robt. J. Lee, M.D. Univ. Camb. F.R.C.P., Lond.; W. Withers Moore, M.D. Univ. Edin., F.R.C.P. Lond.; John S. Stoeker, M.D. Univ. Lond.; John C. Thorowgood, M.D. Univ. Lond., F.R.C.P. Lond.; Francis Warner, M.D. Univ. Lond., F.R.C.P. Lond.; Andrew Clark, F.R.C.S.; G. H. Makins, F.R.C.S.; W. J. Walsham, F.R.C.S.

**ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.**—During the month of July, 95 patients were treated. Sixty of these were in the Hospital on 30th June, and 35 were admitted during the month; 42 were discharged cured and eight were relieved. The average daily sick in the Hospital during the month was 48; 484 patients were treated at the Dispensary, and 18 were vaccinated, making in all 502.

**MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN.**—The adjudicators for the prize essay of this society have this year awarded their prize to Dr. T. Dunean Greenlees, of the asylum at Carlisle, for his essay on "A Contribution to the Study of Diseases of the Circulatory System in the Insane." This prize is open to the competition of all asylum assistant physicians. Dr. Greenlees is a graduate of Edinburgh University.

**THE BROMPTON CONSUMPTION HOSPITAL.**—The report submitted to the quarterly Court of Governors, held on the 6th instant, again exhibits the almost unexampled continuous flow of munificent donations and legacies to the institution. The donations amounted to 250l., and the legacies to 810l. 10s. The whole of the 321 beds in the two buildings had continued to be occupied. The number of patients admitted since the 28th May was 362; discharged, many greatly benefitted, 321; died 37; new out-patient cases, 2,587. Drs. Green and Bruce have been re-elected for a further period of five years, and Mr. H. Herbert Taylor re-appointed assistant resident medical officer for another twelve months.

**WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, 73, WELBECK STREET.**—The annual meeting of the governors and subscribers of this hospital was held on Saturday, August 1st. During the past year the annual subscriptions have increased from 338l. to 384l., and the attendances of patients from 7,914 to 9,489 exclusive of 1,253 attendances for electrical treatment.

**NORTH LONDON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.**—The Fishmongers' Company has contributed 50 guineas to the funds of this hospital.

**CHARITABLE BEQUESTS.**—The late Mrs. Martha Donohes, of Upper Gardiner, Dublin, has bequeathed the following sums to institutions in that city:—300l. each to the Mater Misericordæ Hospital and the Children's Hospital; 200l. each to the Deaf and Dumb Institution, Cabra; the Male Blind Institution, Glasnevin; and the Asylum for Blind Females at Merion; and 300l. to the Hospice for the Dying, Harold's Cross. Mrs. Lucy Eliza Lucy, late of 3, College Road, Brighton, leaves by her will 500l. to the Royal Free Hospital, Gray's Inn Road, London.

**CORK STREET FEVER HOSPITAL, DUBLIN.**—The monthly meeting of the Committee was held on the 6th instant at the hospital. The number of patients on the 30th June was 49; admitted during the month of July, 52; died, 3; discharged cured, 50; remaining in hospital, 48. The registrar reported that the two cases of small-pox which were admitted during the past month still remain in the hospital, but are now convalescent; there had been no fresh cases. The epidemic of measles, prevalent for the past few months, had almost disappeared. Scarlatina was slightly on the increase, and typhoid fever cases had been few in number.

**DEATH OF DR. NATHANIEL CAMERON.**—The deceased was a native of Abernethy, on Speyside, and had a distinguished career at Aberdeen, both in arts and medicine, carrying off high prizes in both departments. He graduated with the highest academical honours, and subsequently became Assistant-Demonstrator of Anatomy in Aberdeen University. After acting as resident physician at the Macelesfield Infirmary for a brief period, Dr. Cameron, in 1878, entered the Army Medical Department, and went out to Sierra Leone. His death, which was due to fever, took place on July 10th.

**THE BRITISH ASSOCIATION.**—At the meeting of the British Association which is soon to be held in Aberdeen, an interesting collection of rare books will form a pleasing feature. The Earl of Crawford and Balesares, whose library alone is valued at 25,000l., has kindly offered to lend some of his gems, in addition to the many rare works from the libraries of the University and those of gentlemen in the neighbourhood.

**THE IMPROVED INDUSTRIAL DWELLINGS COMPANY.**—The report presented at the 44th half-yearly general meeting, held on the 6th instant, shows that the average death-rate in their dwellings had been further reduced in 1884 to 14.27 per 1,000, as compared with 20.3 in the metropolis generally. The lower death-rate had been accompanied by a birth-rate higher than the general average of the metropolis.

**SURGEON-GENERAL ROGERS,** principal medical officer of the Egyptian Army, has, on the recommendation of the Commander-in-Chief of that force, been appointed president of a committee to enquire into the report upon the rations of the native troops.

**MORTALITY, HASTINGS.**—Dr. C. T. R. Shaw, Medical Officer of Health, in his quarterly report ending June last, states that with a population of 47,930, only 155 deaths had occurred, or at a rate of 12.98 per cent.

**WHOOPIING-COUGH, FINCHLEY.**—Dr. J. Turle, Medical Officer of Health, at the meeting of the Local Board, on Monday, stated he could not give the Board any approximation to the number of cases of whooping-cough in the district. Several local practitioners had informed him that the disease was so extremely prevalent in the locality, and the cases in their hands so numerous, that they had been unable to keep an account of them.

**TASMANIA.**—The Tasmanian Government in some statistics published, state that vital statistics for the past year also demonstrate that the health of the people is as good as ever it was, and that there are no signs of this climate, famous for its healthiness, deteriorating in any way.

**FILARIA SANGUINIS HOMINIS.**—It would appear that we are now within a measurable distance of completing the life history of this interesting and important parasite. At a recent meeting of the Sei-I-Kwai in Tokyo (*vide* Transactions of that Society, No. 6), Mr. W. de L. Estlake made an interesting statement as to Dr. Manson's latest views on the subject. Dr. Manson suggests that the *Paludina*, a large freshwater univalve, is the intermediary host. It will be remembered that Dr. Manson has already shown how the filaria is swallowed by the mosquito, and how the worm progressively grows in the inside of the mosquito until it has attained its full development; the mosquito then dies, and the worm is liberated into a stagnant pond. The *Paludina* inhabits stagnant water, and moreover it has a peculiar habit of crawling along the surface of the water

eating everything it comes across, and it certainly devours the eggs of the mosquito as well as the partially decomposed or dissolved body of the mosquito. This mollusc is largely eaten both by the Chinese and Japanese. Mr. Eastlake proposes to carry out the following experiments, which should be decisive as to the correctness or otherwise of Dr. Manson's theory. (1) To inject *filaria* into some large water-beetle. Put the beetle into a receptacle filled with stagnant water and containing *Paludina Stelmaphora*. So soon as the beetle dies, make periodical microscopic examinations of both water and *Paludina*. (2) To put *filaria* directly into water in which there are *Paludina* or inject them into *Paludina* and watch the result. (3) To let the patient be bitten by mosquitoes, collect these, and put them into water in which there are *Paludina*, and then carefully watch the result. Dr. Suzuki (who had just previously reported a case, with result of *post mortem* examination in which *filaria* had been present in the blood three months before death) observed that the mollusc in question was used as bait to catch a kind of fish which the Japanese eat raw. So that it is possible that the worm passes through two intermediary hosts before reaching the human stomach; anyhow we shall look with much interest for the report of the projected experiments.

**BRAIN NOMENCLATURE.**—Professor Wilder, the President of the American Neurological Association, has distinguished himself in this direction. He has founded a new science which he calls neuronomy. His industry in coining words is even greater than that for searching out new cells, nerve-tracts and blood-vessels in the brain, which is considerable. No one will dispute his title to the fame of having devoted more time to the naming the contents of the cranium than any other English-speaking man. One is inclined to exclaim: "Heaven forbid another from a like undertaking!" The study of the brain has now become so complicated that it requires a bold determination on the part of the student to undertake it. It is as if he had entered a primeval forest in which wanderers, according to their own sweet will, had blazed trees in every direction, until all the monarchs of the forest had received one or more instructing gashes, resulting in a wilderness more confounding than ever—the old traces becoming lost, and intermingled with the new. Could all the explorers in brain anatomy come together, settle upon a common basis, and adopt a universal nomenclature which should pass current everywhere, a great boon would be conferred. Possibly Professor Wilder could succeed in pressing his nomenclature to a universal adoption, but it will take more than one generation to receive it with a cheerful acquiescence, and to accord to it the credit which we to-day are so slow to give, and the appreciation which, justly or not, is withheld.—*New York Medical Record*.

**A FERTILE WOMAN.**—The *Lyon Medical* (July 12) cites the case of a peasant woman, who, at all events, has done her part in the endeavour to repair the deficiency of population of which the French statisticians are so bitterly complaining. She has brought forth 27 children, of whom 25 are alive and in good health, only six being girls. In one year five made their appearance, three on the 2nd January and two on 27th December. She is now 68 years of age and her husband is 73, and both continue their agricultural employment, assisted by six sons. All these children have received a good education, and three of the sons are in the army at Tonquin, two of them have attained high distinction. Two of the three married daughters seem disposed to follow in their mother's footsteps, one of them 34 years of age having had nine children and the other five, two of whom are twins.

**DIRTY HANDS.**—Cleansing dirty hands would seem to be, according to Dr. Förster, of Amsterdam, if not an impossible, at least one of the most difficult of procedures. In a series of experiments which he has been pursuing, he finds that, after the most diligent washing with soap and water, with the aid of a nail-brush, following this up with the use of strong solutions of carbolic or boric acid, chloride of zinc or perchloride of iron, and having well dried them with napkins previously washed in scalding water, yet hands so dealt with remain impure. In fact, if, after

taking all these minute precautions, the fingers are placed in a solution of sterilized flesh-peptone, or are pressed on gelatine of Koch's second culture, these substances rapidly develop micro-organisms. Nor is it of any use trying to purify the hands with the carbolic acid solution of 2½ per cent. which is usually employed, or even with phenicated glycerine at 10 per cent. Happily Dr. Förster has found that these difficulties are to be met by the very simple procedure of employing one-half or one per 1,000 of corrosive sublimate, which at once removes all micro-organisms or their germs. But he adds, as a caution, that drying the hands afterwards with a towel which has not been previously disinfected, at once gives rise to a production of the micro-organisms. "Washing the hands" is therefore by no means the simple process that all the world believes it to be.—*Gazzetta Med. Italiana*.

**NEW TEST FOR CITRIC ACID.**—C. Mann states in the *Zeit. Anal. Chem.* that if citric acid be evaporated to dryness with glycerol, treated with aqueous ammonia and again dried it gives a deep green colour with peroxide of hydrogen. Nitric acid if similarly treated also yields a green colour, but this changes to dark blue on warming. Tartaric and malic acids give no reaction.

**DETECTION OF SMALL QUANTITIES OF SUGAR IN URINE.**—When urine containing less than 1 per cent. of sugar is heated with Fehling's solution, it becomes opalescent and greenish, or dark yellow, in colour, but does not deposit cuprous oxide. According to G. Buchner, this is due to the presence of uric acid and creatinine, which should be removed, by first adding to the urine a solution of copper sulphate, 1 to 10, then warming and filtering from the precipitate. The filtrate containing excess of sulphate of copper is next treated with Rochelle salt and potash solution, and warmed. Under these conditions the smallest quantity of sugar is indicated by the precipitation of red cuprous oxide.—*Chem. Centralblatt*.

**A CURIOUS COLLECTION OF SKELETONS.**—The celebrated doctor-naturalist Daubenton, who, in 1745, was nominated, at the recommendation of Buffon, one of the curators of the *Muséum d'Histoire Naturelle*, busied himself in forming collections of all kinds. Among these was a very curious, but also a very repulsive one. It was only known to have existed, but had disappeared and never could be found. Some days ago, however, one of the Museum assistants, in rummaging about in a loft, discovered, to his great astonishment, a number of skeletons of most extraordinary forms. He made known his find to the directors, MM. Fremy and Quartefages, and after an examination these *savants* came to the conclusion that this was really the famous collection of Daubenton, which had been sought for for nearly 80 years. The collection was made up of the skeletons of the inhabitants of the *Cour des Miracles* (since rendered so famous by Victor Hugo in his *Notre Dame de Paris*). For more than 40 years Daubenton, who lived until he was 84, made every effort to secure the remains of all the deformed and mutilated beings of all sorts who inhabited this locality; and a most singular collection has been the result.—*Lyon Medical*.

**ST. JOHN'S AMBULANCE ASSOCIATION.**—At the Guildhall, on Saturday next, the Lord Mayor presiding, the Princess Christian will present about 700 certificates to the City and Port of London District Classes.

#### APPOINTMENTS.

- ACKLAND, W. R., L.D.S. Eng.—Demonstrator to the Dental Hospital of London, *vice* William Hern, resigned.  
 BERESFORD, CHARLES W., M.R.C.S. Eng., L.S.A. Lond.—Medical Officer to the Flamstead District, Hemel Hempstead Union, *vice* Mr. G. P. Bernard, deceased.  
 BLAKISTON, AUBREY, L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the Wareham First and Morden Districts, Wareham and Purbeck Union, *vice* Dr. Joseph H. Webster, resigned.  
 COOK, HENRY SAMUEL, M.R.C.S. Eng., L.S.A. Lond.—Assistant Medical Officer to the Workhouse of the Parish of Birmingham, *vice* Mr. W. C. Dendy, resigned.  
 DRESCHFELD, JULIUS, M.D., F.R.C.P.—Visiting Physician to the Royal Lunatic Asylum, Manchester.

GILMORE, RICHARD WHATELY, L.R.C.S. Ire., M.B. Dub.—Medical Officer to the Broughton District, Glanford Brigg Union, *vice* Dr. James Tittley, resigned.

HAWKINS, F. H., M.B.—Physician to the St. George's and St. James's Dispensary, Golden Square, W., *vice* F. Lucas Benham, M.D., M.R.C.P., resigned.

HINDLE, JAMES, L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the Rillington District, Malton Union, *vice* Dr. Adam C. Lyon, resigned.

HOWE, J. D., M.R.C.S., L.S.A. Lond.—Assistant Medical Officer to Monsall Fever Hospital, Manchester, *vice* W. A. Evans, M.B. Lond., resigned.

JOHNSON, GEORGE H., L.R.C.P., M.R.C.S.—Honorary Surgeon to the Teignmouth Infirmary.

MOORE, EDWARD HEAD, L.R.C.P. Edin., L.S.A. Lond.—Medical Officer to the Mylor District, Falmouth Union, *vice* Dr. Greenwood, resigned.

SIMMONS, F., M.B. Ed.—Resident Physician to the Chelsea Hospital for Women.

SIMPSON, H., M.D. Lond., M.R.C.S., L.S.A.—Visiting Physician to the Royal Lunatic Asylum, Manchester.

SMITH, GEORGE COCKBURN, M.R.C.S. Eng., L.R.C.P. and L.R.C.S. Edin.—Medical Officer to the Middleton Cheney District, Banbury Union, *vice* Mr. F. C. Lawson, resigned.

THYNE, THOMAS, M.D. Edin., M.R.C.S. and F.R.C.S. Eng.—Medical Officer to the Millcorner and Cockfoster District, Edmonton Union, *vice* Dr. Livingston, deceased.

WEBB, THOMAS LAW, L.R.C.P. Lond., M.R.C.S. Eng.—Medical Officer to the Workhouse, Madeley Union, *vice* Mr. James Procter, resigned.

VACANCIES.

ASYLUM FOR IDIOTS, EARLSWOOD, REDHILL, SURREY.—Assistant Medical Officer. (*For particulars see Advertisement.*)

FROME UNION.—Medical Officer for the Nunney District, in succession to Mr. W. H. Wood, resigned. Area, 13,831 acres. Population, 2,384. Salary, £77 per annum.

LINCOLN COUNTY HOSPITAL.—House Surgeon. Salary, £100, with board, lodging, and washing. Candidates must be unmarried, doubly qualified, registered, and under 40 years of age. Copies of testimonials to W. B. Danby, Secretary, on or before Aug. 1<sup>st</sup>.

NORTH EASTERN HOSPITAL FOR CHILDREN, HACKNEY ROAD, E.—Physician. Candidates must be Fellows or Members of the Royal College of Physicians, London. Applications, with qualifications and testimonials, to be addressed to the Secretary, City Office, 27, Clement's Lane, E.C. (from whom further particulars may be obtained), on or before August 31<sup>st</sup>.

REETH UNION.—Medical Officer for the Muker District, in succession to Mr. F. J. Turner, resigned. Area, 40,368 acres. Population, 2,003. Salary, £45 per annum.

ROYAL BERKSHIRE HOSPITAL, READING—House Surgeon. Salary, £90, with board and lodging in the hospital. Candidates must be members of one of the Royal Colleges of Surgeons of Great Britain and Ireland, and Licenciates of the College of Physicians or of the Apothecaries' Company, and be able to produce testimonials of good character. Applications, with testimonials, to be sent to the Secretary by August 15<sup>th</sup>.

SHIPSTON-ON-STOUR UNION.—Medical Officer. (*For particulars see Advertisement.*)

ST. GEORGE IN THE EAST, PARISH OF.—Medical Superintendent for the Infirmary, in succession to Dr. M. J. O'Conuor, deceased.

STOCKTON-UPON-TEES HOSPITAL AND DISPENSARY.—House Surgeon (non-resident). Salary, £200 per annum. Candidates must be doubly qualified. Applications, stating age, with recent testimonials or copies, to be sent to the Secretary not later than August 24<sup>th</sup>.

SUSSEX COUNTY HOSPITAL.—Assistant Physician. (*For particulars see Advertisement.*)

MARRIAGE.

GILES—BISSILL.—On June 2, at the Parish Church, Sleaford, by the Rev. George W. R. C. Kent, Curate of St. Martin's, Salisbury, assisted by the Rev. A. G. Langdon, vicar of the Parish, Oswald Giles, Surgeon, Sleaford, late of St. George's Hospital, London, to Harriette Helen, younger daughter of J. H. Bissill, F.R.C.S., of Sleaford.

DEATHS.

GRIGG, J. C., F.R.C.S., at 40, Bedford Street, Covent Garden, on August 4<sup>th</sup>, in his 50<sup>th</sup> year.

O'CONNOR, M. J., L.R.C.P., M.R.C.S., late of Eldon House, Mile End Road, on August 3<sup>rd</sup>, aged 62.

SMALL, T. G., M.D., of Dublin, at Albano, on August 3<sup>rd</sup>, aged 82.

NOTES, QUERIES, AND REPLIES.

MACLEAN TESTIMONIAL FUND.

First List of Subscribers.

*Directors-General:* T. Crawford, Sir G. Logan.—*Inspectors-General of Hospitals:* T. D. Hume, T. Longmore, W. Mackenzie, J. Macpherson, H. M. Macpherson, J. Murray.—*Deputy Inspector-General of Hospitals:* G. Saunders.—*Surgeons-General (Army Medical Staff):* G. Balfour, H. B. Hassard, W. S. Murray, C. D. Madden, W. A. Mackinnon, M. F. Manifold, H. H. Massey; (*Indian Medical Service:*) E. Balfour, Sir J. Fayrer, Sir W. G. Hunter, W. J. Moore, G. Smith.

K. McLEOD, Secretary and Treasurer.

BRADLEY FUND.

We have received from Dr. Jeffreys, of Chesterfield, the following first list of subscriptions to this fund:—Sir Wm. Jenner, Bart., K.C.B., Sir Henry Thompson, Mr. Lawson Tait (Birmingham), Mr. Marston Buszard, Q.C., M.P., £10 10s.; Sir Andrew Clark, Bart., Mr. W. Adams (Henrietta Street), £5 5s.; Sir Edwin Saunders, Dr. Robert Martin (Queen Anne Street), Mr. Geo. D. Pollock (Grosvenor Street), Mr. C. J. Wheelhouse (Leeds), £5; Mr. Lennox Browne (Leeds), Mr. Noble Smith (Queen Ann Street), *The Medical Press and Circular*, Mr. James W. Barry (Bournemouth), Dr. Francis McLoughlin (Londonderry), £3 3s.; Sir Wm. MacCormac, Mr. Jonathan Hutchinson (Cavendish Square), Dr. George Johnson (Savile Row), Dr. Martin D. Bartolomé (Sheffield), Mr. W. Favell (Sheffield), Dr. Keeling (Sheffield), Mr. Arthur Jackson (Sheffield), Dr. W. R. Thomas (Sheffield), Mr. Simeon Snell (Sheffield), Mr. Henry Sewell (Wimpole Street, W.), Dr. J. M. Kennedy (Peterborough), Dr. F. Richardson Cross (Clifton, Bristol), Mr. G. Booth, J.P. (Chesterfield), Dr. J. P. Smith (Lowestoft), £2 2s.; Dr. Alf. Eddowes (Market Drayton), £2; Dr. Balthazar D. Foster (Birmingham), Dr. Peter Redfern (Belfast), Mr. Bernard M. S. Roth (Wimpole Street, W.), Dr. P. H. Mules (Bowden), Dr. J. Lawrence (Darlington), Mr. D. B. Balding (Royston, Herts), Dr. J. Barr (Liverpool), Mr. R. Bowes (Richmond, Yorkshire), Mr. Frank H. Hodges (Leicester), Dr. W. P. Herringham (Bedford Square, W.C.), Dr. Roger Prosser (Bromsgrove), Dr. W. Collier (Oxford), Mr. Wm. Martin (Walkden), Dr. Geo. Brown (London), Dr. Wm. Benthall (Derby), Mr. A. H. Laver (Sheffield), Dr. H. A. Powell (Beckenham), Mr. H. Fearnside (London), Mr. Josh. A. Locking (Hull), Mr. Geo. Walter Tait (Knowle, Birmingham), Dr. Louchlan Aitkin (Bournemouth), Dr. W. A. Satchell (St. Servan, France), Mr. Jno. Bluett (Chesterfield), Mr. Richard Jeffreys (Chesterfield), £1 1s.; Dr. J. M. Finch (Boro' Asylum, Leicester), £1; Mr. J. Goodwin Shea (Chesterfield) Dr. Thomas Morgan (Montgomery), Mr. J. B. James (Bermanscey), Dr. Tom Nevill (Pimlico Road, S.W.), Dr. Grif Griffiths (Swansea), Dr. J. F. Fry (Swansea), Dr. J. B. Fry (Swindon, Wilts), 10s. 6d.; Mr. G. P. Francis (Bourton, Dorsetshire), Dr. De Vere Hunt (Bolton), Dr. Josh. Rogers (31, Montague Place, W.C.), Mr. Alfred Reckless (Sheffield), Mr. F. M. Corner (Poplar), Dr. J. W. Buckle (Storrington, Sussex), Dr. J. S. Johnston (Sheffield), 10s.

## AN APPEAL.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—I desire to acknowledge with sincere gratitude the prompt and liberal response to my appeal on behalf of the widow and daughters about whose case I wrote last week. I hope speedily to announce the restoration of the piano and the relief of these ladies from their difficulties:—Henry Smith, Esq., F.R.C.S., £3 3s.; Dr. George Johnson, John Colebrook, Esq., J. Lennox Browne, Esq., Henry Stear, Esq., £2 2s.; Sir Edwin Saunders, £2; W. B. Owen, Esq., Prof. Humphry, Dr. Van Vestrant, James Taylor, Esq., F.R.C.S., Nath. P. Blaker, Esq., Dr. Bull, Dr. Walter Satchell, £1 1s.; Prof. Joseph Bell, S. Carrick Steet, Esq., F.R.C.S., Dr. Connel, Dr. N. Henry K. Kane, Dr. Kealey, £1; S. Burrows, Esq., 10s. 6d.; Dr. Travers, H. ## THE BRADSHAW LECTURE.

ON

### MORBID ARTERIAL TENSION.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS, AUGUST 18TH.

By JAMES F. GOODHART, M.D., F.R.C.P.,

Senior Assistant Physician and Lecturer on Pathology at Guy's Hospital.

It falls to the lot of the Bradshaw lecturer of to-day, to deal with circumstances that are sadly peculiar, and which—young being the days of the foundation—no one has hitherto been called upon to handle. He is here to-day not in his own right, so to speak, but to fulfil the duty, to reap the pleasures, in this instance but sad ones, which are some of the obligations of friendship. In happier fate we should have listened to one of the most distinguished of the younger Fellows of this College, as he pointed, as assuredly he would have done, from the honoured and brilliant Past, to the hopes of a robust and seething Present, and then, perhaps, on to the

"What Now discovers not, Hereafter knows,"

VOL. II. 1885. No. 1834.

and the boundless capacity of the Future, fit subject of discourse by one whose enthusiasm seemed as limitless as it was prodigal.

But Mahomed's destiny was not this; his Presence has gone onwards, and we who remember its individuality and its vigour may well make it our business to enquire what of the Essence—

"The Living Power, if that which lived  
True Life, live on"

—of that lost individuality is here.

But, although thus fettered, as I think, in the choice of a subject upon which to lecture—for there are other matters upon which, as being more conversant with them, I would the rather dwell—when I come to examine them, my bonds are those not of restraint, but of freedom. For on the one hand, the memory of the most illustrious Past, although not dead, yet sleepeth, and the task of wakening may most gently and naturally come by Time's substitutions and the more vivid impressions of its latest finished effort, the more recent Dead. And on the other, in this particular instance, my subject happily embraces the work, not of Mahomed only—not of him first, far from it, though changeful fortune gives him now a courteous, sad, respectful precedence—but of such distinguished Fellows of the College past and present as Bright, Sibson, George Johnson, Owen Rees, Sanderson, Gull, Sutton, Dickinson, Broadbent, Galabin, and others. Indeed, when once the enumeration is begun, I know not where one is to stop, so many,

according to my idea of what arterial tension embraces, have worked at some branch or other of it.

The subject, therefore, is appropriate whether for a Bradshawe lecture in ordinary, or for one delivered under the, let us hope, long peculiar circumstances which attach to that of 1885, or whether for a lecture emanating from this College, for it concerns itself with a matter which by the work of many of its Fellows has been made, and still is, one of the leading pathological and clinical questions of the day.

I could not, of course, attempt in one short hour to review the whole history of arterial tension, a history practically concurrent with that of the circulation of the blood. Nor is anything of that soporific kind my purpose in this the middle of August. I am only concerned with the latest developments of arterial tension, the application of the idea to what, for want of a better term, I shall call the household explanation of disease. By that, I mean an explanation which can be made to apply to such multiform conditions that, from one point of view, it is a morbid agency the importance of which can hardly be over-rated; from another, it bears more the aspect of a faded Cambridge blue, so little of depth is there in the colour it contains.

These two alternatives will, I believe, fairly represent the value set upon the idea, or the fact, by practical men in the present day. I do not mean the conception of its value in the mind of the absorbed pathologist: he looks at things with an æsthetic severity of conviction that may chance to arrive at conclusions which are beside and beyond our everyday realities. He works for to-morrow rather than to-day. His mood must often seem to be:

"Yet still shall I speed  
On my way without heed,  
Nor mourn for the wreck that is doing  
For my calm, cold light  
Is my own delight,  
And I smile on the ashes of ruin."

The stress of the fight comes not on him, the upheavals produced by his dicta come upon the sons of men, and theirs is the stress in clambering the rugged crevasses of discovery.

Now, arterial tension and Bright's disease have danced so much together of recent years, that it is necessary to occupy much of the time with the aspect of the question derived from their association. Bright in his day noticed the hypertrophy of the left ventricle that occurs in chronic renal disease, and attributed it to the impurity of the blood, and to the extra work thus thrown on the heart, in consequence of the refusal of the tissues to allow a free passage to material of which they disapproved.

His words are these: "Either the altered quality of the blood affords irregular and unwonted stimulus to the organ immediately, or it so affects the minute and capillary circulation as to render greater action necessary to force the blood through the distant subdivisions of the vascular system." Dr. George Johnson in his earlier writings maintained much the same view, but abandoned it in deference to the teaching of modern physiologists, for what is now well-known as the stop-cock theory, which supposes, and no doubt justly so, that the function of the muscular coat of the arterioles is a controlling one, and that when blood is ill adapted to the tissues control will be increased, and the blood shut off more or less from the tissues. This must necessarily create obstruction behind, throw increased work upon the heart, and thus account for the hypertrophy of the left ventricle. Fully examined, there is not much objection to that way of stating the case, but there is just a touch of fancy in the stop-cock simile which provokes the criticism that it smacks too much of a purposive volition. The arteries might

seem to say to the heart you shan't, and the heart to retort you shall, or as Dr. Dickinson writes: "the heart and arteries are thus represented as acting in antagonism, and hypertrophied by the efforts each makes to get the better of the other, the arteries contracting beyond their wont in the endeavour to shut the blood out of the tissues, the heart using increased efforts in the attempt to overpower their resistance and drive it in, and both, like conflicting athletes, are increased in muscle by the exercise." Dr. Johnson takes exception to that way of stating the case, but it is a clear way of putting the issue raised by a too dogmatic insistence on the stop-cock analogy. In that light the theory does seem to me unphysiological. There is no strife in Nature, and if the hypertrophy of the vessels exist, as it surely does, then both it and the increase of the muscular tissue of the heart must be part of one common process, one purpose if you will, which is consistently and adequately explained by the effort of the entire muscular element of the circulatory system to forward a fluid to which the absorptive or appropriative powers of the tissues are ill adapted. I must say I find myself in complete accord with Dr. Dickinson, and Bright was probably well advised in confining himself to the facts. The bare supposition that the heart is large because it has more work to do is quite unassailable. Nevertheless, Dr. Johnson advanced us an important step by insisting upon the thickening of the vessels, because so little attention had been paid to it. Bright, however, had noticed it, and you will see at once that the knowledge of that time implied its existence. It *must* be so. An athlete uses certain muscles for a certain purpose, and he, perhaps, doubles their size. We don't question the cause or the nature of the hypertrophy; the heart does double duty owing to some impediment in one or other of its valves. Who questions the reason of its increase in size? If the stomach or the intestine have to overcome obstructions, and we find them thickened, again, who disputes the nature of the thickening. It goes without saying. In all these instances we see simple illustrations of a common physiological principle admitted by all. What reason, then, is there to discuss whether the muscle of the arterial coat hypertrophies? Of course it does, when excessive work is demanded of it, just as organic, or any other muscular fibre elsewhere. Therefore, to the question, Is the muscular coat of the arterioles thickened in chronic renal disease? I reply not so much by a demonstration of the fact, which is, perhaps, not so easy as might at first hand appear, but by an appeal to the entirely *a priori* ground that it must be so. And I do this with intention, in the conviction that the appeal to demonstration and to demonstration only in the present day is too absolute. No doubt it is on the whole the safest ground to tread, but appearances admit often of various interpretations, while, within such limits as its present use, I believe my argument to be unassailable.

Some particular feature will, I say, admit of various interpretations. Thus, Sir William Gull and Dr. Sutton write:—"As to the hypertrophy of arterioles we may say that, though the muscle in some of the larger arterioles especially seemed to be increased, yet we are still sensible of the difficulty of giving a true interpretation to such an appearance." They lay stress upon the possibility that irregular and unusual contraction of the vessels, and a want of constancy in the natural thickness of the layer in different arteries of equal calibre, may simulate disease; and those of us who are familiar with the pitfalls which abound, even for the wary, in latter-day microscopy may well be ready to admit that these are no mere captious reservations of the hostile critic. I, however, agree with Dr. George Johnson, Dr. Dickinson, Dr. Galabin and

others, that a comparison of comparable specimens is not so difficult as to throw doubt upon the reality of the hypertrophy.

As regards the existence or not of spasm, Dr. Johnson's position is to my mind inadequate by just so much as he rejects the function of the muscular coat of the arterioles as an auxiliary force in forwarding the circulation. I am aware of the difficulty of this question: that physiologists as a body are in favour of his position, and that demonstrable evidence against it is either absent, or indecisive. Nevertheless, I cannot conceive of the evolution of a circulatory system upon lines which, whatever name is applied to them, must be antagonistic. Dr. Johnson makes use of the term "an antagonism of forces." I would rather believe that, developed for a common purpose, and by a gradual evolution, heart and arteries so work together under natural circumstances that we cannot detect their harmony; and that when it is possible to study the action of the muscular coat it approximates to the conditions of disease. We say, for instance, that non-striated muscular fibre acts slowly and persistently, and that such an action is inconsistent with the lightning wave which would be necessary if the muscular arterioles were a propulsive power. But muscle, organic or other, acts as it is taught to do; the pupil, the œsophagus, the intestine, the uterus, the bladder, none of them act alike, and whether the aid to the circulation be vermicular or what not it cannot be but that the aid is positive. Some years ago, Dr. Charlewood Turner gathered the evidence on this head into a very able paper, his conclusion being entirely in favour of a considerable propulsive force being exerted by the muscular arterioles.<sup>1</sup> Dr. Dickinson also takes this view, and in withstanding the increased blood-pressure it surely must count for something if it be but the pigmy to the giant.

A pure control theory seems to me to bristle with difficulties in the direction I have indicated; but take the one case of digitalis, which will appeal as much as any to our practical interest in the question. Digitalis is said to increase the strength of action of the muscular wall of the heart on the one hand, of the arteries on the other.

If the muscular coat of the arterioles controls and retards the circulation, the undoubted diuretic action of the drug is not easy to explain; and if, as the control theory supposes, the stop-cock action is considerable, it would always be a question whether it would do more good by its action upon the heart than harm by its action upon the vessels. At any rate, the increased action of the latter might very conceivably, in a failing heart, bring about sudden dissolution.

It cannot be said with any certainty that this is one of the risks of its administration. The drug is not without its risks, but they are primary and central to the heart itself, and it would seem that the action of digitalis teaches that the muscular coat of the arterioles makes for propulsion rather than retardation of the circulation.

But there can be no muscle, and no physiological muscular action, without the risk of, probably, under such circumstances as these, the frequent exhibition of morbid muscular action or spasm. It is clear that a muscular action which leads to hypertrophy might easily pass into spasm under conditions similar to, but in excess of, those which have provoked the increased action. And indeed the assumption of some such spasm, if not necessary, is, at any rate, agreeable to many of the phenomena of Bright's disease. I may instance the headache and the renal asthma, both of which are sometimes much relieved by nitrite of

amyl and nitro-glycerine, drugs which unquestionably relax spasm, and promote dilatation of the peripheral vessels.

Thus far I have devoted myself to the opinions of Dr. Johnson—firstly, because they preceded others; and secondly, by the effective presentation and vigorous advocacy of their author they have done much to promote our advanced knowledge, and to widen the borders of their own field of interest. It requires indeed but little imagination to believe that without this stage of its growth the present conception of arterial tension would yet have to be developed. But be this as it may, the subject now expands in two noteworthy directions: by the hypothesis that chronic Bright's disease is an arterio-capillary fibrosis, or generalised tissue-change, on the one hand; and by the use of the sphygmograph on the other, and it is remarkable how these two lines of observation tend to support each other. As a direct recoil from Dr. Johnson's teaching we may take the former first, although both proceeded independently and concurrently. I said a direct recoil from the teaching of Dr. Johnson, but it was not that; in point of time, and in the position it assumed in the discussion, it seemed to be; but it was rather the outcome of an approach of the question of the nature of chronic Bright's disease from the clinical side, or from a general rather than a local standpoint. Epigrammatically stated from the paper of Sir William Gull and Dr. Sutton it is this: "Old age is not an entity, but a set of conditions predisposing to that state which is called chronic Bright's disease." And while to most this comes in natural order when the prime of life is run, yet to some old age is no matter of years and averages, but the running down of a spring set for an individual. It comes at times even to children. In the tints of summer, yes, even in those of spring, you can read old age if you will. And although chronic Bright's disease is in many cases associated with renal disease, it is not essentially a matter of organs, the generalised change in the tissues of the whole body is the essential, and to some this comes not by kidney chiefly, but by lung chiefly, by brain, by heart, and so on.

Now here comes a difficulty in dealing with the case. May I say that this is a magnificent scheme of decay, which, to discredit, would be to do for this line of thought what I understand is meant by the expression "taking the romance out of life"? Still-life has the *equivalent* of *romance* attaching to it, which to many of us is most attractive, suggestive, propulsive. We often hear it said in the present day this or that is mere sentiment, as if no solid worth attached to it, but I should like to know whether life would be worth living with all that is comprehended in the term "sentiment" cut out of it. What progress would be made in its absence? And I make bold to say before the Fellows of a College the reputation of which is based upon a firm foundation of fact laid by many generations of distinguished men, that pathology would lose much of its interest, much of the energy which characterises it and makes it so indispensably and helpfully the groundwork of medicine—physiology complete—if it chained us too subserviently to the march of facts. There are some, yes, many, happily, who are absorbed upon the foundations, but they do not comprise the whole body of workers, and we cannot and would not do without the soul-inspiring idea, the fond imagining of the more precise knowledge of the future, forecast and sketched by the hand of genius.

This is a digression which will be pardoned, in that it helps me to convey what is, I think, both the strength and the weakness of the argument of Sir William Gull and Dr. Sutton. The idea is a suggestive one, and it is largely true. Pathology is distinctly the richer for it, but it derives its strength less from the

<sup>1</sup> "On the Function of the Vessels in relation to the Circulation of the Blood." St. Thomas's Hospital Reports, New Series, Vol. vi, 1875.

labours of the histologist than from the bird's-eye view, the intuition, may I call it so, of experience. There is ground in plenty for the argument that we wear out by tissues or systems; there is, I think, a fair amount of evidence admitting of the opinion that chronic Bright's disease with contracted kidney is a generalised degeneration; but to base it upon the non-existence or unimportance of muscular hypertrophy in the arterioles, and to ascribe the thickening which exists to an essential hyalin fibroid degeneration, is equivalent to the unskilful selection of a battle-field.

How far, then, do I think it true? Perhaps an answer to that question may best be arrived at by continuing upon the other, how far it is not true. And going to the other end of the circuit, there are groups of cases which admit of no doubt, in which the disease in the kidney is certainly the cause of the changes in the heart and arteries. One of the first steps in the direction of proof of this kind was made by Dr. Galabin, when he showed that the heart and arteries are hypertrophied in a large proportion of cases of chronic parenchymatous nephritis (which, as a group, I may, perhaps, still call the large white kidney group, although the kidney is often contracted), and which are indubitably primarily renal. I have taken up the cases where he left off, and have collected from the *post-mortem* records all the cases of chronic parenchymatous nephritis that occurred in the ten years 1873 to 1882, amounting in all to 191. At the lowest estimate, taking the average of the healthy heart at twelve ounces, which is full high, 103 were above this and 83 below it. But the proportion claimed by hypertrophy is considerably higher than this, for in the minority are fifteen children under ten and seven more between ten years and fifteen, and others in which the left ventricle is stated to be thick or markedly hypertrophied, although the actual weights would not indicate this. I think the preponderance may fairly be put at two to one. It has been said that hypertrophy is less frequent in these cases than in the granular kidney. But figures do not show this well. I have tabulated also the cases of granular kidney, recorded in our Reports, a total of 342 cases, and taking the average again as 12 ounces 103 are below that line and 226 above it. But it is not easy to come to a positive opinion in this way. I think Dr. Dickinson makes the observation that some of the cases of parenchymatous nephritis are primarily cases of granular kidney, and in looking over a large number of cases like this, one cannot but be confirmed in the opinion, derived from clinical study, that it is quite impossible to separate too arbitrarily between the one form of disease and the other. The more acute form of disease is often far more insidious than is usually taught; the granular kidney frequently winds up with tubal or parenchymatous changes.

Perhaps I may remark, in passing, that a large series of observations of this kind may possibly throw some light upon the moot point, the rate at which the heart can put on muscle; for the heart has been found large in some cases in which there was every probability of the renal disease having existed but a few weeks.

Such differences as do exist between the two classes of cases are of more *practical* moment than of worth as distinctions. For in the first place it may be said that the failure of health and of nutrition will not infrequently combine, so to reduce the arterial tension, as to deprive the circulatory system of any excuse for hypertrophy. The damage, too, in these cases is much more severe at any one time than the granular kidney can show; the left ventricle has, in consequence, more tendency to dilate, and thus to relieve the excessive tension and forestall the hypertrophy by the death of the patient. I put it thus pointedly as a

fact of importance. In proportion as the renal disease is sudden and severe, so is the risk of dilatation of the heart. The more insidious it be the more likely is the cardiac hypertrophy to be present in greatest perfection. Serious acute renal disease means sudden increase of arterial tension, and the imposition of greatly increased labour on the heart, and rapid dilatation of its wall becomes a serious risk.

I speak with some diffidence before those of larger experience than my own; but surely this is corroborated by clinical observation. The most acute and sudden form of renal disease with which we are acquainted is undoubtedly that following scarlatina, and it is in just these that acute dilatation of the heart occurs most typically. That coming next in severity is the chronic parenchymatous nephritis, in which dilatation is common, and although it is more or less combined, it also closely competes, with the hypertrophy. The granular kidney which has small and inappreciable beginnings, and which drags its slow course through many years, while it cannot be said by any means to be ignorant of dilatation, is, nevertheless, the disease in which the well-known simple hypertrophy is most often found, and to a degree which is perhaps never so under other circumstances.

There is another fact of similar bearing. It is this: that while granular kidney often terminates in cerebral hæmorrhage (86 times in 117 cases of apoplexy<sup>2</sup>), the subject of chronic parenchymatous nephritis rarely dies by that means. Bartels states that he has never known death to occur in such cases from apoplectic effusion, and it is certainly a rare occurrence.<sup>3</sup>

At first sight this might seem to be agreeable to such as maintain that the disease, of the vessels is a peculiar one and independent of the nephritis, for here is a severe form of renal disease, and the large heart in most cases, yet seldom apoplexy. But the better explanation is probably that I have given: it is obvious that dilatation of the heart is unfavourable to the occurrence of apoplexy, it relaxes the tension at the centre which would otherwise be put on at the periphery, and death comes about by cardiac failure, and not by peripheral hæmorrhage.

I have only time to add on this point that it applies, of course, not only to parenchymatous nephritis, but to all cases, more or less, in which there happens to be dilatation of the left ventricle. It is worth remembering, for it cannot be unimportant, whether the risks of an individual are those of apoplexy or of the more gradual process of cardiac failure, and the undoubted value of a drug such as digitalis in many of these cases is a ready criterion of the importance of the point in the matter of treatment.

I have still something to add concerning the pathology of the arterial changes. Enough has been said about the reality of the muscular hypertrophy; but what about the excess of hyalin fibroid material and the atrophy of the muscular coat in the arteries that have been observed? I have no doubt of the correctness of the observation, and very little difficulty in explaining it. There is a general demand for extra labour and a physiological response represented by hypertrophy; but in the process not only does the muscle thicken, the other constituents of the arterial coats *must* thicken too, and thus the excess of hyalin-fibroid—of the connective of the coats of the vessels—is natural to the circumstances. But, further, when once a growth is started which operates impartially upon several varieties of tissue, high and low, if the

<sup>2</sup> "Guy's Hospital *Post-mortem* Records," 1873 to 1882.

<sup>3</sup> "Eight times in 191 cases, of which four admit of question, being not improbably cases of granular kidney with an acute parenchymatous change superadded. Cerebral hæmorrhage is still rarer in lardaceous disease, as Dickinson notes."

conditions for obtaining supplies are in any way prohibitory, as may be concluded is the case with the arterial coats, to judge from the frequency with which, even in otherwise sound bodies, atheromatous changes are met with, the least specialised, or less dainty feeders, are likely to have the best of it and to supplant the more highly specialised. There are plenty of instances in pathology of the ease with which embryonic or structureless tissue gets a living by the process which is popularly known as "sponging." There could not indeed be a more apt term, for these lowly organised tissues seem to live by a process of simple soaking. Take an *ante-mortem* polypus in the heart, or even those larger masses of thrombus which sometimes form in the apex of the left ventricle. In either case there are considerable tracts of clot which must have maintained themselves in this manner, and if you tell me that these things are dead, then so are we in great part (as has indeed been contended), for they are no more so than several of the parts of the living body; and I would have it that they thus live. But, perhaps, it may be said that the life of a clot is no fair evidence that definite structures will live after such a menial fashion. If so, there is the well-worn case of the dissecting aneurysm, with its false channel as good as the natural one, as far as its lining membrane is concerned; or there is the still more ancient question of the nature, true or false, of the coats of an aneurysmal sac. The largest sac we can take, and that is no mean limit, will show as irreproachable a lining membrane, even to its reproduction of disease, as the vessel from which it springs—so that, brushing aside the cobwebs of the intellectual Tarantula, it is impossible but that new coat has formed. Perhaps some may contend that it is formed by means of the legitimate blood-supply procured from the vasa vasorum. That may be allowed to be possible, but not the least of the advantages of holding such an office as this is, that one becomes entitled for one short hour to an opinion, and consequently I venture to adhere to the view (not by any means a novel one), that the internal coat of the vessel or sac, as the case may be, is derived directly from the blood-stream, by what may, perhaps, be described as a natural asphalted process, the blood being asphalted, roller, and clerk of the works all in one. I dare not presume too much, or I should be inclined to investigate the mode of life of foreign bodies in the peritonæum and in the joints; of our natural cartilages and intervertebral substance, and even of tendon, notwithstanding the noteworthy observations of Dr. Mitchell Bruce upon its system of canals. I must, however, content myself with the statement that physiological and morbid phenomena alike appear to show that a perfectly natural tissue may not only *live*, but be the best of its kind in this easy way, while more highly-strung tissues, such as muscle, give way and disappear. Therefore I see no contradiction in the fact that in the tissues and vessels of chronic renal disease, the muscle may certainly be thick in some parts, wasted in others; or that the vessels can be recognised as well by the hyalin-fibroid thickening of the coats as by the muscle.

But stronger, and, perhaps, less fanciful ground in favour of the existence of degenerative changes in this disease may be found in what no one now questions, viz., that strain or overwork leads to disease. Nay, more, bearing in mind the observations of Dr. Moxon, upon ulceration of the aorta by friction, and on the nature of atheroma, it may be said that wear and tear lead to *inflammation*, and if there may be a question about this in the aorta, though I do not think there can be, there can be no question whatever in the pulmonary artery, where, when we meet with atheroma, there will generally be plenty of evidence that there has been obstruction in the passage

of the blood through the lungs. What is true for the larger vessels is still more so for the smaller, for inflammatory processes are certainly more luxuriant in them than in the starveling products which constitute atheroma. Hence as the direct outcome of the overwork, we might expect more or less hyper-nucleation of the coats of the arterioles, and ultimate fibrosis. This is a point of importance, very properly insisted upon by Dr. Dickinson, and I may add not only in regard to the changes attaching to chronic renal disease, but also in dealing with the question of the nature of disease in the smaller vessels.

But not only do these cases of chronic parenchymatous nephritis testify to the potency of renal disease in causing hypertrophy of the heart and arteries, there are instances of granular kidney in children and adolescents which are to be traced directly to scarlatinal nephritis, and occasionally to poisoning by lead. Degenerative changes of any kind, although not unknown, are not common at these periods of existence, and it is therefore by so much the more certain that the renal disease initiates the circulatory changes. The same may be said of the occasional cases where the kidneys are spoiled by chronic obstruction to the passages; and finally, there are the experiments of Gravitz and Israel upon the lower animals, in which it has been found that an inflammation of the kidney can be produced by the temporary ligature of the renal artery on the one side, which, if the animal live long enough, is followed in course of time by contraction of the kidney, and sometimes by hypertrophy of the heart also.<sup>4</sup>

The arguments that have been used against the renal origin of the cardiac and vascular changes, although based upon admitted facts, are by no means conclusive; for instance, it is said that the kidney may undergo extreme degeneration without being attended by any such ulterior effects, and this is about equally true as regards the heart, as has been shown, for both forms of disease, the granular and parenchymatous. But the argument which is held to explain the same fact in relation to lardaceous disease, will apply to *these* forms of renal affection also. It is only in such cases as the excretory area is disproportionately small for the body weight that the *effect* must be sought for. If the body wastes and the heart fails, the kidney may be small indeed, yet sufficient for its day, just as the chronic phthisic could not possibly have lived on had not the progressive wasting compensated the balance. It is also true that the general changes may be extreme, and the kidneys only a little granular or coarse; but this may mean much less than it appears to do, for very aberrant organs may look most meek to the naked eye.

These constitute the main points adverse to the contention of Sir William Gull and Dr. Sutton in its entirety. They show conclusively that renal disease will produce hypertrophy of the heart and of the smaller arteries, and this is indeed admitted by most pathologists, of whom I will specially mention Dr. Dickinson as having as long ago as 1877 said all that one can possibly say now.

But there is another aspect of the question, and this it is which provides ground for a belief in the existence of diffused degenerative changes such as have been described.

I suppose that ever since Bright's time, it has been felt by all that albuminuria must often be but a rough

<sup>4</sup> In looking over our *post-mortem* records for the purposes of this lecture, I have noted one case of one-sided disease, the other kidney being only hypertrophied in which the heart was enlarged. Dr. Galabin had previously noted two others in earlier years, and there are several in which one kidney having been long destroyed or substantially crippled, the other having undergone inflammatory changes in addition to the hypertrophy, characteristic disturbances have followed.

and a late test of disease—that there are conditions preceding it which, if we could recognise them, would tell us more; and one of the earliest of my medical experiences was the work of Dr. Owen Rees in the wards at Guy's, upon the detection by tincture of galls of morbid conditions of the urine which could not be reached by the nitric acid test. That line of research has been developed of recent years by tests of greater delicacy, and we now hear talk of physiological albuminuria, peptonuria, and so on. So far as my own experience has gone, I have not met with much encouragement in the field of pre-albuminuric precipitates, and all the less because it holds out hopes of great things as regards the early detection of disease. Peptonuria and physiological albuminuria do not seem to me at present to have shed much light on anything, not even on gout or indigestion, which are ever ready to coquette with novelty—yet ideas of this kind are beginning to colour our thoughts and our practice. Only the other day I saw a lady suffering much from headache, and with a variable but often copious albuminuria of seven or eight weeks standing to our knowledge. I need not go into the details of the case, it will suffice to say that although it was admittedly obscure, I thought that some serious organic disease of the kidney must exist. It was arranged that another opinion should be obtained, and one for which assuredly I am not wanting in respect. This resulted in the verdict that the headache was megrim (which was quite possible), and that the albuminuria was a functional one dependent upon malnutrition.

But I must not pursue this question. I have no wish to prejudge its issue—only at present its promise hangs back a little, and we have hitherto learnt more from sphygmographic observation.

And it is here that Mahomed entered the field. The way being prepared by Burdon-Sanderson, he improved upon Marey's instrument, and soon settled down to an elaborate investigation of the pulse tracings of disease, and he, more than any other, has familiarised us with the characteristics of the pulse of high tension. If others have treated the subject with a more philosophic delicacy of perception of the fallacies which strew the path of this method of investigation, as perhaps they have, it was a matter of earlier training and culture, not of spirit, and he was too enthusiastic to be self-contained.

I say this intentionally, because looking back upon the history of the sphygmograph, if it can be said as yet to have a history, I doubt whether the observations of Mahomed have received quite their due meed of estimation. Yet his was the work which kept the subject going, and of which our present knowledge is in great part the development.

If I were to choose from Mahomed's many papers that which has always seemed to me the most valuable, I should select one published in the "Transactions of the Royal Medical and Chirurgical Society for 1874,"<sup>5</sup> on the Pre-albuminuric stage of Bright's Disease. It bears directly upon the present part of our subject. In it, it was shown precisely that morbid conditions of the pulse (high tension) precede any evidence of disease in the kidney, and he draws the conclusion from a number of observations that the vascular condition is the cause of the albuminuria and not the converse, as had been generally supposed.

His observations and conclusions seem to be particularly worthy of credence, because they no more than state in terms of greater precision what had been long known. There was nothing new in the knowledge that the pulse is hard under certain circumstances—let the early and long day of venescence

attest that. There is no novelty in the assertion that careful purgation is the best means of preventing or combating the onset of scarlatinal dropsy—let the sheet anchor of the treatment of Bright's disease attest that. The sphygmograph but told us in one sense what we knew before, but it told its tale with a graphic interest which had much of the merit of a new discovery. It did not educate the finger, but it reduced the composite of the impressions derived from touch.

And this account of high tension, demonstrated by the sphygmograph, but not unknown before, leans obviously towards the hypothesis advanced and supported by Dr. Walshe<sup>6</sup> as early as 1849, that Bright's disease is not renal, but primarily a blood disease. It is fair to suppose that the blood is under such conditions as those of acute gout, lead poisoning, blood poisoning of some other kinds, some states of anæmia, and so on, in a condition which renders it repulsive to the tissues, and that the kidney only suffers in common with the other members. And it is quite possible—nay, there are grounds for believing—that under circumstances which apply to, and are imposed upon all, it may suffer more than the rest by reason of some disability inherent in its anatomical structure, for example; or an undue readiness of its glandular elements to undergo degenerative changes; or a disproportionate activity of function—for it is hardly to be supposed that there is no maid-of-all-work in a household so economically conducted as ours. At any rate, it is well known that diseased conditions of the kidney—of the epithelium chiefly, but not only—are common enough in the *post-mortem* room in all sorts of cases, which could not by any means be primarily renal, and such changes are probably far more common than allied ones in the liver. The greater frequency of the occurrence of lardaceous disease in the kidney might also be an instance in point. It must, however, be said that the apparent precedence of high tension does not necessarily carry the conclusion that the kidney follows the lead of the blood. It may still be that the excess of tension is compassed, if not by albuminuria, yet by some milder form of renal inadequacy, to adopt Sir Andrew Clark's happy, if somewhat gossamer term, as the initial fault. The pathologist has no right to be contemptuous of function. It cannot be but that it sometimes fails first; it cannot be but that it *often* fails before any appreciable structural change is manifest. So that in scarlatina, gout, and such like conditions, it may so be that the tension is responsive to the visceral failure.

But if this importance attach to function, as it surely must, it may be contended on the other hand that it supports the probability of the production of an arterio-capillary fibrosis by means other than renal defect. Can it be, with other excretory organs of probably no less importance, viz., the skin, the liver, and the intestine, that the kidney monopolises the power of thus rendering the blood distasteful to the tissues? Surely some of the many disorders of a huge viscus like the liver must be efficient, even if gout be discredited for being a trimmer; and it is possible enough, it is probable enough from the clinical side of the case, that certain morbid states of the nervous system, "worry," for example, when expressed in terms of nervous action, by their influence on the peripheral circulation, will bring about the same result. Indeed, Dr. Clifford Allbutt, in one of his many attractive and suggestive papers, has taken up this very question, and has narrated cases, if I mistake not, of granular kidney which have seemed to date their origin from prolonged anxiety; and Dr. Broadbent has alluded<sup>7</sup> to the increase

<sup>5</sup> On the *Ætiology of Bright's Disease and the Pre-albuminuric Stage.*

<sup>6</sup> "Bright's disease" not essentially a renal disease, but essentially and primarily a blood disease.—*Lancet*, 1849, vol. ii, p. 29.

of tension that may be observed in states of nervous excitement in hysteria and other diseases of brain and spinal cord.

A good deal has sometimes been made of the occurrence of a general arterial disease with hypertrophy of the heart, without renal disease, in young people, but it is very exceptional. More common, but still rare, is the same combination in older people. Of the former class I cannot say that I have seen a single example, although for twelve years I have been on the look-out in our *post-mortem* room; of the latter I can count fourteen in the ten years collated. But I must say, that holding as I do to the probability of the existence of a general arterio-capillary fibrosis, I am for ever wondering at the small amount of tangible evidence that is to be obtained from the deadhouse. As a matter of practice, a thick sodden appearance of the arteries but rarely points wrongly to chronic renal disease. Some years ago MM. Bouchard and Charcot published some observations<sup>8</sup> upon the dependence of cerebral hæmorrhage upon the presence of miliary aneurysms on the cerebral arteries. Heschl, Meynert, Bastian, Douglas Powell, and Charlewood Turner have since then met with a similar condition. MM. Bouchard and Charcot consider the disease to be a sclerosis of the outer coat of the vessels leading to atrophy of the muscular coat, and thence to weakening of the walls and aneurysm. One cannot but suppose that here is the same change as that described by Sir W. Gull and Dr. Sutton, to the accuracy of whose observations independent testimony is thus afforded. They also contend for the special nature of the disease, although they would confine the sphere of its action to the vessels of the brain; but this lands us in a dilemma, for, on the one hand, it would seem to traverse the observations, too numerous to admit of the least doubt, that renal disease is the common associate of apoplexy (63 cases are given, a large proportion of which must have been, and obviously were, accompanied by renal disease and hypertrophy of the heart); and, on the other, if it be, as it must be, the change with which we have been so much occupied, it cannot be simply local, since so many other observers unite in saying that it is a generalised one, even though they differ as to the nature of the precise change.

But scant time remains to allude to what is perhaps the strongest evidence in favour of the generalised nature of the changes which include chronic Bright's disease. It is referred to by Walshe; Sir William Gull and Dr. Sutton depend much upon it; and it forms the subject of some of Mahomed's latest work in a paper on chronic Bright's disease without albuminuria.<sup>9</sup> I may say that I reject such a nomenclature as this. Bright's disease, if it means anything, means nephritis, and if it be true that it is but a part of a much larger subject, some more expansive title, arterio-capillary fibrosis for instance, must be found to incorporate it.

It is certainly a remarkable fact in the disease, if, being an affection of one organ, it should so frequently present symptoms apparently so remote that it is not difficult to overlook the primary disease altogether. There is no doubt that the urine is for long free from albumen in some of these cases (although I think myself that that feature has been rather strained); and perhaps the only tangible abnormality pointing to the kidney will be the low specific gravity of the fluid. Some die of apoplexy, some of asthma, some of cardiac failure, some of pneumonia. Of 100 cases given by Mahomed,<sup>10</sup> 74 presented the symptoms of diseases other than renal.

I will also make use of another fact, which seems to me to point in the same direction—it is the great frequency of granular changes in the kidney in the *post-mortem* room. There have been as many as 70 cases in one year out of a total of 490, or in a seventh of all the cases, and 463 cases in ten years; a number doubtless under the mark, as the slighter degrees are so common as sometimes to escape attention. This does, I think, tend to confirm the suggestion I have already put forward, that the life-history of the kidney is one of early senility, and that it runs in this respect with baldness, grey hair, and the atheromatous aorta, any of which *may* be the symptoms of essential disease, but which are more often milestones; and milestones, happily, with their faces blurred.

I had intended to have taken up, more fully than I can do now, another and somewhat neglected aspect of my subject: the frequency and practical importance of the effects of pulmonary arterial tension. I am, of course, well aware of Dr. George Johnson's work, in this direction *also*; and some of my hearers must have listened to or read his Lumleian lectures delivered here in 1877. But my own attention was called to it more particularly by a case that came under the care of Dr. Moxon, in Guy's Hospital, two or three years ago, which for some time was under my own observation. It must suffice to say of it that the only symptom of much obtrusiveness was a peculiar bruit in the pulmonary area, which upon the whole we thought not unlikely to be due to an aortic aneurysm, with possibly some communication with the pulmonary artery. It eventually proved to be an enormous dilatation of the pulmonary artery dependent upon a fibroid state of lung. The preparation is on the table before you. Since then I have been surprised at the frequency with which dilatation of the pulmonary artery, not of course always in this excess, has come under my notice. Now every case of chronic bronchitis and of mitral disease are more or less cases of pulmonary tension, and the indications of its presence in the alteration of the character of the second sound are to be found in every text-book. To such cases I am not alluding, but to a pathological and clinical extension of the subject which on both sides requires development.

Those of us who have been in the way of making numerous inspections will, I think, assent when I say that every now and then a puzzling case of this kind is met with: the symptoms during life have been those of severe bronchitis and emphysema, and yet the bronchial tubes are practically dry, and the emphysema, if it cannot be said not to exist, is, at any rate, not more demonstrably present than the fatty heart which is so often made to satisfy the unlightened conscience of a coroner's jury. But the pulmonary artery is dilated and perhaps atheromatous. It is difficult to say what the origin of these cases is; I only know that the lung has sometimes seemed practically sound, and I have been in the habit of explaining them by supposing that if some of us are born with large hearts, others are born with little ones, and some in like manner are provided at the outset with lungs which are inadequate to their requirements. But, however this may be, something has happened which has left the lung comparatively sound, and made dilatation of the pulmonary artery the main disease.

It has often happened to me in the *post-mortem* room to have to ask the question, in many cases, alas! without answering it—Which has been the more to blame, hypertrophy or dilatation of the heart and arteries? It is indeed impossible to mete out the relative share of each in a given result. But it is quite clear that the relative effects of the two cannot be unimportant. Extensive dilatation, for instance, of any of the cavities of the heart, while on the whole

<sup>8</sup> "Nouvelles Recherches sur la Pathogénie de l'Hémorrhagie Cérébrale." *Archives de Physiologie*, 1868.

<sup>9</sup> "Guy's Hospital Reports," Series iii, vol. xxv.

<sup>10</sup> The Clinical Aspects of Chronic Bright's Disease. "Guy's Hospital Reports," Series iii, vol. xxiv.

lethal, certainly has some compensatory aspects; while extreme hypertrophy, on the whole conservative and protective, as certainly hurries some lives on to a catastrophe. But, in this instance, observation tends to exalt the importance of dilatation, and I may remind you that there is *post-mortem* evidence that even in so common an ailment as anæmia the pulmonary artery may undergo dilatation (Russell and Bramwell).<sup>11</sup> I think, then, it is fair to conclude that the pulmonary artery sometimes dilates under certain transient conditions of pulmonary disturbance, and afterwards remains so permanently as the substantive disease.

I can only add that the clinical importance of these cases is neither small nor uninteresting. There is no need to intrude upon you the well-worn discussion of the nature of the hæmic murmur, but you will see that the ready dilatation of the pulmonary artery, if it be a fact, revitalises this question, and gives it fresh prominence and purpose.

This, thus hastily sketched, is the subject, such are the scenes, which occupied one of the hours of Mahomed's short but busy day. I know that they possess far more importance for some minds than for others. Some of us never think in terms of arterial tension at the bed-side. With some it is descent; with some the wear and tear of life; with some nervous action; with some blood; with some our environment lit by Professor Tyndall's beam that forms the more suggestive pose of the mobile Study, whose servants we in common are, but whose masters we, reverently all, might wish to be. Each of us has his ruling idea which lights his path and guides his hand in ways innumerable helpful, but unknown to any save himself. Yet though we must in this sense be negative to lines of thought not obviously in harmony with our own, we can always gauge their value justly by studying that line which best serves *us*.

It was said in my hearing the other day by one who, saying it, made it well worth the saying, that he did not feel altogether satisfied with his life's work. It was not enough for him to have been in the van of scientific medicine, he would have liked to have been able to say "This is my discovery." In more general way I have sometimes thought that medicine is less happy than painting or sculpture, which can have all a life's work visibly before it, and point with satisfaction to its numerous creations. There is something in the idea, but it wants in depth. One may be well content to have been in the van—it is a truer evidence of worth than the one discovery. Wherever I go I hear of Addison spoken of by his pupils, not as the discoverer of a disease, but as a master teacher whose hold still bends them to an almost reverential admiration. I hear of Bright, not so much as a name attaching to a disease, but as that of a man whose observations are worth attention whatever they relate to. I hear of Latham and of Murchison in like manner—we shall hear of those we may not mention in their presence. Such as these influence their fellows by a power quite independent of their additions to our knowledge.

Mahomed's name will not live upon discovery; dying unfortunately so young, it would be but a flimsy conceit of the hour to suppose that it will live in any sense beyond the lives of his own friends and the precincts of his school. Progress is as relentless as death, and although it is a glorious resurrection, it is none the less a grave. Even the gentle Emerson says: "What care we who sung this or that, it is we at last who sing." All the more, then, may we dwell upon a name to-day which, could one depict on

canvas or in the history of scientific medicine the individual elements in the wave of progress, during the last ten years, whether by the work itself, by the stimulus to thought which that work has proved, or by the ζυμη of personal contact, would certainly be largely represented.

Only this more. Pardon the personal tribute:

Then notes came pouring through the wicker bars,  
Climbed half a rapid arc of song, and stopped.  
\* \* \* \* \* I turned and passed along;  
But Time and Death, Eternity and Change,  
Talked with me ever, and the climbing song  
Rose in my hearing, beautiful and strange.

## ON THE TREATMENT OF CONTINUED FEVER, ESPECIALLY BY ANTIPYRIN.

By W. WILSON, M.D., F.R.C.P., of Florence.

TEN years ago, at the meeting of the British Medical Association at Edinburgh, Dr. Beddoe read an interesting paper on two cases of fever which he had observed at Bristol, these bore no resemblance to typhoid, but corresponded in their symptoms with the synocha of Cullen, or the continued fever of Murchison, save in their longer duration; the late Sir Robert Christison supported Dr. Beddoe's views, and afterwards in a conversation with me, stated that he had met with fifteen similar cases during a period of 25 years. The opinion of the meeting was almost unanimously opposed to the existence of simple idiopathic fever, lasting beyond a very limited period; holding that all those of long duration must be typhoid, though wanting in many of the special phenomena characteristic of that disease. No member quoted a case corresponding to that under discussion, and I myself had never met with a case; during the last five years, however, several have fallen under my notice, and it is generally recognised by Italian physicians. It might be objected that these also were cases of typhoid, but then comes the question what train of phenomena constitutes typhoid? One of the principal characteristics of typhoid is the inability on the part of the patient to assign the usual date of its commencement. He complains of having felt weak and languid with loss of appetite, nights more or less disturbed, for an uncertain time, and takes to his bed because "he could not get about any longer." He suffers from occasional chilliness, but no positive shivering, perspirations which do not diminish the temperature, and pains generally. The rise of temperature is gradual, not abrupt, and the general depression is not commensurate with the elevation of temperature. Murchison held that the most constant attendant on typhoid was enlargement of the spleen, then came diarrhoea, rose-coloured eruption, tympanites, &c., with more or less cerebral disturbance. I will now give shortly the history of two cases.

CASE I.—Miss S., aged 12, of very delicate frame, on the 23rd of April, when the heat was not excessive was taken by her father for a very long walk, and much fatigued; on the following day she was seized with shivering, followed by a temperature of 104.5° to 105°. Up to this time she had been perfectly well. There was throughout the attack no enlargement of the spleen, very little diarrhoea (purgative medicine had been given), no rash, or distension of the abdomen, no cerebral disturbance, tongue furred, but not characteristic of typhoid. My opinion was that it was not

<sup>11</sup> Bramwell on Diseases of the Heart, p. 197.

typhoid. The late Professor Buresi was called in consultation, who concurred with me, and regarded it as a case of simple continued fever, likely to last three weeks. The case was treated by cold compresses, ice and quinine, lasted three weeks, and the patient recovered perfectly.

CASE II.—Mr. M., aged 40, perfectly well up to the 24th March, on which day he assisted at a crowded tea-party, and rode home in an open carriage, without a great coat, exposed to a cold wind; that same evening he was seized with shivering, lasting half-an-hour, followed by a high temperature and quick pulse. Throughout there was no enlargement of the spleen, no abdominal affection or cerebral disturbance, and constipation, not diarrhoea; he suffered severely from pain in the head of a neuralgic character. The fever ran its course in three weeks, the temperature never rising above  $103.2^{\circ}$ . Through imprudence he had a relapse, which lasted two weeks. The most striking peculiarity out of many which I could mention, was the irregularity of the exacerbations, the acme of the fever occurring at any period of the 24 hours. He had lived during the whole winter on the third floor of an hotel which was perfectly healthy.

This was one of the first cases in which I employed the antipyrin. When first seen he was suffering from intense headache with a temperature of  $103.5^{\circ}$ . An ice-bag was applied to the head, and wet compresses round the body. It immediately became evident that he was intolerant of cold, the pain in the head increased, the pulse became intermittent and small, and there was severe shivering, though the temperature was but slightly reduced. Small doses of aconite every ten minutes were then tried, and then salicylate of soda. These failing, 20 grains of antipyrin were administered. The effect was most striking: in half-an hour he was bathed in a profuse perspiration, the pain completely disappeared, and ten grains repeated every hour for four hours reduced the temperature from  $103.5^{\circ}$  to  $99^{\circ}$ , and the pulse from 110 to 80. A return of high temperature was met by further doses of antipyrin. In this case the highest temperature occurred sometimes in the morning and sometimes in the evening. He also took quinine in large doses, which I believe to be always called for when there is marked intolerance of cold. I have formerly been often struck by the inefficacy of large doses of quinine with a high temperature; with a temperature over  $104^{\circ}$ , it could not be depended upon, and often produced unpleasant symptoms. Professor Körner, of Milan, maintains on the strength of experiments that the action of quinine is destroyed or nullified in a temperature over  $104^{\circ}$ , and I now invariably reduce the temperature before administering quinine, for it is reasonable to suppose that, as its action is destroyed by a temperature over  $104^{\circ}$ , it must be also modified or diminished by a temperature of lesser intensity, I therefore always take the precaution of reducing it within certain limits before giving quinine. It appears to me that one reason why quinine finds less favour in England than in Italy, is, that in the latter typhoid is so often complicated with malaria.

CASE III.—Miss P., who had arrived the day before from Naples, where her sister had been laid up with fever for three weeks, sent for me on April 18th. Her temperature was  $103.5^{\circ}$ . Pulse 108. She complained of violent headache. Compresses, with ice, were applied, causing great discomfort and severe shivering, without relieving the head or materially diminishing the temperature. There was no enlargement of spleen, diarrhoea or eruption. Twenty-five grains of quinine produced vomiting, relieved by ice pills. Nausea having ceased, a gramme of antipyrin was administered, and half that quantity every hour till the temperature was reduced. After the second dose

profuse perspiration ensued, and five hours after the temperature was normal, and the pulse 80. Instructions were then given to repeat the antipyrin on the temperature reaching  $100^{\circ}$ . The patient had been ill about a week or ten days before I saw her. Convalescent on the 1st May.

CASE IV.—Col. B. complained on the 22nd April of having felt chilly for two days; his temperature was  $104^{\circ}$ , and pulse 120. There was violent headache, his tongue was furred and slightly yellow, there was no enlargement of spleen, and no diarrhoea, the bowels, on the contrary, being constipated; 20 grains of antipyrin produced copious perspiration and immediate cessation of headache, and two further 10 grain doses brought the temperature down to normal. The temperature was kept down persistently by 10 grain doses, and the patient was convalescent in sixteen days.

CASE V.—Miss R. had been suffering from shivering, or rather chilliness, for two days (from Rome). The temperature was  $103.3^{\circ}$  and pulse 100. There was no enlargement of spleen, the bowels were constipated. Scruple and ten grain doses of antipyrin reduced the temperature when 20 grain doses of quinine had been given ineffectually. This treatment was persisted in, and the patient was convalescent on the 24th day. In this case equal parts of kairin and antipyrin were tried. The effect was more powerful; but the mixture was suspended on account of its nauseous flavour, and because it made the urine a mahogany red colour.

CASE VI.—A. M., seen on the night of 25th April. On arrival from Rome, he had been ailing for several days, and had been seized with shivering in the train, and violent headache. A draught of chloral and bromide of potassium was ordered and produced sleep, but no mitigation of the symptoms. On April 26th, temperature  $102.3^{\circ}$ , pulse 100, intense headache, pain in limbs, enlargement of spleen, the subsequent symptoms indicating typhoid. At 11 a.m., 20 grains of antipyrin were given, to be repeated in 10 grain doses every hour, till temperature reduced; ice compress with bag to head was tried, but not tolerated. The first dose of the antipyrin produced violent perspiration and cessation of headache in ten minutes. The patient declared he felt relief directly it was swallowed. Here quinine was badly borne, as well as cold, and the case was treated throughout with antipyrin. At the commencement there was great and persistent nausea; an emetic of ipecacuanha was given, followed by eight grains of calomel, according to the German system. Both were efficient, and afterwards all irritation of the stomach ceased; on the fourteenth day no antipyrin was administered by way of experiment, and as the temperature rose to  $102.3^{\circ}$  in the afternoon, the antipyrin was again resorted to, and continued till convalescence in four weeks.

CASE VII.—C. C.; this was a severe case of typhoid malaria. The patient arrived from Rome on the 22nd April; on the 24th he had shivering, followed by high temperature, intense headache, pains in the limbs, diarrhoea and enlargement of the spleen. Temperature  $104^{\circ}$ , pulse 120. Twenty grains of antipyrin produced profuse perspiration, and after four 10 grain doses the temperature fell to  $99^{\circ}$ , and pulse to 80. The following day the temperature again rose to  $103^{\circ}$ . Excessive nausea, tongue thickly furred. An emetic, followed by eight grains of calomel produced vomiting, and moderate purging (two evacuations). After this there was no further complaint of sickness, except occasionally from medicine (antipyrin and quinine), which was relieved by large doses of bismuth and  $\frac{1}{10}$  gr. of morphia. The malarious element manifested itself by the frequent high morning temperature. On the 10th there was a copious rash, and again on the 15th. After the first few days the antipyrin ceased to produce

perspiration, and the high temperature remaining more or less persistent, it had to be raised to half-drachm doses. On April 29th, 12.30 p.m., temperature 104°6'. Thirty grains of antipyrin were given to be repeated every hour, at 3.50 it had to be suspended on account of vomiting, temperature 101°6'; at midnight, the temperature again rose to 104°; after two full doses it fell to 100°8'. No perspiration. May 3rd, 8.20 p.m.—Temperature 104°2'. Thirty grains of antipyrin repeated at 9.50 and at 10.50. It was then suspended on account of nausea. At 12.20 the temperature had fallen to 98°. May 9th, 8.40 p.m.—Temperature 104°6'. After four doses of twenty grains each the temperature was reduced to 99°5'. This patient was at first most intolerant of cold, but by putting on the compresses warm, and gradually reducing the temperature with ice bags, it was finally borne without inconvenience; the temperature never again reached 103°, but it was the third week of fever. Large doses of quinine were administered, to the extent of 30 grains each dose, without effecting any great reduction of the temperature. The combination of 30 grains of antipyrin with 30 grains of quinine had the effect of producing nausea, but not of materially increasing the action. The attempt was made to inject 10 grain doses under the skin, but was suspended after two injections, as it produced considerable inflammation. The patient objected to the administration by the rectum.

CASE VIII.—A severe case of typhoid. Spleen three inches below the ribs. Diarrhœa, rose rash, meteorism, delirium for twelve days. Hæmorrhage from nose and bowels. At the commencement the antipyrin reduced the temperature of 104° in a marked manner, but then produced vomiting. An emetic was given; as the stomach was still intolerant of the remedy it was introduced into the rectum, 20 grains every hour, with good results, but after an attack of hæmorrhage from the nose to the extent of some 12 to 14 ounces. The pulse became so alarmingly weak that it was necessary to suspend the antipyrin and cold compresses, with ice bags, with port wine and brandy in full doses substituted. The patient is now (June 28) progressing favourably.

CASE IX.—Mrs. W., 65, fat and flabby. Suffered for many years from intermittent fever in Russia, and North and South America. This was a case of typhomalaria, with enlargement of spleen and liver. Severe hæmorrhage from the bowels thrice repeated, and profuse diarrhœa. Here the rate of the pulse, and the danger of hæmorrhage recurring, militated against the regular use of antipyrin. Once, however, when the temperature at 3 a.m. had reached 103°, fifteen grains were given. Violent perspiration followed, and in twenty minutes it fell to 99°. As there is suspicion of a fatty heart, the remedy was not exhibited further, the patient, on June 28th, being still in a critical state.

In these mixed forms of fever cold, as a rule, is not well borne. The action of antipyrin in cases of pure typhoid is most satisfactory in reducing the temperature and pulse, and relieving pain, but fails in fevers of the intermittent type. In the so-called typhomalaria quinine in large doses is indispensable. In all the above cases it was associated with antipyrin. Both are contraindicated where there is great depression of the circulation from whatever cause. The latter is most useful before administering quinine, and where this is given in divided quantities, 20 grains before the final dose frequently insures its full action. The effect is much more rapid and striking when it excites perspiration; in these cases a 10-grain dose is as potent as 30 grains where the skin remains dry. For many years I have been in the habit of giving an emetic under the circumstances already mentioned, but it was with fear and trembling that I first ventured on

10 grain doses of calomel. I do so now without hesitation if the patient is robust, and the disease in its first stage. In the cases of H. A. and C. C. there was a troublesome attack of urticaria, but whether this had any connection with the administration of the antipyrin I am unable to say. Quinine in large doses certainly will produce it.

In most patients of good robust constitution, antipyrin may be given with freedom, but it should be given with great caution when the reverse is the case. In spite of this, when it is of great importance to reduce the temperature before bed-time, I have not hesitated to combine the last two doses with brandy, and follow it with another dose two hours afterwards, and thus generally succeeded in securing a good night. It is prudent to begin with a gramme, followed by half grammes; if well borne, the quantity may be increased up to 3ʒ. An intelligent nurse with experience of the pulse, and good cognac, are important factors in the treatment.

I do not claim for antipyrin or quinine the power of rendering abortive, or shortening the duration of a continued fever, but by careful watching and management the temperature may be kept as a rule within safe limits, thereby economizing strength, preventing complications and securing a better convalescence. It is a good plan to withhold food during its administration, and to instruct the nurse as to temperature at which it should be given, securing if possible a low temperature at night, which will be more effective in procuring sleep than the administration of any narcotic. The ice-bag to the head and cold compresses to the body, when well borne, are most useful auxiliaries.

Rheumatic fever is a rare disease in Italy, but in England with severe hyperæmia I should think it would be as valuable as it certainly is in pneumonia in private practice. The graduated bath for adults is impracticable, and any substitute for it is to be welcomed; but in spite of the potency of antipyrin, where cold is well borne I still bind my faith on cold compresses reaching from the chin to the hips, with half a dozen large ice-bags—one to the head, one under each axilla, and the remainder distributed over the chest and abdomen. There is no danger of deranging the stomach, and the patient can be plied with nourishment. The effect of antipyrin is certainly more quickly secured than that of quinine, but the intermission or remission obtained is more transient.

### CASE OF CÆCAL CARCINOMA.

By ARTHUR FOXWELL, M.B. Cantab, M.R.C.P.,  
Assistant Physician to the Birmingham General Hospital.

ON July 4th you reported a lecture of Dr. Bristowe's on two cases of malignant disease of the cæcum, both of which were admitted under his care during my tenure of his house physiciancy. Since then a third has come under my notice whilst resident medical officer at the General Hospital, Birmingham.

On December 12th, 1884, I admitted, under the care of Dr. Rickards, Matilda A., a widow 65 years old. Her family and previous histories were good, the latter containing no suggestion of dyspepsia or intestinal trouble. On May-day, 1884, she first noticed a tender lump in her belly which was the seat of smarting pains. At this time, too, she lost her appetite and suffered from flatulence. The lump had grown rapidly since; great loss of strength went *pari passu* with its growth, and the digestive troubles had continued,

irritability of bowel and occasional offensiveness of stool being added to the previous ones. There had been no vomiting of blood or food, and no melæna.

On admission she was a much wasted, worn, and weary-looking woman with an earthy complexion. She complained of flatulence, anorexia, and extreme weakness. The abdomen was tensely distended, though not very large; in outline almost hemispherical, but a prominent knob was visible to the right of the umbilicus which distinctly moved with respiration, though to a much less degree than did the liver. On palpation a hard escarpment was felt reaching from near the umbilico-pubic line at the junction of its lower and middle thirds up and out to the right nipple line, where it ended three fingers' breadth below the ribs, over which breadth of three fingers there was gurgling on pressure. From this escarpment a hard smooth plane sloped back into the right iliac and lumbar fossæ, filling up the whole of the former, but in the latter easily admitting one's fingers round, and, to some extent, underneath it. Quite superficially it was separated from the ilium by half an inch, but it soon seemed to join this bone. It allowed extremely little movement in any direction. On percussion the abdomen generally was tympanitic; between the tumour and the liver ordinary colic resonance existed, and resonance of similar quality extended round the upper half of the right lumbar region; over the tumour the note was uniformly dull; there was a narrow band of partial resonance between it and the ilium. The liver edge was felt one inch below the ribs in the right nipple line, and was separable from the tumour except in the situation of the gall bladder; its surface appeared smooth and hard. There was considerable œdema of legs, labia, and back. She gradually sank and died on December 29th. There had been occasional incontinence of urine. The stools were loose and watery, two or three in the day; sometimes, especially at night, they were passed into the bed; they never contained blood. There was no vomiting, nor did she complain of nausea. The temperature twice reached 100°, but usually varied from 97·8° to 98·2°. The urine contained a trace of albumen with an occasional hyaline cast, and had a specific gravity of 1020.

*Autopsy.*—Much emaciation; some œdema of legs. A hard nodulated lump, the size of a cocoa-nut, to be felt in the right iliac region. When the abdomen was opened, the tumour was found to be adherent to the anterior abdominal wall for about two square inches: when these adhesions were torn through, it moved freely on the iliacus. The growth involved the cæcum with the termination of the ileum and the beginning of the ascending colon. The ileum passed for two inches over its lower front part. On slitting up this gut all its posterior wall was found to be gone, its cavity opening directly into a deep sloughy chasm, which was continued into the cæcum. Here and there bridges of tissue were stretched across this yawning abyss, whose walls were ragged, black and irregular, with stringy tags of half decomposed tissue adherent to them. The cavity of the cæcum was considerably lessened by ingrowths, and the ascending colon, instead of arising from its summit, was placed by a slight rotation of the mass behind and more internally than usual. The opening into the colon was constricted, admitting only the tip of the fore-finger. The vermiform appendix was behind the growth; its opening, though narrowed, was not occluded. No trace of the valve existed, and the whole of the lining of the cavity was similar to the growth near the ileum. In section, the tumour was white, opaque, and soft; it yielded a juice, and was easily destroyed by pressure. Under the microscope it proved to be the usual adenoid form of cancer, but no

well-formed columnar cells could be seen, not even in the outermost layers of the cell groups next the stroma. The nuclei were indistinctly seen, and the size and shape of the cells were very various. There was but little stroma, and the surrounding tissues were cancerously infiltrated. A "bird's nest" was, however, occasionally detected. The liver weighed 71 ounces. Throughout it showed secondary deposits varying from a pea to a walnut. These, under the microscope, exhibited a growth similar to that of the cæcum, the cells being especially clustered around the portal spaces, whilst the spaces themselves were almost free from the growth. In the neighbouring lobules the malignant cells had permeated everywhere separating individual hepatic cells, many of which latter had become large fat globules. There was very little inflammatory infiltration of small round cells. The right kidney lay close to the growth, but was not adherent to it. Both kidneys were granular and contracted. There were no enlarged mesenteric glands, nor was the spleen increased in size. The uterus had several pea-sized polypi on its mucous surface.

*Remarks.*—There could have been no doubt here that one was dealing with a malignant tumour which had involved the commencement of the large gut, but to decide where this tumour had first arisen was not so easy. Dr. Rickards looked upon it as a primary tumour of the cæcum, or near portion of the ascending colon. I, wrongly as it proved, was more inclined to regard it as arising primarily in the glands, and involving the gut secondarily by contiguous extension; its great size, the impossibility of defining its deep origin, and above all, its remarkable fixity inducing me to this diagnosis. The fixation was probably chiefly owing to the size of the tumour, wedging it in firmly between the right lumbar fossa and the tense abdominal wall; the adhesion to this wall most likely having been quite recent, since free movement during respiration was noted on admission. The complete absence of melæna and the small amount of bowel disturbance are remarkable, considering the large tract of gut involved and the amount of ulcerous erosion.

I have to thank Dr. Rickards for his kind permission to publish this case, and Dr. G. C. Bull, the hospital pathologist, for the *post-mortem* report.

## THE PRACTICE OF ANÆSTHESIA, LOCAL AND GENERAL, WITH ESPECIAL REFERENCE TO THE MODES EMPLOYED AND THEIR PHYSIOLOGICAL SIGNIFICANCE.<sup>1</sup>

By DUDLEY W. BUXTON, M.D., B.S., M.R.C.P.,

Administrator of Anæsthetics at University College Hospital.

It was pointed out that the desiderata of a perfect or ideal anæsthetic agent, were an absolute analgesia without the invasion of other than sensory areas. It was proposed to enquire how nearly the various members of the group of anæsthetics approached this ideal. Upon these lines it was intended to show how far the physiological behaviour of the agents brought them into the category of safe or dangerous anæsthetics. The researches of Dr. Brown-Séquard were described, in which he asserts that local application of vapours to the mucous membrane of the trachea, larynx, posterior wall of the pharynx, and in some

<sup>1</sup> An abstract of the opening address in a discussion upon Anæsthesia, before the Section of Pharmacology and Therapeutics of the British Medical Association at Cardiff, 1885.

cases to the skin of the back, is competent to produce a lasting analgesia while consciousness is unaffected. The behaviour of chloroform was then passed under review. It was shown that experimental evidence existed proving that chloroform could kill: (1) by causing spasmodic apnoea, owing to the irritation by the too concentrated vapour producing reflex closure of the larynx and paralysis of the respiratory muscles; (2) by reflexly inhibiting the heart's action, through irritation of the pulmonary endings of the vagi; (3) by accumulation of the chloroform in the blood giving rise to toxic effects on the centres in the medulla oblongata; and (4) lastly, it was pointed out that chloroform is a protoplasm poison affecting the heart muscle and nervous substances directly. Admitting that the cases in which sudden death might occur were not capable of being diagnosed beforehand, or provided against, it was pointed out that if chloroform vapour was only given when much diluted the dangers of the (3) and (4) modes of deaths were minimised. Ether, too, was capable of causing sudden death through syncope, but such cases were very rare. The greatest danger of ether was over-dosage of the blood, which, when saturated beyond a certain point, gave rise to paralysis of respiration through poisoning of the respiratory centre. Even in these cases it was pointed out that (1) ether being highly volatile, and (2) not being a protoplasm poison save in huge doses, the patients usually recovered when the chest was freed from the ether vapour by a few minutes artificial respiration. There was a danger of untoward results following upon etherisation in some cases, due to catarrh of the bronchi and laryngeal irritation. Upon the whole, it was believed that chloroform was farther from the perfect anæsthetic because its influence rapidly spread, involving areas of the nervous system concerned in controlling vital function, and because it was an active protoplasm poison. Ether, although remote from the ideal, still was less dangerous than chloroform. Methylene was referred to, and the experiments of Regnault and Villejean were cited as showing (1) that the so-called methylene dichloride is a compound of chloroform and methylic alcohol; (2) that true bichloride of methylene or methene bichloride cannot be employed as an anæsthetic, since it produces choreiform and epileptiform convulsions.

The second part of the opening address, that devoted to local anæsthesia, was owing to the shortness of time at the disposal of the section curtailed. It was contended that rhigolene had been found of service only in very minor operations, as its influence was very slight, and non-permeating. The ether spray, it was pointed out, caused pain both in freezing and thawing tissues, while it so hardened and altered the appearance of parts as to cause inconvenience to the operator.

Cocaine certainly possessed valuable properties, and had won its way to a position from which it would hardly be ousted. Even cocaine, as its action appeared to be confined to a small area, failed in affording analgesia save in minor operations.

The speaker deprecated the idea that he did not attach as much importance to the practical as to the physiological aspects of anæsthesia; he had from the great extent of the subject been compelled to confine his remarks to the physiological, trusting others would enter as fully into the practical bearings of the subject.

---

CITY OF DUBLIN HOSPITAL.—The financial exigencies of this hospital having rendered the closing of the greater part of it imperative, a commendable movement has been started by some philanthropic ladies to organise a bazaar in aid of its present urgent needs, which will be under the patronage of Her Excellency the Countess of Carnarvon.

# Medical Times and Gazette.

SATURDAY, AUGUST 22, 1885.

As a proof of the gradual enlightenment on the subject of cholera prevention which is taking place in France, it is satisfactory to learn that at the meeting of the French Association for the Advancement of Science, held last week at Grenoble, resolutions were unanimously passed condemning sanitary cordons and fumigations as useless and dangerous measures. The only precautions to be taken on the land frontiers were the medical examination of travellers, the examination of travelling carriages, and the disinfection by exposure to damp heat of linen clothes and bedding. The Association, however, declared its belief that the only way to intercept cholera was by stopping vessels from the East from entering the Red Sea. Meanwhile, there is but little abatement of the cholera in Spain. During the first fortnight of August there were 69,193 cases with 25,322 deaths, and since then the record up to the 19th inclusive of this month is 22,622 cases with 7,866 deaths. The effects of the disease have been most severely felt in the provinces of Saragossa, Granada, Madrid and Navarre, though the latest returns indicate a diminution of the number of cases in Saragossa. It is stated, and probably there is much truth in it, that owing to the excitement many cases of illness are diagnosed as cholera which present no resemblance to that disease. The strict regulations in Madrid with regard to the isolation of infected houses are causing much indignation. When a case occurs in a house no one is allowed to leave that house even to obtain food or assistance, and any friend or relative who enters an infected house is compelled to remain there and undergo seven days quarantine. Some much-needed sanitary reforms in the shape of pulling down over-crowded houses, &c., are said to be in contemplation by the authorities in Madrid. The latest advices from Marseilles show that from twenty to thirty fatal cases are recorded daily in that city, and the cholera has now undoubtedly appeared at Toulon.

DR. FERRÁN, undaunted by his rejection for the Bréant prize, is continuing his inoculations at Albacete. Dr. Ferrán appears to have misunderstood the reply of the Paris Academy of Sciences to his application for the prize, which reply was to the effect that they would require some statistics as to his results before adjudging the prize, for he undertook in the course of a week to have his statistics carefully prepared and forwarded. But this was not what was wanted, as is evident from the reply of M. Vulpian, in which it is stated that the Commission had not asked for M. Ferrán's statistics, but for official statistics emanating from the Spanish authorities. It is much to be desired that on a question like cholera, which concerns to so large an extent the whole human race, the Spanish Government should feel bound to enlighten all nations as completely as possible as to the value of M. Ferrán's vaccination.

OUR Paris Correspondent writes:—The Annual Meeting of the French Scientific Association at Grenoble has been marked, in the Medical Section, by a most interesting discussion. Dr. Chauveau read a paper on preventive inoculation of cholera, in which he loudly sounded the praises of Dr. Ferrán, whom he considers as being "placed above all criticism," as far as his personal sincerity is concerned. He attempted to dispose of the various objections raised against the principles and practice of the Spanish doctor, and concluded that "the inoculations performed by Dr. Ferrán ought to be followed with attention, notwithstanding the unscientific character of his previous studies and his present practice." Immediately after this, Professor Bouchard read a paper, summing up the data which arise from the experiments conducted in his laboratory and his hospital practice. He has ascertained that excessive contraction of the pupil is a familiar symptom of the later stages of cholera, and from this and other phenomena he draws the conclusion that uræmia has very properly been placed among the complications of cholera. He then proceeds to show that Koch's doctrine is absolutely untenable in presence of the results of clinical observation. If the morbid agent or microbe exclusively inhabited the intestinal tube, antiseptic injections ought to destroy it. Professor Bouchard administered, therefore, iodoform 1 gramme and naphthaline 5 grains daily to his patients, but without any beneficial results. He then injected into the veins of rabbits a large amount of cultivated liquid, containing an immense amount of comma bacilli: the animals died shortly, but without any symptoms of cholera, and millions of comma bacilli were found in their tissues. The death of these animals is therefore due to the presence in large quantities of this bacillus, but not to cholera poison. By heating the liquid previous to injection to a temperature of from 112° Fahr. to 212° Fahr., the bacilli are destroyed, and injections with this sterilized liquid prove innocuous. Now if any chemical poison existed in the injected substance, it would not have been destroyed by a temperature of 212° Fahr. On the other hand, the injection of the urine of patients affected with cholera kills rabbits, with all the symptoms of the confirmed disease, viz., diarrhœa, cramps, lowering of temperature, albuminuria, and lastly, suppression of urine. The diarrhœa, although similar in appearance to that of cholera, contains no comma-bacilli.

FROM these facts Professor Bouchard draws the conclusion that the poison of cholera is eliminated by the urine and not by the stools of the patient, and that Koch's bacillus has nothing to do with the production and propagation of cholera. An animated discussion took place between Messrs. Chauveau and Bouchard. The issue in point can only be solved by direct experiments, and, strange to say, Dr. Chauveau had not made any. He explained this by expressing the fear that he might have been charged with propagating cholera by experiments of this kind. Such an objection, if allowed to prevail, would knock the science of bacteriology on the head, and would do

more for the cause of anti-vivisection than all the labours of Miss Cobbe.

WHAT is the essential nature, and what are the causes of cholera? Dr. John Chapman could not have chosen a more opportune moment for once more laying before the public his views on the answers to the above questions than the present. In great measure this, his latest essay on the subject entitled "Cholera curable," is a recapitulation of what he has stated in one form or another on several occasions during the last twenty years, supported and endorsed by the accumulated experience of that period, and especially by the outbreak in Paris last year. Dr. Chapman's thesis is that all the symptoms of cholera are due to simultaneous and abnormal superabundance of blood in, and excessively preternatural activity of, both the spinal cord and the sympathetic nervous centres, and he maintains that this proposition affords a clear and consistent account of all the phenomena of cholera, and indicates how it may be successfully treated. Amongst the remote predisposing and exciting causes Dr. Chapman awards the first place to solar heat. This, in his opinion, acts directly by producing that condition of superabundance of blood associated with great excitement which is the immediate cause of the phenomena. The theory of some blood poison engendered by the heat does not at all commend itself to him. Among other causes bad food, eating to excess, alcoholic drinks, opium, purgatives, and impure water are all competent to conduce to cholera. Fear, again, as he says, is well known to be a potent cause of cholera, and this is intelligible on his hypothesis of its nervous origin, but quite inconsistent with the theory of an organic poison or a microbe.

DR. CHAPMAN is in entire accord with Indian authorities in believing that cholera is not a contagious disease, and he discusses at considerable length Koch's views on the comma bacillus, as well as those of the opponents of the bacillary origin of the disease. The way he disposes of the fact that Koch's comma bacillus presents differences in regard to cultivation from other comma bacilli, is not the strongest part of his argument, and he would have done wisely, perhaps, if he had left this subject alone, for he says a comma bacillus bred in and fattened on cheese, and one produced in the lower part of the human intestine, may so resemble each other in appearance as to be indistinguishable; "but they must need, I imagine, to be elaborately 'educated' before they can exactly resemble each other in manners and general deportment. Probably, however, appropriate 'cultivation' during two or three generations, would render them in all respects identical." Last year Dr. Chapman had the satisfaction of seeing his views confirmed by the Marseilles Commission, who arrived at the conclusion that the nervous theory of cholera is that which best explains its physiological pathology. In regard to prevention, the chief thing to be done is avoidance of all the enumerated causes at all seasons of the year, and, though he does not believe in its communicability from the sick to the healthy, Dr. Chapman gives a word of caution against

unnecessary exposure to insalutary influences which are more than ordinarily dangerous during a cholera epidemic. As regards medicinal treatment, Dr. Chapman holds that purgatives, especially castor oil and calomel, and sulphuric acid are positively dangerous, whilst from the bromides of potassium and ammonium he thinks some benefit might be expected especially during the algide stage, and, at any rate, he holds that they would not do any harm; but the treatment which he especially recommends, as based on his theory of the disease, consists in the application of ice to the spine by means of elongated bags. During the epidemic in Paris, by the courtesy of Professor Peter, he had the opportunity of trying this treatment in twelve cases with the very encouraging result that ten recovered. We earnestly hope that if any cases of cholera should occur in this country this very simple, inexpensive, and rational line of treatment will receive a fair trial.

THE *Lancet* has not taken up a wise line in reference to the Washington Congress. It has either been misinformed as to the facts and the importance of the unfortunate dispute now going on in America, or else it has wilfully shut its eyes to them. It is absurd, for instance, of the *Lancet* to attempt to minimize the differences which have caused the withdrawal from the Congress of almost every man of mark in America. The fact that nearly every medical journal of any repute in the United States has vigorously condemned the action of the American Medical Association, and given its warm support to the men who are contending for the freedom of the profession against the selfish designs of a clique, should in itself have induced the *Lancet* to give a little more attention to the question before taking the wrong side with such a light and careless heart. The sole fact that seems to weigh with the *Lancet* is that Dr. Flint has been appointed President of the Congress, or rather that his original appointment has been confirmed by the new Committee. Dr. Flint's is no doubt a powerful name to shelter oneself behind. He is incontestably one of the most eminent representatives of the profession in the United States, and it has been a source of profound sorrow to those who have felt constrained to withdraw from the Congress, that in doing so they have had to part company with him. But we cannot blind ourselves to the fact that Dr. Flint, eminent and honoured as he is, has in the present instance allowed himself to be made the instrument of a minority. The part which Dr. Flint would take in this lamentable strife has been foreseen and discounted. The men of Boston, Philadelphia, and Baltimore who withdrew from the Congress knew that he would not follow them. The fact is that Dr. Flint is bound up with the American Medical Association, and an honourable feeling of loyalty no doubt constrains him to accept its decisions, however much he may deplore them in his secret heart.

If the British Medical Association—a body five times more representative of the English profession than the American Medical Association is of the profession in the United States—had played the same part

in reference to the London Congress that the American Association is attempting to play in connection with the Washington Congress, the *Lancet* would not have been able to find language strong enough to use in condemnation of such action, and we are simply at a loss to understand the reasons which have actuated its present policy. Surely the *Lancet* cannot have realized the fact that the American Medical Association, *i.e.*, a body representing only 10 per cent. of the profession in the United States, has decided that no American practitioner shall be admitted to the Congress who is not either a member of the Association or a delegate appointed by a State or county medical society. In other words, if the American Medical Association has its way, between thirty and forty thousand American practitioners will be kept as much outside the Congress as if they were not medical men at all. Is the *Lancet* prepared to give its support to a narrow and illiberal innovation of that sort? Would our contemporary be surprised to learn that this question of principle will henceforward form the main ground of conflict? It may be answered that any American practitioner can purchase the right to become a Member of the Congress by joining the American Medical Association. True, but will the foreign visitors let the Congress be thus turned into an instrument for forcing men to join the Association who would not join it of their own free will? It is evident that on this question all the leading men who have withdrawn from the Congress will be on the same side with the thousands of practitioners who are at present outside the American Medical Association. And on the other side whom have we? Dr. Flint, the wire-pullers of the Association, and the *Lancet*.

WE are very sorry that our contemporary has committed itself to that side, which everyone who knows the facts and judges them with sobriety must admit to be the wrong one. Its American readers will scarcely welcome such ill-timed and ill-instructed advocacy. The only hope for the Congress lies not in a postponement of disputes till after it is over, but in an unconditional surrender by the American Medical Association of the position which it has so unwisely taken up, and in the rehabilitation of the original committee. On these points, we believe that the leading men who have retired from the Congress are unanimously determined, and will admit of no compromise. If they still stand aloof, there will be no Congress in spite of the *Lancet's* confident prophecies. Our contemporary seems hardly to realise the extent and importance of the withdrawals. To take one section alone, that of ophthalmology, not more than four or five men of any reputation are left on it. Dr. Agnew, Dr. Knapp, and Dr. Jones, of Chicago, have been removed from their offices by the new committee of the American Medical Association, while Drs. Thomson, E. Williams, Burnett, Derby, Norris, Seely, Theobald, Wadsworth, and H. W. Williams have all declined to hold office in connection with it. A similar state of things prevails in almost every other section, so that unless the practitioners who have withdrawn can be induced to return, the European guests who go to Washington in 1887 in search of

scientific discussion will have to provide it for themselves. Under such circumstances, we doubt if many will care to encounter the discomforts of the Atlantic passage.

THE sanitary authorities of the Borough of Windsor have been much perturbed of late by the persistent publication of certain statements in a local magazine, edited by a leading clergyman in the town, with respect to the unsanitary condition of certain quarters of the borough. The Reverend Editor is trenchant in his attacks, and puts forward the facts which he claims to be able to support with a force and courage worthy of the Church Militant. In last week's number of the *Lancet*, there appeared the report of a Special Commission on the sanitary condition of Windsor, in which his statements are not only supported, but very considerably amplified and added to. The reception which this report has received in Windsor has been remarkable. The residents, jealous of the reputation of their town, would have their medical advisers combine to take action against such calumnies. The medical practitioners of Windsor, on the other hand, refrain from any such policy, and bid their indignant fellow-townsmen to look more closely into the matter.

By a report of a meeting of the Windsor Town Council acting as the Urban Sanitary Authority, held on August 12th, it is made clearly evident that the insanitary condition of those parts of the town to which their energetic pastor has called attention, has been known to that august body for several years past, and that the defects which have been repeatedly brought to their notice have never been remedied. The report is a gem of its kind. Written with the apparent object of utterly confounding the reverend gentleman's allegations, it remains to bless them altogether, substantially confirming them in almost every particular. We gather from it that in one road a collection of manure is rendering life unpleasant to the inhabitants, that in another the drains are of an old and obsolete pattern, and that some of the houses have been well known to be without closet accommodation since July, 1883, that a ditch which runs in the town has been for two years a proclaimed nuisance, that there are houses which have no back premises the inhabitants having to cross the street to the back premises of the houses opposite for all sanitary purposes, and many other unpleasant facts, all pointing in the direction of persistent and obstinate neglect, not on the part of the medical officer, who has evidently made numerous reports, but on that of the superior authority to whom such reports have been made.

It is only fair to Dr. Casey, the Medical Officer of Health in question, to note the following facts. During the last five years there has been but one death from enteric fever and an epidemic of measles only. The "poisonous ditch" to which reference has been made is upon Crown property, and was reported upon by him two years ago, but his report has been neglected by the Crown authorities. The by-laws and defective

water-closet accommodation have been for some time under consideration, and new regulations including the abolition of dustbins are in process of being enforced. No complaint as to impure water has hitherto been made, but he has condemned and caused several public wells to be closed during his tenure of office. The fact that the general death-rate has been about 20.0 per 1,000, and that the town has been singularly free from infectious diseases, must also be taken into consideration. In fact, the most substantial charge on the part of our contemporary seems to be the want of a fever hospital, and we understand that a piece of land has been acquired for this purpose for a temporary building in case of necessity.

THE deaths in London last week having been 151 below the average, there has been a proportionate drop in the death-rate, which has fallen, as will be seen from our chart, from 22.0 to 18.8. The chief cause of the diminished mortality is undoubtedly the lessened number of 'deaths from diarrhoea, under which head 222 deaths are recorded as against 348 and 309 in the two previous weeks. From small-pox there were 15 deaths, and the number of patients under treatment at the end of the week had fallen to 399. The fall in the number of deaths from

The upper line represents the general death-rate and the lower line the zymotic death-rate per 1,000 in London for the past ten weeks.

measles continues, but they reached 49 last week, being only 8 more than the average. Diphtheria and enteric fever each claimed 13 victims last week, and scarlet fever only 9. The weather was on the whole fine, the mean temperature of the air was 59.6°, or 2.9° below the average, and 48.4 hours of sunshine were recorded. In the provinces measles still hangs about Liverpool, where 16 deaths were recorded. The diar-

rhœa epidemic has nearly exhausted itself at Leicester, but has made terrible havoc in Liverpool, Birmingham, Manchester, Salford, Preston, Leeds, and Sheffield.

At this season of the year, as a rule, complaints are wont to be made on the subject of river-pollution, and the present season forms no exception to the rule. This year it is the Wey which has attracted most attention. One of the complainants describes it as a filthy ditch, and speaks of the water as of an inky colour and highly offensive. This was too much for the Mayor of Godalming, who forthwith rushed into print to denounce the anonymous detractor of the Wey, and to assure his readers that on a recent occasion when a navigation commission had made their annual inspection of the river they had unanimously agreed that the water was free both from colour and smell. But so long as a considerable portion of the sewage from Guildford and other towns passes into it, and this is admitted to be the case by the Mayor himself, he must not be surprised if complaints of this kind arise, even though it can be shown, as in the present case, that most of the apparent contamination is due to chemical and mechanical impurities from tanneries and a paper mill.

THE pestiferous condition of the River Lea below Tottenham has been the subject of indignant comment in the daily press for some weeks past. Shortly before the close of the Session a question on this subject elicited from Mr. Balfour the encouraging, but scarcely satisfactory reply, that permanent works for so dealing with the Tottenham sewerage as to abate the nuisance had been sanctioned, and that in the meantime temporary measures towards the same end were being undertaken. Some idea of the abominable state of the water and of the exhalations which rise from it may be gathered from the fact that boating has been so generally abandoned that the boat-masters, who are compelled to pay a licence of ten shillings per annum for every boat they have afloat, complain that many have not earned that amount; while the members of the various rowing clubs declare that a race "cannot be decided on aquatic merit so much as on the capacity for existing in the atmosphere of a sewer." Nowadays, the utmost which can be reasonably demanded in the case of a river running through a populous district is that its water shall be clear, odourless and bright, and at least so little impure that fish can live in it. The state of the lower Lea is now a scandal and a danger, as well as a cruelty to the large number who have been accustomed to find a means of pleasant and healthy recreation on its waters. It is intolerable that the filthy steam which no one would think of drinking should be permitted to rise from its bed to poison the air that is breathed by those who are compelled to live in its neighbourhood, and who would fain enjoy the health-giving pleasures which it was once capable of yielding.

OUR Vienna Correspondent writes: The four candidates for the extraordinary professorship in the University of Vienna, whose election has occupied the

Vienna "Professoren Collegium" for a longer time than one might fairly have expected, on account of some formal objections on the part of the Minister of Education, have at last obtained their well-merited promotion from the Minister of Public Instruction. In other words, the election of Professors Wölfler, Hofinskl, Ultzmann, and Mauthner has been confirmed by the Minister of Education and the Emperor. I will take this opportunity of giving your readers some details of the career of the two younger of these new Professors, one of whom comes into close relation with those of your fellow countrymen who come here for improvement in practical surgery. I allude to Professor Anton Wölfler, the late assistant to Professor Billroth, and as he has been justly termed in your Journal, the distinguished Professor's right-hand man. Professor Wölfler is one of our youngest extra-ordinary professors, having obtained his professor's degree at the age of 34. He was for ten years assistant to Professor Billroth, a quite exceptional circumstance considering that the appointment of clinical assistant usually only runs for four years. In 1881 Dr. Anton Wölfler became Privat-Docent, and both as a simple assistant as well as a Privat-Docent he had the most crowded private courses; his propædentic courses, his courses on operations and ligatures, attracted both Vienna and foreign students, who confessed that besides his technical skill and his sound knowledge he also possessed eminent gifts as a teacher. His literary activity dates from 1876. He has written on hydro- and pyonephrosis, proving that chronic hydronephrosis was caused by the formation of valves; on the treatment of the fistula of the stomach and on gastrorrhaphia, and, indeed, much of his later work deals with operations on the stomach and intestinal canal. When Billroth successfully performed his first resection of the pylorus, in 1883, Wölfler published a book on the subject which has been translated into English, Italian, and Russian. The method of suturing the stomach and intestine which is called by his name has been generally accepted and recently discussed by Gussenbauer. In cases where resection of the pylorus cannot be performed Wölfler has proposed to unite the stomach with the intestinal canal; in such cases he proposed making a communication between the stomach and the intestines, the so-called gastro-enterostomy which has since been carried out with success by Billroth, Rydygier, and Lücke in cases of cicatricial stenosis of the pylorus; the importance of this operation in stenosis of the intestine was discussed in 1883 at the Surgical Congress at Berlin. Your readers may remember that Professor Billroth, at the Society of Physicians of Vienna, recently described the operation as an "ingenious idea." In 1882 Dr. Wölfler published an elaborate monograph on the treatment of carcinoma of the tongue. The histology of the thyroid gland and goitre have also been dealt with by him in two large volumes; a third volume on the treatment of the goitre is about to appear. Recently Wölfler has devised a new method of suturing tendons which has been proved practicable, and another method of dealing with the amputated stump of the uterus after the removal of fibromata by laparotomy. These very important contri-

butions will be sufficient to illustrate the great and fertile services of our new professor who, as a pupil of Billroth's, may justly rank with other pupils of the eminent professor, Czerny, of Heidelberg, and Miculicz, of Crakow.

MEDICAL chemistry, which is taught in Vienna, in the "Pathological Institution" attached to the "General Hospital," is very well officered in Vienna by Professor Ludwig and by his assistant, the newly elected Professor Mauthner, both Professors of the Medical Faculty. Julius Mauthner was born in Vienna in 1852, and entered the University in 1870. As early as 1871 he obtained a post in the laboratory of Professor Ludwig, and in 1876 he became his assistant. Dr. Mauthner, having obtained the grade of "Privat-Docent" of medical chemistry, obtained in 1879 permission to make a year's tour through Germany, in the course of which he enjoyed many opportunities of enlarging his knowledge. He spent his year at the Universities of Strasbourg and Munich, working in the laboratories of Hoppe Seyler, and Voit, and attending their lectures and those of Professors Schmiedeberg, Kundt, and Pettenkofer. Subsequently, Mauthner returned to the laboratory of Professor Ludwig, whose assistant he is still. He also worked in the physiological laboratory of Professor Brücke, and, on being elected Privat-Docent, delivered lectures on a departmental medical chemistry which gave full satisfaction. The works he has published bear both on medical chemistry and on physiology: they are, "The Maternal Circulation in the Placenta of a Rabbit;" "Contributions to our Knowledge of Neurin," and on "The Effect of the Neurin on Albuminoid Bodies;" "Chemical Examination of the Springs of Carlsbad" (published with Professor Ludwig); "On the Influence of Ammonia on Chinon-like derivatives of Naphtol" (with Professor Ludwig); "On the Propion Bromide and Acryl Acid," and also "On the Methods of Detecting Prussic Acid in Legal Medico-legal Examinations" (with Professor Ludwig); "On the Rotatory Polarization of Cystin and Tyrosin;" "On the Behaviour of Naphtol in the Organism after its application to the Skin"; "Precautions against Errors in cases of Poisoning by Arsenic." Professor Mauthner has also written on the determination of the presence of atropine in a corpse which had been buried for eight months. The Vienna "Professorencollegium" has had it in its power to reward the services of Dr. Mauthner, awarding him besides his professorship a yearly grant of one thousand florins. The ability of Professor Hofinskl in general surgery, and that of Professor Ultzmann as a urologist is also well-known, so that it may safely be said that the Vienna Medical Faculty has considerably strengthened its hands by electing four such extra-ordinary professors.

OWING to recent changes brought about by death or retirement in the higher ranks of the German Universities, a considerable redistribution of professional seats has been taking place of late. The vacancy caused at Würzburg, by the migration of Professor Gerhardt to Berlin, has been filled by the appointment

of Professor Teube, of Erlanger. The chair of anatomy, so long occupied by Henle, at Göttingen, will for the future be taken by Professor Merkel, of Königsberg, who will be succeeded as Professor of Anatomy in the latter University by Dr. Stieda, of Dorpat.

THE medical and other students of Dorpat University have honoured Prof. Bunge on his departure for Basle by a torchlight procession and a farewell oration by Student of Medicine Epstein. The seniors acknowledged their interest in the departing professor by a farewell dinner.

PROF. STIEDA, of Dorpat, has been chosen (his being the first of three proposed names) as Professor of Anatomy at Königsberg.

THE arrangements for the opening of the Metropolitan Medical Schools appear to be now complete. At St. George's, the introductory address will be given by Mr. Timothy Holmes; at St. Mary's, it will be given by Mr. Pepper; at King's College, by the Bishop of London; at the Middlesex, by Dr. Fowler; at St. Thomas's, by Mr. MacKellar; at University College, by Professor Schäfer; and at the Westminster, by Mr. Cowell. At St. Bartholomew's, Charing Cross, Guy's, and the London, the session opens without any introductory address.

THE *London Gazette* of this week announces that Her Majesty the Queen has been graciously pleased to confer the Albert Medal of the Second Class upon Edward Charles Thompson, M.B. Univ. Dubl., Surgeon of the Tyrone County Infirmary, for conspicuous heroism displayed in endeavouring, on the 4th of April last, to save the life of a child named Herbert Mitchell, suffering from diphtheria.

ON Tuesday, the 18th instant, in the Belfast Police Court, John R. Thompson was brought up in custody, charged with having forged a medical certificate purporting to emanate from the Royal University of Ireland. The certificate represented that Mr. Thompson passed a matriculation examination as a medical student in the University in October, 1880, and was signed apparently in the usual way by the secretaries of the University. The Royal University was incorporated in April, 1880, but its first examination was not held until December, 1881, so that the non-genuineness of the certificate became at once apparent. The case is not yet decided, the accused having been remanded for a week on bail, himself in 200*l.* and two sureties in 100*l.* each. Meanwhile, we may direct attention to a very reprehensible practice which prevails in the secretarial department of the Royal University, of the official signature of the secretaries being made by means of a stamp. This should certainly be put a stop to.

By the death at an advanced age of Dr. William Walker, one of the most distinguished of our professional brethren in Edinburgh has passed out of sight. For 33 years he served as oculist to the Royal Infir-

mary, and he had the honour of being oculist to Her Majesty in Scotland. Some years ago he filled the office of President of the Royal College of Surgeons, and it was only a short time since that he finally retired from his hospital appointments.

THE latest, though probably not the last of the numerous lunacy trials that have recently arisen, has terminated as all must have foreseen who were at the pains to follow the evidence. The charges brought against Dr. Crosskey by Mr. Hillman were practicably reducible, as was pointed out by Baron Huddleston, to the one charge of want of due care in signing the certificate of his insanity. And yet when the facts were elicited it appeared that the very opposite was the case, and that Dr. Crosskey had exercised especial care in drawing up his certificate, and had not entered in it certain matters on which the plaintiff had spoken to him because he had no evidence as to their truth or falsity. No lack of *bona fides* was or could be imputed to Dr. Crosskey, who had known the plaintiff for many years, and could have had no possible motive for wishing to make out that Mr. Hillman was insane when he was really sane. And had the case rested there, with the unsupported evidence of plaintiff and defendant in flat contradiction, there can be little doubt that the verdict must still have been for the defendant. But seeing that Dr. Crosskey was able to produce nearly a score of witnesses, many of whom had known the plaintiff for a long time, and who all swore that they had independently from his acts and words arrived at the conclusion that the plaintiff was insane within a few hours of the certificate being signed, the prompt decision of the jury in his favour was natural. Of course this case is quoted as an instance of the need for the reform of the existing regulations as to lunacy certificates, but after all, in this particular instance, the medical man only gave effect to what was practically a popular verdict, and it is pretty certain that the same result would have been arrived at under any statutes where the decision was allowed to be influenced by common sense and not red tape.

A FORTNIGHT ago we called attention to a speech of Dr. Angus Fraser's, in which very serious charges were brought against the managers of the Aberdeen Royal Infirmary. The committee of management having demanded some explanation from him, that gentleman has lost no time in supplying overwhelming evidence in support of one of his charges, viz., that relating to the deficient nursing arrangements. Not to mention occurrences which took place some time ago, we notice that in the middle of last July one of the surgeons to the Infirmary received a message from the house-surgeon that secondary hæmorrhage had taken place in an amputation case. On arriving at his ward soon after the receipt of this message, the surgeon in question found the patient collapsed and pulseless, but no house-surgeon, or nurse, or anyone in charge of the patients. More recently still, Dr. Fraser paid a visit to the wards on a Sunday

morning between ten and eleven in the forenoon, and going through nine wards (six medical and three surgical), found a nurse present in only one. Such a state of things is scandalous, and if these facts do not justify a hospital physician in bringing forward charges of gross neglect against the authorities, we are at a loss to conceive of any degree of laxity that would do so. This mis-management is already bringing about its inevitable result, viz., that the poorer classes of the population are losing faith in the institution, for Dr. Fraser states that two of the largest employers of labour in the city have informed him that in consequence of the unsatisfactory internal arrangements of the Infirmary, they find the utmost reluctance on the part of their work-people to avail themselves of its benefits. Now that the managers have brought upon themselves this public condemnation and overwhelming proof of their shortcomings, we may hope for speedy and effective measures of reform.

SOME of the remarks made by Mr. B. Hicks in the course of an inquest held by him last Monday at Ham, will come as an unpleasant revelation to some local dignitaries. The corpse had been recovered from the Thames on the previous Friday morning in that advanced stage of decomposition which is usual after nearly three weeks immersion in the water at the present period of the year. It was carried for two miles on a grocer's cart, and was then deposited in the stable of a public-house, close by the road-side, on wooden trestles, without a shell, and covered only by a cloth, the nearest mortuary being at Kingston, some four miles distant. It was under these circumstances that the *post-mortem* examination was made. The body was viewed by a jury, who expressed the not astonishing opinion that its presence there "was enough to cause an epidemic in the locality." After commenting on these disgraceful revelations, and ordering the immediate removal of the body to the Kingston mortuary, the coroner pointed out that publicans are not bound to take in a body, and that when they refuse to do so the legal place of deposit is the house of the churchwardens; adding that "it would be a good thing for the parish when a body was taken to their house." It is very likely that churchwardens are not always the chief or the only opponents of sanitary reform within their district. But it certainly seems probable that, other and milder arguments failing, the bringing of an evil thus literally to their own doors would prove a very effectual means of rousing their energies and of directing their influence towards securing within their own neighbourhood adequate provision for treating the dead with decency, and for protecting both the feelings and the health of the living from needless outrage.

CAPITAL punishment possesses some Circean attraction for the amateur philanthropist. Those who are not prepared to abolish it altogether, are anxious to so modify its methods as to replace the deterrent image of grim death by the almost seductive oblivion of a judicial euthanasia. To this end the mysteriously subtle power of electricity has been oftentimes invoked.

An English surgeon recently recommended that as the condemned criminal left his cell "a powerful current should be turned on" to a brass plate let into the floor of the corridor, so as to substitute a rapid and painless demise for the horrors which have now and again even recently disfigured the ghastly operations of the hangman. The idea was doubtless conceived in a kindly spirit, but the directions are too vague to be of much practical value; and good authorities are as doubtful as men who have not themselves submitted to the *experimentum crucis* can well be, as to whether death by electricity is by any means the painless process which the popular mind conceives. A more merciful method is suggested by an American physician, who suggests the "hypodermic administration of morphine as a substitute for hanging in the execution of criminals;" taking the ground that while hanging is often rapid and painless, it is sometimes slow and cruel; and being of opinion that the medical profession should suggest to the State a method of killing free from objectionable features. This last idea is, we fear, impossible of realisation. The morphine plan would certainly fulfil some of its requirements; and it is scarcely probable that the most calculating criminal would set to work to contract and foster the "morphia habit" with the view of rendering himself physiologically unable to pay the last debt of justice in the manner legally prescribed. But it is not well that any suspicion of secrecy should enter into the administration of public justice; and the law of this country would assuredly and rightly look askance at the suggestion that it should even seem to adopt the methods of the prisoner.

TRAVELLERS by the underground railway have been almost daunted into accepting partial asphyxia as a part of the price which must be paid for a convenient means of locomotion; and custom, after a while, makes it almost tolerable to many. Yet even the most optimist of cockneys, if any such there be, is apt to be roused to temporary wrath when he journeys over that specially brumous section of the line which extends between Gower Street and Baker Street for the first time after his senses have been purified and strengthened by a few week's sojourn in real country air; and for the nonce even he realises something of the evils to which thousands of his fellow-creatures submit every day almost without complaint. The hardened frame of the adult may indeed bear repeated temporary exposure to these conditions without appearing to suffer very much therefrom. But this can scarcely be true of children. Perhaps it is only because their elders have become habituated to the evil that its influence upon the large and increasing number of young children who now regularly travel in this manner has hitherto escaped special comment. At certain hours of the morning and afternoon school-children from eight and nine years of age and upwards form a very large proportion of the passengers; not a few of them may be observed studying the school-books which they are carrying to or from home—and this, too, under anything but favourable optical conditions. Surely, if we have grown too lazy or too dis-

heartened to try to help ourselves in this matter, we might be stimulated to make some united effort for the improvement of conditions which we admit as injurious to ourselves, but which must be infinitely more pernicious for the young who are ignorantly and helplessly subjected to them. The condition of some parts of the underground railway is a reproach to the rich city which boasts of its possession. The difficulties which would attend its adequate ventilation are not so great as those which have been successfully solved in the case of many a deep and extensive colliery; and there is no sufficient reason why these should still be allowed to interfere with the comfort and to impair the health of a huge travelling population.

TWELVE months ago a new departure in medical literature was inaugurated by the establishment of an International Centralblatt, having for its object the record of *all* work published in the medical world upon the subject of Laryngology and of diseases of those other parts adjacent to the larynx which by silent assent have become recognised as appertaining to the range of the throat specialist. Edited by Dr. F. Semon in London, and published by Hirschwald in Berlin, the work which started with but modest pretensions has obtained a greater measure of success than was anticipated even by its editor. It is only when an attempt is made to collect together the complete current literature on a single subject that an idea can be obtained of the vast amount of writing that is continually being poured forth for the benefit, or otherwise, of those who are specially interested in it. Thus it happens that in the case of this Centralblatt, its projected size has in many monthly numbers been far exceeded, and still the mass of literature to be dealt with steadily increases. Although receiving a well-merited measure of support on all hands, it is obvious that the calculations which regulated the working expenses of a small work are not applicable to the maintenance of a great one. At the close of the present year, ending in June next, it is proposed to increase the price of the Journal in order to meet the extra expenditure which its size involves. We do not anticipate that the numerous subscribers, who by their co-operation have already endorsed the value of the work, will object to render this additional aid in the cause to which they are most of them devoted.

THE latest pamphlet of the National Health Society is from the pen of its chairman, Mr. Ernest Hart, and is entitled London Old and New. In it, Mr. Hart with his wonted felicity reminds us of the insanitary state, in so far as all domestic arrangements were concerned, in which for centuries our forefathers were content to live. A thousand years ago the houses were of the roughest kind, and the furniture, including the beds and bedding, of the most crude description. In the twelfth century the subject of drainage had already become a public question, and from that time onwards regulations were at various times passed for the efficient cleansing of the Wall Brook, the Fleet,

and the other streams that served to convey the surface drainage to the river. The refuse of the slaughter-houses appears to have been a source of nuisance from very early days, and many ordinances were passed with intent to repress it. Gradual changes in the system of drainage necessitated by the constantly increasing population led to the conversion of the Fleet ditch into a sewer, and finally to the establishment of the present system, whereby three main sewers on each side of the Thames carry all the sewage of London to be discharged into the Thames some miles lower down. In conclusion, Mr. Hart points to the comparative mortality as the best proof of the efficacy of the various measures for improvement. From 1620 to 1643 the mortality was 70 per 1,000, for 1728-1757 it was 52, for 1800-1810 it was 29, and for the four years of the current decade it is 20.9. Notwithstanding this, however, there is plenty of work for the National Health Society to do, in combatting dirt, disaster and disease in our over-populated metropolis.

At the Royal College of Physicians on Tuesday last, the interest of the Bradshawe Lecture and the personal attributes of the Lecturer combined to bring together into the small theatre an audience which would have been thought numerous at one of the Spring Lectures, but which was quite phenomenal during the latter weeks of August. But the endurance displayed by this audience was even more phenomenal than its numbers. For the space of 55 minutes these devoted gentlemen, including in their ranks the President and most of the permanent officers of the College, quietly submitted to a slow development of the early stages of suffocation without allowing a murmur of discomfort to escape them, and without any attempt to remedy the evil by the admission of some less polluted air through the medium of an open door. Dr. Goodhart must indeed be gratified that his earnest and thoughtful address was able to prevail against the feelings of approaching asphyxia under which all his hearers were labouring. But such a state of things is little short of scandalous. Why should the authorities permit within their own walls an evil which they are never weary of condemning when it is found within those of their neighbours? The Fellows, if it so please them, are at liberty to hold their meetings or lectures in an attic, which is only accessible on the one side by a circuitous back stair, and on the other by a chicken-ladder. But having invited the attendance of their Members and Licentiates they are not at liberty to deprive them of respirable air. It is not long since that the President took occasion to deplore the small attendance at the College Lectures. So long as they are delivered in the present den he might well congratulate himself that there is any attendance at all.

WE desire to call the attention of our readers to the announcement respecting medical registration, which appears in our advertisement columns. It contains the annual reminder to members of the profession that it is their duty to give notice of any change of address, and to reply to any letter of enquiry from the Branch

Office, under penalty if they neglect either of these things of finding their names removed from the Register. It must be obvious to anyone that it is quite impossible that the Register should be accurately kept, if those who are on it do not keep the Registrar duly informed of their whereabouts, or give any sign of continuing existence when appealed to by letter; and as the Register is the official roll of the profession, it is needless to insist on the necessity of its information being true in every particular. Those whose names have been removed in accordance with the above clauses, can be restored to the Register by making application to their Branch Registrar.

#### THE BRADSHAWE LECTURE AT THE COLLEGE OF PHYSICIANS.

THE lecture delivered on Tuesday last by Dr. Goodhart was true to its title, and well adapted to the occasion. Chosen to fill the place of the late Dr. Mahomed, whose early loss the profession so deeply deplores, Dr. Goodhart did well to select the subject of arterial tension which Dr. Mahomed so indefatigably worked at and advanced in no small degree. The lecture was strictly a review, and as such more suitable to occupy the single available hour than an attempt, however condensed, to present the result of any original work. Such a review could not have been in better hands than Dr. Goodhart's, at once a friend of Dr. Mahomed, a member of the Staff of Guy's which has contributed so much to our knowledge of the subject of renal disease, and a learned and thoughtful physician and pathologist. The shortness of the allotted time was enough to account for this review being almost entirely a criticism of the relationship between arterial tension and Bright's disease, rather than a consideration of such tension in its wider aspects; but if further justification were necessary, it would be found in the fact that it was especially in its connection with renal symptoms that this question was studied by Dr. Mahomed.

The lecture was introduced by an earnest tribute to the memory of Dr. Mahomed, marred only, in common with some other parts of the oration, by somewhat obscure and laboured rhetoric, quite out of harmony with the author's usually clear and simple style. Dr. Goodhart then addressed himself to a criticism of the two well-known theories as to the pathology of Bright's disease—the stop-cock or spasmodic hypothesis of Johnson, and the "general fibrosis" of Gull and Sutton. In rejecting the first of these notions, Dr. Goodhart, among other arguments, laid stress on the *a priori* unlikelihood of the action of the muscular coat of the arterioles being in antagonism to the cardiac function, and called the effects of digitalis to his aid in supporting the view that its function is that of propulsion, not retardation of the blood-current. This same *a priori* method of reasoning was adduced as favouring, in this instance, the view that the muscular coat is really hypertrophied in the affection under discussion. More work is thrown on the structure, urged the lecturer, and it *must* get thicker

whether it can be always demonstrated to do so or not. It is not everyone who can safely handle such a method of argument in pathology, and there are those whom we should distrust had they said, as Dr. Goodhart said, that the appeal to demonstration, and to demonstration only, is too absolute in the present day. But, within limits, and checked by sound knowledge, sober argument on *a priori* grounds is not only permissible, but even necessary, and we freely admit that Dr. Goodhart is justified for his enlightened use of it here. Similarly, when treating of the arterio-capillary fibrosis theory, and styling it "a magnificent scheme of decay" which the true romance of pathology cannot afford to lose, Dr. Goodhart said the idea was a suggestive one, and largely true. But it was true, not owing to there being much force in the microscopical observations on which it is but apparently founded, but rather from being based on what the lecturer somewhat riskily called the "intuition of experience." The excellent remarks which followed in criticism of this theory, showing how far it is applicable, and when it fails to be sufficient, must be read in full in order to be appreciated. That some cases of chronic renal disease are primarily renal was Dr. Goodhart's distinct opinion, which few, perhaps, will dispute. But he was equally clear that Bright's disease of the kidney is often a part of a general degeneration. Though much was to be said in favour of the view, expressed long ago by Dr. Walsh, and emphasized by Dr. Mahomed through his sphymographic observations, that Bright's disease is primarily a blood, not a kidney affection, and that an altered vascular condition precedes the albuminuria, it was urged that in some cases there might be a visceral failure at first, and that an undiscovered cause of "renal inadequacy" might possibly be the earlier link in the morbid chain. On the whole, the lecturer inclined to the theory of arterio-capillary fibrosis, on grounds more collateral than direct, and emphasized the fact that the subjects of Bright's disease were apt to suffer from many symptoms other than renal. On the other hand, he reminded his audience of the very frequent discovery of granular kidneys in the *post-mortem* room.

In some very short remarks at the close of his lecture, Dr. Goodhart touched on the subject of increased tension in the pulmonary circulation, and drew notice to the fact of dilatation of the pulmonary artery in cases of obstructed circulation in the lungs, whether occurring in emphysema, mitral disease, or other chronic affections. This may happen, he said, in various degrees; and the exciting cause may not always be discoverable *post-mortem*. This passing glance at a very interesting matter was almost disappointing, unavoidable as it doubtless was. But the subject is important enough, and not the least in its possible relation, as was suggested, to anæmia, for us to hope that we may hear Dr. Goodhart further upon it, perhaps at some future time when he speaks again to the College of Physicians.

## THE REPORT OF THE ARMY MEDICAL DEPARTMENT FOR THE YEAR 1883.

### [SECOND ARTICLE.]

WE are aware that many advantages have been claimed for foreign service now that short enlistment is the rule. Men and boys of all classes are supposed, for example, to benefit by travel, and the opportunities of seeing many cities and varieties of mankind. In the days of long service, soldiers hardly had much time, after getting their discharge, to avail themselves at home of the knowledge acquired abroad; since it sometimes happened that a regiment serving in India for twenty years or more on a stretch, brought back only half-a-dozen of the rank and file who were serving when the Corps marched down to Gravesend to embark for the East. But even under the present system, when men return still young to civil life, foreign service has its drawbacks. Epidemics are more frequent and more fatal than in England, sanitation is obstructed by the apathy and ignorance of native populations, and deviations in rain-fall and temperature produce outbreaks of fever, malaria, and scurvy in foreign stations, to an extent unknown in England. In time of peace, enforced idleness in hot climates plays mischief with the morality of soldiers, who fall a prey to loose women and bad drinks, and a campaign, although very welcome to the soldier, is often attended with privation, discomfort, and many elements of disease. The year 1883 was comparatively quiet, no campaigns are recorded, and the outbreaks of cholera were few in India, but it is sufficient to examine the returns of death and invaliding from abroad, and then compare them with those of the United Kingdom, to be aware that the defence of an Empire makes large demands on the lives and health of English troops. The death-rate per 1,000 in the United Kingdom was 6·28, while that of troops at home and abroad was 9·57. The mortality at different stations varies greatly, it is as low as 3·91 at Cyprus, and it is but 4·56 at the Cape, while it mounts to 15·46 at the Mauritius, and 12·03 for India generally. But we cannot be sure of the ratio of mortality to be confidently expected at any foreign station. The average at the Cape, so low in 1883, has been a very different thing at other times, and if we take the average for ten years, and compare the Cape with the United Kingdom, we find the former mounts to 40·63, while the latter is but 7·73 per 1,000. Cyprus, so healthy in 1883, was not so in other years, the death-rate there per 1,000, calculated on the returns for five years, ran up to 20·05. The mortality in India keeps pretty steadily the same.

The year 1883 was much healthier than usual, as the death-rate calculated for ten years is given as 17·93 per 1,000. Invaliding varies greatly, 84·71 per 1,000 were sent home from Egypt in 1883, and Canada, Ceylon, and the Cape furnished large proportions of sick men sent to England for change of air. Recovery, however, seems to have been tolerably rapid, as the ratio per 1,000 of men finally discharged only exceeded the United Kingdom rate, in the case of Egypt. We

**HEALTH OF HOVE.**—Dr. Kebell, the Medical Officer of Health, in his quarterly report ending June, gives the death-rate of the town at 13·3 per 1,000. The zymotic rate was as low as 0·5 per 1,000.

have noticed the variations in disease produced by abnormal rain-fall. In Bengal, at most stations, there was a great decrease in paroxysmal fevers in 1883, and the return remarks, "These satisfactory results are in great measure accounted for by the scanty rain-fall experienced during the year in the season of the periodical rains." In Madras, however, we find an outbreak of enteric fever, attributed to the same cause, and we are informed that at Bangalore, "The medical officers in charge of the station hospitals were not able to state definitely the cause of the disease in that station, but they both allude to the impurity of the water supply, and one states that in June, July, and August it was very bad, owing to deficient rain-fall." The scanty rain-fall may possibly have been indirectly the cause of the prevalence of scurvy, as the supply of vegetables seems to have been affected. At Gwalior, for instance, where scurvy was very prevalent, we learn that "for about three months of the year, the potato ration was very inferior, and at the time other culinary vegetables were not procurable." Lime-juice was issued generally for nearly three months. The medical officer recommended the use of a species of sorrel as an antiscorbutic food, but the men, always suspicious of innovation, refused to eat it. We find obstructed sanitation causing enteric fever at the Mauritius; the Report notices "the noxious vapours perceptible in some of the streets, and those issuing from house drains, are undoubted sources of danger, especially to new arrivals. It seems probable that both in town and country, the predisposing causes of disease are on the increase, and the soil which was formerly able to exercise a disinfecting influence is now, in the vicinity of settlements and villages, becoming overcharged with impurities. The principal outbreak of cholera occurred in Egypt, but we have already noticed it, in our issue of September 27th, 1884. In the present report we find it remarked, "That the experience of this outbreak does not bear out the assertion that those in attendance on cholera patients are *not* more liable to contract the disease than others, as the men of the Army Hospital Corps suffered out of all proportion to the other branches of the service."

With regard to diseases due to the conduct of the men serving abroad, we find dyspepsia and syphilis figuring largely. In the opinion of many medical officers, dyspepsia means the effects of over-drinking. The principal medical officer in Bengal, who doubted formerly the spread of temperance, is still more doubtful in 1883. He refers to his report for the previous year, in which he said, "On the assumption that the comparative prevalence of dyspepsia was in relation to the drinking habits of the men, the conclusion was drawn from the statistics of that year that there was more inebriety in it than in 1881. On the same assumption, it would seem that there was more intemperance in 1883 even than in 1882." With regard to venereal disease, we observe that while in England the rate for all forms amounted to 260.0 per 1,000, it swelled in the Mauritius to 389.3 per 1,000. Everything seems to have been favourable to foster the different forms of venereal disease. The senior medical officer states that "the infantry furnished by

far the larger portion of the cases, probably owing to their closer proximity to the town, and many cases are known to have been imported into the island by the detachment of Welsh Regiment." The type of disease was severe, and he remarks, "it is very prevalent among the lower Indian population." It seems strange that no sanitary measures whatever should have been adopted. The Indian women were beyond control, but surely the detachment of the Welsh Regiment should have been inspected on arrival, and soldiers suffering from disease might, at least, have been prevented from spreading it. We are accustomed to find the Contagious Diseases Act treated from a semi-religious point of view, but it is strange to observe it as a possible political question also. In Egypt, the foreign prostitutes are exempt from any but *consular* laws. We have noticed the result of foreign service in the case of English troops. What effect has climate on the wives who accompany the men abroad, and on the children who are born to them? The returns are exceedingly unfavourable. In the United Kingdom, the deaths among women were 6.27 per 1,000, while in Bengal the proportion increased to 20.26 per 1,000, in Bombay to 25.08, and at Madras the rate was 16.97 per 1,000. The deaths among children at the Indian presidencies were double those of the United Kingdom. In Canada, the ratio of deaths among children actually amounted in 1883 to 73.71 per 1,000. We have sometimes thought "a soldier is better accommodated than with a wife," and these statistics tend to strengthen our opinion, but looking at the possibility of the abolition of all preventive acts, and the enormous ravages of syphilis, we are almost inclined to advocate "permission to marry" to be largely extended. The appendix to the report contains some interesting papers. The account of the Conferences held at Geneva, on the invitation of the Red Cross Society, is deserving of notice; and so are the instructions given to the medical staff of the Suakin force. Altogether, the Departmental Yellow Book for 1883 is a well-arranged history of the endeavours of the medical staff to arrest disease.

---

## REVIEWS AND NOTICES OF BOOKS.

---

*A Manual of Dermatology*; by A. R. ROBINSON, M.B., L.R.C.P. & S. Edin. New York: D. Appleton & Co., 1885, pp. 647.—Dr. Robinson has succeeded in compiling a conscientious and fairly complete *resumé* of our present knowledge of dermatology. His reading and experience are obviously extensive, and he acknowledges his indebtedness to the works of Dühring, Hyde, Wilson, Tilbury, Fox, Hebra, Neumann, Kaposi and Ziemssen. Throughout the book an evident and perhaps justifiable bias towards the views of the Vienna school is perceptible, but, whilst due deference is paid to the work of English writers, little or no notice is taken of that of the French school, which, in England at all events, now attracts considerable attention, and exercises considerable influence. The classification of Hebra is wisely adopted, and pretty rigidly adhered to, with certain modifications rendered necessary by our increasing knowledge. The author's intelligent conception

of his subject is testified to by his recognition of the close relationship subsisting between the erythemata, the bullous non-contagious inflammatory diseases, and some of those conditions usually included under the designation of purpura, repeated mention being made of the occurrence of cases forming connecting links between these apparently widely separated classes of disorders. Throughout the work, prominent and warrantable attention is paid to the little-studied and interesting subject of the histology of skin lesions, the author's previously published works upon which are well known and appreciated. We cannot but think, however, that his microscopical researches have led him astray in some instances, especially in regard to Lichen ruber and Lichen planus, which he regards as totally distinct affections, classifying the former amongst the hypertrophies of epidermis, the latter amongst the papular inflammatory diseases. Clinically, no definite demarcation can be determined, and the majority of cases presenting themselves in practice are indeed intermediate in type, and might best be described in a separate group, as recently suggested by Unna. The assertions that Lichen planus is generally attended with very little itching, and that it is aggravated by the administration of arsenic, are certainly erroneous and misleading. Dermato-syphilis is treated of in a long and careful chapter on the lines laid down by Kaposi, but it appears to us that too many fine distinctions are drawn between the thirteen forms of syphilide described and minutely differentiated, and that clearer ideas would be imparted to the reader by a broader and more graphic treatment of the subject. Lichen circinatus is not recognised, but the author's description of seborrhœa corporis corresponds closely to the characters of the disease usually described under the former name. Impetigo contagiosa is classified among the acute contagious inflammatory disorders between vaccine and anthrax, in accordance with the views as to its nature originally enunciated by Tilbury Fox, but no longer maintained by dermatologists. Erythema nodosum is regarded as a disease distinct from erythema multiforme, and perhaps with reason, but it can certainly not be considered as synonymous with urticaria tuberosa. Again, herpes iris and herpes gestationis are described under the term of herpes, although both are almost indubitably forms of bullous erythema, and ought to be widely dissociated from herpes zoster, along with which they are classified. The identity of pompholyx is admitted with some justifiable reservations as to its relationship with herpes; with less reason ecthyma is described as a distinct disease. The statement that prurigo is practically unknown in England is too sweeping, although cases sufficiently severe to correspond to Hebra's well-known description are certainly rare here as elsewhere; the condition recognised in this country as Lichen urticatus, which presents many points of affinity to true prurigo, although hinted at, is not distinctly described. The assertions that the bronzing of skin in Addison's disease has been shown "to have no connection at all with degeneration of the supra-renal capsules," and that molluscum contagiosum "is in no way contagious," ought not to pass without notice and protest. The chapters on Lupus erythematosus and vulgaris are good, and the existence of an ill-defined group of cases, best described as scrofulodermata, is duly acknowledged. The description of rodent ulcer as a superficial and chronic form of epithelioma appears to us reasonable and consistent with facts. It is much to be regretted that throughout the work misspellings, typographical errors, careless writing and ungrammatical Latin should abound. The book is so well-planned, so exhaustive, and so thoroughly in touch with the spirit of modern dermatology that these faults are doubly conspicuous.

*Liverpool Medico-Chirurgical Journal*, No. 9, July, 1885.

London: H. K. Lewis.—This number opens with a paper on tubercular meningitis in children, by Dr. Martin Oxley, which gives a good account of the disease, but does not add to our knowledge on the subject; he mentions two cases of recovery after what he considered unmistakable signs of tubercular meningitis had declared themselves. Dr. Alexander, in an able article, defends excision of the

hip in certain stages of disease of the hip joint. He disapproves of the operation in the late stages, nor does he recommend it as an early procedure; the indications for the operation are the formation of abscesses and sinuses about the head of the bone. He never removes the great trochanter, and thereby avoids exposing the medullary canal, a point of the utmost importance in regard to the probable result. Mr. Reginald Harrison makes a valuable communication, illustrated by several woodcuts, on some changes in the form of the prostate and the floor of the bladder, in which he gives an account of two cases where the projecting third lobe of the prostate was torn through by forced catheterisation, the patient making a good recovery and the impediment to the flow of urine being completely removed. Dr. W. Williams analyses a series of cases of rheumatic fever treated by salicylate of soda, which he gives in ten grain doses every two hours; any toxic symptoms that arise he finds may be removed by diminishing the dose of the drug, but not the frequency of its administration, and the addition of a mercurial purge. Mr. Chauncy Puzey records a very interesting case of chronic pyæmia following an injury to the upper end of the shaft of the femur in which, following the law pointed out by Sir James Paget, all the secondary manifestations were confined to the shafts of the long bones. The last of the original communications consists of some notes of *post-mortem* examinations, made for coroners and in private practice, by Mr. F. W. Lowndes.

*Transactions of the American Surgical Association.* Vol. II. Edited by Dr. MEARS. Philadelphia: Blakiston, Son & Co., 1885, pp. 531.—We spoke of the first volume of these Transactions in terms of almost unqualified praise, and we are pleased to welcome a second volume of nearly equal merit with the first. The Association was only founded in 1880, in order to allow men who practise surgery in its truly comprehensive sense to come together for consultation and social intercourse from every part of the great American continent. Quite apart from the social aspect of these gatherings, they are useful to advance surgery not among the members of the Association only, but by the publication of such volumes as the one now before us, in the world at large. We find valuable papers on subjects of current interest, as well as the opinions and criticisms of those who listen to the papers, and the one and the other acquire additional value from this fact. In the present volume, among the more interesting papers, may be mentioned those on Wounds of the Intestines, by the late Professor Gross, probably one of the last, if not the last, of the numerous contributions made to surgery by this veteran author; on Traumatic Cephalhydrocele, by Dr. Conner (a subject quite recently discussed before the Clinical Society by Mr. Thomas Smith and Mr. Godlee); on Opening and Drainage of Abscess Cavities in the Brain, by Dr. Fenger; Surgical Interference in Cerebral Abscess, by Dr. Nancrede; besides many others too numerous to mention. We shall hope to see many succeeding volumes, and we trust they may all prove equally interesting with their predecessors.

## ABSTRACTS AND EXTRACTS.

THE RED CROSS.

A REPORT on the Conference held in September, 1884, at Geneva, by the representatives of various Governments and National Aid Societies, is furnished and commented upon by Surgeon-General Longmore, in the "Yellow Book" of the Army Medical Department for 1883. It may interest our readers if we select some of the passages which treat of the past history and future prospects of the "Red Cross" movement, which owed its origin to Mr. Henri Dunant, a Swiss, who had seen the horrors of "Solferino" in 1859. The first International Conference took place at Geneva in October, 1863, and fourteen Governments were then represented, whose delegates

almost without exception signed the Convention. England formed a branch under another name in 1870, soon after the breaking out of the Franco-Prussian War, and the Queen became the patron of "The National Society for Aid to the Sick and Wounded." All the world knows how liberally this Society behaved when supplying gifts of money and stores both to the German and French soldiers. Three International Conferences were subsequently held, one at Paris in 1867, a second at Geneva in 1868, and a third at Berlin in 1869, and at these meetings additions to the original articles of agreement were proposed; but they were never ratified, nor grafted on the original Convention of 1864. The Conference of 1884 was determined upon, because 20 years had elapsed since the original Convention, and much experience had been gained in the meantime by the National Aid Societies, as well as the International Committee of Geneva. Twenty-two States were represented at the Conference under notice, and the "United States" were included in the list. The work undertaken may be classed under three heads. In the first place, an alteration in the "principle" of the organisation was considered; in the next, the evils which had infected the original system were denounced; and lastly, many important matters of detail were proposed, calculated to extend and improve the work of Red Cross Societies. The programme of subjects originally proposed for consideration contained 23 questions, of which 14 were discussed, those which bore on any important matter being grouped together. The organisation of the International Committee was proposed to be improved by the subordination of all nationality. The question was put: "Should not the International Committee devote itself by preference in time of war to the sick and wounded of the retreating army without distinction of nationality?" The Central Committee of the Red Cross of Russia expressed itself convinced that there was an absolute necessity for an international institution perfectly neutral, whose authority should be recognised by the Powers who had accepted the Geneva Convention of 1864. Two other questions were considered bearing upon this proposal, namely, the general principles which should over-rule the relations of the National Committees, and also the best way of correspondence with the Aid Societies of an enemy's army. No conclusion was arrived at with regard to centralisation during the Conference of 1884, and this matter was postponed for consideration at the next meeting. But it seems to us the question of international central control was to a great extent answered by the reply given to another question, which ran as follows: "What are the proper relations to be established in time of war between the Military Authority and the Aid Societies?" It was answered by a resolution "That no international regulations can determine the relations between States and their Voluntary Aid Societies." We pass on to the evils which had sprung up since the formation of Red Cross Societies. We find a strong feeling of indignation was evinced against many persons who had dishonestly employed the special marks of the Red Cross Association. Some had displayed the emblems for the mere purpose of gratifying curiosity, others had used them to carry on the work of spies, and traders had paraded the insignia as a mere "shop mark" to advertise their wares. The Committee, however, found it impossible to put a stop to this degradation of the "Red Cross" by legal means of an ordinary kind, and confined themselves to denouncing these nefarious practices. It seems to us that the military authorities have a remedy at hand in the case of spies, and they are not likely to approve of a central international authority which might complicate matters by an assertion of separate jurisdiction. We perfectly agree with the opinion of Surgeon-General Longmore "that there is only one principle on which a system of voluntary aid can be adapted to military organisation in time of war, and it is, that the voluntary must for the time become incorporated with the military establishment." In other words, the philanthropists must sacrifice all foolish notions of independence, and become a subordinate portion of the army to which they have attached themselves. The suggested improvements in matters of detail were numerous, and sometimes not practicable. A desire, for instance, was expressed "that the dimen-

sions of 'ambulance stretchers' be rendered uniform in all armies." We agree with Surgeon-General Longmore "that the change in the dimensions of stretchers would not infrequently involve changes in other parts of the ambulance *materiel*, in some cases even of railway conveyances." We imagine the War Office would look coldly on any proposal of the kind made even by the British National Aid Society. We are glad to see the "Conference" declared its opinion that "the concurrence of Committees of ladies with the work of Red Cross Societies is indispensable," and it recommended that Aid Societies should develop in time of peace the instruction of ladies, to whose charge might be committed the superintendence of local ambulances and stationary Red Cross hospitals. The Central Committee at Berlin proposed the question: "In what way, in default of an international convention on the point, can the assistance of military surgeons at the disposal of non-belligerent powers be obtained for service on a theatre of war?" The Conference came to the conclusion that the Governments who have subscribed to the Geneva Convention should be asked to accept a proposal, that non-belligerent States should place all the Medical Staff they can spare at the disposal of belligerents. We agree with Surgeon-General Longmore that peace establishments would have few doctors to spare.

The Conference also recommended "That professional associations of men employed in the service of sick persons should be formed." Such a step, we are glad to know, has already been taken in England by the formation of a Medical Staff Corps for the Volunteers, and it is perhaps possible to connect the training of ladies with this wise development of Volunteer organisation. Papers were read at the Conference on many interesting subjects, and there were demonstrations of means of help for wounded men, and also an exhibition of the application of electric lighting to fields of battles. One special question was sent from the Central Society at Berlin: "What measures have been or ought to be taken by aid societies in order that the identity of the dead and wounded may be established?" The difficulty appears to have arisen chiefly in the French and German armies. We learn from the Report, "It too often happens that identification tablets or small distinguishing metal plates, when such are worn suspended from the neck, as they are ordered to be in French and German armies, are removed by strangers and kept as relics." Baron de Holleben, President of the Central Prussian Committee, stated "there were some who attached a sinister significance to the identification plates, to which they had given the name of 'Todt-marken' or death-marks, and had therefore superstitiously thrown them away, or had even exchanged their own plates with others belonging to comrades." The Conference could not determine upon any satisfactory plan which would obviate such perverted ingenuity as this, and simply voted "That each National Aid Committee ought to procure the adoption of a mark of identification for use in the army of its country." A few subjects not included in the programme were submitted for consideration, and we observe with regard to dressings for the wounded, that the Conference recorded its desire, that antiseptic dressings may be employed, as a rule, in the surgical service of all armies in the field. The next Conference is fixed to take place at Carlsruhe in 1886 or 1887. Much good may arise from these meetings, in the adoption of practical suggestions, of all measures calculated to alleviate the sufferings inseparable from war, and not a little good may follow the exposure of sentimental shams, and the desire of independence on the part of well-intentioned but foolish persons who, confident in their own pure motives, would rather rule than serve in military hospitals.

AN ECHINOCOCCUS CYST IN THE RIGHT AURICLE.—Dr. Ignatief, of Moscow, reports a case of death from impaction of an echinococcus cyst in the right auricle, which occurred during an operation for evacuation of the sac in the liver. The patient was an unusually well-grown and healthy girl, 18 years of age, the daughter of well-to-do peasants, and housemaid at the country seat of a gentleman where a number of dogs were kept, with which she was fond of

playing. Some months before admission to the hospital she had noticed a tumour in the epigastrium, which speedily attained the size of a fist, and then appeared to cease growing; she had no pain, but complained of shortness of breath and a sense of constriction at the chest on running upstairs or any exertion. Examination of the abdomen showed about two inches above the navel the sharply notched margin of a tumour, the dulness over which was complete, and occupied a trapezoidal area, the wider end of which was towards the left. The heart's impulse was felt outside the nipple line, but beyond the mechanical effect of the tumour in raising the diaphragm and displacing the heart, there was nothing to notice. The tumour moved with respiration, but fremitus was absent. Every function, digestive, hepatic, renal, menstrual, &c., was normal, and the nature of the case did not admit of doubt. In view of the increasing interference with the action of the heart, and of the possible rupture of the cyst, which was already very tense, an operation was resolved on with the entire concurrence of the patient. This was undertaken by Dr. Kusmin, chloroform being administered by Dr. Sakov. The operation, conducted under antiseptic precautions, consisted in an incision three inches long in the linea alba, the vessels being seized with Pease's forceps and tied with catgut. When the peritonæum was reached, it was carefully opened with the scissors and the flaps secured by silken ligatures, so as to expose the tumour to view. The next step was to have been the connection by sutures of the peritonæum covering the cyst with the parietal layer, so as to prevent the escape of fluid into the abdominal cavity. But while the fourth suture was being inserted, the patient's pulse was observed to stop suddenly, and without any warning, she made two, and two only, gulping inspirations, and rapidly became cyanotic. Sylvester's method of artificial respiration, tracheotomy and faradization of the phrenic nerves were tried without the least success, the cyanosis rapidly increased, and after half-an-hour the case was abandoned. During the whole of this time not a single pulsation of the heart had been felt. At the *post-mortem* examination made by Dr. Rosenberg, the whole left lobe of the liver was found to have been converted into a cyst, from the anterior wall of which all parenchyma had disappeared, it was collapsed, the fluid having escaped into the abdomen. The vena cava having been tied and thoracic viscera removed entire, the right auricle and part of the vena cava were found to be filled by a sausage-like body, which proved to be an echinococcus cyst, ruptured and rolled on itself. It was this that had so suddenly arrested the heart's action. Where the inferior vena cava and the walls of the liver cyst were in contact and adherent, a small irregularly circular aperture was seen communicating between the two, through this the collapsed echinococcus cyst had passed into the vein. The lungs, &c., presented the usual appearances seen in death from asphyxia. Apart from the unusual circumstances of the fatal termination, it is interesting to observe that nearly all cases of echinococcus in man have been those of persons who, like this young woman, have been in the habit of allowing dogs to lick their mouths, or otherwise to play freely with them.

**THE PNEUMONIA-COCCUS OF FRIEDLANDER.**—Dr. George M. Sternberg, U.S.A., in a paper which appears in the July number of *The American Journal of the Medical Sciences*, calls attention to the so-called pneumonia-coccus of Friedlander, which he claims is, in fact, identical, specifically, with a micrococcus which he previously described, and which is found in normal human saliva, and with that found by Pasteur in the blood of rabbits which had been injected with the saliva of a child which died of hydrophobia in one of the Paris hospitals. This micrococcus he names *Micrococcus-Pasteuri*. The capsule, or mucous envelope, which sometimes surrounds this micrococcus, described by Friedlander in 1883, and photographed by Sternberg two years previously, cannot be accepted as a distinguishing character of this species, inasmuch as it is not constantly present, and the circumstances upon which its development depends have not been accurately determined. It is established that this is a pathogenic organism, as far as certain lower animals are concerned, and that its pathogenic power varies under different circumstances. It

seems extremely probable that this micrococcus is concerned in the aetiology of croupous pneumonia, and that the infectious nature of this disease is due to its presence in the fibrinous exudate into the pulmonary alveoli. But this cannot be considered as definitely established by the experiments which have thus far been made upon lower animals. The constant presence of this micrococcus in the buccal secretions of healthy persons indicates that some other factor is required for the development of an attack of pneumonia; and it seems probable that this other factor acts by reducing the vital resisting power of the pulmonary tissues, and thus making them vulnerable to the attacks of the microbe. This supposition enables us to account for the development of the numerous cases of pneumonia which cannot be traced to infection from without. The germ being always present, auto-infection is liable to occur whenever from alcoholism, sewer-gas poisoning, crowd-poisoning, or any other depressing agency, the vitality of the tissues is reduced below the resisting point. We may suppose also that a reflex vaso-motor paralysis, affecting a single lobe of the lung, for example, and induced by exposure to cold, may so reduce the resisting power of the pulmonary tissue as to permit this micrococcus to produce its characteristic effects. Again, we may suppose that a person, whose vital resisting power is reduced by any of the causes mentioned, may be attacked by pneumonia from external infection with material containing a pathogenic variety of this micrococcus having a potency, permanent or acquired, greater than that possessed by the same organism in normal buccal secretions.

**ON THE SIGNIFICANCE OF OSSEOUS LESIONS IN THE DIAGNOSIS AND TREATMENT OF INHERITED SYPHILIS.**—A paper on this subject, by Dr. R. Lomer, of Berlin, appears in the *Zeitschrift für Geburtshilfe und Gynäkologie* (Band X., Heft 2). It refers to the disease of the bones described by Wegner. Dr. Lomer holds that the presence of these changes in a well-marked form is proof of syphilis; and applying this test, comes to the conclusion that the large majority of cases of premature labour are due to this disease. General practitioners, in Dr. Lomer's opinion, know very little about these bone lesions. They are to be demonstrated by exposing the femur and making a longitudinal section of it. In a healthy bone, the junction of cartilage and bone is a simple line, either straight or undulating, but sharp and well defined. In a syphilitic bone it is a broad layer, from which irregular processes project into the cartilage. The epiphysis is either quite loosened, or there are deep fissures in the bone below the line of ossification. In some cases these changes can be easily seen with the naked eye, but in others they may be so slight as to need microscopical examination of carefully prepared sections. Although this disease indicates syphilis, yet a normal condition of the bones is not proof of the absence of syphilis. Dr. Lomer puts before his readers the following generalizations, based on the examination of 43 fetuses which had died in utero. When the bone disease is well marked, the liver and spleen are abnormally large. It makes no difference in the degree of the changes present, whether the syphilis is derived from one or both parents, whether in the parent the disease is one year old or ten, whether secondary symptoms have persisted or not, whether the parent has been treated or not, or whether the child be large or small. Syphilitic fetuses differ in appearance from non-syphilitic. The latter are brown and mummified, the former flesh-coloured and more œdematous. In the non-syphilitic the mother can commonly assign a date for the infant's death, and the weight of the fetus corresponds to the period indicated by her statement. This is not the case with the syphilitic; and in them the placenta is commonly unusually heavy in proportion to the weight of the fetus.

**THE REMOVAL OF TUMOURS OF THE ABDOMINAL WALL, WITH THEIR PERITONÆUM.**—Dr. M. Säger, of Leipzig, contributes to the *Archiv für Gynäkologie* (Band XXIV., Heft 1) an interesting paper on this subject. It deals with the removal of tumours of the belly wall so closely and extensively applied to the peritonæum, that this membrane can only be preserved uninjured by a difficult

dissection, after which a large thin sheet of peritonæum free from its main vascular connections, will be left. In such circumstances, some operators have adopted the easier course of cutting away the tumour with its peritonæal covering, and taken great pains to bring together the edges of the peritonæal wound, leaving the skin which covered the tumour as a large loose bag over the stitched-up incision. Others have filled up the gap by stitching omentum into the wound, without great success. Sängér here publishes a case in which he simply stitched together the margins of the incision through the skin and muscles, leaving the large surface from which the tumour had been removed uncovered with peritonæum; so that after closure of the wound a great part of the anterior abdominal wall was left bare of peritonæum. Three similar cases have been published before, one by Esmarch, two by Sklifossowsky. All four were successful. In only one of them (Esmarch's) was drainage employed. In order to determine the behaviour of the parts affected when this course has been adopted, Dr. Sängér has made experiments upon animals; and he finds, that just as after a destruction of skin, healing takes place, and fresh epidermis is formed, so after removal of part of the peritonæum new endothelium is produced. The paper concludes with a general survey of all the cases of tumour of the abdominal wall known to the author.

**RUPTURE OF THE VAGINA DURING COITUS.**—In the *Boston Medical Journal* for April 30th, an instance of this rare occurrence is recorded. The woman, æt. 44, was of ordinary size and well-developed; she began to menstruate at 15, and ceased to do so at 38. She had been for six years married to a sailor, and there had been no dyspareunia; she had never been pregnant. Senile atrophy of the vagina appears to have proceeded rapidly during her husband's last voyage, of four months' duration, and on his return coitus was affected with difficulty; it was accompanied with intense lancinating internal pain on the right side, and followed by a profuse hæmorrhage. Examination revealed a recent longitudinal rent in the upper third of the vagina on the right side about an inch in length and opening into the cellular tissue to the depth of half an inch. A case is quoted from Zeiss, in which coitus six weeks after delivery produced a deep rent in the right vault of the vagina; the uterus was greatly retroflexed, and the cervix adherent to the right side of the pelvis, but the dimensions of the vagina seemed normal. In a later number of the same journal, Dr. Mundè relates two cases of dangerous hæmorrhage from rupture of the vagina during a first coitus; in neither case was there any disproportion of organs, and the vagina appeared perfectly healthy. In both the rent was truly one of the vaginal walls, and not of the hymen merely. In one case the fissure was an inch in length, in the other it extended for fully two and a half inches, and was quite half an inch deep. A firm tamponade of alum-cotton discs was successful in controlling the bleeding. These records are of interest, since the possibility of such an accident has been denied by some writers.

**CASE OF DOUBLE UTERUS AND VAGINA WITH UNCOMPLICATED LABOUR.**—An interesting case of double uterus and double vagina was seen for the first time in the Alexandrov Hospital in Kharkov, by Dr. Kemarski, after labour had commenced. (*Vrach*, May 23, old style.) The existence of a furrow above the umbilicus, on the right of which there was a strongly contracting uterine portion, while another portion contracting less forcibly was situated on the left of it, together with the discovery of a vaginal septum torn and rolled up into a cord, sufficed to call attention very early to the nature of the case. The labour only lasted three hours, and was perfectly normal. After it was over an examination was made, and it was found that a tough vaginal antero-posterior septum existed in the upper and middle thirds, the posterior attachment was perfect, but the anterior border of the septum had been torn away from the anterior wall of the vagina. The os uteri was single, but within the cervical canal an antero-posterior septum was found, which divided the uterus into two unequal, but apparently independent divisions. The case is interesting as showing that this abnormality, which has been said to give rise to difficult, dangerous or prolonged labour, so as

usually to require operative interference, does not necessarily cause any difficulty whatever. The mother and child did perfectly well.

**FÆCAL FISTULA AFTER OVARIOTOMY.**—Dr. C. D. Palmer, of Cincinnati, lately communicated to the Ohio State Medical Association a case in which, while the patient was recovering from ovariotomy, a fæcal fistula formed, communicating inwardly, it was believed, with the lower small intestine, the external opening presenting in the median line midway between the umbilicus and the symphysis. This continued to discharge a small quantity of fæcal matter. In the subsequent discussion it was mentioned that fæcal fistula had occurred to several operators, and it was the general opinion that this would probably close.—*Cincinnati Lancet*.

**OPERATIVE MEASURES FOR THE RELIEF OF PYLORIC STENOSIS.**—Dr. Randolph Winslow, in an able paper in *The American Journal of the Medical Sciences* for April, 1885, has collected and analysed all the recorded cases, 85 in number, of operative interference for the relief of pyloric disease. He fully discusses the technique of the different procedures, and presents the following deductions:—(1) In cancer of stomach not producing stenosis, anodynes should be given in quantities sufficient to relieve distress, and no operation should be performed. (2) Pylorotomy for carcinoma is followed by 76 per cent. mortality, hence it should only be very exceptionally performed in those cases where, with marked stenosis, the pylorus is not adherent to the neighbouring organs, and the patient is young and fairly strong. (3) In other cases of carcinomatous stenosis, as only very temporary benefit can be obtained, gastro-enterostomy should be performed. (4) In cicatricial stenosis digital divulsion should be performed, but if this is impossible owing to great thickening of the walls, resection in those who are well nourished, and gastro-enterostomy in the debilitated, will both be followed by good results. (5) Hæmorrhage or perforation from ulcer or other cause than stenosis, does not present indications for pylorotomy. (6) Duodenostomy, gastrostomy for the passage of a tube, and complete gastrectomy should all be replaced by gastro-enterostomy.

**A TEETHING SYRUP.**—M. Paul Vigier recommends (*Gazette Hebdomadaire*, July 24th) what he terms a *sirup de dentition* to assuage the pain suffered by infants while cutting their teeth, especially the canines: hydrochlorate of cocaine 10 centigrammes, simple syrup 10 grammes, tincture of saffron 10 drops. The painful gums should be gently rubbed with some of this several times a day.

## MEDICAL NEWS.

**UNIVERSITY OF LONDON.**—Preliminary Scientific (M.B.) Examination.—Pass List.—Entire Examination.

*First Division.*—George Thomas Congreve Barber, Queen's and Mason Colleges, Birmingham; Stephen Henry Bates, University College; \*Arthur Bousfield, King's College; \*Charles Richard Box, St. Thomas's Hospital; Arthur Norman Boycott, St. Thomas's Hospital; \*Herbert Caiger, University College and Birkbeck Institution; \*John Alfred Codd, Pembroke House, Lytham, and Private study; William Marshall Davidson, St. George's Hospital; Frances May Dickinson, Clapham High School and Bedford College, London; \*Thomas Archibald Dukes, Epsom College; Gabriel William Stabel Farmer, University College; James Howard Green, Owens College; Elias George Hall, University College, Bristol; Richard Tanner Hewlett, King's College; \*George James Hill, Normal School of Science and Birkbeck Institution; Herbert Henry Horden, University College; Charles McGowan Kitching, Guy's Hospital; Arthur Colborne Lankester, St. Thomas's Hospital; Arnold William Warrington Lea, Owens College; \*Randle Leigh, University College, Liverpool; \*Joseph Johnston Macgregor, St. Bartholomew's Hospital; Arthur Manknell, Yorkshire College, Leeds; Geoffrey Colley March, Owens College and Giggleswick Grammar School; Edward Percy Paton, St. Bartholomew's Hospital; John Edward Platt, Owens College and Private study; Hugh James Moore Playfair, King's College; Charles Henry Powers, University College and St. Mary's Hospital; Herbert Ramsden, Owens College; Joseph Stewart Richards, Guy's Hospital; John Robertson, Guy's Hospital; Henry Stephen Sandifer, King's College; Amy Sheppard, University College, London, and Mason College, Birmingham; Mary Louisa Sprigg, University College and Private tuition; Mary Darby Sturge, Mason College, Birmingham; Robert Edwin Williams, Guy's Hospital.

*Second Division.*—Albert Ashton, Owens College; Robert Cozens Bailey, Private tuition; Albert Brook Batley, Yorkshire College and St. Thomas's Hospital; Ellen Margaret Tinné Berthon, University College and London School of Medicine for Women; Samuel Victor Johnson Brock, University College; Frank Calder, University College and Medical School Bristol; Henry Albert Caley, University College; David Cannan, University of Glasgow and St. Bartholomew's Hospital; \*Lionel Vernon Cargill, King's College and School; Richard Henry Carlisle, University College, Liverpool; Blackwell Charles, University College; Alfred Clark, University College and Middlesex Hospital; William Adams Clark, St. Bartholomew's Hospital; John Tertius Clarke, St. Thomas's Hospital; Archie Tillyer Collum, Epsom College; Frank Septimus Colton, University College; Victor Albert Louis Edward Corbould, Epsom College; Albert Corner, Epsom College; Howard Distin, King's College; Edward Miall Dobinson, Guy's Hospital; Percy William Dove, St. Bartholomew's Hospital and Private study; \*Edward Robert Charles Earle, University College; William McAdam Eccles, University College and School; Percy Charles Evans, University College; Edward Desmond FitzGerald, St. Bartholomew's Hospital and Private tuition; Charles John Girling, Guy's Hospital; John Guest Gornall, The Leys School, Cambridge; Frank Grange, Charing Cross and St. Thomas's Hospital; John William Geary Grant, St. Thomas's Hospital; Joseph Green, Owens College; John Harvey, University College Liverpool and Private study; \*John Sydney Hicks, London Hospital; Leonard Erskine Hill, University College and Private study; Thomas Walter Hinds, Cranbrook Grammar School and University College; John Armistead Home, Marlborough College and St. Bartholomew's Hospital; \*Ernest Wickham Hore, University College; \*William James How, University College and Private study; Edward Victor Hugo, St. Bartholomew's Hospital; \*Charles Murray Kirton, Chatham Hospital, Ramsgate, London Hospital, and Private study; Henry Brunton Kitchen, University College; Mary Adela McCulloch Knight, University College and University of Adelaide; Harry Lambert Lack, Belle Vue House, Eaton, and Private tuition; Frederick Lewis, Epsom College and St. Mary's Hospital; Thomas Lissaman, University College and St. Bartholomew's Hospital; Alice McLaren, University College and Private tuition; Samuel Francis Mawson, Owens College; Charles Carter Moxon, Yorkshire College, Leeds; Harry Augustus de Beauvoir Nelson, University College; Samuel Nicklin, Queen's and Mason Colleges, Birmingham; William Nuttall, Owens College; Frederick Layton Orr, University College; Harold Burgess Osburn, King's College and St. Thomas's Hospital; Charles Reginald Palmer, University College, Liverpool; Edwin Stephen Pasmore, University College; Reginald Spencer Pearson, Owens College; Eric Leonard Norman Pridmore, University College; George Lancelot Rolleston, Marlborough and University Colleges; Henry Roscoe, Owens College; \*Gerald Allpress Simmons, University College and Private study and tuition; John Herbert Sykes, Huddersfield and Owens Colleges; Albert Edward Tebb, Guy's Hospital; \*Benjamin Pope Viret, St. Bartholomew's Hospital and St. Paul's School; Wilfrid Brougham Warde, St. Bartholomew's Hospital; Ernest Edwin Ware, St. Thomas's Hospital and Private tuition; John Alfred Waring, University College; Garibaldi Watson, Anderson's College and Royal Infirmary, Glasgow; \*Samuel Williams, University College, Cardiff; Alfred Field Henry Wray, St. Bartholomew's Hospital; John Young, University College.

#### Honours Candidates recommended for a Pass:—

James Macdonald Gill, Nonconformist Grammar School and Guy's Hospital; Orestes Victoriano Pisani, Private study; \*Thomas Frank Ricketts, Guy's Hospital and University College; Joseph Watts Roberts, University College, Liverpool and Private study.

#### Two Subjects of the Examination†:—

Henry Moore Bowman (*C., B.*), St. Bartholomew's Hospital; Joseph Richard Buckley (*C., B.*), Owens College and The Leys, Cambridge; George Elam (*C., B.*), University College and Private study; John Fawcett (*C., B.*), Dulwich College; Alfred Edward Prest Hughes (*C., P.*), St. Thomas's Hospital and King's College; Theodore Henry Ionides (*C., P.*), University College and Private tuition; Ernest Courtenay Lomas (*C., B.*), Owens College; Algernon Wilson Lyons (*C., B.*), King's College; Arthur Ernest Madge (*P., B.*), University College and St. Bartholomew's Hospital; Hugh Fraser Mantell (*C., P.*), University College; William Penberthy (*C., B.*), London Hospital; Joseph John Perkins (*C., B.*), Owens College; Arthur Gordon Reid (*C., B.*), Dalhousie and Edinburgh Universities; William Henry Townsend Storrs (*C., B.*), King's College.

#### One Subject of the Examination†:—

Annette Matilda Benson (*Z.*), Private tuition; William Jenner Best (*P.*), Cavendish College and London Hospital; Frank George Bushnell (*C.*), St. Paul's School and University College; Charles Sempill De Segundo (*B.*), St. Bartholomew's Hospital; Philip Rashleigh Dodwell (*Z.*), University College; Douglas Drew (*C.*), University College and Private study; Henry Augustus Edmonds (*Z.*), Guy's Hospital; William Charles Ellis (*C.*), St. Thomas's Hospital and Private study and tuition; Gerald Dudley Freer (*P.*), Private study; William Britain Morton (*C.*), Richmond School, Yorkshire and University College; Edward Herbert Robinson (*P.*), Owens College; Henry Albert Thorne (*B.*), University College; George Cecil Trask (*C.*) Somerset College, Bath and Private tuition.

The Candidates marked \* have also passed in the Mathematics of the Intermediate Examination in Science, and have thus become admissible to the B.Sc. Examination. The subjects taken up by the Candidates marked † are

indicated by initials after the name,—*C.*=Chemistry; *P.*=Physics; *B.*=Biology; *Z.*=Zoology. *N.B.*—The names of Candidates who have obtained Honours do not appear in this List.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the July sittings of the examiners of Glasgow the following candidates passed the First Examination for the triple qualifications:—

H. H. H. Addenbrooke, William Armour, William Bell, Robert Boyle, John Henry Brice, Joseph Cantley, Michael Casey, H. Chadwick, W. G. Dick, Charles Doherty, G. H. Douthwaite, M. H. Eames, Charles A. Fergus, David L. Hamilton, H. L. Homer, Alfred E. Huband, C. B. Humphreys, Samuel Hunter, L. P. Jackson, John R. Jones, John A. Jones, E. R. Kavanagh, William S. Kidd, James M'Cartney, Michael M'Laughlin, William Magec, Henry B. Maunsell, Patrick O'Gorman, Robert W. Roberts, John Rogerson, Edmund Ryan, George H. Walker, William Williams, George T. Woods.

The following students have passed the Second Professional Examination:—

Richard Ambler, Dugald Buchanan, Edward Brooks, Edward Clarkson, Edward H. Corder, James Gordon, Edward Gray, A. H. Hoffman, John Hoyle, John Owen Jones, John Kennedy, Walter H. Large, Walter M'Gibbon, Alexander D. M'Lean, Alfred J. M'Lean, J. A. H. Mogg, Robert D. Poichard, George Thomas Woods.

The following gentlemen passed the Final Examination for the triple qualification, and were admitted L.R.C.P. Ed., L.R.C.S. Ed., and L.F.P.S. Glas.:—

Andrew Alexander, Berwick; Henry William Bryant, Edinburgh; Edward Clarkson, Darlington; William W. Clegg, Leeds; James Blair Donaldson, Edinburgh; M. M. Gandevia, India; Thomas J. G. Garrett, Manchester; Walter Macgibbon, Edinburgh; Arthur R. Owst, Blackheath; H. N. Rademeyer, South Africa; David Sturrock, Edinburgh; John T. Wiuter, Manchester.

The following were admitted L.R.C.P. Ed., and L.F.P.S. Glas.:—

G. C. Bezbarow, Glasgow; Robert Kerr, Glasgow.

THE SOCIETY OF APOTHECARIES, LONDON.—The following gentleman passed his examination in the Science and Practice of Medicine, and received a certificate to practise, on Thursday, August 13th, 1885:—

William Scott Tebb, M.R.C.S., Albert Road, Regent's Park.

On the same day

Alfred William Hill, Adelaide, South Australia; John William Pugh, Llannan, Cardiganshire,

passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise.

REFORM AT THE COLLEGE OF SURGEONS.—At a very full meeting of the East Anglian Branch of the British Medical Association, held at Bramtree on August 7th, Mr. Abbott read a paper on the Association of Members of the Royal College of Surgeons. He briefly explained the objects of the Association, and the reforms in connection with the election of Members of the Council of the College which the Association wished to bring about, and concluded by moving, "That this meeting protests against the conduct of the Council of the Royal College of Surgeons of England in refusing all the demands of the Members." This was seconded by Dr. Kellett, of Halstead. The President (Dr. Elliston, of Ipswich) said:—"I may say I have not felt very warmly on the subject, except that I thought every Fellow of the College should be allowed, at all events, to vote on the election of Members of the Council. The question is now whether that privilege should be extended to all the Members of the College. I am open to conviction, but I always thought that it would be sufficient if Members who have attained the distinction of Fellows of the College should be allowed to vote by papers instead of being compelled to be present in London. This, I think, would be an important reform. We have now to consider whether that should be advanced a stage further, and every Member should have the privilege now accorded to a Fellow, and the more I think of it the more I feel that we should have more power. College matters, as we are all interested in the College of Surgeons and the schools of the medical profession. It is for you to decide whether we shall pass the resolution, as Mr. Abbott seems to have convinced me that it is necessary we should claim the

privileges to which the resolution refers." Mr. C. B. Keetley said, "I feel sure that all the Fellows who wish an alteration in the constitution of the College would like the whole of the Members to have as much power in the management of affairs as they themselves had. Of course I am only speaking for myself. I am a Member and a Fellow as well, and I do not consider that when I became a Fellow I became better able to form a reasonable opinion on the matters which come before the College than when I was a plain Member. If the subjects which came before the College were pure surgery, there might be some excuse for keeping matters in the hands of the Fellows; but as a matter of fact, all the subjects which come before the Council are purely business and general matters, upon which it is not at all impossible for a Member to have as good an opinion as a Fellow. In analysing the difference between a Fellow and a Member, if you take the money that has been paid it seems to me it would be impossible for the most ingenious person to prove that an individual who has paid 20*l.* to the College has not a right to have a voice in the management of its affairs as well as an individual who has paid 40*l.* or 50*l.*, and if one were to go through the whole of the differences I think there can be only one conclusion, viz., that Members have a perfect right to a voice in the management of the College. Lately the agricultural labourers have been added to the franchise, and the great argument was that they had the right. I won't say whether I think they are qualified, but surely no one will say that an independent medical man is not able to express an opinion upon the questions which come before the College. I hope this meeting will support the resolution, or some such resolution as that proposed by Mr. Abbott." The resolution was carried unanimously.

NAPLES AND THE CHOLERA.—A correspondent of the *Times* sends the following:—"The great disaster of Spain had filled Neapolitans with apprehension, but the news from Marseilles has added immensely to it. It was about this time last year that the arrival of cholera in Naples was officially announced, and it had come *via* Marseilles, as nearly as it was possible to ascertain; nothing less surprising than that it should come again. The Syndic, in a telegram to the Ministry of the Interior, well interprets the public feeling:—"We are assured by commercial authorities that the cholera is in Marseilles. The alarm of this population, not yet recovered from recent suffering, can be readily imagined. I am entreated to beg you to put all vessels arriving from that city in quarantine at Asinara." Their request was immediately complied with. Vessels arriving from Marseilles, Corsica, or Algiers with clean bills of health will be subjected to seven days of quarantine, but when they suspected they are to undergo a quarantine of 21 days. Happily Nisida is closed, and Asinara will be the receiving place for all suspicious vessels. That cholera has been in Marseilles for some time there can be no doubt, though doctors have denied it and the Press has been silent. People have, as usual, been blinded by reports of the malady being only cholera, the common summer malady; and in the interval cholera has been seeking out all the snug corners, and there are many of them in which to nestle. The same thing happened in Naples last year; cholera had slain many before its presence was officially announced, and then came the terrible panic and the awful destruction of human lives. In truth alone there can be safety. Both in Marseilles and Naples it was well known that the plague was there, but black was called white, and white black, and people were put off their guard by official concealment. What the state of Marseilles is I cannot say, but what that of Naples is the public Press informs us. The *Pungolo* says that 'our grandsons will have to gut the city,' and the *Roma* and some other journals are never weary of speaking of the filth and pestilential smells. And all this after the hopes that were raised by the magniloquent declarations of the Government and our local rulers. A vast deal of time was lost in sending up plans, and a great deal of time was lost before they were returned under sentence of condemnation. They were too grandiose, as is everything Italian—the practical and the useful are overlooked—and it was pointed out that while the plans were calculated to make half Naples a paradise, that part

which had been most afflicted with cholera, and which was inhabited by artisans and the poorer classes, was comparatively neglected. One positive good has been done in the introduction of a supply of excellent water, but little else. The cholera is at our doors—and it knows where it will be well housed—and we have the hottest summer that has been known for several years." A few days later the same correspondent writes:—"All are surprised," says the *Roma*, 'at the official and officious denials up to the 5th instant, of the existence of cholera in Marseilles. Those denials are inexplicable. The Government was either aware or not of the facts. If it was aware, why deny them and take precautions later? If not, why not dismiss the Italian Consul at Marseilles?' From the statements of the Press I gather that the first case happened there on June 26 in the Rue Tamaris; the second on the next day in the Rue Roquebrunc. In July there were many cases, yet neither the doctors nor the Press spoke of them. Meetings of the Consular body were held, and everything was reported to be all right. 'They were merely sporadic cases—cholera.' Yet the people died. Now that the reappearance of the malady in Marseilles is assured, the greatest alarm prevails, and the authorities are awakening. Our Syndic telegraphed an entreaty that quarantine should be imposed on all vessels arriving from France. Next it was requested that crowds of Italian operatives, being fugitives, should be stopped on the frontier. This was followed up by another telegram from the Syndic to the Ministry of the Interior, as also to the Prefects of Cuneo and Porto Maurizio, asking to be informed of the names of those who, after having undergone a medical inspection, were bound for Naples. With all the precautions taken, however, a 'caso sospetto' was met with at Voltri. The poor fellow had come from Marseilles, was taken ill at Savona, was rejected at every station, and died in the railway carriage. His two companions continued their journey, but on arriving at Genoa were placed under inspection in a hospital. With this exception, the public health on the Ligurian Riviera is declared to be 'ottima,' as it is said to be throughout the whole kingdom, but no one gives credence to official assurances, and this is one of the sad consequences of the system of concealment and deception which has constantly been adopted. The municipal authorities of Naples are active enough, it is to be hoped not too late. At a meeting of the Sanitary Commissioners three or four days since, it was ordered by the Syndic to flush all the sewers and drains of the city at night; but hitherto, despite the arrival of the waters of Serino, the urgent request to have the hot, dusty streets watered has been neglected." On August 13th, he wrote, "Whether it arose from a consciousness of negligence or inactivity during the last year, our local authorities are now making every effort to meet and repel a possible enemy. The Assessor of Public Health has ordered 2,000 wells containing impure water to be closed. Why was not this done before, when a separate commission was appointed to examine the wells of this city and a report was issued as their condition? The order has been given, but we have to wait for the execution of it, which is a widely different thing. The closing of wells will create a dearth of water in many parts of Naples, and therefore the Syndic, at a meeting of the Council on Monday, announced that the number of fountains will be increased from 160 to 200. He promised also 'that the watering of the city should be provided for, and that on the distant supposition of a choleraic invasion directions had already been given for the formation of gratuitous kitchens, to which the Government would contribute largely.'"

THE WASHINGTON CONGRESS.—Up to the present writing, we have (says the *New Orleans Medical and Surgical Journal*) heard of six resignations from the original committee of seven—Drs. Flint, Billings, Johnston, Brown, Hays, and Engelmann. Other resignations will surely follow; a list of those who have so far resigned all connection with the Congress, including the adherents of the New Code who have been displaced, contains many historical names, that would be sadly missed in an international gathering of representative medical men. Already it is painfully evident that it is simply impossible to organize the

American meeting of the International Medical Congress upon the plan adopted by the Chicago Committee. Truly, we stand to-day a divided household, and unless some reconciliation can be effected, the failure of the Congress is inevitable. The present situation is deplorable beyond expression. A mighty responsibility rests on the present committee of organization. The members must realize the impossibility of organising the Congress in further pursuance of the policy recently adopted. For the sake of harmony, through which alone the Congress can succeed, and the profession escape a national disgrace, the committee should make concessions to the gentlemen who feel aggrieved by their action; and such concessions to those who have resigned, as well as those who have been displaced, should meet only friendly responses and pledges of harmonious co-operation. We favour the organization of a National Committee of peace-makers, composed of representatives from the States and Territories, to be appointed by the Presidents of State and Territorial Societies; from the district of Columbia, to be appointed by the President of the District Society; and from the Army, Navy and Marine Hospital Service, to be appointed by the ranking medical officer of each service. It is contemplated that a committee, constituted as above suggested, would be very potent in reconciling the differences now existing between the committee of arrangements, on the one part, and, on the other, the gentlemen who have been displaced and those who have voluntarily resigned all connection with the organization as now proposed. This committee failing in its purpose, we suggest that it is better to appeal the matter, as it now stands, to the American Medical Association for final adjudication. The *Medical News* of August 8th, writing on the same subject says: The profession recognizes that on account of recent events there is imminent danger of its not being able to meet the obligations which it incurred by the invitation extended in its name at Copenhagen, and its members naturally look around to see what means can be found to avert the impending disaster which threatens to defile its good name. The clearest and cleanest way out of the false position into which the profession has been entrapped by the plotters at New Orleans is for all appointees to discredit them completely by declining to accept office at their hands, and thus their organization must, of necessity, collapse. Already this has been largely done, and upwards of one hundred of the most eminent of their appointees have declined to be tools in their hands, and the sooner the remainder follow suit, the sooner will the way be opened to the profession to redeem its plighted honour. . . . Rapid disintegration still characterizes the new organization of the Congress. This week we are called upon to chronicle more resignations, and the list includes one Vice-President of the Congress, three Vice-Presidents of Sections, and several Members of Councils. The very large number of appointees who have declined to accept office under the New Orleans committee are all Old Code men, both in principal and practice, and for the most part they are members of the American Medical Association. They recognize the falsity of the issues which were raised at New Orleans, and they have promptly placed their emphatic seal of condemnation upon the most disgraceful piece of intrigue which has yet marred the history of that body, and which is in imminent danger of placing an ineffaceable stigma upon the good name of the whole American medical profession.

**THE SANITARY STATE OF BATH.**—"F. G. S.," writing to a daily contemporary on this subject, thus describes the state of the river Avon: "The river, as far as the city is concerned, consists of two elongated millponds, undisturbed by a ripple except at flood times. These ponds, receiving the sewage of 50,000 persons, are at the present time simply settling tanks for sewage, the river constituting an open drain with the disadvantage of possessing little or no fall. Fortunately, in ordinary seasons, the whole valley of the Avon being narrow in its course, heavy rainfalls produce floods which, while they inflict injury on some of the low-lying districts, flush the river and save the city from the natural consequences of a bad system of drainage. It must be borne in mind that the Avon as it enters the city has already received the unpurified drainage of Chippenham, Trowbridge, Bradford-on-Avon, and other places. Still, in a

run of some miles, much of this impurity is neutralized, and if the Bath sewage were taken out of the river probably no danger would arise. The authorities are aware that to cast their drainage into the stream that runs for over two miles by their streets and villas is scarcely in accordance with sanitary science, but the difficulties and expense of a change naturally have delayed action. I now write to urge on the authorities, by the publicity of your columns, to be wise in time, and by arrangement with the millowners to flush their river, or deodorize the sewage, or adopt such other measures as some independent expert may advise. I do not hope much from local authorities, ever adverse to expenditure, but I do hope those members of the State who have charge of the public health may supply the needed impulse, and so avert what may possibly become so great a danger." To this letter Dr. Brabazon replied as follows: "As Medical Officer of Health for the city of Bath, I may be permitted to speak with some authority on the sanitary condition thereof, and a perusal of the health statistics for the quarter ending July 1st, and applicable to present date, will be a brief and practical refutation of any present insanitary conditions; and, while humbly acknowledging, in common with all cities and the inhabitants thereof, 'our sins and weaknesses,' I trust that the sanitary record of Bath may never be worse. Extract from quarterly report of Medical Officer of Health for city of Bath for the quarter ending July 1st, 1885:—Mortality from all causes, per 1,000 annually, 19.3; ditto, deducting deaths in hospital, 15.9. Zymotic mortality, 0.0. Mortality from all causes, England and Wales, 19.3; ditto, 28 great English towns, London included, 20.6. Zymotic mortality of these 23 towns, 2.80. For sake of comparison, which is in no way intended to be 'odious' or invidious, I have ventured to subjoin to the health statistics of Bath those of other towns collectively. It must be remembered that Bath is 'heavily handicapped' in comparative mortality statistics. Her population is considerably composed of invalids, and largely, in proportion to population, of those aged from 60 upwards; but when, under these disadvantages, in a population of 51,835, the annual average mortality from all causes is 19.3 per 1,000, and the zymotic mortality for four months *nil*, it may safely be inferred that no special insanitary causes exist to alarm the public or excite misgivings of 'F. G. S.'"

**TYRO-TOXICON: CHEESE POISON.**—At the meeting of the Michigan State Board of Health, July 14th, 1885, Dr. Vaughan presented a report of his investigations on poisonous cheese. It is well known that cases of severe illness follow the eating of some cheese. Such instances are of frequent occurrence in the North German countries and in the United States. In England they are less frequently observed, while in France, where much cheese is made and eaten, these cases are said to occur very rarely. A few years ago the reputation of a large cheese factory in northern Ohio was destroyed by the great number of cases of alarming illness arising from eating its cheese. Dairymen know this cheese as "sick" cheese. . . . Dr. Vaughan has succeeded in isolating the poison, to which he has given the name tyro-toxicon (from two Greek words which mean cheese and poison). It is a product of slight putrefaction in the cheese which probably occurs in the vat, as the curd has been known to poison a person. By this slight putrefaction, or excessive fermentation as it may be called, a large amount of butyric acid is formed, and this in the presence of the casein of the cheese is capable of developing a poison. Different samples of poisonous cheese contain different amounts of the poison. The same weight of cheese from one cake furnished three times as much poison as that from another cake. The poison was obtained in long needle-shaped crystals which are freely soluble in water, chloroform, alcohol and ether. The smallest visible fragment of a crystal placed upon the end of the tongue causes a sharp stinging pain at the point of application, and in a few minutes dryness and constriction of the throat. A slightly larger amount produced nausea, vomiting, and diarrhoea. The poison is volatile at the temperature of boiling water, and for this reason even poisonous cheese may be eaten with impunity after being cooked. The substance has also a marked, pungent odour, and through the nose one can obtain sufficient of the volatile poison

to produce dryness of the throat. This is true, however, only of the isolated poison. In the cheese the taste and odour of the poison are both modified to such an extent that they would not be recognised as has already been stated.—*Weekly Medical Review*.

IS PEPSIN AN ALBUMINOID?—A German chemist has come to the conclusion that pepsin does not belong to the albuminoid group. His method was as follows: The stomach of a calf was beaten up, with the addition of common salt, in a mortar, and sufficient water added to form a saturated solution with the salt. After allowing the solution to remain three days, it was drained away, slightly acidulated, and subjected to dialysis. The resulting solution, freed from salts, was then digested for 7-14 days at 40°, and the pepsin further purified by adding calcium chloride and precipitating the calcium as phosphate, collecting the precipitate and isolating the pepsin by redissolving in hydrochloric acid and dialysing the solution. The product, which was highly peptic, did not give any reaction with tannin, mercuric chloride, platinum chloride, or lead acetate. The only precipitant found by the author for the pepsin was alcohol.

EXPERIMENTS IN HORSE-FLESH FOOD.—M. Deeroix, a retired veterinary officer of the French army, and a renowned hippophagist, in a paper presented to the Academy of Medicine, and printed in full in the *Annales d'Hygiène* for June, while rejoicing in the progress which the employment of horse-flesh as food has made in France, now seeks to carry the matter a step further by demonstrating, as the result of numerous experiments performed upon himself and friends, that the flesh of animals suffering from disease is not obnoxious to the health of its consumers. He believes that in the present state of public and professional opinion a vast quantity of what might form a most valuable source of supply is now lost. In the first place, the movement, first started by Isidore Geoffrey St. Hilaire about 1850, and so energetically pursued by an energetic committee, has completely succeeded, for horse butcheries now exist in all the great towns of France. In Paris, there are about 100, which, in 1884 disposed of 14,548 horses, 346 asses, and 32 mules, or a total of 14,926 animals. Disabled horses fetch now about 100 francs more than they used to do, while more than three millions of kilogrammes of a wholesome food becomes attainable by the poorer classes. But M. Deeroix now details a long series of experiments which he has conducted during many years, first in Algiers and afterwards in Paris, with the object of showing that the employment of the flesh of horses which have suffered from various diseases is not injurious to health, and he believes that it is a great error to exclude such from the market. After describing the various modes of cooking horse-flesh, he passes in detailed review his experiences in eating the flesh of horses which have suffered from various diseases, among which may be mentioned pleuro-pneumonia, typhoid pneumonia, glanders, farcy, &c. Thirty of these trials are minutely detailed. But he has also taken another step, and performed numerous experiments (19 instances of which are given in detail) of eating the flesh of animals that had been condemned in the public markets as diseased and unfit for food. Until 1870 he did not speak publicly of the investigations in which he was engaged, but during the siege of Paris he not only affirmed the innocuity of this kind of food, but distributed large quantities of meat furnished by regimental horses dying of disease. The soldiers also seeing their veterinary surgeon consuming such flesh, after awhile readily partook of it. This memoir presented to the Academy, is, however, the first occasion on which the facts of the investigation have been detailed. The following are the conclusions which M. Deeroix arrives at:—(1) Hippophagy is alike advantageous to those who have horses which would otherwise be sold to the knackers, and to those desirous of obtaining at a low price wholesome and highly nutritious meat. (2) In case of necessity, as in a famine, we may employ the cooked flesh of animals who have either died or been slaughtered on account of any disease whatever. (3) Under ordinary circumstances, flesh which may contain virus capable of being transmitted to the human species

should be excluded from consumption. (4) Medicinal substances administered to sick animals do not render the muscular flesh (there may be some doubt concerning visceral flesh) unwholesome, although some of these, especially turpentine, may render its taste detestable. (5) Persons who accidentally partake of the meat of animals which have suffered from cattle plague, glanders, or rabies, need be under no uneasiness on discovering the mistake. (6) The best, and the only efficacious guarantee against contagious diseases, is the thorough cooking of the meat. (7) As regards other diseases, the inspectors should be more circumspect in their seizures. It is better to obtain meat of an inferior quality, but harmless, than to get no meat at all.

INFLUENCE OF HOT DRINKS ON DIGESTION.—Dr. W. Noschel has made some observations on the action of hot drinks and hot food on the stomach, and finds that hot tea given after dinner in quantities not exceeding three beer glasses full had no effect on the digestion; but when given in still larger quantities, it usually retarded the process. He could not detect any special effect from the use of hot or cold solid food. When the stomach-sound was used, he found that it could be introduced with great facility after applying a 5 per cent. solution of cocaine to the pharynx with a brush.

OPERATIONS IN MISSION HOSPITAL IN CASHMERE.—Cashmere contains, in addition to its numerous shawl manufactories and papier maché and silver industries, an admirably conducted hospital attached to the mission of the Church Missionary Society, the present medical officers of which are Messrs. Arthur Neve, F.R.C.S.E., and H. D. McCulloch, M.B., C.M. In the report of last year's work just issued, they say: "Although the number of out-patients is not larger than last year, the wards have been much fuller, and the operations more numerous and more severe. There have been 5,366 out-patients who paid 13,700 visits to the hospital. About 1,000 other patients were treated when itinerating in the valley or on a journey to Ladak; 1,054 operations were performed, of which 339 were major. Only 6 deaths occurred. During 1883, with 800 operations, we had only 1 death. Last year growing experience and the increasing confidence of patients has allowed bolder measures. No cases in which operative relief seemed possible were turned away. Many patients have come over 200 miles for treatment. One man totally blind was brought 250 miles and over snow passes. Both his eyes were successfully operated on. He walked back seeing." In the detailed list of operations we notice 32 successful cases of nerve stretching for leprosy, 3 excisions of the hip, and 344 minor eye operations.

WATER SUPPLY, ARBROATH.—An addition of considerable extent has been made to the Arbroath Water Works. The public water supply of the town, since September, 1871, has been procured from a well sunk in Nalt Loan. About two years ago, a larger and deeper well was sunk in proximity with the other, and in order to provide additional storage space, and to give such a pressure to the water as would send it to the top of the highest house in the town, the Commissioners of Police decided to erect a water tower on Keptie Hill. This building has just been finished. It is to contain three water tanks. Two of these have been erected, and the third will be proceeded with at once. Their holding capacity is 250,000 gallons, and this quantity may be held in reserve, as the mains can be supplied without the water entering the tanks. There are still a number of private wells in the town, but the public supply is largely used for domestic purposes. For manufacturing purposes, the water of the Brothbeckburn, is the chief source of supply. About 8,000*l.* will be the cost of these new works.

OUR ANCESTORS.—A weekly contemporary publishes the following letter from an anonymous correspondent: During eight centuries—say to the time of the Norman conquest—one's direct ancestors amount to a far greater number than would at first be contemplated. Taking three generations to a century, one has father and mother (2), grandparents (4), great-grandparents (8). At the end of the second century the number of ancestors springs to 64. Following

the calculation you will find that at the end of eight centuries one is descended from no less than 16,000,000 ancestors. Intermarriage, of course, would reduce this estimate, and there is no doubt it must have largely prevailed. But the figures are so enormous that, in spite of all, I venture to suggest that the words "All ye are brethren" are literally true.

**HELMHOLTZ ON PHYSIOLOGICAL OPTICS.**—A second edition of Professor von Helmholtz's "Handbook of Physiological Optics" will shortly be published, and a public appeal is made by the editor, Dr. Arthur König, Nene Wilhelmstrasse, 16, in Berlin, to all writers upon the subject for references to their respective publications. As the work is intended to be comprehensive in its scope, and to contain a complete bibliography of the subject, the editor desires especially to receive references to any monographs or dissertations that may have appeared in other than the special medical journals. The subject is one with which many English workers have associated themselves, and it is desirable that in a work appearing under the ægis of Professor v. Helmholtz's name, their labours should not remain unrecognised.

**A HEALTHY DISTRICT.**—The Sanitary Inspector reported to the last meeting of the Liberton Parochial Board and Local Authority, that the district was free from epidemic disease, and the health of the parish was satisfactory. In view of the cholera on the Continent, the Medical Officer and the Sanitary Inspector were instructed, in regard to sanitary arrangements, to take all necessary precautions in the district.

**THE CITY AND PORT OF LONDON DISTRICT AMBULANCE SOCIETY.**—At the Guildhall, on Saturday, the Princess Christian presented the certificates to the successful pupils. The District Secretary read a brief report of the work of the district for the past year. During the six years they had been at work, the total number of persons who had received instruction in the classes of the district was 4,497, and the total of certificates granted was 3,300.

**VACCINATION GRANT.**—Mr. W. D. Jefferson, No. 1 District of the Ripon Union, has for the second time received a vaccination grant of 14*l.* 4*s.*

The Local Government Board has decided to prohibit the importation into England of rags from the districts affected with cholera.

**UNIVERSITY OF GLASGOW.**—Our attention has been drawn to the fact that the name of Mr. Leonard Williams was omitted from the lists published by us of Candidates who had passed the Final Examinations for M.B. and C.M. in this University last month.

**CORRIGENDA.**—On page 231, col. 2, last line, for "propitable" read "profitable"; and on page 232, col. 1, first line, for "subtilités l'épargne" read "subtilté, l'épargne."

**REARING PREMATURE INFANTS.**—Prof. Tarnier presented at the Académie de Médecine two children born at the sixth month, whom he had succeeded in rearing by the aid of the couveuse, and forcible feeding with woman's milk. Eight grammes of milk were injected through a caoutchouc tube into the stomach every hour for the first three days, and then 16 grammes were injected every 3 hours. It is necessary to begin with small quantities, or the child becomes swollen by an acute œdema through hypernutrition. The couveuse is used at a temperature of 30° to 37° C. The younger the infant, the higher the temperature employed. Dr. Blot observed that he regarded the couveuse as a useless procedure, as the same results are attainable by the employment of cotton and bottles of hot water. M. Tarnier said that during the employment of the couveuse he had on several occasions been astonished at the rapid disappearance of the sclerema of infants.—*Compte-Rendu Général.*

**DETECTION OF ARSENIC IN PRESENCE OF ANTIMONY.**—For the detection of arsenic in antimony salts, as tartar emetic, H. Hager recommends that half a gramme of powdered tartar emetic should be mixed with five or six cub. centim. of solution of potash and a few pieces of zinc

and magnesium riband added. This mixture is then to be heated until gas is abundantly evolved, when a few more pieces of metal are to be introduced together with a bit of ammonium chloride, the upper part of the tube or flask is now to be loosely plugged with cotton wool, and a slip of paper soaked in nitrate of silver solution placed over the mouth, the tube is then to be immersed in water at from 50° to 70° C. If arsenic is present the paper becomes darkened by the reducing action of the arsenious hydride evolved.—*Chemical Centralblatt.*

## APPOINTMENTS.

**BATHO, WILLIAM, M.R.C.S. Eng., L.S.A.**—Medical Officer to the Amesbury and Winterbourn District and to the Workhouse, Amesbury Union, *vice* Mr. C. J. Pyle, resigned.  
**BEEVOR, E. C., M.D. Lond., M.R.C.P.**—Physician to Out-Patients to the Great Northern Central Hospital.  
**EVANS, ROBERT, M.R.C.S. Eng., L.R.C.P. and L.M. Edin.**—Assistant Medical Officer to the Workhouse and Infirmary, Hackney Union, *vice* Mr. Arthur Fuller, resigned.  
**JOLIFFE, A. R., M.R.C.S., L.S.A. Lond.**—Sen'or House Surgeon to the Cheltenham General Hospital, *vice* Dr. Power, resigned.  
**MACKELLAR, A. O., M.Ch., F.R.C.S.**—Chief Surgeon to the Metropolitan Police, *vice* Mr. T. Holmes, resigned.  
**MCCLURE, HENRY, M.D., M.Ch. Ire.**—Medical Officer to the Cromer District, Erpingham Union, *vice* Mr. R. McKelvie, resigned.  
**MEARS, ROBERT, M.R.C.S. Eng., L.R.C.P. Edin.**—Medical Officer to the Atherstone District and to the Workhouse, Atherstone Union, *vice* Mr. Thomas Handford, resigned.  
**RODWAY, EDWIN AUGUSTUS, L.S.A.**—Medical Officer to the Hamsterley District, Auckland Union, *vice* Mr. C. Alworthy, deceased.  
**SMITH, LLOYD G., M.B., C.M. Edin.**—House Surgeon to the Deaconesses Institution and Training Hospital, Tottenham.  
**TAIT, LAWSON, F.R.C.S.**—Consulting Surgeon to the Samaritan Hospital for Women, Nottingham.

## VACANCIES.

**ASYLUM FOR IDIOTS, EARLSWOOD, REDHILL, SURREY.**—Assistant Medical Officer. (*For particulars see Advertisement.*)  
**COVENTRY AND WARWICKSHIRE HOSPITAL.**—House Surgeon. (*For particulars, see Advertisement.*)  
**NORTH EASTERN HOSPITAL FOR CHILDREN, HACKNEY ROAD, E.**—Physician. Candidates must be Fellows or Members of the Royal College of Physicians, London. Applications, with qualifications and testimonials, to be addressed to the Secretary, City Office, 27, Clement's Lane, E.C. (from whom further particulars may be obtained), on or before August 31st.  
**SHIPSTON-ON-STOUR UNION.**—Medical Officer. (*For particulars see Advertisement.*)  
**STOCKTON-UPON-TEES HOSPITAL AND DISPENSARY.**—House Surgeon (non-resident). Salary, £200 per annum. Candidates must be doubly qualified. Applications, stating age, with recent testimonials or copies, to be sent to the Secretary not later than August 24th.  
**WESTON-SUPER-MARE HOSPITAL.**—House Surgeon. Salary, £70 per annum, with board, lodging, and washing. Candidates must possess a registered Medical and Surgical qualification and be unmarried. Applications and testimonials to be sent to the Honorary Secretary on or before September 5th.

## DEATHS.

**ADAMS, R. S., M.R.C.S., L.S.A.,** at 33, High Street, Lymington, Hants, on August 11th, aged 52.  
**BECKINGSALE, J. E., F.R.C.S., J.P.,** at Newport, Isle of Wight, on August 10th, aged 75.  
**GOODACRE, Rev. F. B., M.D.,** Rector of Wilby and Hargham, Norfolk, on August 14th.  
**NASH, JOHN PEARSON, M.D.,** Surgeon-Major of H.M. Madras Army (retired), at 41, Portsdown Road, Maida Vale, on August 17th, in his 57th year.  
**TURNOUR, C. C., M.D.,** at Perth, West Australia, on June 30th, aged 33.  
**WALKER, WILLIAM, F.R.C.S.,** Surgeon Oculist to the Queen in Scotland, at 47, Northumberland Street, Edinburgh, on Aug. 16th, aged 71.

## NOTES, QUERIES, AND REPLIES.

### BRADLEY FUND.

DR. JEFFREYS writes to us as follows:—I have received the following additional subscriptions towards the Bradley Fund:—Mr. Eric Erichsen (6, Cavendish Place), £5 5*s.*; Dr. Dyson (Sheffield), Dr. William Richardson (Deputy-Inspector General, R. N.), Mr. C. N. Macnamara (13, Grosvenor Street, W.), Dr. Clifford Allbutt (Leeds), Mr. John Hall (Sheffield), £2 2*s.*; Dr. Van Vestrant (Birmingham), Dr. Martin (Sheffield), Mr. J. F. F. Parr (Sheffield), Dr. R. E. Burgess (Kettering), Mr. J. F. Churchill (Chesham), Mr. Matthew Leach (Sheffield), Dr. J. Swain Scriven (Belper), Dr. Robertson Mutch (Nottingham), Dr. Samuel Mitchell (Wadsley,

Sheffield), Dr. G. P. Hadley (Birmingham), Dr. Johnston (Tow Law, Darlington), £1 1s.; Mr. Henry Steare (Saffron Walden), Mr. John Baines (Summerhill, Birmingham), Dr. W. H. Higgins (Leicester), Mr. Henry Heywood (Dulwich, S.E.), £1; Mr. W. H. Booth (Sheffield), Mr. William Dale James (Sheffield), 10s. 6d.; Dr. Henry Denne (Edgbaston, Birmingham), Mr. W. Maxwell Burman (Wath), 10s.

Also would you kindly correct two mistakes in the list which appeared in your issue of August 15th. Dr. Balthaser Foster's subscription should have been £2 2s. instead of £1, and Dr. Francis McLoughlin should have been Dr. Thomas McLaughlin.

AN APPEAL.

[TO THE EDITOR OF THE MEDICAL TIMES.]

SIR,—I enclose a further list of the subscriptions sent in answer to my appeal on behalf of the widow and her two daughters, and am thankful to say that I have already received more than the amount for which I asked, so that no further contributions are required.

As usually happens in genuine cases, the worst was not told until the feelings were unlocked by the arrival of unexpected relief. These poor ladies "have often known what it is to eat dry bread for three days, and not much of that."

The piano has been restored and all immediate necessities provided for; other arrangements will be made on my return to town. I trust that any inaccuracies in the list which may occur, in consequence of my being away on holiday, will be excused.

I remain, Sir, your obedient servant,  
W. H. BROADBENT.

Mrs. Ritchie, £7; Dr. Bowles, A. E. Cumberbatch, Esq., The British Medical Benevolent Fund, £5; Sir William Gull, £3; Dr. Tuckwell, John Ferry, Esq., F. Le Gros Clark, Esq., £2 2s.; A Friend, (per Dr. Bowles), J. S. Bartrum, Esq., Mrs. Jelly (Valencia, Spain), C. H. O. (Bristol), £2; Surgeon-Major Roe, A Friend from Yorkshire, J. F. Churchill, Esq., S. G. Sloman, Esq., Sir George Burrows, T. Corbett, Esq., Dr. Sutro (for Medical Benevolent Fund), £1 1s.; C.E.C. (M.D.P.), Dr. E. Jackson, Dr. Maxwell, £1; R. E. Burges, Esq., 10s. 6d.; Dr. S. Thompson, Dr. Atkinson, 10s.

COMMUNICATIONS RECEIVED—

Prof. GAIRDNER, Glasgow; Dr. GOODHART, London; Dr. DONKIN, London; Mr. J. T. W. BACOT, Seaton, Devon; Dr. MAXWELL, Woolwich; Dr. WILLOUGHBY, London; Dr. CLIFFORD BEALE, London; Dr. GIBBONS, London; Dr. CASEY, Windsor; Dr. J. H. PACKARD, Philadelphia; THE SECRETARY OF THE SOCIETY OF APOTHECARIES, London; MESSRS. WOOLLAMS & Co., London; Mr. JOHN COLAM, London; Mr. H. G. HILL, London; Dr. J. F. EASMON, West Africa; THE REGISTRAR-GENERAL FOR SCOTLAND, Edinburgh; THE SECRETARY OF THE EAST ANGLIAN BRANCH OF THE BRITISH MEDICAL ASSOCIATION; THE REGISTRAR-GENERAL FOR ENGLAND, London; THE REGISTRAR OF THE GENERAL MEDICAL COUNCIL, London; Mr. T. MOIR, Glasgow; Mr. W. D. JEFFERSON, Ripou; Mr. JEFFREYS, Chesterfield; OUR PARIS CORRESPONDENT; OUR DUBLIN CORRESPONDENT; OUR VIENNA CORRESPONDENT; OUR EDINBURGH CORRESPONDENT.

BOOKS RECEIVED—

Report on the Sanitary Condition of the Wandsworth District during the year 1884—Sanitary Suggestions, by Sampson Low, Jun., B.A. Cantab., Etc.—Some Personal Observations on the Work of Lawson Tait, by A. Vander Veer, M.D.—The Treatment of Mastitis by Bandaging and Rest, by P. A. Harris, M.D.—Annual Report of the Board of Works for the St. Giles' District—The Climate of Llandudno, by James Nicoll, M.D.—Report of the Commissioners in Lunacy to the Lord Chancellor—Chronic Pulmonary Phthisis, by Hermann Weber, M.D.—Annual Report of the Medical Officer of Health for the Borough of New Windsor for 1884.

PERIODICALS AND NEWSPAPERS RECEIVED—

Lancet—British Medical Journal—Medical Press and Circular—Centralblatt für Chirurgie—Gazette des Hôpitaux—Gazette Médicale—Pharmaceutical Journal—Wiener Medicinische Wochenschrift—Gazette Hebdomadaire—Nature—Centralblatt für Gynäkologie—Le Concours Médical—Centralblatt für Klinische Medizin—Philadelphia Medical News—Weekblad—Le Progrès Médical—Berliner Klinische Wochenschrift—Centralblatt für die Medicinischen Wissenschaften—Deutsche Medicinische Wochenschrift—The Hospital Gazette—New York Medical Journal—Louisville Medical News—Boston Medical and Surgical Journal—Philadelphia Medical Times—Revue Médicale—Revista de Medicina—North Carolina Medical Journal—The New Orleans Medical and Surgical Journal—The Chemist and Druggist—Annales Médico-Chirurgicales—The Dublin Journal of Medical Science—The Medical World—Revue de Médecin—Revue de Chirurgie—Indian Medical Gazette—The Journal of the British Dental Association—The Canada Lancet—The Detroit Lancet.

HOSPITAL OPERATING DAYS.
